THE CLASSIFICATION OF PURELY INFINITE C*-ALGEBRAS USING KASPAROV'S THEORY

(PRELIMINARY VERSION: 27.05.2022)

After Eberhard Kirchberg's death in August, 2022, his wife Sommai agreed to make this manuscript accessible to the mathematical public. The manuscript contains a wealth of deep results, ideas, and techniques, but it is not completely finished. The manuscript is in the form in which we found it on his computer and we did not make any changes.

The plan is that Jamie Gabe and Mikael Rørdam will add an explanatory text and that the manuscript will be published via the University Library of the University of Münster. In the meantime it will be available at:

https://ivv5hpp.uni-muenster.de/u/echters/ekneu1.pdf

For the time being, please refer to this manuscript as

Eberhard Kirchberg, *The Classification of Purely Infinite C*-Algebras Using Kasparov's Theory*, manuscript available at https://ivv5hpp.uni-muenster.de/u/echters/ekneu1.pdf

Münster, July 18, 2023

The Classification of Purely Infinite C*-Algebras Using Kasparov's Theory

(preliminary version: 27.05.2022)

Eberhard Kirchberg

Contents

Attempt to give a very short overview (abstract)

First we consider a simple special case and show that KK-equivalent *simple* purely infinite separable unital nuclear C^*-algebras A and B are isomorphic if the group isomorphism from $K_0(A)$ onto $K_0(B)$, that are induced by the KK-equivalence, maps the K_0-class $[1_A]$ of the unit element of A in $K_0(A)$ to the class $[1_B] \in K_0(B)$.

We call them *pi-sun algebras*, because they are automatically simple by the requirement of the algebraic property that for each non-zero $a \in A$ there are elements $c, d \in A$ with $cad = 1_A$. It yields that pi-sun algebras are isomorphic if their K_*-groups are isomorphic by an isomorphism that maps the K_0-classes of their unit elements into each other and if both are KK-equivalent to Abelian C^*-algebras, i.e., if the Universal Coefficient Theorem applies to both of them.

Comment on this.

Here are the first question:
Is KK-equivalence to commutative C^*-algebras really needed?
Is each p.i.s.u.n. algebra A isomorphic to $A \otimes \mathcal{O}_\infty$?
Is $A \otimes \mathcal{O}_2$ isomorphic to $\mathcal{O}_2$ if A is a separarable unital nuclear simple C*-algebra?
Give references for or against it (with cite or refs)
Where are examples or counter-examples?

The considerations are based on the here applicable Cuntz–Kasparov isomorphism $KK(A, B) \cong \mathrm{Ext}(A, SB)$ and the homotopy invariance of $KK(A, B)$, that will be used to show that the natural group-morphism from the Rørdam groups $R(A, B)$ – a sort of "unsuspended" and "nuclear" E-theory – into $\mathrm{Ext}(A, SB)$ is an isomorphism. The last step for this proof of the functorial equivalence will be done in Chapter 8.

M. Rørdam was/sounded not happy with my interpretation
of -- from him defined groups $R(A, B)$.
Perhaps my interpretation is different
and I should call them $\mathbb{GK}(A, B)$.

A similar partly classification is given later for *non-simple* separable stable nuclear *strongly* purely infinite C^*-algebras. Those algebras absorb the Cuntz-algebra $\mathcal{O}_\infty$ tensorial, i.e., a separable nuclear C^*-algebra A is isomorphic to $A \otimes \mathcal{O}_\infty$, if and only if, A strongly purely infinite (cf. Definition 1.2.2), that is, if A satisfies a generalized Weyl–von-Neumann–Voiculescu type theorem for weakly residually nuclear maps (cf. Chapters 5 and 10).

The basic study of properties of tensorial self-absorbing unital separable C^*-algebras will be postponed to Chapter 11 because it has another nature, e.g. it is not really related to pure infiniteness.

We remove in Chapter 12 by study of some properties of ultrapowers some technical additional assumptions that we added in the other chapters to make the some of the proofs, e.g. in Chapter 6, more transparent: We contain a proof that $\mathrm{Prim}(A)$ for separable non-simple C^*-algebras A has always a natural property that we call "Abelian factorization" property 1.2.4. It leads to a rather long study over the interrelations between general Dini spaces (i.e., second countable locally quasi-compact point-complete T_0-spaces), "coherent" Dini spaces and second countable locally compact Hausdorff spaces and is not only related to functional analysis.

The in Chapter 6 made additional assumption – that the considered separable stable σ-unital nuclear C^*-algebras have some property that is (formally) weaker than "regular" factorization through a l.c. Hausdorff space for their prime ideal space – can here (in this book) only be reduced in Chapter 12 where we use that every separable C^*-subalgebra of an ultra-power (or more generally in that what we call "corona algebras") is contained in a bigger separable C^*-algebras that contains a nice Abelian C^*-algebra with the much stronger property that it not only separates the ideals but is also "regular" in the sense of our Definition 1.2.9. (or B.4.1 ????)..

This is a much stronger property than regular factorization. And regular factorization is usually stronger than having an Abelian C^*-subalgebra that separates the ideals of a stable separable C^*-algebra (with the additional property that it can be done in a way that the norm functions of its elements exhausts all Dini functions on $\mathrm{Prim}(A)$).

A special consequence of our classification results is the following:

If A and B are separable stable nuclear C^*-algebras and if there is a homeomorphism γ from the T_0-space $X := \mathrm{Prim}(A)$ of primitive ideals in A onto $\mathrm{Prim}(B)$, then we prove the existence of an isomorphism ψ from $A \otimes \mathcal{O}_2$ onto $B \otimes \mathcal{O}_2$, such that ψ induces γ in the sense $\psi(J \otimes \mathcal{O}_2) = \gamma(J) \otimes \mathcal{O}_2$ for $J \in \mathrm{Prim}(A)$. The ψ with this property is unique up to approximate unitary equivalence.

We generalize Kasparov's equivariant functor $\mathcal{R}\,\mathrm{KK}^G(X;\, .,.)$ (here only in the case where the group G is trivial) to some kind of generalized "actions" of locally quasi-compact T_0-spaces X on C^*-algebras (cf. Definitions 1.2.6 and 1.2.10). We denote this functor by $\mathrm{KK}(X;\, A, B)$. In fact, we show that Kasparov's KK-functor extends in a natural way to a functor $\mathrm{KK}(\mathcal{C};\, A, B)$ from the category of matrix operator convex cones (m.o.c. cone) $\mathcal{C} \subset \mathrm{CP}(A, B)$ into the abelian groups. In this technical approach the algebras itself play then only the role of indices and we have to study only the category of m.o.c. cones, and then to translate it back to the category of C^*-algebras ...

The *main result* of this considerations is the following:
Suppose that A_1 and A_2 are strongly purely infinite, separable, stable and nuclear,

and that there is given an homeomorphism ψ from $X := \mathrm{Prim}(A_1)$ onto $\mathrm{Prim}(A_2)$ and that A and B are $\mathrm{KK}(X; ., .)$-equivalent in a ψ-equivariant manner. Then there exist ψ-equivariant *-monomorphisms $h_1 : A_1 \to A_2$ and $h_2 : A_2 \to A_1$ that induces the given $\mathrm{KK}(X, ., .)$-equivalence, and that $h_2 \circ h_1$ and $h_1 \circ h_2$ unitarily homotopic to the identity maps of A_1 respectively A_2. It implies the existence of an isomorphism $\gamma : A_1 \to A_2$ from A_1 onto A_2, such that γ is approximately unitary equivalent to h_1 and γ^{-1} is approximately unitary equivalent to h_2. (But it is at present still not clear if γ itself can be chosen such that γ is unitarily homotopic to the given h_1.)

On the way of the proof we obtain also several results that are basic for our main results, e.g. the following:

1. Every exact separable C^*-algebra is a C^*-subalgebra of $\mathcal{O}_2$ (Theorem A). More generally we show the following “embedding theorem”:

If a (not necessarily simple) C^*-algebra D is separable, stable and is “strongly purely infinite” in the sense of Definition 1.2.2, and if $X := \mathrm{Prim}(D)$ acts by a map $\Psi_A : \mathbb{O}(X) \to \mathcal{I}(A)$ on a separable stable exact C^*-algebra A lower semi-continuously and upper monotone continuously, then there is a *-monomorphism $h_0 : A \to D$ such that $h_0 \oplus h_0$ is unitarily equivalent to h_0 and that h_0 induces the given action Ψ_A. The h_0 is unique up to unitary homotopy (Theorem K), moreover, h_0 can be realized by a non-degenerate *-monomorphism, if and only if, the action Ψ_A of X on A is non-degenerate.

If D is a non-degenerate stable C^*-subalgebra of a C^*-algebra B, then B is stable, D defines an upper semi-continuous action Ψ_B of X on B, and h_0 defines an element of the semigroup of unitary equivalence classes $[\mathrm{Hom}_{\mathrm{nuc}}(X;\, A, B)]$ of Ψ_A–Ψ_B–residually nuclear *-homomorphisms from A to B.

We use the above h_0 (a generator of some m.o.c. cone $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ to describe the nuclear KK-groups $\mathrm{KK}_{\mathrm{nuc}}(X;\, A, B)$ as classes of unitarily homotopic Ψ-residually nuclear homomorphisms modulo stabilization with $[h_0]$, cf. Theorems B and M:

$$[\mathrm{Hom}_{\mathrm{nuc}}(X;\, A, B)] + [h_0] \cong \mathrm{KK}_{\mathrm{nuc}}(X; A, B)\,.$$

2. The spatial tensor product of two simple C^*-algebras is purely infinite if one of them is not stably finite and the other is non-elementary, cf. Theorem E. More generally the minimal C^*-tensor products $A \otimes B$ of any C^*-algebra A with a strongly purely infinite C^*-algebra B is strongly purely infinite.

3. The UCT holds for all separable nuclear C^*-algebras, if and only if, up to isomorphisms there is only one pi-sun algebra A with $\mathrm{K}_*(A) = 0$, cf. Corollary J ([1]).

??? The question is here: Is every separable nuclear C^*-algebra B KK-equivalent to some pi-sun C^*-algebra A. One can first tensor A with $\mathcal{O}_\infty \otimes \mathbb{K}$ ... (Seems to be that ??: $A \otimes \mathcal{O}_\infty \otimes \mathbb{K}$ is KK–equivalent to A – but here should no

[1] This is a very important observation, that should direct all the further research to the study of all pi-sun algebras A with $\mathrm{K}_*(A) = 0$. Nobody started it yet (January 2022). Why?

commutative C*-algebra be involved by constructing the KK-equivalence ... The KK-equivalence of $\mathcal{O}_2$ with $C_0((0,1])$ should be directly constructed. Same with $\mathcal{O}_\infty$ with C([0, 1]) or with $\mathbb{C}$ ...)

If A is stable, i.e., $A \cong A \otimes \mathbb{K}$ then one can repeat the constructions given by using a suitable unital mono-morphism

$$\mathcal{M}(A \otimes \mathbb{K}) \mapsto 1_{\mathcal{M}(A)} \otimes \mathcal{L}(\mathbb{K}) \subseteq \mathcal{M}(A \otimes \mathbb{K})\,.$$

This operation will be infinitely repeated and the resulting inductive limit (restricted to the tower of images of $A \otimes c_0(\mathbb{K})$ should be KK-equivalent to $A \otimes c_0(\mathbb{K})$ and the obvious endomorphism given by the forward shift $(k_1, k_2, \ldots) \mapsto (0, k_1, k_2)$ on c_0 respectively by the natural endomorphism of the above described inductive limit.

This should be KK-equivalent to $A \otimes c_0(\mathbb{K})$, and the natural shift endomorphism S on c_0 should produce the isomorphism $S \rtimes c_0 \cong Kp$ using $c_0(\mathbb{K}) \cong c_0 \otimes \mathbb{K}$ and $\mathbb{K} \otimes \mathbb{K} \cong \mathbb{K}$ KK-equivalence of $A \cong A \otimes \mathbb{K}$ with the above defined inductive limit that is a stable pi-sun C*-algebra.

4. Hausdorff distances of C^*-convex hulls of elements a, b and distance between the generalized Gelfand-transformations of a and b are the same, cf. Corollary 3.10.12 and Remark 3.11.3.

5. Results on ideal spaces and approximate 1-step-innerness of residually nuclear maps are given in Chapters 2, 3 and 12.

6. Generalized Weyl–von-Neumann–Voiculescu type theorems and asymptotic analogs of them are proven in Chapters 5 and 7.

7. The non-negative Dini functions on Prim(A), cf. Definition 12.2.5, are the generalized Gelfand transforms of elements of A if A is separable and $A \cong A \otimes \mathcal{O}_\infty$ (Proposition 12.2.6 – a very special case of [**447**] –).

CHAPTER 1

Introduction and main results

Following topics should be extracted and published in more detail (also as beamer presentations, and with lists of its definitions of properties in an elementary way).

1.) "Squeezing Property" implies K_1-injectivity. (See Chp. 4. for definitions of this properties!)

Here a question remains:

When K_1-injectivity implies the Squeezing Property?

At least in unital separable nuclear case ?? (Would be nice !)

(But have no idea until now: Jan 2022 !!!)

2.) Precise version of a quasi-trace state on a type-I C^*-algebra that is not a 2-quasi-trace.

See end of Chapter 1 (= Introduction), and the more details in a (still in work) section of the appendices.

Here following questions remain:

What happens if a separable nuclear C^*-algebra has no type-I sub-quotient? Are then all quasi-traces "trivial" or 2-quasi-traces?

3.) Forgotten!!! Try to remember!

Something important ...? Also related to topics in this book, e.g.:

When (all?) pi-sun algebras A satisfy the UCT?

(Has it to do with the existence/non-existence of ?? Cartan sub-algebras ??)

Seems to be studied in new papers (since 2016 –2021)!

For example: Is every separable nuclear C*-algebra B KK-equivalent to a pi-sun C*-algebra?

Not clear what he is thinking here.

Possible ideas? Check it!: $B \otimes \mathcal{O}_\infty$ and $B \otimes \mathcal{K}$ are KK-equivalent to B ? (Seems to be.)

Here $\mathcal{K}$ (– also denoted by $\mathcal{K}(\ell_2)$ –) means the algebra of compact operators on $\ell_2(\mathbb{N})$.

Then the stable separable nuclear C*-algebra $C := B \otimes \mathcal{O}_\infty \otimes \mathcal{K}$ is strongly purely infinite and absorbs $\mathcal{O}_\infty$ tensorial. It should be KK-equivalent to B. (Seems to work!)

Notice that $\mathcal{L}(\ell_2) = \mathcal{M}(\mathcal{K})$ is unitally contained in $\mathcal{M}(C)$, because $\mathcal{M}(C)$ contains a natural unital copy of

$$\mathcal{M}(B) \otimes \mathcal{O}_\infty \otimes \mathcal{M}(\mathcal{K}) .$$

Therefore, there exists an injective non-degenerate endomorphism ρ of C into $1 \otimes 1 \otimes \mathcal{M}(\mathcal{K}) \subset \mathcal{M}(C)$. Here "non-degenerate" means that each of the products $\rho(C)C$ and $C\rho(C)$ are dense in C.

This implies that ρ extends naturally to a unital endomorphism

$$\mathcal{M}(\rho)\colon \mathcal{M}(C) \mapsto \mathcal{M}(C)$$

.

The inductive limit with help of iterations of this unital endomorphism $\mathcal{M}(\rho)$ produces a (huge) unital C*-algebra E with an "distinguished" endomorphism $\lambda\colon E \mapsto E$.

Moreover, there is an injective C*-algebra morphism $\eta\colon C \to ??? \subset E$ such that $\eta(C)$ is an ideal of E with the property $\eta(C) + \lambda(E) = E$

(??? check it ! It is very important)

and $\eta(C) \cap \lambda(E) = \{0\}$. ???

