# Motivations...

A number of stochastic process algebras have been proposed in the last two decades. These are based on:

- Labeled Transition Systems (LTS)
  - for providing compositional semantics of languages
  - for describing qualitative properties
- Continuous Time Markov Chains (CTMC)
  - for analysing quantitative properties

# Motivations...

A number of stochastic process algebras have been proposed in the last two decades. These are based on:

- Labeled Transition Systems (LTS)
  - for providing compositional semantics of languages
  - for describing qualitative properties
- Ontinuous Time Markov Chains (CTMC)
  - for analysing quantitative properties

Semantics of these calculi have been given by variants of the Structured Operational Semantics (SOS) approach but:

- there is no general framework for modelling the different formalisms
- it is rather difficult to appreciate differences and similarities of such semantics.

More Calculi will come: Besides qualitative aspects of distributed systems it more and more important that performance and dependability be addressed to deal with issues related to quality of service.

# Common ingredients of Stochastic PA

### **Randomized Actions**

- It is assumed that action execution takes time
- Execution times is described by means of random variables
- Random Variables are assumed to be exponentially distributed
- Random Variables are fully characterised by their rates.

# Common ingredients of Stochastic PA

### **Randomized Actions**

- It is assumed that action execution takes time
- Execution times is described by means of random variables
- Random Variables are assumed to be exponentially distributed
- Random Variables are fully characterised by their rates.

### Properties of Exponential Distributions

If *X* is exponentially distributed with parameter  $\lambda \in \mathbf{R}_{>0}$ :

- $\mathbb{P}{X \leq d} = 1 e^{-\lambda \cdot d}$ , for  $d \geq 0$
- The average duration of X is  $\frac{1}{\lambda}$ ; the variance of X is  $\frac{1}{\lambda^2}$
- Memory-less:  $\mathbb{P}\{X \le t + d \mid X > t\} = \mathbb{P}\{X \le d\}$

We introduce a variant of Rate Transition Systems (RTS), proposed by Klin and Sassone(FOSSACS 2008), and use them for defining stochastic behaviour of a few process algebras.

We introduce a variant of Rate Transition Systems (RTS), proposed by Klin and Sassone(FOSSACS 2008), and use them for defining stochastic behaviour of a few process algebras.

Like most of the previous attempts we take a two step approach: For a given term, say T, we define an enriched LTS and then use it to determine the CTMC to be associated to T.

We introduce a variant of Rate Transition Systems (RTS), proposed by Klin and Sassone(FOSSACS 2008), and use them for defining stochastic behaviour of a few process algebras.

Like most of the previous attempts we take a two step approach: For a given term, say T, we define an enriched LTS and then use it to determine the CTMC to be associated to T.

- Our variant of RTS associates terms and actions to functions from terms to rates
- The apparent rate approach, originally developed by Hillston for multi-party synchronisation (à la CSP), is generalized to deal "appropriately" also with binary synchronisation (à la CCS).

Stochastic semantics of process calculi is defined by means of a transition relation  $\longrightarrow$  that associates to a pair (P,  $\alpha$ ) - consisting of process and an action - a total function ( $\mathscr{P}, \mathscr{Q}, \ldots$ ) that assigns a non-negative real number to each process of the calculus. Value 0 is assigned to unreachable processes.

・ 同 ト ・ ヨ ト ・ ヨ ト … ヨ

Stochastic semantics of process calculi is defined by means of a transition relation  $\longrightarrow$  that associates to a pair (P,  $\alpha$ ) - consisting of process and an action - a total function ( $\mathscr{P}, \mathscr{Q}, \ldots$ ) that assigns a non-negative real number to each process of the calculus. Value 0 is assigned to unreachable processes.

- $P \xrightarrow{\alpha} \mathscr{P}$  means that, for a generic process Q:
  - if 𝒫(Q) = x (≠ 0) then Q is reachable from P via the execution of α with rate/(weight) x
  - if  $\mathscr{P}(Q) = 0$  then Q is not reachable from P via  $\alpha$

Stochastic semantics of process calculi is defined by means of a transition relation  $\longrightarrow$  that associates to a pair (P,  $\alpha$ ) - consisting of process and an action - a total function ( $\mathscr{P}, \mathscr{Q}, \ldots$ ) that assigns a non-negative real number to each process of the calculus. Value 0 is assigned to unreachable processes.