Now define inductive $D_1 := \eta(C)$, $D_2 := \eta(C) + \rho(C) = C \subseteq \mathcal{M}(C)$,

$\ldots$, $D_3 := C + ...??$

Is it at least the case if B satisfies the UCT? It asks then the weaker question only:

Is at least every separable nuclear C*-algebra B K-equivalent to a pi-sun algebra (in general)?

Can a positive answer for the special case $K_*(A) = 0$ give also a positive answer for the general case?

E.g. that $K_*(A) = 0$ implies $A \cong \mathcal{O}_2$???

Case of $K_*(A) = (\mathbb{Z}, 0)$, as $A \cong \mathcal{O}_\infty$???

Are there relations to the QWEP conjecture?

By definition, a C*-algebra B has the QWEP if B is a quotient C*-algebra $B \cong C/J$ of a C*-algebra C that has the "weak expectation property" (WEP).

A C*-algebra $C \subseteq \mathcal{L}(H)$ has the property WEP, if and only if, there exists a completely positive contraction $V\colon \mathcal{L}(H) \to C^{**}$ into the bi-dual C^{**} of C such that $V(c) = c$ for all $c \in C$.

Perhaps it could follow from (????):

$$C^*(F_\infty) \otimes^{\max} \mathcal{L}(H) = C^*(F_\infty) \otimes^{\min} \mathcal{L}(H)$$

where F_∞ is the free group on countably many (or more!) generators.

In particular, for every C*-representation $d\colon C \to \mathcal{L}(K)$ on a Hilbert space K there exists completely positive contraction $W\colon \mathcal{L}(K) \to d(C)'' \subseteq \mathcal{L}(K)$ with the property that $W(d(c)) = d(c)$ for all $c \in C$. This can be used also as definition, because one can take here a sufficiently universal representation d of C.

(So far the answer to the QWEP question is open for exact C*-algebras.)

All nuclear separable C*-algebras B are WEP algebras, because their bi-duals B^{**} are always injective von-Neumann algebras $B^{**} \cong N = N'' \subseteq \mathcal{L}(H)$ (because $\mathcal{L}(H)$ is injective for each Hilbert space H).

The QWEP conjecture and its possible answer is very important, because is could be that we need some very selective and constructive definition of ultra-filters and approximation methods to get a coherent picture of the desired results with sensible methods.

One can reduce this question a bit if every simple, separable, nuclear, unital, strongly purely infinite C*-algebra A contains a UCT-class member $1_A \in B \subseteq A$ with all other properties the same as A.

This is clearly the case.

Are all separable typ I C*-algebras A in the UCT-class? (Seems to be !)

This must be known.

Is the (separable nuclear) UCT-class closed under extensions, tensor-products and inductive limits? (Seems to be! But with which necessary restrictions?)

Also under crossed products – by actions of amenable groups G on A ?

What about crossed products by an endomorphism? I.e., by an injective action of the natural numbers $\mathbb{N}$

I am not sure what he refers to here.

Look to the Rørdam - Property !! ??Which one?

Preview.

Later add (???) on weak semi-projectivity
of pi-sun (??) algebras and
kernel of η: $\mathrm{Aut}(A) \to \mathrm{Aut}(\mathrm{K}_*(A))$ in UCT case (important!)
and
classification of tensorial self-absorbing algebras in UCT class

Def. of ''pi-sun'' is on 3 places -- 2 with motivation
Is ''pi-sun'' good notation? ??

A long time ago George Elliott [**258**] did conjecture that *simple* separable amenable C^*-algebras can be classified by invariants that are, in some sense, K-theoretic in nature ([1]).

In fact the status of the conjecture of G. Elliott can now described very roughly as a classification up to isomorphisms of those simple separable nuclear C^*-algebras A with following properties:

---

[1] A C^*-algebra A is "amenable", if and only if, A is "nuclear", cf. [**340**] and [**159**]. We rarely use the terminology "amenable" for nuclear C^*-algebras, because we work with matrix operator-convex cones $\mathcal{C}$ of nuclear maps, but not directly with the (co-) homological properties of amenability. But it would be interesting to see if some direct (!) applications of the (co-) homological definition of amenability give additional new insight for answers to the questions and problems that we study here, give new insides of open questions ...

(a) that absorb the Jiang-Su algebra $\mathcal{Z}$ tensorial, in the sense that $A \cong A \otimes \mathcal{Z}$ (see Definition A.3.1 of the Jiang-Su algebra in Section 3) of Appendix A, and

(b) where A is KK-equivalent to some separable commutative C^*-algebra C.

The properties (a,b) are satisfied e.g. for the (Joachim) Cuntz algebra $\mathcal{O}_2$: for (a) because, $\mathcal{O}_2$ absorbs any unital simple nuclear separable C^*-algebra B tensorial, i.e. by isomorphisms $\mathcal{O}_2 \cong \mathcal{O}_2 \otimes B$ for any unital simple nuclear separable C^*-algebra B, – especially if we take the Jiang-Su algebra $\mathcal{Z}$ as B. The property (b) is satisfied with $C := \mathrm{C}_0(0,1]$, because $\mathrm{K}_*(\mathrm{C}_0(0,1]) = \{0\} = \mathrm{K}_*(\mathcal{O}_2)$., – an observation of J. Cuntz. That will be shown later in this book in any detail as partial result of some more general observations.

A basic desire is an explicit answer to the following question: Let A a pi-sun C^*-algebra, i.e., a purely infinite separable unital nuclear C^*-algebra with the property that $\{0\} = \mathrm{K}_*(A)$. Is A isomorphic to $\mathcal{O}_2$?

(Because all separable exact C^*-algebras are C^*-subalgebras of $\mathcal{O}_2$, we can suppose the additional assumption that A is a unital C^*-subalgebra of $\mathcal{O}_2$.)

The algebra $C := \mathrm{C}[0,1]$ of continuous functions on the interval $[0,1]$, and the unital simple C*-algebras $\mathcal{Z}$ (the *Jiang-Su algebra*) and $\mathcal{O}_\infty$ (the *Cuntz algebra* generated by an infinite sequence $s_1, s_2, \ldots$ of isometries with mutually orthogonal ranges) are all KK-equivalent to the algebra complex numbers $\mathbb{C}$ (considered as a unital C*-algebra).

This is Kirchberg's fundamental theorem.

Give here precise references for the observation that $\mathcal{O}_2 \cong B \otimes \mathcal{O}_2$ for unital separable simple and nuclear $C*$-algebras B etc. !!!
Where is the KK-equivalence to commutative $C*$-algebras shown??
Give reference!!!

We say in Section 4 of this introduction more about his formulations and the now (almost) complete state of the proof of the Conjecture of George Elliott. Except in the until now only partially understood case of stably projection-less algebras there is a still remaining questions that is equivalent to the below stated question **(Q2)** that is equivalent to the question if all separable amenable C^*-algebras are KK-equivalent to Abelian C^*-algebras and, to some more general questions that are “in spirit similar” to our question **(Q1)**, namely what additional structure has to be imposed to make sure that a given amenable simple separable stably infinite C^*-algebra can be classified by the so far accepted invariants of simple C^*-algebras, among them e.g. the corona factorization property (CFP) and real rank zero together, or absence of certain types of “infinitesimal” sequences in its Cuntz-semigroup.

Give ref.s to next??
if invariants of K_*-theoretic nature (including the pairing with trace cones) together and with “local approximation” allow to detect if a given separable simple amenable C^*-algebras A tensorial absorbs the Jiang-Su algebra $\mathcal{Z}$. It leads for all separable,

purely infinite and nuclear C^*-algebras A to the important conclusion that A is isomorphic to $A \otimes \mathcal{O}_\infty$ if and only if A is isomorphic to $A \otimes \mathcal{Z}$.

This ????? second ?????

open question is for the stably infinite amenable simple separable C^*-algebras if they are KK-equivalent to an Abelian C^*-algebra $\mathrm{C}_0(X)$:
Give a direct construction of a pi-sun C^*-algebra that is KK-equivalent to $\mathrm{C}_0(X)$ for a given finite polyhedron X. They should meet transparently in the ?????

in the study of the generators and relations of there K_*-theories ?????

Is there any example of ?????

Here are some special questions:

Let A denote a separable C*-algebra ...

The History of this circle of questions:

All of the work on this book was mainly motivated and inspired by the original conjectures of G. Elliott and pioneering ideas of J. Cuntz on this circle of questions. The "easy" beginning sections of the chapters in this book are concerned with an alternative proof of the Elliott conjecture but only in the case of *simple purely infinite separable nuclear* C^**-algebras* A *in the UCT class.* The original definition of purely infinite (simple) algebras given by J. Cuntz [**172**, p. 186] – stated there only in the unital case –, can be reformulated for general unital rings A as: *For each non-zero* $a \in A$*, there are* $c, d \in A$ *with* $cad = 1$. (See proof of [**172**, prop. 1.6] and [**169**, 1.3, 3.4].) Clearly, this definition implies automatically that A is simple. But one has also to require then that A not $\cong \mathbb{C} \cdot 1_A$.

It is easy to see that $K_*(\mathcal{L}(\ell_2)) = 0$, because $B := \mathcal{L}(\ell_2)$ has real rank zero $M_n(B) \cong B$, $(1_B \oplus p) \cong 1_B$ for each projection $p \in B$, and for each unitary in $u \in B$ one finds $q \in B$ and $\xi \in \mathbb{C}$ such that $|\xi| = 1$ and $\|(1-q)u(1-q) + \xi \cdot p - u\| < 1/9$.

(Moreover the unitary group of $B := \mathcal{L}(\ell_2)$ is "globally" contractible to 1, in the sense that ???? WHAT ????)

The elements are all exponentials $u = exp(ih)$ of self-adjoint operators $h^* = h \in B$, because each of them is contained in commutative W*-subalgebra of B.

It follows local contractibility.

(But gives it global contractibility??)

But the Calkin-Algebra $Q(\ell_2) := \mathcal{L}(\ell_2)/\mathbb{K}(\ell_2)$ with $\ell_2 := \ell_2(\mathbb{N})$ is also a simple C*-algebra with K-theory, that is $K_0(Q) = 0$ and $K_1(Q) = \mathbb{Z}$ K-theory, because again $Q(\ell_2) \cong M_n(Q(\ell_2))$ and non-zero projections are equivalent (thus all are stably equivalent), numbers in $K_1(Q)$ are the "indices" (e.g. of the Toeplitz operators on ℓ_2.

Moreover, $Q(\ell_2)$ contains infinitely many ... pair-wise non-isomorphic ... separable simple unital C*-subalgebras with trivial K-theory. (Can they be exact ?

Are there continuously many – or at least countably many – unital, non-nuclear and simple C*-subalgebras of $\mathcal{O}_2$ not pairwise isomorphic?)

If one tensors the Cuntz algebra $\mathcal{O}_2$ with any separable simple exact and unital C*-algebra B, then $A := B \otimes \mathcal{O}_2$ has again trivial K-theory $K_*(A) = 0$.

Thus, only in case of pi-sun C*-algebras A (i.e. purely infinite, separable, unital and nuclear C*-algebras) there is a chance that $K_*(A) = 0$ implies that A is isomorphic to the Cuntz algebra $\mathcal{O}_2$.)

The below given Definition 1.2.1 of purely infinite C^*-algebras is equivalent to this algebraic definition of J. Cuntz if A is a *unital and simple C^*-algebra*, cf. Proposition 2.2.1: It turns out that a *not necessarily simple or unital* C^*-algebra A is *purely infinite* (more precisely: is 1-purely infinite) in the sense of the below given Definition 1.2.1 if every non-zero element $a \in A_+$ is properly infinite, i.e., if there exists a sequence $d_n \in M_2(A)$ (depending on a, and the d_n can be chosen with zeros on the second line: $(d_n)_{21} = 0 = (d_n)_{22}$) with $\lim_n d_n^*(a \oplus 0)d_n = a \oplus a$, ([2]). This is property pi-1, that is a special case of property pi-n defined in Definition **??**

and the, – in a non-trivial manner equivalent – Definition 1.2.1 that is a special case of 1-purely infinite algebras, (i.e., pi(1)-algebras) of the weakly purely infinite algebras defined in Definition 2.0.4.

See Proposition 2.12.12 for the general equivalences **??**.

The name and definition of *nuclear* C^*-algebras is "inspired" – beside is very different – by the description of "nuclear" locally convex vector spaces V by uniqueness of the topology given by any compatible locally convex structure on algebraic tensor products $V \odot W$ with other locally convex vector spaces W, given by A. Grothendieck [**336**]. The C^*-algebra A is *nuclear*, if and only if, there is *only one* C^*-norm on the algebraic tensor product $A \odot B$ for every C^*-algebra B, cf. [**766**] (where it was called " property T " in 1964), and [**509**].

It has been later observed that the C^*-algebra A is nuclear if and only if there exists a *net* $\{V_\tau\}_{\tau \in T}$ of completely positive maps $V_\tau : A \to A$ of finite linear rank that converges in point-norm topology to id_A, (see [**426**] as outlined in our Remark 3.1.2(iii,f) that does *not* factorize through the work of A. Connes on von Neumann algebras, – or consult the paper of Choi and Effros [**145**, thm. 3.1] that applies results of A. Connes on von Neumann algebras).

A. Connes has shown that separable C^*-algebras A are nuclear if they are *amenable* in the sense of Banach algebra theory, cf. [**159**, cor. 2]. Later, U. Haagerup proved that each nuclear C^*-algebra A is amenable in this sense, cf. [**340**, thm.3.1]. We do never use the amenability of nuclear C^*-algebras in our considerations, and read throughout this book "amenable" as synonym of "nuclear".

[2]Here and some other places the notation $x \oplus y$ denotes the "diagonal" 2×2-matrix $[x_{jk}]$ with entries $x_{11} := x$, $x_{12} := 0$, $x_{21} := 0$ and $x_{22} := y$.

We say that a separable C^*-algebra A *is in the UCT class*, if A satisfies the conditions of the Universal Coefficient Theorem of Rosenberg and Schochet [**699**], cf. [**73**, thm. 23.1.1]. An observation of G. Skandalis says that the UCT for a separable C^*-algebra A is equivalent to: *There exists a locally compact metric space X such that A is* KK*-equivalent to* $\mathrm{C}_0(X)$ ([3]).

If a separable C^*-algebra A is KK-equivalent to an Abelian C^*-algebra, then A is also KK-equivalent to an algebra $\mathrm{C}_0(X)$, with X a locally compact *Polish* space that is *locally* (!) a finite CW-complex of dimension ≤ 3. This is because for every countably generated $\mathbb{Z}_2$-graded Abelian group $G = G_0 \oplus G_1$ there is a locally compact Polish space X that is *locally* an at most 3-dimensional CW-complex with $\mathrm{K}^*(X) \cong G$ for those X, cf. Lemma B.11.1 or proof of [**73**, cor.23.10.3]. If G is finitely generated then one can take for X a usual (= global) CW-complex of dimension ≤ 3.

CHECK (and replace if necessary) "equivariant" by some accepted expression ...

It seems likely that every separable nuclear C^*-algebra C is KK-equivalent to a pi-sun algebra A. Then only 2 questions remain: Does there exists a separable, simple, and nuclear C that is not in the UCT class ...

Other question ???

What about $K_*(A) = 0$ for general separable nuclear A ?

Can the UCT-class – in a sense – distinguish between $\mathcal{O}_\infty$ and the Jiang-Su algebra? ...

The proof of the Elliott Conjecture that is given in this book for the very special class of purely infinite, simple, nuclear and separable algebras uses some methods that will be stepwise generalized later to the case of non-simple *strongly* purely infinite (s.p.i.) C^*-algebras cf. Definition 1.2.2. One of the remaining problems for the applicability of the later described ideal-system equivariant classification of separable nuclear s.p.i. C^*-algebras has – among others – to do with the question under which conditional properties a purely infinite nuclear C^*-algebras A becomes strongly purely infinite (which is then in case of separable nuclear A equivalent to $A \cong A \otimes \mathcal{O}_\infty$ or to $A \cong A \otimes \mathcal{Z}$, where $\mathcal{Z}$ denotes the Jiang-Su algebra).

Give reference!! where this is proved here.

Conj.: ?????

(OK!)

If A is separable then $A_c := (A' \cap A_\omega)/\mathrm{Ann}(A)$ is always a unital C^*-algebra.

Here $A \subseteq A_\omega$ is natural embedded via $a \in A \mapsto \pi_\omega(a, a, \ldots)$ into $A_\omega := \pi_\omega(\ell_\infty(A))$ for some ultra-filter ω (= non-trivial character of the commutative C^*-algebra $\ell_\infty(\mathbb{C})$).

(seems that there are counterexamples for next !!)

[3] See [**73**, thm. 23.10.5], cf. also below reasoning for Corollary J.

If A_c has no character then A_c contains a unital copy of the Jiang-Su algebra $\mathcal{Z}$ and $A \cong A \otimes \mathcal{Z}$??? ???? It seems one needs much stronger assumptions ...

At least if A is s.p.i., separable and exact, or ?????

The question is:
Let B a separable unital C^*-algebra without characters. Does B contain a *nuclear* C^*-subalgebra D with $1_B \in D$ and without any character?

Moreover: Does $C := B \otimes_{\max} B \otimes_{\max} \cdots$ contain a copy of $\mathcal{Z}$?

Seems not to be the case ? Need stronger assumptions.

But does C contain unitally a copy of a *unital nuclear* D without characters?

Let D nuclear and unital, but without characters, does $D \otimes_{\min} D \otimes_{\min} \cdots$ contain the Jiang-Su algebra $\mathcal{Z}$?

Seems to have a negative answer ...?

This generalization explores *all aspects* of the technics that we introduce for the study of simple nuclear C^*-algebras and requires some additional study of the m.o.c. cones ...

`Give reference res.nuc. c.p. maps HERE !!` of the later in Definition ????

See the definition of residually nuclear c.p. maps in Definition 3.10.1 defined "residually nuclear" completely positive maps.

The Definition 3.5.9 – here considered in the special case of the ideal lattices of the considered algebras.

The residually nuclear maps generalize fiber-wise nuclear $\mathrm{C}(X)$-modular maps between $\mathrm{C}(X)$-C^*-algebras and generalize asymptotic $\mathrm{C}(X)$-algebras. But a suitable equivariant sort of the UCT and related families of representatives for sufficiently general UCT classes for the classification of non-simple amenable C^*-algebras is not in sight yet. But in case of separable nuclear C^*-algebras A with non-Hausdorff primitive ideal space $\mathrm{Prim}(A)$ of finite *decomposition* dimension ([4]) there could be a chance to find classifying representatives, cf. more in Chapter 8.

This monograph is essentially self-contained and requires only very basis knowledge on C^*-algebras, very elementary facts of K_*-theory and the classical results of J. Cuntz [**169**], [**172**] on his algebras $\mathcal{O}_n$ ([5]).

The proofs of Theorems A and B use that every unital separable exact C^*-algebra is a sub-quotient of the CAR-algebra M_{2^∞} (first shown in cf. [**437**] and

[4] Notice that the decomposition dimension and the covering dimension are very different for non-Hausdorff topological spaces in general!

[5] See Sect. 1 of Appendix A. We need only the defining relations and that $\mathcal{O}_2$ and $\mathcal{O}_\infty$ are simple, purely infinite, separable, unital and nuclear, with $\mathrm{K}_*(\mathcal{O}_2) = 0$, $\mathrm{K}_0(\mathcal{O}_\infty) = \mathbb{Z}$ and $\mathrm{K}_1(\mathcal{O}_\infty) = 0$. And that they really are KK-equivalent to the commutative C^*-algebras $\mathrm{C}_0(0,1]$ and $\mathrm{C}[0,1]$), or the algebra of one point: $\mathbb{C}$ in case of $\mathcal{O}_\infty$.

[**438**]). The ideal-equivariant generalizations in Theorem 6.3.1 is more general than Theorem A but uses similar ideas in its proof. But the point is that those ideas have to be generalized before in an ideal system equivariant manner. Its proof contains implicitly the old result on sub-quotients of M_{2^∞} in [**438**], that is a kind of "inverse" of Glimm's characterization of non-type-I C^*-algebras as a very special case.

We refer the reader to [**73**], [**692**] and [**816**] for the needed basic K-theory, and to [**73**] for some of the later used ideas of KK-theory, but we give in Chapter 4 proofs of those facts in K-theory that will be used for an interpretation of KK-groups as K_*-groups of generated by certain relative commutators.

We call a *simple*, purely infinite, separable, unital and nuclear C^*-algebra A a **pi-sun algebra** ([6]), cf. Chapters 2 and 3 for equivalent definitions and properties, for example, Part(vi) of Proposition 2.2.1 is another reason for our *decision* not to mention the *simplicity* of A in "pi-sun".

The class of *simple* **purely infinite, separable, unital and nuclear** C^*-algebras (in short: **pi-sun** algebras) include the simple Cuntz-Krieger algebras associated to Markov chains [**183**], [**174**] or – more generally – some simple graph-algebras and the Ruelle algebras associated to hyperbolic homeomorphisms of compact spaces [**653**] as well as some C^*-algebras associated to boundary actions of certain groups and to a class of groupoids [**19**], [**507**]. The crossed product C^*-algebra $\mathrm{C}(X) \rtimes \Gamma$ defined by the action of a lattice $\Gamma \subset G$ on the Fuerstenberg boundary X of G is a pi-sun algebra if G is a real connected semi-simple Lie group G without compact factors and with trivial center, [**19**]. Sometimes invariants of pi-sun algebras reflect geometric properties of the underlying dynamical systems, for example the K-theory groups of the Cuntz-Krieger algebras $\mathcal{O}_A$ are the Bowen–Franks invariants of flow equivalence for the related matrix A ([**102**], [**183**]). Many, but not all, Cuntz-Pimsner algebras of Hilbert bi-modules over commutative C^*-algebras, and certain classes of crossed products by "properly outer" actions are strongly purely infinite ([7]).

All pi-sun algebras A in the UCT-class are stably isomorphic to (generalized) Toeplitz C^*-algebras of a suitable Hilbert $\mathrm{C}_0(X, \mathbb{K})$-bi-module $\mathcal{H}$ where X is a locally compact Polish space with $\mathrm{K}^*(X) = \mathrm{K}_*(A)$. This is one of the many possible ways to show that the K-theory invariants are really exhausted by the pi-sun algebras in the UCT-class up to stable equivalence.

To provide the reader just here with at least one example in each stable isomorphism class we give *here* a description of suitable bi-modules $\mathcal{H}$ for given locally compact X (see Chapter 11 for more details):

---

[6] We do not mention the "simplicity" in the name "pi-sun" because the – very first – original algebraic definition of pure infiniteness of *unital* algebras A was: *For* $0 \neq a \in A$ *there are* $b, c \in A$ *with* $bac = 1$. Non-simple p.i. algebras require anyway a much more elaborate classification theory!

[7] Results of [**359**] show that the example of Rørdam [**687**] of a unital simple finite, but stably infinite (!), algebra $\mathcal{R}$ is a full corner of a Cuntz-Pimsner algebra given by a suitable Hilbert bi-module $\mathcal{H}(A, h)$ over $A := \mathrm{C}(S_2 \times S_2 \times \cdots, \mathbb{K})$. Thus, $\mathcal{R}$ is KK-equivalent to A.

Let $D\colon \mathrm{C}_0(X,\mathbb{K}) \to \mathcal{L}(\ell_2) = \mathcal{M}(\mathbb{K})$ be a faithful non-degenerate *-representation that is unitarily equivalent to its infinite repeat $\delta_\infty \circ D \cong D \oplus D \oplus \cdots$. Then $\mathcal{H} := \mathrm{C}_0(X,\mathbb{K})$ becomes a Hilbert $\mathrm{C}_0(X,\mathbb{K})$-bi-module with left action ϕ of $\mathrm{C}_0(X,\mathbb{K})$ on $\mathcal{H}$ given by

$$\phi(f)g := (1 \otimes D(f))g \quad \text{for} \quad f, g \in \mathrm{C}_0(X,\mathbb{K})\,.$$

The corresponding generalized Toeplitz-Pimsner C^*-algebra $\mathcal{T}(\mathcal{H})$ is simple, separable, stable and nuclear, cf. Corollary 2.18.7 ([8]). It is KK-equivalent to $\mathrm{C}_0(X,\mathbb{K})$ (and, hence, to A) by results of Pimsner [**633**, thm.4.4, cor.3.14]. Using Voiculescu's generalization of the Weyl–von-Neumann theorem, cf. [**43**] – or our further going generalizations of it in Proposition 5.4.1, one can show that $\mathcal{T}(\mathcal{H})$ is moreover purely infinite (cf. Corollary 2.18.14). Our Theorem B implies that $A\otimes\mathbb{K}$ is isomorphic to $\mathcal{T}(\mathcal{H})$ if A is a pi-sun algebra that is KK-equivalent to $\mathrm{C}_0(X)$. Since $\mathcal{T}(\mathcal{H})$ is stable and simple, it is the same as the Cuntz-Pimsner algebra $\mathcal{O}_{\mathcal{H}}$. The latter implies that $A \otimes \mathbb{K}$ *is the crossed product* $B \rtimes \mathbb{Z}$ *of some type-I algebra* B *by a suitable automorphism of* B.

In this way, we can see that the possible K_*-invariants are exhausted by the above examples, because they are exhausted by the $\mathrm{K}^*(X)$-groups of locally compact Polish spaces X, cf. Lemma B.11.1. Other constructions of pi-sun algebras with given K_*-invariants have been used by Elliott and Rørdam [**269**]. But all this examples do not say that it is their only appearance. Usually it is not easy to verify from some given informations whether an algebra is a (simple) pi-sun algebra in the UCT class or not. The present status is that there is no general method to detect from defining relations on generators if the universal C^*-algebra defined by this relations is KK-equivalent to a commutative C^*-algebra or not.

See more about the relations between our interpretation of the classification conjecture and its formulations by G. Elliott in Section 4, cf. also [**686**, sec. 2.2].

We consider here at first the special case where A *is simple, separable, nuclear,* $T^+(A) = \{0\}$ *and the real rank of* A *is zero.* Here we denote by $T^+(A)$ the cone of non-negative semi-finite lower semi-continuous traces $\tau\colon (A\otimes\mathbb{K})_+ \to [0,\infty]$.

It turns out that our considerations of the special case of (simple) pi-sun C^*-algebras imply that the general Conjecture of Elliott – here restricted to the particular case of pi-sun algebras – is equivalent to the below stated questions **(Q1)** and **(Q2)**. The notion of simple purely infinite algebras was introduced in [**172**, p. 186] and will be discussed in Chapter 2 in detail. We prefer to work with the below given Definition 1.2.1.

By [**269**], or by Theorem I below, the possible Elliott invariants are exhausted by C^*-algebras in the class of those *simple purely infinite separable nuclear unital* C^*-algebras (here called **pi-sun algebra**) that are KK-equivalent to commutative C^*-algebras, i.e., that are in the "UCT-class".

[8] Since D is unitarily equivalent to its infinite repeat $\delta_\infty \circ D$, the algebra $\mathcal{T}(\mathcal{H})$ is equal to the Cuntz-Pimsner algebra $\mathcal{O}(\mathcal{H})$.

Summing up we get: A complete proof of the Conjecture of Elliott in the case of simple separable nuclear C^*-algebras A and B of real rank zero and with $T^+(A) = T^+(B) = 0$ would imply in particular that the following two long-standing open Questions **(Q1)** and **(Q2)** could be answered affirmative:

(Q1) *Is every simple stably infinite unital* nuclear *C^*-algebra A of* real rank zero *also purely infinite?*
This means: *Is every non-zero projection $p \in A$ infinite in A if A has "real rank zero", A is simple, is nuclear, is separable, and A contains at least one infinite projection $q \neq 0$?*

(Q2) *Is $\mathcal{O}_2$ up to isomorphisms the only (simple) pi-sun C^*-algebra A with* $\mathrm{K}_*(A) = 0$ *?*

Here $\mathcal{O}_2$ denotes the *Cuntz algebra on two isometries as generators* (i.e. $s_1, s_2 \in \mathcal{O}_2$, with $s_1^* s_1 = s_2^* s_2 = 1 = s_1 s_1^* + s_2 s_2^*$ cf. Section 1 of Appendix A or [**169**].

By Theorem E(ii) below, the Question **(Q1)** has a positive answer (also if A has not real rank zero) in the special case where $A \cong B \otimes C$ and where the algebras B and C both are *not "elementary"*, i.e., both are not isomorphic to the compact operators $\mathbb{K}(\mathcal{H})$ on a Hilbert space $\mathcal{H}$ of infinite or finite dimension. Implicitly, our results imply also that a simple *unital* separable nuclear C^*-algebra A is purely infinite, if and only if, the relative commutant $A' \cap A_\omega$ of A in its ultrapower A_ω is *not* stably finite (cf. [**448**, rem. 2.13] for details), and this is the case, if and only if, this relative commutant is purely infinite and simple ([9]). Then, one has $A \cong \mathcal{O}_2$, if and only if, $0 = [1] \in \mathrm{K}_0(A' \cap A_\omega)$ (cf. Corollary G).

But even if it turns out that Question **(Q1)** has a negative answer, we could add to the invariants the pre-ordered "local" Cuntz semigroup $\mathrm{CS}(A)$, cf. Definition 2.4.3, or [**171**], [**175**] for the unital case, as an *almost* K-theoretic invariant. Then we can describe the *purely infinite* algebras in the following way (cf. Corollary 2.4.6):
A *simple* C^*-algebra A is purely infinite – or is isomorphic to $\mathbb{K}(\mathcal{H})$ for some Hilbert space $\mathcal{H}$ –, if and only if, the "local" Cuntz semigroup $\mathrm{CS}(A)$ of A does not contain an "infinitesimal sequence" $[a_n] \in \mathrm{CS}(A)$ in the sense of Definition 2.4.4 of infinitesimal sequences in pre-ordered semi-groups.

Another possible "weak additional assumption" for an answer of question **(Q1)** is the assumption that A has the corona factorization property (CFP) – that we discuss in Section 26 of Appendix A.

If a simple separable C^*-algebra A has real rank zero and satisfies the (CFP) then A is stably finite or is purely infinite.

If $B := A \otimes \mathbb{K}(\ell_2)$ contains an infinite projection P, then this projection is properly infinite by simplicity of B. More generally if $P \in B$ is a projection and

[9] More generally: If a C^*-algebra A has the property that $F(A) := (A' \cap A_\omega)/\operatorname{Ann}(A, A_\omega)$ and A are both separable, then A is simple and *nuclear*, and then only the three cases can occur: $A = 0$, or A and $F(A)$ are both purely infinite, or where $A \otimes \mathbb{K} \cong \mathbb{K}$ and $F(A) \cong \mathbb{C}$, cf. [**448**].

$0 \neq b = PbP$ is an infinite element, then b and P are properly infinite in B by simplicity of B

$\Leftarrow$ Where is this proved?

How the (CFP) should manage that this strong alternative happens?

If one of the (non-zero) projections q is infinite, then q is automatic properly infinite by simplicity of A.

It is sufficient then to consider qAq because then there exists a unital morphism of the Cuntz algebra $\mathcal{O}_\infty$ into qAq. To get that A is purely infinite, one needs that every non-zero projection $0 \neq p \leq q$ is infinite (otherwise no projection in pAp is infinite!).

It needs that each non-zero projection p is infinite, because then p is automatic properly infinite by simplicity of A. This follows from the general property that the set of elements $a \in A$ with $a \oplus p \precsim p$ is a closed ideal of A.

But the assumptions give only that all non-zero projections p have the property that there exists an individual number $n(p) \in (N)$ such that $1_{n(p)} \otimes p$ is infinite in $M_{n(p)} \otimes A$. – It is then there in $M_{n(p)} \otimes A$ properly infinite.