### $P \xrightarrow{\alpha} \mathscr{P}$ means that, for a generic process Q:

- if 𝒫(Q) = x (≠ 0) then Q is reachable from P via the execution of α with rate/(weight) x
- if  $\mathscr{P}(Q) = 0$  then Q is not reachable from P via  $\alpha$

### We have that if $P \xrightarrow{\alpha} \mathscr{P}$ then

•  $\oplus \mathscr{P} = \sum_{Q} \mathscr{P}(Q)$  represents the total rate/weight of  $\alpha$  in P.

# Rate transition systems

### Definition

A rate transition system is a triple ( $S, A, \longrightarrow$ ) where:

- S is a set of states;
- A is a set of transition labels;
- $\rightarrow \subseteq S \times A \times [S \rightarrow \mathsf{R}_{\geq 0}]$

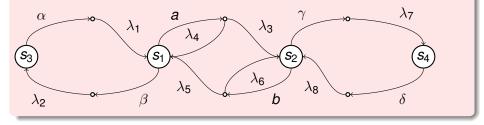

# Rate transition systems

### Definition

A rate transition system is a triple ( $S, A, \longrightarrow$ ) where:

- S is a set of states;
- A is a set of transition labels;
- $\bullet \rightarrow \subseteq S \times A \times [S \rightarrow \mathsf{R}_{\geq 0}]$

### An example of RTS

э

## Some Notation for Rate transition systems

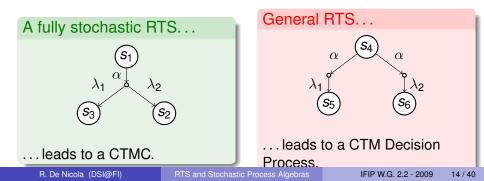

- RTS will be denoted by  $\mathcal{R}, \mathcal{R}_1, \mathcal{R}', \dots,$
- Elements of  $[S \to R_{\geq 0}]$  are denoted by  $\mathscr{P}, \mathscr{Q}, \mathscr{R}, \dots$
- [s<sub>1</sub> → v<sub>1</sub>,..., s<sub>n</sub> → v<sub>n</sub>] denotes the function associating v<sub>i</sub> to s<sub>i</sub> and 0 to all the other states.
- $\emptyset$  denotes the constant function 0.
- $\chi_s$  stands for  $[s \mapsto 1]$ .
- $\mathscr{P} + \mathscr{Q}$  denotes the function  $\mathscr{R}$  such that:  $\mathscr{R}(s) = \mathscr{P}(s) + \mathscr{Q}(s)$ .
- $\mathscr{P} \cdot \frac{x}{y}$  denotes the function  $\mathscr{R}$  such that:  $\mathscr{R}(s) = \mathscr{P}(s) \cdot \frac{x}{y}$  if  $y \neq 0$ , and  $\emptyset$  if y = 0.

# Rate transition systems

### Definition

Let  $\mathcal{R} = (S, A, \rightarrow)$  be an RTS, then:

- *R* is *fully stochastic* if and only if for each *s* ∈ *S*, α ∈ *A*, *P* and *Q* we have: *s* → *P*, *s* → *Q* ⇒ *P* = *Q*
- *R* is *image finite* if and only if for each *s* ∈ *S*, *α* ∈ *A* and *P* such that *s* → *P* we have: {*s*'|*P*(*s*') > 0} is finite

# From RTS to CTMC...

### **Reachable Sets of States**

For sets  $S' \subseteq S$  and  $A' \subseteq A$ , the set of derivatives of S' through A', denoted Der(S', A'), is the smallest set such that:

•  $\mathcal{S}' \subseteq Der(\mathcal{S}', \mathcal{A}'),$ 

• if  $s \in Der(S', A')$  and there exists  $\alpha \in A'$  and  $\mathscr{Q} \in \Sigma_{S}$  such that

 $s \xrightarrow{\alpha} \mathscr{Q}$  then  $\{s' \mid \mathscr{Q}(s') > 0\} \subseteq Der(\mathcal{S}', \mathcal{A}')$ 