Until here we have not used the ... ?????

The nuclearity of A is not considered in all combinations of above listed additional assumptions to get A purely infinite: There could be some weaker additional assumption in case of nuclear A, not found or conjectured yet (2022).

The below given Corollary J shows that Question **(Q2)** is equivalent to the following important open question **(Q2*)**, and that positive answers to **(Q1)** and **(Q2)** together imply a proof of the Conjecture of Elliott in the case $T^+(A) = \{0\}$ and amenable separable A with real rank zero .

(Q2*) *Does every separable* nuclear *C^*-algebra satisfy the Universal Coefficient Theorem?*

Here the Universal Coefficient Theorem (=: UCT) in the sense of Rosenberg and Schochet is considered, [**699**]. We refer the reader to [**73**, sec. 23]. A separable C^*-algebra satisfies the UCT, if and only if, it is KK-equivalent to a commutative C^*-algebra (cf. [**73**, thm: 23.10.5], [**726**, prop. 3.5], [**699**, cor. 7.5]). It suffices to consider in question **(Q2)** simple purely infinite A with $\mathrm{K}_*(A) = 0$ that are fixpoint-algebras A of circle actions on $\mathcal{O}_2$, cf. Corollary J.

We use a careful explained and conceptual approach for proofs in case of simple algebras, that is not the shortest possible way in this special case, but illustrate more involved generalizations that allow later to generalize some of the results to non-simple algebras: the results allow to classify all separable stable nuclear C^*-algebras up to tensor products with the Cuntz algebra $\mathcal{O}_\infty$ by its KK-equivalence classes for some generalized ideal-system equivariant KK-theory. We consider the non-simple case and the needed definitions in the second part of this introduction.

In Chapter 12 we give the proofs of lemmas and propositions which are used to extend the ideas for simple algebras to the non-simple case.

If we consider all from this general viewpoint, then, in Chapters 2 and 3, we establish the implication { purely infinite $\Rightarrow$ "strongly" purely infinite } in the particular case where $\mathrm{Prim}(A)$ consists only of one point. In Chapters 5 and 7 we study the consequences of this implication. Generalizations of results of Chapters 2 and 3 to the case of non-simple algebras are in parts joint works with E. Blanchard and M. Rørdam. Detailed proofs did appear in separate papers, ([**462**], [**463**], [**92**], [**93**]), cf. remarks in Chapters 2 and 3.

Our exposition is completely self-contained and needs only basic knowledge on C^*-algebras, as e.g. functional calculus and some basic observations of KK-theory from textbooks, e.g. [**73**]. The use of some ideas from [**172**] will be explained in Chapter 4 and Appendix A.

Notice that this *very detailed introduction contains all the proofs of the Corollaries C, D, F, G, H, J, L and N.*

Only the very key Theorems A, B, E, I, K, M and O will be proved in the chapters of this book, together with some other independent results that could be initial for some future research.

1. The case of simple purely infinite algebras

We consider first the case of simple C^*-algebras. The spatial tensor product of C^*-algebras A and B by $A \otimes B$ it is the completion of the algebraic tensor product $A \odot B$ with respect to the minimal C^*-norm on it, cf. [**766**]. C^*-algebras A are called **exact** if the functor $B \mapsto A \otimes B$ (here with spatial = minimal tensor product) is an exact functor on the category of C^*-algebras (see [**428**]-[**438**], [**810**] and Chapters 3 and 6).

Obviously every nuclear C^*-algebra A is exact, by the definition of nuclearity via uniqueness of the C^*-norm on the algebraic tensor product $A \odot B$ for each C^*-algebra B ([**766**], [**509**]).

The following Theorems A, B and E in the case of simple algebras (and Theorems K and M in the non-simple cases) are the fundamental results of this book. ...

THEOREM A. *Let A denote a unital separable C^*-algebra.*

(i) *A is exact, if and only if, A is isomorphic to a C^*-subalgebra of $\mathcal{O}_2$.*
(ii) *A is nuclear, if and only if, A is isomorphic to the range of a unital conditional expectation from $\mathcal{O}_2$ onto a C^*-subalgebra of $\mathcal{O}_2$.*

Clearly Part (i) remains true if A is not unital because A is exact if and only if its unitization $\widetilde{A}$ is exact.

The embedding of unital separable exact A into $\mathcal{O}_2$ as expressed in Part (i) can be always taken as unital *-monomorphism from A into $\mathcal{O}_2$, because $\mathrm{K}_*(\mathcal{O}_2) = 0$

implies that every non-zero projection $p \neq 1$ of $\mathcal{O}_2$ is the range of an isometry, cf. [**172**] and Lemma 4.2.6(ii).

A slight modification of the arguments in the proof of Corollary C (below) shows that Theorem B(i)-(iii) implies that any two unital monomorphisms $h, k\colon A \to \mathcal{O}_2$ are unitarily homotopic in the sense of the below given definition. In particular, they are approximately unitarily equivalent.

We prove Theorem A in Chapter 6. The idea of the proof is the following: Our Weyl–von-Neumann–Voiculescu type theorem for p.i. algebras (see Chapter 5)

give exact cite for our WvNV-theorem in Chp.5 !!!

implies that sub-quotients of $\mathcal{O}_2$ are isomorphic to subalgebras of $\mathcal{O}_2$. We apply Glimm's theorem to the anti-liminal algebra $\mathcal{O}_2$, and then we use the characterization of separable exact algebras as sub-quotients of the CAR algebra M_{2^∞}, [**438**]. Certainly, one could also use directly the natural inclusion of M_{2^∞} into $\mathcal{O}_2$. But then one does not get the additional result that the embedding of unital *nuclear* A into $\mathcal{O}_2$ can be chosen such that the conditional expectation in Part (ii) of Theorem A, is an *extreme point* of the linear contractions of $\mathcal{O}_2$, cf. Remark 6.2.2. It implies e.g. that there are unital separable nuclear C^*-algebras A and unital embeddings of A into $\mathcal{O}_2 \cong \mathcal{O}_2 \otimes 1 \subset \mathcal{O}_2 \otimes \mathcal{O}_2 \cong \mathcal{O}_2$ that can not be "conjugate" in $\mathcal{O}_2 \otimes \mathcal{O}_2 \otimes \mathbb{K}$ by using automorphisms of $A \otimes \mathcal{O}_2 \otimes \mathbb{K}$ and $\mathcal{O}_2 \otimes \mathcal{O}_2 \otimes \mathbb{K}$, though even all unital C^*-monomorphisms of A into $\mathcal{O}_2$ are unitarily homotopic (in the sense of Definition 5.0.1 in Chapter 5).

Theorem A will be used to formulate and prove the below stated Theorem B, which we start to explain now:

Suppose that A is a separable unital exact C^*-algebra. Theorem A shows the existence of unital *-monomorphisms $h_1\colon A \to \mathcal{O}_2$ and $h_2\colon \mathcal{O}_2 \otimes \mathcal{O}_2 \to \mathcal{O}_2$, because $\mathcal{O}_2 \otimes \mathcal{O}_2$ is nuclear. We define a unital *-monomorphism $h_0^u\colon A \to \mathcal{O}_2$ by $h_0^u(a) := h_2(h_1(a) \otimes 1)$. If B is a unital C^*-algebra which contains a (fixed) unital copy of $\mathcal{O}_2$, then h_0^u defines a unital nuclear *-monomorphism from A into B (which we fix from now on).

We define $h_0\colon A \otimes \mathbb{K} \to B \otimes \mathbb{K}$ by $h_0 := h_0^u \otimes \mathrm{id}_{\mathbb{K}}$.

Let D, E be C^*-algebras and $h\colon D \to E$, $k\colon D \to E$ C^*-morphisms. We say that h and k are **unitarily equivalent** if there is a unitary u in the multiplier algebra $\mathcal{M}(E)$ of E such that $u^*k(\cdot)u = h$, and we say that h and k are **unitarily homotopic** ([10]) if there exists a strongly continuous map $t \mapsto U(t)$ from $\mathbb{R}_+ = [0, \infty)$ into the unitary operators in $\mathcal{M}(E) \subseteq \mathcal{L}(E)$ such that $\lim_{t\to\infty} U(t)^*k(b)U(t) = h(b)$ for every $b \in D$. (Note that this does *not* imply that h and k are homotopic: unitarily equivalent morphisms are unitarily homotopic, but unital inner automorphisms are not necessarily homotopic to the identity map.) If h and k are unitarily homotopic, then h is homotopic to $U(0)^*k(\cdot)U(0)$ in the usual sense. But we can conclude homotopy from unitary homotopy in the case

[10] Compare with the more general Definition 5.0.1 in the case where $h, k\colon D \to \mathcal{M}(E)$.

where the unitary group of $\mathcal{M}(E)$ is connected, e.g., if E is stable and σ-unital, if E is an AF-algebra, or if E is purely infinite and simple and $\mathrm{K}_1(E) = 0$, cf. [**172**], e.g. in case $E = \mathcal{O}_\mathrm{n}$, $n = 2, 3, \ldots, \infty$. Under this very special circumstance the unitary homotopy becomes considerably *stronger* than homotopy. But homotopy implies unitary homotopy in some cases, see Corollary D and the remarks below Corollary L and Theorem M.

Let $[\mathrm{Hom}_{\mathrm{nuc}}(D, E)]$ denotes the classes of unitarily equivalent nuclear *-homomorphisms from D into E. If $\mathcal{M}(E)$ contains a unital copy $C^*(s,t) \subseteq E$ of $\mathcal{O}_2$, then one can define the **Cuntz addition** $[h] + [k] := [h \oplus_{\mathcal{O}_2} k]$ of unitary equivalence classes of morphisms $h, k \in \mathrm{Hom}_{\mathrm{nuc}}(D, E)$ by:

$$h \oplus_{\mathcal{O}_2} k(d) := \; sh(d)s^* + tk(d)t^* \qquad \text{for} \quad d \in D\,,$$

where s and t denote the canonical generators of the copy of $\mathcal{O}_2$ in E. The definition is independent – up to unitary equivalence – of the choice of the representatives h and k of the unitary equivalence classes $[h]$ and $[k]$ and of the chosen unital copy of $\mathcal{O}_2$. $\mathrm{Hom}_{\mathrm{nuc}}(D, E)$ becomes with Cuntz addition a commutative semigroup. All that follows from the observation of Cuntz [**172**] that $t_i = us_i$ where $u = \sum t_i s_i^*$ is unitary if s_i and t_i for $(i = 1, ..., n)$ are canonical generators of unital copies of $\mathcal{O}_\mathrm{n}$ (i.e., $t_i^* t_i = s_i^* s_i = 1$, $\sum t_i t_i^* = \sum s_i s_i^* = 1$).

The Cuntz addition coincides with the natural addition of morphisms if E is *stable*, i.e., if $E \cong F \otimes \mathbb{K}$ for some C^*-algebra F, because the "natural" embedding $\mathbb{K} \oplus \mathbb{K} \subset M_2(\mathbb{K}) \cong \mathbb{K}$ is defined by a selection of a unital copy of $\mathcal{O}_2$ in $\mathcal{L}(H) = \mathcal{M}(\mathbb{K})$, and this copy is so natural or artificial as the Cuntz addition is in general: It becomes "natural" or "well-defined" only after *passage to unitary equivalence* classes. It is useful to remind this phenomenon if one seeks for generalizations of this constructions to the case where one wants to get some sort of "equivariant" isomorphisms up to conjugacy for actions of groups, quantum-groups, (or specific sub-systems of ideals) by suitable generalizations of our approach, because then one can only expect some sort of outer co-cycle conjugacy, sometimes only by 2-co-cycles.

The natural map $\mathrm{Hom}(A, B) \ni h \mapsto [h - 0] \in \mathrm{KK}(A, B)$ is given by the Kasparov module $(h, B, 0)$, i.e., $\phi := h$, $E := B$ and $F := 0$. Or some other equivalent constructions, as e.g. by the natural isomorphism $\mathrm{KK}(A, B) \cong \mathrm{Ext}(SA, B)$ and the mapping cone construction.

We compare the semi-group of unitary equivalence classes of nuclear morphisms in $\mathrm{Hom}_{\mathrm{nuc}}(A \otimes \mathbb{K}, B \otimes \mathbb{K})$ with nuclear KK-theory and nuclear Ext-theory in Chapters 8 and 9, using Theorem 4.4.6 and other basics from Chapter 4. A natural semigroup morphism

$$\alpha\colon\; \mathrm{Hom}_{\mathrm{nuc}}(A \otimes \mathbb{K}, B \otimes \mathbb{K}) \to \mathrm{Ext}_{\mathrm{nuc}}(A \otimes \mathbb{K}, SB) \cong \mathrm{KK}_{\mathrm{nuc}}(A, B)$$

is defined as follows:

We define a nuclear *-monomorphism

$$\psi_h \colon A \otimes \mathbb{K} \to \mathcal{M}(SB \otimes \mathbb{K})/(SB \otimes \mathbb{K})$$

(i.e., a representative of an element of $\mathrm{Ext}_{\mathrm{nuc}}(A\otimes\mathbb{K}, SB)$) for a given representative $h\colon A\otimes\mathbb{K} \to B\otimes\mathbb{K}$ of $[h] \in \mathrm{Hom}_{\mathrm{nuc}}(A\otimes\mathbb{K}, B\otimes\mathbb{K})$. It gives the Busby invariant of an extension $[h-0]$ in $\mathrm{Ext}_{\mathrm{nuc}}(A\otimes\mathbb{K}, SB)$, which is just the mapping cone construction. It can be described with help of the natural monomorphisms and isomorphisms

$$B \otimes \mathbb{K} \subset \mathrm{Q}(\mathbb{R}_+, B \otimes \mathbb{K}) := \mathrm{C_b}([0,\infty), B \otimes \mathbb{K})/\, \mathrm{C_0}([0,\infty), B \otimes \mathbb{K})$$

and ???

Is this the correct definition?

Or have we to take here $0 \oplus (B \otimes \mathbb{K})$? **??**

Or can we use here that $B \otimes \mathbb{K} \subset \mathrm{C_b}([0,\infty), B \otimes \mathbb{K})$?

Compare with image of $[(h, B, 0)] \in \mathrm{KK}(A, B)$
by the map $\mathrm{KK}(A, B) \to \mathrm{Ext}(A, SB)$!!!

Or explore here that $B \otimes \mathbb{K} \subset \mathrm{C_b}([0,\infty), B \otimes \mathbb{K})$?

$$(B \otimes \mathbb{K}) \oplus (B \otimes \mathbb{K}) \subset \mathrm{Q}(\mathbb{R}_-, B \otimes \mathbb{K}) \oplus \mathrm{Q}(\mathbb{R}_+, B \otimes \mathbb{K}) \cong \mathrm{Q}(\mathbb{R}, B \otimes \mathbb{K})$$

and $\mathrm{Q}(\mathbb{R}, B \otimes \mathbb{K}) \subset \mathcal{M}(SB \otimes \mathbb{K})/SB \otimes \mathbb{K}$, where we use the notation

$$\mathrm{Q}(X, D) := \mathrm{C_b}(X, D)/\, \mathrm{C_0}(X, D)$$

for a locally compact space X and a C^*-algebra D. Then ψ_h is defined by

$$\psi_h(a) := (0, h(a)) \in (B \otimes \mathbb{K}) \oplus (B \otimes \mathbb{K}) \subset \mathrm{Q}(\mathbb{R}, B \otimes \mathbb{K}).$$

The corresponding extension of $A \otimes \mathbb{K}$ by $SB \otimes \mathbb{K}$ is the well-known *mapping cone* C_h of h, see [**73**, p. 236/237].

We denote by $[h-0]$ the class of h in $\mathrm{Ext}_{\mathrm{nuc}}(A \otimes \mathbb{K}, SB)$.

`Next red nearly a black-out??`
`One has to add the universal trivial extension`
$H_0 \colon A \otimes \mathbb{K} \to \mathcal{M}(SB)/SB$ `and gets` $[h-0] = [k-0]$
`if and only if`
$H_0 \oplus h$ `and` $H_0 \oplus k$ `are unitary equivalent` $\mathrm{mod}\, SB$ `!!`

We have that $[h-0] = [k-0]$ in $\mathrm{Ext}_{\mathrm{nuc}}(A \otimes \mathbb{K}, SB)$ if h and k are stably unitarily equivalent by unitaries in $\mathcal{M}(\mathrm{C_0}(\mathbb{R}_+, B \otimes \mathbb{K}))/\, \mathrm{C_0}(\mathbb{R}_+, B \otimes \mathbb{K})$, because, for unital B, every unitary of $\mathcal{M}(\mathrm{C_0}(\mathbb{R}_+, B \otimes \mathbb{K}))/\, \mathrm{C_0}(\mathbb{R}_+, B \otimes \mathbb{K})$ lifts to a unitary in $\mathcal{M}(\mathrm{C_0}(\mathbb{R}_+, B \otimes \mathbb{K}))$, but those unitaries are given by strictly continuous maps from $\mathbb{R}_+$ into the unitaries of $\mathcal{M}(B \otimes \mathbb{K})$ ([11]).

[11] In this particular case the unitary equivalence can be given by an operator-norm continuous path $t \mapsto \exp(ih_1(t)) \cdot \ldots \cdot \exp(ih_n(t))$ with continuous maps $t \mapsto h_k(t) = h_k(t)^* \in B \otimes \mathbb{K}$.

In particular, $\alpha([h]) := [h - 0]$ is well-defined, and the natural isomorphism $\mathrm{Ext}_{\mathrm{nuc}}(A \otimes \mathbb{K}, SB) \cong \mathrm{KK}_{\mathrm{nuc}}(A, B)$ maps the element $[h - 0]$ into the usual KK-difference of h and the zero morphism, which is given by the $\mathrm{KK}_{\mathrm{nuc}}$-class of the Kasparov module $(B, h, 0)$.

The key result for the classification of pi-sun algebras is the following Theorem B, which combines three essentially different "theorems" as Parts (i)+(ii), (iii) and (iv).

THEOREM B. *Let A be a separable unital exact C^*-algebra and suppose that B is unital and contains a copy of $\mathcal{O}_2$ unitally. Let $h_0\colon A \otimes \mathbb{K} \to B \otimes \mathbb{K}$ the up to unitary homotopy unique *-monomorphism that is defined by Theorem A.*

(i) *The map $\alpha\colon [h] \mapsto [h - 0]$ (given by the mapping cone construction by h) is a semigroup epimorphism from the semigroup of unitary equivalence classes $[h]$ of nuclear C^*-morphisms $h \in \mathrm{Hom}_{\mathrm{nuc}}(A \otimes \mathbb{K}, B \otimes \mathbb{K})$ onto $\mathrm{KK}_{\mathrm{nuc}}(A, B)$, and*

(ii) `Needs to prove first homotopy invariance of` $\mathrm{R}(h_0\,;\, A, B)$`?`
`The decomposition argument works now well ! ??`
$[h - 0] = [k - 0]$ in $\mathrm{KK}_{\mathrm{nuc}}(A, B)$ if and only if $h \oplus h_0$ and $k \oplus h_0$ are unitarily homotopic.

(iii) *If moreover B is purely infinite and simple, then $h \oplus h_0$ is unitarily homotopic to h for* all **-monomorphisms $h \in \mathrm{Hom}(A \otimes \mathbb{K}, B \otimes \mathbb{K})$.*

(iv) `Check again proof of part (iv)!`
`Does it work for stable` D `and` E `? ??`
*Let D and E separable C^*-algebras and $h\colon D \to E$, $k\colon E \to D$ *-monomorphisms such that $h \circ k$ is unitarily homotopic to id_E and $k \circ h$ is unitarily homotopic to id_D.*

Then there exists an isomorphism φ from D onto E that is unitarily homotopic to h.

`Can only prove -- so far -- that:`

Then there exists an isomorphism φ from D onto E that is approximately unitary equivalent to h.

Notice here that $\mathrm{KK}(A, B) = \mathrm{KK}_{\mathrm{nuc}}(A, B)$ if one of A or B is nuclear.

The proof of Parts (i) and (ii) of Theorem B is given in Chapter 9. We prove Part (iii) in Chapter 7 and Part (iv) in Chapter 10.

One can use the *result* of Theorem B to relax the above given very special definition of the "zero-element" h_0 as follows.

A C^*-algebra morphism $h\colon A \otimes \mathbb{K} \to B \otimes \mathbb{K}$ is unitarily homotopic to h_0, if and only if, there exist *-monomorphisms $k_1\colon A \otimes \mathbb{K} \to \mathcal{O}_2 \otimes \mathbb{K}$ and $k_2\colon \mathcal{O}_2 \otimes \mathbb{K} \to B \otimes \mathbb{K}$ such that

$h = k_2 k_1$?????? (or only h unitarily homotopic to $k_2 k_1$??) **??**

and $B \otimes \mathbb{K}$ is the closed ideal generated by $k_2(\mathcal{O}_2 \otimes \mathbb{K})$. This can be seen from Theorem B and following general observations (1)-(3) using [**172**]:

(1) If $\mathcal{O}_2 \cong C^*(s,t) \subseteq B$ is a given copy of $\mathcal{O}_2$ in B with $1_B \in \mathcal{O}_2$, then every (non-zero) C^*-morphism $h\colon \mathcal{O}_2 \otimes \mathbb{K} \to B \otimes \mathbb{K}$ that generates $B \otimes \mathbb{K}$ as the closed ideal of $B \otimes \mathbb{K}$ generated by the image of h, i.e., the C^*-morphism h satisfies $(B \otimes \mathbb{K})h(\mathcal{O}_2 \otimes \mathbb{K})(B \otimes \mathbb{K}) = B \otimes \mathbb{K}$, is "unitary homotopic" in the multiplier algebra $\mathcal{M}(B \otimes \mathbb{K})$ – in the sense of Definition 5.0.1 – to a C^*-morphism $k \otimes \mathrm{id}_{\mathbb{K}}\colon \mathcal{O}_2 \otimes \mathbb{K} \to B \otimes \mathbb{K}$, where $k\colon \mathcal{O}_2 \to B$ is a unital C^*-morphism.

This new copy $k(\mathcal{O}_2)$ of $\mathcal{O}_2$ can be different from the given copy $C^*(s,t)$ and k is not necessarily homotopic in $\mathrm{Hom}(\mathcal{O}_2, B)$ to the C^*-morphism $h\colon \mathcal{O}_2 \to B$ defined by $h(s) := s$ and $h(t) := t$, because it can happen that the class $[k(s)s^* + k(t)t^*]$ is non-zero in $\mathrm{K}_1(B)$ ([12]).

(2) The *statements* (i) and (ii) of Theorem B are independent of a particular selection of a unital copy of $\mathcal{O}_2$ in B.

(3) $h_0\colon A \otimes \mathbb{K} \to \mathcal{O}_2 \otimes \mathbb{K}$ is unitarily homotopic to $k \otimes \mathrm{id}_{\mathbb{K}}$ by Parts (i,ii,iii) of Theorem B because $\mathrm{KK}(A, \mathcal{O}_2) = 0$, cf. [**172**].

It requires that Thm. B is correct with ????

But this can be shown also by elementary considerations form $\mathrm{K}_*(\mathcal{O}_2) = 0$, the K_1-injectivity of $\mathcal{O}_2$ and of $\mathcal{D}_2 := \mathcal{O}_2 \otimes \mathcal{O}_2 \otimes \cdots$, if one uses both of [**172**] and the Elliott-Rørdam isomorphism $\mathcal{O}_2 \cong \mathcal{D}_2$.

The proof of Parts (i) and (ii) of Theorem B is given in Chapter 9, using Chapters 7, 8 and ????. It can be outlined as follows:

We extend α to a semigroup morphism from $\mathrm{Hom}_{\mathrm{nuc}}(A \otimes \mathbb{K}, \mathrm{Q}(\mathbb{R}_+, B \otimes \mathbb{K}))$ into $\mathrm{Ext}_{\mathrm{nuc}}(A \otimes \mathbb{K}, SB) \cong \mathrm{KK}_{\mathrm{nuc}}(A, B)$ in the obvious way.

(It is formally almost the same definition as for the mapping cone construction!)

We use basic observations in Chapter 4 to recognize that

$$[h_0] + \mathrm{Hom}_{\mathrm{nuc}}(A \otimes \mathbb{K}, \mathrm{Q}(\mathbb{R}_+, B \otimes \mathbb{K}))$$

is naturally isomorphic to the Grothendieck group $\mathrm{R}(A, B)$ of the semi-group of unitary equivalence classes of morphisms in $\mathrm{Hom}_{\mathrm{nuc}}(A \otimes \mathbb{K}, \mathrm{Q}(\mathbb{R}_+, B \otimes \mathbb{K}))$.

```
in between: there is a new way to apply directly Theorem 4.4.6,
using Section 5 of Chapter 8!
proof property (CD) first?
```

It requires some careful technical observations and in essence an independent proof for homotopy invariance of $\mathrm{R}(A, B)$ with respect to the second variable B

In fact is not clear if the older variant does that,
except by N.Ch. Phillips argument,
seems not to work by application of Theorem 4.4.6,
because $[k \oplus H_0] = [H_0]$ in $\mathrm{Ext}(A, SB)$
does (perhaps) not automatically imply that $k \oplus h_0$
and h_0 are stably asymptotically homotopic.

[12] This is one of the reasons that we pass to stable algebras

--> This is now at the end of Chp. 8 fixed.

Is it still open if the ''algebraic'' KK
is really homotopy invariant?.
Needs that evaluations at $t \in [0,1]$ define
isomorphisms $\mathrm{KK}([0,1]\mathcal{C};\, A, \mathrm{C}([0,1], B)) \to \mathrm{KK}(\mathcal{C};\, A, B)$.
Here, the operator homotopy seems to be enough?

to show that α induces an isomorphism of $\mathrm{R}(A, B)$ and $\mathrm{Ext}_{\mathrm{nuc}}(A \otimes \mathbb{K}, SB)$. This yields, in particular, a proof of Theorem B(ii).

??? Next needs first to show the injectivity of $G(h_0;\, A, B) \to G(H_0;\, A, B)$ to get the homotopy invariance !!!

The natural isomorphism $\mathrm{Ext}_{\mathrm{nuc}}(A \otimes \mathbb{K}, SB) \cong \mathrm{KK}_{\mathrm{nuc}}(A, B)$ and the homotopy invariance of $\mathrm{KK}_{\mathrm{nuc}}(A, B)$ imply that, for a nuclear asymptotic C^*-morphism k from $A \otimes \mathbb{K}$ into $B \otimes \mathbb{K}$, i.e., , for $k \in \mathrm{Hom}_{\mathrm{nuc}}(A \otimes \mathbb{K}, \mathrm{Q}(\mathbb{R}_+, B \otimes \mathbb{K}))$, $h_0 \oplus k$ is unitarily equivalent to all its "up/down-scales", given by homeomorphisms of $\mathbb{R}_+$.

But we show this homotopy invariance directly and use the resulting scaling invariance much earlier in the way of proving that α induces an isomorphism from the continuous Rørdam groups $\mathrm{R}(A, B)$ onto $\mathrm{KK}_{\mathrm{nuc}}(A, B)$.

next? Senseless? Correction?

It means that the powerful Theorem B can be used

(and are used here ?) as a reminder of several results that can be deduced from Theorem B but can be also proved independently by other methods.

The homotopy invariance implies, for

$$k\colon A \otimes \mathbb{K} \to \mathrm{Q}(\mathbb{R}_+, B \otimes \mathbb{K})\,,$$

the existence of $h \in \mathrm{Hom}_{\mathrm{nuc}}(A \otimes \mathbb{K}, B \otimes \mathbb{K})$ that is unitary equivalent to $h_0 \oplus k$ in

$$\mathrm{Hom}_{\mathrm{nuc}}(A \otimes \mathbb{K}, \mathrm{Q}(\mathbb{R}_+, B \otimes \mathbb{K}))\,.$$

Does it prove finally Part (i) of Theorem B ???

The absorption result (iii) of Theorem B is an asymptotic version (given in Chapter 9) of the generalized Weyl–von-Neumann–Voiculescu theorem (cf. Chapter 5), and Part (iv) of Theorem B is a "continuous" version of a result of Elliott, cf. [**256**], [**678**], and Chapter 10.

Notice that our proof of Part (iv) is more general, because it needs only assumptions on D and E that are independent and weaker than all those required for A and B in Theorem B. In particular, exactness, amenability (nuclearity), stability or pure infiniteness are all not used.

Theorem B leads to the below given classification results Corollaries C and H.

If A and B are pi-sun algebras, then we find pi-sun algebras C and D, such that C and D both contain $\mathcal{O}_2$ unitally, and $A\otimes\mathbb{K}\cong C\otimes\mathbb{K}$, $B\otimes\mathbb{K}\cong D\otimes\mathbb{K}$, cf. J. Cuntz [**172**]. If E or F is nuclear and separable, we have $\operatorname{Hom}(E,F)=\operatorname{Hom}_{\mathrm{nuc}}(E,F)$ and $\mathrm{KK}(E,F)=\mathrm{KK}_{\mathrm{nuc}}(E,F)$. Thus, by Theorem B, for $z\in\mathrm{KK}(A,B)$, there is a *-monomorphism $h\in\operatorname{Hom}(A\otimes\mathbb{K},B\otimes\mathbb{K})$ such that $z=[h-0]$ and that $h(A\otimes\mathbb{K})$ contains a strictly positive element of $B\otimes\mathbb{K}$.

If moreover $z=[h-0]$ is a KK-equivalence and $w=[k-0]\in\mathrm{KK}(B,A)$ is the KK-inverse of z then $[\mathrm{id}_A-0]=z\otimes_B w=[kh-0]$ in $\mathrm{KK}(A,A)$ and $[id_B-0]=[hk-0]$ in $\mathrm{KK}(B,B)$. By Theorem B(ii)+(iii), hk is unitarily homotopic to $\mathrm{id}_{B\otimes\mathbb{K}}$ and kh is unitarily homotopic to $\mathrm{id}_{A\otimes\mathbb{K}}$. `Depends from validity of OLD B(iv)`

By Theorem B(iv), there exists an isomorphism λ from $A\otimes\mathbb{K}$ onto $B\otimes\mathbb{K}$ which is unitarily homotopic to h.

Let $\gamma\colon\mathrm{KK}(A,B)\to\operatorname{Hom}(\mathrm{K}_*(A),\mathrm{K}_*(B))$ be the natural functor from $\mathrm{KK}(\cdot,\cdot)$ into $\operatorname{Hom}(\mathrm{K}_*(\cdot),\mathrm{K}_*(\cdot))$ given by $\gamma(z)\colon[x]\in\mathrm{K}_*(A)\mapsto[x]\otimes_A z\in\mathrm{K}_*(B)$, see [**73**, sec. 23.1]. Then $\gamma([h-0])=\mathrm{K}_*(h)$ if $h\in\operatorname{Hom}(A\otimes\mathbb{K},B\otimes\mathbb{K})$, cf. Chapter 8 for more details.