### Mapping $(\mathcal{S}, \mathcal{A}, \rightarrow)$ into $(Der(\mathcal{S}', \mathcal{A}'), \mathbf{R})$

Let  $\mathcal{R} = (\mathcal{S}, A, \rightarrow)$  be a *fully stochatics* RTS, for  $\mathcal{S}' \subseteq \mathcal{S}$ , the CTMC of  $\mathcal{S}'$ , when one considers only actions  $A' \subseteq A$  is defined as  $CTMC[\mathcal{S}', A'] \stackrel{def}{=} (Der(\mathcal{S}', A'), \mathbf{R})$  where for all  $s_1, s_2 \in Der(\mathcal{S}', A')$ :

$$\mathbf{R}[s_1, s_2] \stackrel{\text{def}}{=} \sum_{\alpha \in \mathcal{A}'} \mathscr{P}^{\alpha}(s_2) \quad \text{with } s_1 \stackrel{\alpha}{\longrightarrow} \mathscr{P}^{\alpha}$$

# Strong Markovian Bisimilarity

### **Definition (Bisimulation)**

### Given a generic CTMC $(S, \mathbf{R})$

An equivalence relation *E* on *S* is a Markovian bisimulation on *S* if and only if for all (s<sub>1</sub>, s<sub>2</sub>) ∈ *E* and for all equivalence classes
 *C* ∈ *S*<sub>/*E*</sub> the following condition holds: **R**[s<sub>1</sub>, *C*] = **R**[s<sub>2</sub>, *C*].

### Definition (Bisimilarity)

Given a generic CTMC  $(S, \mathbf{R})$ 

• Two states  $s_1, s_2 \in S$  are strongly Markovian bisimilar, written  $s_1 \sim_M s_2$ , if and only if there exists a Markovian bisimulation  $\mathcal{E}$  on S with  $(s_1, s_2) \in \mathcal{E}$ .

### Rate aware bisimulation

Definition (Rate Aware Bisimilarity)

Let  $\mathcal{R} = (\mathcal{S}, \mathcal{A}, \rightarrow)$  be a RTS:

An equivalence relation *E* ⊆ *S* × *S* is a *rate aware* bisimulation if and only if, for all (*s*<sub>1</sub>, *s*<sub>2</sub>) ∈ *E*, and <u>*S*</u> ∈ *S*<sub>/*E*</sub>, and for all *α* and *P*:

$$\mathbf{s}_1 \xrightarrow{\alpha} \mathscr{P} \Longrightarrow \exists \mathscr{Q} : \ \mathbf{s}_2 \xrightarrow{\alpha} \mathscr{Q} \land \mathscr{P}(\underline{S}) = \mathscr{Q}(\underline{S})$$

Two states s<sub>1</sub>, s<sub>2</sub> ∈ S are rate aware bisimilar (s<sub>1</sub> ~ s<sub>2</sub>) if there exists a rate aware bisimulation *E* such that (s<sub>1</sub>, s<sub>2</sub>) ∈ *E*.

#### Theorem

Let 
$$\mathcal{R} = (S, A, \longrightarrow)$$
, for each  $A' \subseteq A$  and for each  $s_1, s_2 \in S$  and  $(S, \mathbf{R}) = CTMC[\{s_1, s_2\}, A']: s_1 \sim s_2 \Longrightarrow s_1 \sim_M s_2$ 

Notice that *rate aware bisimilarity* and *strong bisimilarity* coincide when one does not take into account actions.

# PEPA: Performance Process Algebra

## Systems

PEPA systems are the result of *components* interaction via *activities*:

- Components reflect the behaviour of relevant parts of the system,
- activities capture the actions that the components perform.

### **Activities**

Each PEPA activity consists of a pair  $(\alpha, \lambda)$  where:

- $\alpha$  symbolically denotes the performed action;
- $\lambda > 0$  is the rate of the (negative) *exponential* distribution.