But $[1_A]=[1_A\otimes p_{11}]\in\mathrm{K}_0(A)$ and $\mathrm{K}_0(h)([1_A\otimes p_{11}])=[h(1_A\otimes p_{11})]\in\mathrm{K}_0(B)$, where p_{jk} here denotes the natural basis of $\bigcup_n M_n\subseteq\mathbb{K}$ with $p_{jk}^*=p_{kj}$ and $p_{jk}p_{\ell m}=\delta_{k,\ell}p_{jm}$ i.e., p_{11} is the "upper left corner minimal non-zero projection" in $\mathbb{K}$. Thus, if $z=[h-0]$ and $\gamma(z)$ maps $[1_A]$ to $[1_B]$, then $[h(1_A\otimes p_{11})]=[1_B\otimes p_{11}]$, and, by [**172**], there exist a unitary $v\in\mathcal{M}(B\otimes\mathbb{K})$ with $v^*h(1_A\otimes p_{11})v=1_B\otimes p_{11}$. $b\in B\mapsto b\otimes p_{11}\in B\otimes\mathbb{K}$ is an isomorphism from B onto $(1\otimes p_{11})(B\otimes\mathbb{K})(1\otimes p_{11})$. Let μ be the inverse of this isomorphism. Then $\varphi(a):=\mu(v^*h(a\otimes p_{11})v)$ is a unital *-monomorphism from A into B with $[\varphi-0]=[h-0]=z$ in $\mathrm{KK}(A,B)$, because composition with $a\mapsto a\otimes p_{11}$ (respectively with μ and $v^*(\cdot)v$) induce the identity on $\mathrm{KK}(A,B)$, cf. [**73**, chap. VIII].

If h is moreover unitarily homotopic to λ by $u(t)\in\mathcal{M}(B\otimes\mathbb{K})$ and λ is an isomorphism from $A\otimes\mathbb{K}$ onto $B\otimes\mathbb{K}$, then we find as above a unitary $w\in\mathcal{M}(B\otimes\mathbb{K})$ such that $w^*\lambda(1_A\otimes p_{11})w=1_B\otimes p_{11}$ and $\psi(a):=\mu(w^*\lambda(a\otimes p_{11})w)$ is an isomorphism from A onto B. $t\to u_1(t):=v^*u(t)w$ defines a unitary homotopy from $v^*h(\cdot)v$ to $w^*\lambda(\cdot)w$. In particular, $\lim_{t\to\infty}u_1(t)^*(1_B\otimes p_{11})u_1(t)=1_B\otimes p_{11}$. Thus there exists $t_0>0$ such that a small perturbation of $b(t)=\mu(1_B\otimes p_{11}u_1(t)1_B\otimes p_{11})$ for $t>t_0$ defines a unitary homotopy from φ to the isomorphism ψ.

The above arguments prove that Theorem B has the following corollary:

Corollary C. *Suppose that A and B are pi-sun algebras.*

(i) *Every $z\in\mathrm{KK}(A,B)$ such that $\gamma(z)$ maps $[1_A]\in\mathrm{K}_0(A)$ to $[1_B]\in\mathrm{K}_0(B)$ is given by a* unital *C^*-morphism $\varphi\colon A\to B$, such that $z=[\varphi-0]$.*
Also here is to check: $z-[\varphi-0]$ is perhaps only modulo the kernel $\mathrm{KK}(A,B)\to\operatorname{Hom}(\mathrm{K}_0(A),\mathrm{K}_0(B))$ determined!

(ii) *`Check proof of C(ii) again!` ??*

If z is moreover a KK*-equivalence and $\varphi\colon A \to B$ is a unital *-monomorphism with $z = [\varphi - 0]$,*

then there are an isomorphism ψ from A onto B and a continuous map $t \mapsto u(t)$ from $\mathbb{R}_+ = [0, \infty)$ into the unitaries of B, such that

$$\psi(a) = \lim_{t\to\infty} u(t)^* \varphi(a) u(t) \quad \text{for all } a \in A\,.$$

Thus, $z = [\psi - 0]$.

In particular, $\mathrm{Aut}(A) \ni \varphi \mapsto [\varphi - 0] \in \mathrm{KK}(A, A)$ *maps onto the invertible elements $z \in \mathrm{KK}(A, A)$ with $\gamma(z)([1_A]) = [1_A]$.*

Two automorphisms of A have the same image in $\mathrm{KK}(A, A)$*, if and only if, they are unitarily homotopic.*

The KK-equivalence of unital endomorphisms φ and ψ gives
that $\psi(1) = \varphi(1)$ and that
$\phi_0 \oplus h_0$ and $\psi_0 \oplus h_0$ on A^{st} are unitarily homotopic.
Now ''absorption'' , i.e., $\phi_0 \oplus h_0$ unitary homotopic to ϕ_0.

Corollary C implies the following Corollary D, because KK is homotopy invariant (*without assuming UCT !*), and homotopy equivalences fixes the K_0-class of the unit element. Here we consider general homotopy (in the usual sense), and not our above defined *unitary* homotopy (cf. also Definition 5.0.1).

Corollary D. *Homotopy equivalent pi-sun algebras are isomorphic.*

Next depends from old version of Cor. C(ii) ??

The isomorphism can be chosen such that it is unitarily homotopic to the C-morphism that defines the homotopy equivalence.*

One of the problems is:
Let $\alpha\colon A \to A$ and $\beta\colon A \to A$ such that
$\alpha \circ \beta$ and $\beta \circ \alpha$ are unitarily homotopic to id_A.
Is α unitarily homotopic to an automorphism of A ?
Really? Is that enough?

Notice that here A is "stably infinite" if $A \otimes \mathbb{K}$ contains a full properly infinite projection. In case of simple A this is equivalent to the existence of a (non-zero) infinite projection in $A \otimes \mathbb{K}$. The following theorem shows that finite but not stably finite simple C^*-algebras must be necessarily "tensorial prime". Its proof is given in Section 3 of Chapter 2.

Theorem E. *Suppose that A and B are simple C^*-algebras, that are not isomorphic to the algebra of compact operators on a Hilbert space.*

(i) *If A or B is stably infinite, then the spatial tensor product $A \otimes B$ is purely infinite (and simple).*
(ii) *If $A \otimes B$ is nuclear and is stably infinite, i.e., $A \otimes B \otimes \mathbb{K}$ contains an infinite projection, then $A \otimes B$ is purely infinite.*

In particular, $A \otimes B$ is purely infinite if B is pi-sun and A is simple, e.g. $A \otimes \mathcal{O}_n$ is pi-sun for $n = 2, \ldots, \infty$ and each simple, separable, unital and nuclear C^*-algebra A ([13]).

Notice here, that the identity map id of $A \otimes \mathcal{O}_2 \otimes \mathbb{K}$ is homotopic to $\mathrm{id} \oplus \mathrm{id}$, because this is true for $\mathcal{O}_2$, cf. [**172**]. Thus, $\mathrm{KK}(A \otimes \mathcal{O}_2, A \otimes \mathcal{O}_2) = 0$ and $\lambda\colon a \in \mathcal{O}_2 \mapsto 1_A \otimes a \in A \otimes \mathcal{O}_2$ must necessarily define a KK-equivalence $z = [\lambda - 0] \in \mathrm{KK}(\mathcal{O}_2, A \otimes \mathcal{O}_2)$. By Theorem E and Corollary C, λ is unitarily homotopic to an isomorphism from $\mathcal{O}_2$ onto $A \otimes \mathcal{O}_2$. In the same way one can see that for *pi-sun* A with $\mathrm{KK}(A, A) = 0$ the only element of $\mathrm{KK}(\mathcal{O}_2, A) = 0$ is given by an isomorphism from $\mathcal{O}_2$ onto A. (Here we have used that $\mathcal{O}_2$ is pi-sun, cf. [**172**].)

The map $\varphi(a) = a \otimes 1$ is a unital monomorphism from A into $A \otimes \mathcal{O}_\infty$, and $z = [\varphi - 0]$ is just the Kasparov tensor product of $w = [id_A - 0]$ with the KK-equivalence $[\varphi_1 - 0]$ given by $\varphi_1\colon t \in \mathbb{C} \mapsto t \cdot 1 \in \mathcal{O}_\infty$. Thus, z is a KK-equivalence (– or use [**73**, 17.8.5 and 17.8.6] twice, or see the related arguments used in Chapter 8 for the generalization to $\mathrm{KK}(X; \cdot, \cdot)$ and $\mathrm{KK}(\mathcal{C}; \cdot, \cdot)$ –). So we get from $\varphi(1_A) = 1_A \otimes 1_{\mathcal{O}_\infty}$ and from Corollary C that *φ is unitarily homotopic to an isomorphism from A onto $A \otimes \mathcal{O}_\infty$*. Thus, we obtain the following corollary of Theorems B, E and Corollary C:

Corollary F. *If A is a separable unital nuclear simple C^*-algebra, then:*

(i) *$A \otimes \mathcal{O}_\infty$ is a pi-sun algebra.*
(ii) *$A \otimes \mathcal{O}_\infty \cong A$ if and only if A is pi-sun.*
(iii) *$A \otimes \mathcal{O}_2 \cong \mathcal{O}_2$.*
(iv) *If A is pi-sun, then $\mathrm{KK}(A, A) = 0$ if and only if $A \cong \mathcal{O}_2$.*

Perhaps proof more generally:

`Give first ref's to:` $\mathcal{O}_n$ `is pi-sun!`

(ii,1) The C^*-algebra $A \otimes D$ is strongly p.i. in sense of Definition 1.2.2 for every non-zero C^*-algebra A and for every (non-zero) strongly p.i. C^*-algebra D.

In particular this applies to $D := \mathcal{O}_\infty$.

(ii,2) For every nuclear separable strongly p.i. C^*-algebra A there exists an isomorphism φ from $A \otimes \mathcal{O}_\infty$ onto A.

(ii,3) If a C^*-algebra A is isomorphic to $A \otimes \mathcal{O}_\infty$, then there exists an (other) isomorphism φ from $A \otimes \mathcal{O}_\infty$ onto A such that the endomorphism $a \in A \mapsto \varphi(a \otimes 1) \in A$ is unitarily homotopic to the identity map id_A on A.

(In particular, the isomorphism $\varphi^{-1}\colon A \to A \otimes \mathcal{O}_\infty$ has the property that $\varphi^{-1}(J) = J \otimes \mathcal{O}_\infty$ for each closed ideal J of A.)

Way of proof:

It is enough to show:

---

[13] If $B = \mathcal{O}_n$ then one can allow here also $A = M_k$, $k = 1, 2, \ldots$, or $A = \mathbb{K}$ by [**172**], cf. refhere in book appendix A???

(1) $A \otimes D$ is strongly p.i.

[should be in Chp. 2 ready?]

(2) $\mathcal{O}_\infty$ is strongly p.i., because pi-sun, and $\mathcal{O}_\infty \otimes \mathcal{O}_\infty \cong \mathcal{O}_\infty$,

[should use Chp. 2,4, 11 ???]

(3) Separable nuclear s.p.i. C^*-algebra A has property: $1_{F(A)}$ is properly infinite in $F(A) := A' \cap A_\omega$.

[should be first in Chp. 2 ?]

(4) $\mathcal{O}_\infty \otimes \mathcal{O}_\infty \otimes \cdots \subseteq F(A)$ (unitally) implies for separable A that $A \cong A \otimes \mathcal{O}_\infty$

[Should be first in Chp. 11 complete?

Needs that $\mathcal{O}_\infty \otimes \mathcal{O}_\infty$ has approximately inner flip and that $x \in \mathcal{O}_\infty \to x \otimes 1 \in \mathcal{O}_\infty \otimes \mathcal{O}_\infty$ is approximately unitary equivalent to an isomorphism from $\mathcal{O}_\infty$ onto $\mathcal{O}_\infty \otimes \mathcal{O}_\infty$.]

(5) Prove all of (ii,3) for $A = \mathcal{O}_\infty$ and then for $A \otimes \mathcal{O}_\infty$ (– In place of $A \cong A \otimes \mathcal{O}_\infty$). Then use the isomorphism of $A \otimes \mathcal{O}_\infty$ onto A.

M. Rørdam [**678**] gave a proof for the isomorphism $A \cong A \otimes \mathcal{O}_2$ if A is unital, separable and contains an approximately central sequence of unital copies of $\mathcal{O}_2$. A modification of an idea of G. Elliott leads us to a more general result from [**438**, cor. 2.4(II)] (see also [**786**]) at the end of Chapter 10:
There is an isomorphism $A \cong A \otimes B \otimes B \otimes \cdots$ if A contains an approximately central sequence of unital copies of B in A, and if the C^*-monomorphisms $b \mapsto b \otimes 1_B$ and $b \mapsto 1_B \otimes b$ are approximately unitarily equivalent in $B \otimes B$. Notice that then B is automatically nuclear and simple by an argument from Effros and Rosenberg [**243**], cf. Corollary 10.3.5. In the case of non-unital separable A, one has to require that B has an approximately inner flip, and that a copy of B is unitally contained in $F(A) := (A' \cap A_\omega)/\operatorname{Ann}(A, A_\omega)$, then one gets $A \cong A \otimes B$ if A is stable or contains an approximate unit consisting of projections. We get the equivalence of $B \subseteq F(A)$ and of $A \cong A \otimes B$ for (general) separable A if B has the additional property that B is unitally contained in the ultrapower $\mathcal{E}(B,B)_\omega$ of tensorial join algebra

$$\mathcal{E}(B,B) := \{ f \in \mathrm{C}([0,1], B \otimes B)\,;\; f(0) \in B \otimes 1\,,\; f(1) \in B \otimes B \,\}\,.$$

See [**448**, thm. 4.5(3)]. The property follows from the K_1-injectivity of B, and is therefore satisfied for all C^*-algebras B that are purely infinite or that absorb the Jiang-Su algebra tensorial by

Rørdam ?????? citation ? ... Def. of K_1-injectivity of B ?

But the latter property is now known for all separable C^*-algebras B that absorb tensorial, – i.e., in sense $B \otimes E \cong B$ –, a tensorial self-absorbing separable C^*-algebra E, because all this E absorb the Jiang-Su algebra $\mathcal{Z}$ tensorial by a result of W. Winter in [**831**].

Is the K_1-bijectivity not secure by $\mathcal{Z}$ absorption from work of M. Rørdam?
Check Ref's again:

This property is now established for all tensorial self-absorbing separable E with approximately inner flip that allow in addition to apply the Künneth Theorem, e.g. if they are in the UCT-class. This is because W. Winter [**831**] observed that all those absorb the Jiang-Su algebra $\mathcal{Z}$ tensorial.

The tensorial absorption $B \otimes \mathcal{Z} \cong B$ of $\mathcal{Z}$ implies K_1-injectivity, and allows to deduce that $\mathcal{U}_0(B) = \mathcal{U}(B)$ if B is tensorial self-absorbing, separable and is in the Künneth Theorem class.

On the other hand, – by Corollary F(iii) –, we have that $\mathcal{O}_2 \cong \mathcal{O}_2 \otimes \mathcal{O}_2 \otimes \cdots$. Thus $\mathcal{O}_2$ contains an approximately central sequence of unital copies of $\mathcal{O}_2$. Again by Corollary F(iii), this together implies the following corollary.

Corollary G. *Let A be a simple, separable, unital and nuclear C^*-algebra. Then $A \cong \mathcal{O}_2$, if and only if, A contains an approximately central sequence $\psi_n \colon \mathcal{O}_2 \to A$ (of copies of $\mathcal{O}_2$) unitally.*

With other words: *$A \cong \mathcal{O}_2$, if and only if, A is simple, separable, unital and nuclear, and $A' \cap A_\omega$ contains a copy of $\mathcal{O}_2$ unitally.*

Recall that the natural group morphism $\gamma\colon \mathrm{KK}(A, B) \to \mathrm{Hom}(\mathrm{K}_*(A), \mathrm{K}_*(B))$ is an epimorphism if A satisfies the UCT. Moreover, if A and B both satisfy the UCT and $\gamma(z)\colon \mathrm{K}_*(A) \to \mathrm{K}_*(B)$ is bijective, then $z \in \mathrm{KK}(A, B)$ is a KK-equivalence, cf. [**73**, prop. 23.10.1]. Therefore, we obtain from Corollary C the following.

Corollary H. *Suppose that A and B are pi-sun algebras, and that A satisfies the universal coefficient theorem* (UCT) *for* $\mathrm{KK}(A, \cdot)$.