## Syntax

If A is a set of *actions*, ranged over by  $\alpha, \alpha', \alpha_1, \ldots$ , then  $\mathcal{P}_{PEPA}$  is the set of process terms  $P, P', P_1, \ldots$  defined by:

$$P ::= (\alpha, \lambda).P \mid P + P \mid P \mid \mid_L P \mid P/L \mid A$$

$$\frac{\alpha \neq \beta}{(\alpha, \lambda).P \xrightarrow{\alpha} [P \mapsto \lambda]} (ACT) \qquad \qquad \frac{\alpha \neq \beta}{(\alpha, \lambda).P \xrightarrow{\beta} \emptyset} (\emptyset \text{-ACT})$$

$$\frac{P \xrightarrow{\alpha} \mathscr{P} Q \xrightarrow{\alpha} \mathscr{Q}}{P + Q \xrightarrow{\alpha} \mathscr{P} + \mathscr{Q}} (SUM) \qquad \qquad \frac{P \xrightarrow{\alpha} \mathscr{P} Q \xrightarrow{\alpha} \mathscr{Q} \alpha \notin L}{P \mid \mid_L Q \xrightarrow{\alpha} \mathscr{P} \mid \mid_L \chi_Q + \chi_P \mid \mid_L \mathscr{Q}} (INT)$$

$$\frac{P \xrightarrow{\alpha} \mathscr{P} Q \xrightarrow{\alpha} \mathscr{Q}}{P \mid \mid_L Q \xrightarrow{\alpha} \mathscr{P} \mid_L \mathscr{Q}} \frac{\alpha \in L}{\varphi \mid \mid_L \mathscr{Q}} (COOP)$$

$$\frac{P \xrightarrow{\alpha} \mathscr{P} \alpha \notin L}{P/L \xrightarrow{\alpha} \mathscr{P}/L} (P \text{-HIDE}) \qquad \qquad \frac{\alpha \in L}{P/L \xrightarrow{\alpha} \emptyset} (\emptyset \text{-HIDE})$$

$$\frac{P \xrightarrow{\alpha} \mathscr{P}_{\alpha} \forall \alpha \in L.P \xrightarrow{\alpha} \mathscr{P}_{\alpha}}{Q \mid \perp \chi_{\alpha} \in L} (HIDE) \qquad \qquad \frac{P \xrightarrow{\alpha} \mathscr{P} A \stackrel{\Delta}{=} P}{A \xrightarrow{\alpha} \mathscr{P}} (CALL)$$

- The rate of a binary complementary synchronization mainly depends on the one of the triggering *activity*
- The synchronization rate of  $\overline{a}$  and a depends on the rate of  $\overline{a}$ , on the weight of the *selected a* and on the *total weight* of a (i.e. on the *sum* of the weights of *all a*-transitions).

 Two synchronizations can occur with rates:

$$\lambda \cdot \frac{\omega_1}{\omega_1 + \omega_2} \qquad \lambda \cdot \frac{\omega_2}{\omega_1 + \omega_2}$$

• The overall sum of the synchronization rates is the same as the one of the output, i.e. it does not depend on the number of available (input) partners.

# STOCCS: stochastic semantics

#### Theorem

In StoCCS parallel composition is associative up to rate aware bisimilarity, i.e. for each P, Q and R,  $P|(Q|R) \sim (P|Q)|R$

RTS and Stochastic Process Algebras

IFIP W.G. 2.2 - 2009 36 / 40

э

# Outline...

#### Motivations

- 2 Rate-based Transition Systems
- 3 Stochastic CSP: PEPA
- 4 Stochastic CCS: StoCCS
- 5 Conclusions and Future Directions

# Summing Up

- We have introduced Rate Transition Systems and have used them as the basic model for defining stochastic behaviours of processes.
- We have introduced a natural notion of bisimulation over RTS that agrees with Markovian bisimulation.
- We have shown how RTS can be used to provide the stochastic operational semantics of PEPA and CCS.
- We have discussed the generalization of the approach to  $\pi$ -calculus and (in another paper) MarCaSPiS.

3

# **Future Work**

- Use RTS to model other formalisms
- Use the RTS approach as general framework for modelling other PA semantics (non-deterministic, truly-concurrent, probabilitistic,...)
- Consider alternative semantics synchonisation rates:
  - based on phase type distributions
  - based on Interactive Markov Chains
- Develop tools directly for RTS rather than for CTMC.

# Thank you for your attention!