(i) *If $\sigma_* = (\sigma_0, \sigma_1)\colon \mathrm{K}_*(A) \to \mathrm{K}_*(B)$ is an element of* $\mathrm{Hom}(\mathrm{K}_*(A), \mathrm{K}_*(B))$ *such that $\sigma_0([1_A]) = [1_B]$ in $\mathrm{K}(B)$, then there is a unital *-monomorphism $\tau\colon A \to B$ such that $\mathrm{K}_*(\tau) = \sigma_*$.*
(ii) *If B also is in the* UCT*-class and σ_* is an* isomorphism *from $\mathrm{K}_*(A)$ onto $\mathrm{K}_*(B)$ and $\tau\colon A \to B$ is a unital *-morphism with $\mathrm{K}_*(\tau) = \sigma_*$, then there is a* *-isomorphism *$\psi\colon A \to B$ from A* onto *B*
NEXT has to be checked again: ??
such that ψ is unitarily homotopic to τ .

Check proof again!
At least ψ and τ are approximately unitary equivalent!?
In particular, $\mathrm{K}_*(\psi) = \sigma_*$.
(iii) *If* $\mathrm{Ext}^1(\mathrm{K}_*(A), \mathrm{K}_*(B)) = 0$ *, then all unital *-monomorphisms $\tau\colon A \to B$ with $\mathrm{K}_*(\tau) = \sigma_*$ are unitarily homotopic.*

We list here some immediate consequences of Corollary H:

$$\mathcal{O}_\infty \cong \mathcal{O}_\infty \otimes \mathcal{O}_\infty \otimes \cdots$$

by an isomorphism that is *unitarily homotopic* to

$$\tau\colon a \in \mathcal{O}_\infty \mapsto a \otimes 1 \otimes 1 \otimes \cdots \in \mathcal{O}_\infty \otimes \mathcal{O}_\infty \otimes \cdots \,,$$

because both algebras are pi-sun with UCT and K_*-groups $\mathbb{Z}[1]$ and 0 (i.e., here $\mathrm{K}_*(\tau)$ is a K_*-isomorphism and $\mathrm{Ext}^1 = 0$).

But we outline also alternative
proofs of the latter conclusions, by proving first
the homotopy invariance of a general version of Rørdam groups.

In the beginning we gave explicit examples of pi-sun algebras A in the UCT-class with prescribed $\mathrm{K}_*(A)$ using Cuntz-Pimsner algebras, and we give some alternative construction further below. It follows that Corollary H(i) implies:
*If B is pi-sun and $G_*^{(n)} \subseteq \mathrm{K}_*(B)$ is an increasing sequence of finitely generated graded subgroups with $[1_B] \in G_0^{(n)}$ and $\bigcup_n G_*^{(n)} = \mathrm{K}_*(B)$, then there is a sequence (A_n) of pi-sun algebras in the UCT-class, unital *-morphisms $\tau_n\colon A_n \to A_{n+1}$ and a unital *-morphism $\eta\colon A \to B$ for $A := \mathrm{indlim}_n A_n$ with $\mathrm{K}_*(A_n) = G_*^{(n)}$, $\mathrm{K}_*(\tau_n)$ the inclusion $G_*^{(n)} \hookrightarrow G_*^{(n+1)}$ and $\mathrm{K}_*(\eta \circ \tau_n)$ is the inclusion $G_*^{(n)} \hookrightarrow \mathrm{K}_*(B)$ In particular, $\mathrm{K}_*(\eta)$ is an isomorphism from $\mathrm{K}_*(A)$ onto $\mathrm{K}_*(B)$.*

Since A is in the UCT-class, Corollary H(ii) now implies:

Next works also if Corollary H(ii)
has to be corrected to weaker version,
where KK-equivalences are not all expressible by isomorphisms.

*If B is in the UCT-class, then the above *-morphism $\eta\colon A \to B$ can be chosen as an isomorphism from A onto B.*

We denote by $\mathrm{Aut}(\mathrm{K}_*(A), [1])$ the automorphisms of the $\mathbb{Z}_2$-graded Abelian group $\mathrm{K}_*(A)$ that fix the element $[1_A] \in \mathrm{K}_0(A)$.

Then we get from Corollary H:
Suppose that A is pi-sun and satisfies the UCT.

This is partly still in question ?? Or oK?

The composition $\gamma \circ \alpha$ of the map α given in Theorem B(i) with the natural map $\gamma\colon$ $\mathrm{KK}(A, A) \to \mathrm{End}(\mathrm{K}_*(A))$ defines an epimorphism *???????*

$$\gamma \circ \alpha\colon\ \mathrm{Aut}(A) \to \mathrm{Aut}(\mathrm{K}_*(A), [1])\,.$$

If $\mathrm{Ext}^1(\mathrm{K}_*(A), \mathrm{K}_*(A)) = 0$, then the kernel of this epimorphism ????????

Must check how the kernel of

$$\mathrm{KK}(\cdot,\cdot) \to \mathrm{Hom}_*(\mathrm{K}_*(\cdot), \mathrm{K}_*(\cdot))$$

looks like?

is equal to the set of those automorphisms of A that are unitarily homotopic to id *of A.*

Every pi-sun algebra A in the UCT-class is anti-isomorphic to itself. Moreover, if $[1_A] = 0$ in $\mathrm{K}_0(A)$, then there is a kind of "co-multiplication"-like unital monomorphism $A \otimes A \to A$. It comes from a – not necessarily unital – commutative algebra $C \subset A$ that is KK-equivalent to A (via this embedding), and from the diagonal map $\widehat{C} \ni \chi \mapsto (\chi, \chi) \in \widehat{C} \times \widehat{C}$. It is co-commutative and co-associative.

A first application of the above general results is the following:
Let A_m be finite direct sums of algebras of form $C(X, M_k(\mathcal{O}_\mathrm{n}))$, where X are compact metric spaces and $k = 1, 2, \ldots$, $n = 2, 3, \ldots$. Let $h_m\colon A_m \to A_{m+1}$ be unital C^*-morphisms and $B := \mathrm{indlim}(h_m\colon A_m \to A_{m+1})$. It is easy to see that $B \cong B \otimes \mathcal{O}_\infty$, because above we have seen that $A_n \cong A_n \otimes \mathcal{O}_\infty$ and $\mathcal{O}_\infty \cong \mathcal{O}_\infty \otimes \mathcal{O}_\infty \otimes \cdots$. In particular B is purely infinite if B is simple (see Corollary 3.2.23 for a more general result). The algebras A_n and therefore B are in the UCT class. Thus Corollary H classifies the simple one's of those inductive limits up to isomorphism.

To see which invariants are exhausted in given classes of metric spaces X and values k, m, we need to calculate the K_*-invariants, because the corresponding realizations by C^*-morphisms can be obtained from Theorem B using the UCT ([14]). The below described construction (before Theorem I stated below), gives a simpler way to produce pi-sun examples representing given KK-classes of nuclear separable C^*-algebras. This construction can be generalized to the category of C(X)-algebras (see end of Chapter 11).

An separable C^*-algebra A satisfies the UCT if and only if, A is in the "bootstrap category" or "bootstrap class" N (see [**699**] or [**73**, def. 22.3.4] for a definition), if and only if, A is KK-equivalent to a commutative C^*-algebra by an observation of G. Skandalis [**724**].

G. Elliott and M. Rørdam have shown that, given any pair of countable commutative groups G_0 and G_1 and a distinguished element $g_0 \in G_0$, there exists a simple purely infinite separable unital nuclear C^*-algebra A in the (little) bootstrap class N_ℓ such that $(\mathrm{K}_0(A), [1_A]) \cong (G_0, g_0)$ and $\mathrm{K}_1(A) \cong G_1$, cf. [**269**, thm. 5.6], and [**679**, thms. 3.1, 3.6]. Our Corollary H says that such A is unique if we consider simple pi-sun algebras in the UCT class. In particular, simple pi-sun algebras in the bootstrap class N are automatically in "small" bootstrap class N_ℓ.

A more general result by a rather simple method is given by the following Theorem I if we combine this with [**73**, cor.23.10.3] or Lemma B.11.1.

---

[14] The K_*-groups and its group homomorphisms for certain "elementary" CW-complexes X can be calculated in good cases with help of the Künneth theorem, 6-term exact sequence, Bott periodicity and Mayer-Vietoris sequence. The calculation of $\mathrm{K}^*(X)$ for a arbitrary CW complex X is not straight-forward, except one knows explicitly the involved elements of $\mathrm{Ext}(\mathrm{K}^{*+1}(X_n), \mathrm{K}^*(\mathbb{R}^n))$ and of $\mathrm{Hom}(\mathrm{K}^*(X_n), \mathrm{K}^*(\mathbb{R}^n))$ that correspond to attaching n-cells to the $(n-1)$-dimensional CW-subcomplex X_n, ...etc.

We describe now an almost functorial construction of simple separable exact purely infinite algebras $P(A)$, such that $P(A)$ is KK-equivalent to a given separable exact C^*-algebra A

Check: Now on new places?!
Check again the exact case! Check references!!! ([15]).

Let A be a separable *exact* C^*-algebra and let ${\mathcal{O}_\infty}^{\mathrm{st}} := (1-s_1s_1^*)\mathcal{O}_\infty(1-s_1s_1^*)$, where $s_1, s_2, \ldots$ are the canonical generators of $\mathcal{O}_\infty$. Then ${\mathcal{O}_\infty}^{\mathrm{st}}$ contains a copy of $\mathcal{O}_2$ unitally, cf. [**172**] or Lemma 4.2.6(iii). We let $A_t := A \otimes {\mathcal{O}_\infty}^{\mathrm{st}}$ if A is unital, and define A_t as the natural unital split extension of $\mathcal{O}_2 \cong 1_{\mathcal{M}(A)} \otimes \mathcal{O}_2$ by $A \otimes {\mathcal{O}_\infty}^{\mathrm{st}}$ if A is not unital, i.e., we have then a unital split-exact sequence

$$0 \to A \otimes {\mathcal{O}_\infty}^{\mathrm{st}} \to A_t \to 1 \otimes \mathcal{O}_2 \to 0 \,.$$

The algebra A_t is a unital separable exact C^*-subalgebra of $\widetilde{A} \otimes {\mathcal{O}_\infty}^{\mathrm{st}}$ and contains a copy of $\mathcal{O}_2$ unitally. The injective C^*-morphism $\eta_0 \colon a \in A \mapsto (a \otimes (s_2 s_2^*)) \in A_t$ defines a KK-equivalence of A with A_t. Clearly, the algebra A_t is nuclear if and only if A is nuclear.

The Theorem A provides a unital *-monomorphism $h_0^u \colon A_t \to \mathcal{O}_2 \subset A_t$, e.g. as described before Theorem B, and then define a unital *-monomorphism for $a \in A_t$ with help of isometries $t_1, t_2 \in \mathcal{O}_2 \subset {\mathcal{O}_\infty}^{\mathrm{st}} \subseteq A_t$ by

$$h(a) := t_1 \, a \, t_1^* + t_2 \, h_0^u(a) \, t_2^* \,,$$

that is here expressed using the Cuntz-addition – discussed in Chapter 4 ([16]) – of the identity map and h_0

$$\mathrm{id}_{A_t} \oplus_{t_1,t_2} h_0^u \colon \; A_t \to A_t \,.$$

Now simply let $P(A) := \mathrm{indlim}(h \colon A_t \to A_t)$ the "stationary" inductive limit with natural defining monomorphisms $h_n^\infty \colon A_t \to P(A)$ given by $h_{n+1}^\infty h = h_n^\infty$, and let $\eta(a) = h_1^\infty(\eta_0(a)) \in P(A)$ the associated natural unital embedding from A_t into $P(A)$.

The author has outlined the proof of the following easy theorem at the

Check again: ??

Conference on Operator Algebras and Quantum Field Theory (in Rome, Italy) July 1996.

THEOREM I. *Let A be a separable exact C^*-algebra. Then:*

(i) *The algebra $P(A)$ is a* simple, *separable and* exact *C^*-algebra that contains a copy of $\mathcal{O}_2$ unitally.*
(ii) *$P(A) \cong P(A) \otimes \mathcal{O}_\infty$. In particular, $P(A)$ is* purely infinite.

[15] See [**810**] or Chapters 3 and 6 on the here needed definition and basic properties of exact C^*-algebras.

[16] The "Cuntz sum" defined in Chapter 4 is the base of our there discussed version of KK-groups that is "constructive" in some sense.

(iii) *The monomorphism* $\eta\colon A \to P(A)$ *defines a* KK*-equivalence* $[\eta - 0]$ *between* A *and* $P(A)$*.*
(iv) *There is a conditional expectation from the hereditary* C^**-subalgebra* $D \subseteq P(A)$*, that is generated by* $\eta(A)$*, onto* $\eta(A) \cong A$*.*
(v) $P(A)$ *is nuclear, if and only if,* A *is nuclear.*

A proof of a more general result for continuous fields is given in Chapter 11. We surround the discontinuity of the functor $\mathrm{KK}(X\,; P(A), (\,\cdot\,))$ with respect to inductive limits, and use the continuity of $\mathrm{KK}(X; (\,\cdot\,), P(A))$ in the sense of [**73**, thms. 21.5.2, 19.7.1] and some considerations of E-theoretic nature, the X-equivariant continuous version of the

??? Effros-Rørdam ??? or Elliott-Rørdam ??

groups considered in Chapter 7.

`Check next red and over-next again!`
`check correct refs to Chapter 11`
`Are so many footnotes necessary?` **??**

In fact, we prove in Chapter 11 a more general result for continuous fields $(A_x)_{x\in X}$ of exact C^*-algebras A_x on a compact metric space X with the additional property that the C^*-algebra $\mathcal{A}$ of continuous sections is exact ([17]):
We take again $:= \mathcal{A}\otimes \mathcal{O}_\infty{}^{\mathrm{st}}$ if $\mathcal{A}$ is unital, and define $\mathcal{A}_t$ as the natural unital split extension of

$$\mathrm{C}(X, \mathcal{O}_2) \cong [\mathrm{C}(X)1_{\mathcal{M}(\mathcal{A})}] \otimes \mathcal{O}_2$$

by $\mathcal{A}\otimes \mathcal{O}_\infty{}^{\mathrm{st}}$ if $\mathcal{A}$ is not unital.

`Not clear if the` $\mathrm{C}(X)$`-algebra` $\mathcal{A}_t$ `is again continuous and has unital fibers that are the minimal unitizations of fibers of` $\mathcal{A}$
`Check construction and its continuity.`
`Compare with fibre-wise construction!`

Then we can use the sub-triviality theorem of E. Blanchard [**89**] ([18]), to get a unital $\mathrm{C}(X)$-module *-monomorphism $h_0^u\colon \mathcal{A} \to \mathrm{C}(X, \mathcal{O}_2) \subseteq \mathcal{A}$. We define again the Cuntz sum $h := \mathrm{id}_{\mathcal{A}_t} \oplus h_0^u$ and let then $\mathcal{P}(\mathcal{A}) := \mathrm{indlim}(h\colon \mathcal{A}_t \to \mathcal{A}_t)$ – the stationary inductive limit. All the operations are compatible with the above defined (fiber-wise) constructions of $(A_x)_t$ and $P(A_x)$ for the fibers A_x of $(A_x)_{x\in X}$. It turns out that $(P(A_x))_{x\in X}$ is a continuous field of C^*-algebras, and that $\mathcal{P}(\mathcal{A})$ is the algebra of continuous sections of this field. By construction, $\mathcal{P}(\mathcal{A})$ is exact, and is $\mathrm{C}(X)$-module isomorphic to $\mathcal{P}(\mathcal{A}) \otimes \mathcal{O}_\infty$. Further, the *-monomorphisms $\eta_x\colon A_x \to P(A_x)$ define a $\mathrm{C}(X)$-module monomorphism η from $\mathcal{A}$ into $\mathcal{P}(\mathcal{A})$.

---

[17] By [**471**], this is equivalent to exactness of all A_x and the continuity of the field $(A_x \otimes B)_{x\in X}$ for each separable C^*-algebra B. It follows e.g. from nuclearity of the fibers A_x and the continuity of the field.

[18] Theorem A implies a proof of the sub-triviality. The sub-triviality itself is a special case of Theorem K below.

We show in Chapter 11 a more general result:
The monomorphism η *defines a* $\mathrm{KK}(X;\,\cdot,\cdot)$*-equivalence between* $\mathcal{A}$ *and* $\mathcal{P}(\mathcal{A})$. ([19]).

At the end of Chapter 11 we outline a different construction that leads to $\mathrm{KK}(X;\,\cdot,\cdot)$-equivalent exact (respectively nuclear) *stable* algebras $P(A)$ with primitive ideal space isomorphic to a T_0 space X that acts monotone-continuously on A (cf. the definitions below and Theorems 11.4.1 and O):
One starts with a suitable "universal" Hilbert bimodule and builds the corresponding Cuntz-Pimsner algebra. The universality of the construction has the advantage that G-actions of locally compact groups G on $(A_x)_{x\in X}$ lead in a natural way to G-actions on $(P(A_x)\otimes\mathbb{K})_{x\in X}$ ([20]).

Furthermore, we modify in Chapter 11 the above described (non-universal !) construction of $A \Rightarrow P(A)$ in a way that we get (cf. Theorem 11.0.7):
Suppose that A *is a unital separable nuclear* C^**-algebra,* G *is a discrete countable* exact *group, and that* $\alpha\colon G\to\mathrm{Aut}(A)$ *is group-morphism. Then there exist a pi-sun algebra* B*, a group-morphism* $\beta\colon G\to\mathrm{Aut}(B)$ *and a* G*-equivariant* unital *monomorphism* $\eta\colon A\to B$ *that defines a* KK^G*-equivalence* $[\eta]\in\mathrm{KK}^G(A,B)$.

The latter construction plays nicely together with permutation actions of G on multiple tensor products.

`Next is wrong! ??`

$\mathcal{P}_\infty$ is isomorphic to the crossed product $({\mathcal{O}_\infty}^{\mathrm{st}}\otimes{\mathcal{O}_\infty}^{\mathrm{st}})\rtimes\mathbb{Z}_2$ *by the flip automorphism* $a\otimes b\mapsto b\otimes a$ *on* ${\mathcal{O}_\infty}^{\mathrm{st}}\otimes{\mathcal{O}_\infty}^{\mathrm{st}}$.

Here $\mathcal{P}_\infty$ denotes the unique pi-sun algebra in the UCT-class with $\mathrm{K}_0(\mathcal{P}_\infty)=\{0\}$ and $\mathrm{K}_1(\mathcal{P}_\infty)=\mathbb{Z}$.

(But it is likely that the $\mathbb{Z}_2$ crossed product by the flip on $\mathcal{P}_\infty\otimes\mathcal{P}_\infty$ is isomorphic to ${\mathcal{O}_\infty}^{\mathrm{st}}$.)

The flip automorphism is approximately inner on ${\mathcal{O}_\infty}^{\mathrm{st}}\otimes{\mathcal{O}_\infty}^{\mathrm{st}}$, because the flip on $\mathcal{O}_\infty\otimes\mathcal{O}_\infty$ is approximately inner:
(U_n) a sequence of unitaries that approximately implement the flip.

Then $[U_n,(1-s_1s_1^*)\otimes(1-s_1s_1^*)]\to 0$ in $\mathcal{O}_\infty\otimes\mathcal{O}_\infty$. Small perturbations of the U_n produces unitaries V_n that commute with $(1-s_1s_1^*)\otimes(1-s_1s_1^*)$.

The $W_n := V_n\cdot((1-s_1s_1^*)\otimes(1-s_1s_1^*))$ are unitaries in ${\mathcal{O}_\infty}^{\mathrm{st}}\otimes{\mathcal{O}_\infty}^{\mathrm{st}}$ that approximately implement the flip on ${\mathcal{O}_\infty}^{\mathrm{st}}\otimes{\mathcal{O}_\infty}^{\mathrm{st}}$.

Let us now consider an other *application of Theorem I*:
If A is a separable *nuclear* C^*-algebra, then there is a pi-sun algebra $B=P(A)$ which is KK-equivalent to A and contains a unital copy of $\mathcal{O}_2$.

---

[19] The bi-functor $\mathrm{KK}(X;\mathcal{A},\mathcal{B})$ is, for compact metric spaces X, the same as the Kasparov functor $\mathcal{R}\,\mathrm{KK}^G(X;\,\cdot,\cdot)$, with $G=$ the trivial group.

[20] At least in the case where the fibers A_x are nuclear, because then, by Theorem M(iii), there are $\mathrm{C}(X)$-module isomorphisms of $\mathcal{P}(\mathcal{A})\otimes\mathbb{K}$ onto any other p.i. stable separable nuclear $\mathrm{C}(X)$-algebra $\mathcal{B}$ that is $\mathrm{KK}(X;\,\cdot,\cdot)$-equivalent to $\mathcal{A}$ and has simple fibers B_x.

In particular $\mathrm{K}_*(B) \cong \mathrm{K}_*(A)$. We can find a separable *commutative* C^*-algebra D with $\mathrm{K}_*(D) \cong \mathrm{K}_*(A)$, cf. [**73**, cor. 23.10.3], [**715**] or Lemma B.11.1.

We replace D by a KK-equivalent pi-sun algebra E, which contains a unital copy of $\mathcal{O}_2$. Then E satisfies the UCT and there is an isomorphism λ from $\mathrm{K}_*(E)$ onto $\mathrm{K}_*(B)$. By the UCT for E, there exists $z \in \mathrm{KK}(E, B)$ with $\gamma(z) = \lambda$, and by Corollary C there exists a unital monomorphism φ from E into B such that $z = [\varphi - 0]$, and thus $\lambda = \mathrm{K}_*(\varphi)$. But then

$$\lambda \colon \mathrm{K}_*(E) \to \mathrm{K}_{(*-1) mod 2}(SB) = \mathrm{K}_*(B)$$

is the connecting map for the six term exact sequence for the mapping cone C_φ and therefore $\mathrm{K}_*(C_\varphi) = 0$. C_φ is nuclear because C_φ is an extension of nuclear C^*-algebras.

If $\mathrm{KK}(C_\varphi, C_\varphi) = 0$, then $\mathrm{KK}(C_\varphi, F) = 0$ for every (σ-unital) C^*-algebra F. By the six term exact sequence for KK one gets that B and E are KK-equivalent, i.e., that A is KK-equivalent to a commutative C^*-algebra.

Hence, *if the nuclear separable C^*-algebra A is* not KK*-equivalent to a commutative C^*-algebra, then* $\mathrm{KK}(C_\varphi, C_\varphi)$ *is not trivial, and the pi-sun algebra $N := P(C_\varphi)$ satisfies* $\mathrm{K}_*(N) = 0$ *but* $\mathrm{KK}(N, N)$ *is non-zero.*

We can go a bit further to a more special class of algebras that is sufficient to decide the UCT-problem by following observations ([21]):
There is a circle action on $\mathcal{O}_2$ with simple and purely infinite fix-point algebra B_0 in the UCT-class with $\mathrm{K}_0(B_0) = \mathbb{Z}^2$, $\mathrm{K}_1(B_0) = 0$ *and* $0 = [1] \in \mathrm{K}_0(B_0)$.

Indeed: Take $B_0 := P(\mathbb{C} \oplus \mathbb{C})$ in Theorem I. It is a pi-sun algebra that is KK-equivalent to $\mathbb{C} \oplus \mathbb{C}$ and contains a copy of $\mathcal{O}_2$ unitally. By Corollary F(ii), $B_0 \cong B_0 \otimes \mathcal{O}_\infty$ by an isomorphism that is unitarily homotopic to $b \mapsto b \otimes 1$, and, – by Corollary H(ii) –, there is an *automorphism* ψ of B_0 such that

(i) $\psi_0(m, n) = (n, n + m)$ for $(n, m) \in \mathbb{Z}^2 \cong \mathrm{K}_0(B_0)$ (hence $\mathrm{id} - \psi_0$ has determinant $= -1$),
(ii) ψ^n is strictly outer (in the sense of [**578**]) for every $n \neq 0$, because $\psi_0^n \neq 0$ for all $n \neq 0$.
(iii) $B_0 \rtimes_\psi \mathbb{Z} \cong (B_0 \rtimes_\psi \mathbb{Z}) \otimes \mathcal{O}_\infty$

In part (iii) we could also use that $B_0 \cong B_0 \otimes \mathcal{O}_\infty$ and then change ψ to $\mathrm{id}_{\mathcal{O}_\infty} \otimes \psi$ to omit the proof of pure infiniteness for $B_0 \rtimes_\psi \mathbb{Z}$. One can see, e.g. by [**578**] or by Proposition 2.18.1, that $C := B_0 \rtimes_\psi \mathbb{Z}$ is *simple*, because B_0 is simple and ψ satisfies (ii). It is known that C is nuclear, because B_0 is nuclear and $\mathbb{Z}$ is amenable, and that C is in the UCT-class because B_0 is in the UCT-class (cf. [**73**, 22.3.5g]). It follows that C is a pi-sun algebra in the UCT-class with $\mathrm{K}_*(C) = 0$, by Corollary F(ii) and by the Pimsner-Voiculescu sequence [**73**, thm.10.2.1]. Then B_0 is the fixpoint algebra of the (dual) $\mathbb{R}/\mathbb{Z}$-action on C, and $C \cong \mathcal{O}_2$ by Corollary H(ii).

---

[21] Build the tensor product of the example [**73**, 23.15.12] of Blackadar with $\mathcal{O}_\infty$ to get a version of N.

Now we consider any separable nuclear C^*-algebra D and let $B_0 := P(\mathbb{C} \oplus \mathbb{C})$ and $A := P(D) \otimes B_0$. The natural embedding η of $D \oplus D \cong D \otimes (\mathbb{C} \oplus \mathbb{C})$ into $P(D) \otimes P(\mathbb{C} \oplus \mathbb{C})$ defines a KK-equivalence $\eta \colon (D \oplus D) \to A$, because KK-equivalences are compatible with tensor products if one of the factors are nuclear, cf. [**389**, lem. 2.1.27]. The algebra A is the fixpoint algebra of a circle action on $P(D) \otimes C \cong \mathcal{O}_2$, by Corollary F(iii).

Together with Corollary F(iv) and [**73**, cor.23.10.8] the above reductions (to the case of pi-sun A with $\mathrm{K}_*(A) = 0$ and to the fix-point algebra of a circle action) on $\mathcal{O}_2$ prove the following.

COROLLARY J. *For every separable nuclear C^*-algebra D there is a pi-sun algebra A with $[1_A] = 0$ in $\mathrm{K}_0(A)$ and a *-monomorphism $\eta \colon D \oplus D \hookrightarrow A$ such that*

(i) *$[\eta]$ is a KK-equivalence of $D \oplus D$ and A.*
(ii) *A is a fix-point algebra of a circle action on $\mathcal{O}_2$.*

In particular, every separable nuclear C^*-algebra is KK-equivalent to a commutative C^*-algebra, if and only if, every pi-sun algebra A with $\mathrm{K}_*(A) = 0$, that is isomorphic to a fixpoint algebra of a circle action on $\mathcal{O}_2$, is also isomorphic to $\mathcal{O}_2$ itself.

Thus, Questions (Q2) and (Q2*) have the same answer, and we can limit (Q2) to the case where A is the fix-point algebra of a circle action on $\mathcal{O}_2$.

`revise/check next text blue/red text`

One can even step a bit further: If we consider $P(A^{op} \oplus A) \otimes B_0$ in place of A, then we can see by the above arguments that the possible existence of a *separable and nuclear* example B that does *not* satisfy the UCT implies the existence of pi-sun A with $\mathrm{K}_*(A) = 0$ that is anti-isomorphic to itself, that does *not* satisfy the UCT, and A is the fix-point algebra of a circle action on $\mathcal{O}_2$. The reason is that Thus, the non-existence of an anti-automorphism does not necessarily produce a counterexample for the UCT in the class of amenable separable C^*-algebras.

If one considers the class of arbitrary (not necessary simple) separable nuclear stable C^*-algebras that have trivial KK-theory (e.g. contractible algebras) then every separable nuclear C^*-algebra is KK-equivalent to a fixed point algebra of a $\mathbb{Z}_2$-action of one of them. But one has to consider also *inner* actions, e.g. given by conjugation by a symmetry in the multiplier algebra.

On the other hand one can say: If the fix-point algebra of the flip automorphism $\Pi(a \otimes b) := b \otimes a$ on $\mathcal{O}_2 \otimes \mathcal{O}_2$ (respectively on ${\mathcal{O}_\infty}^{st} \otimes {\mathcal{O}_\infty}^{st}$) is isomorphic to $\mathcal{O}_2$ (respectively to ${\mathcal{O}_\infty}^{st}$) then the Cuntz standard form A^{st} is isomorphic to the fixed point-algebra of a $\mathbb{Z}_2$-action on $\mathcal{O}_2$.

The reason is, that this conjectures together imply the conjecture that the fix-point algebra of of the flip on $\mathcal{P}_\infty \otimes \mathcal{P}_\infty \cong {\mathcal{O}_\infty}^{st}$ is isomorphic to $\mathcal{O}_2$. The flip is an order-2 isomorphism of ${\mathcal{O}_\infty}^{st}$ that changes the signs of elements in $\mathbb{Z} \cong \mathrm{K}(\mathcal{O}_\infty)$.

Similar arguments show that the Künneth Theorem on tensor products holds for all separable nuclear C^*-algebras, if and only if, $\mathrm{K}_*(A \otimes A) = 0$ for all pi-sun

A with $\mathrm{K}_*(A) = 0$ that is the fix-point algebra of a circle action on $\mathcal{O}_2$ and is anti-isomorphic to itself ([22]).

If one has such a C^*-algebra A, then one can consider $C := P(A \otimes \mathcal{O}_\infty)$ and ask if ?????? $C := \mathcal{O}_\infty{}^{\mathrm{st}}$.

In particular, let $D := pCp$ for a projection $p \in C$ with $1 = [p] \in \mathrm{K}_0(C) \cong \mathbb{Z}$. Is D tensorial self-absorbing ?

Here we say that a unital separable D is a **tensorial self-absorbing** algebra if $D \ncong \mathbb{C}$ and the unital monomorphism $D \ni d \mapsto d \otimes 1 \in D \otimes D$ is approximately unitarily equivalent to an isomorphism from D onto $D \otimes D$ (see [**448**, sec.4.def.4.1]).

We mention this, because it shows that the UCT-problem and related problems have connections with the question of the classification of the tensorial self-absorbing algebras A – without assuming before that A is in the UCT-class !

A special case of the UCT problem is the following interesting and long standing open question:
Let A a separable unital tensorial self-absorbing algebra that has the property that M_n is not unitally contained in A for every $n > 1$. Is $A \cong \mathcal{O}_\infty$ or $A \cong \mathcal{Z}$? Here $\mathcal{Z}$ denotes the Jiang-Su algebra. The answer is positive in the UCT-class. But so far one has no idea what happens without UCT.

Is M_n also not unitally (!) contained in $A \otimes \mathcal{O}_\infty$? There exist no projection in $A \otimes \mathcal{O}_\infty$ with $n[p] = [1]$ in $\mathrm{K}_0(A \otimes \mathcal{O}_\infty) \cong \mathrm{K}_0(A)$ ...

2. Towards a classification of non-simple purely infinite algebras

In the period from 1995-2015 the author has studied methods that allow to generalize the classification of pi-sun algebras to a classification of non-simple nuclear strongly purely infinite stable separable C^*-algebras.

`Compare the 2 below given blue discussions of [442, lem.3.8]`

A report on results and outline of the proofs has been published in [**442**]. But the important "abstract" Lemma [**442**, lem.3.8] was not proved there and the author has to regret for his claim "It is a straight-forward proof" (Es ist ein Gradeaus-Beweis). Indeed, the author had overseen that the list of conditions in the technical Lemma [**442**, lem. 3.8] is incomplete:
The surjectivity of the there considered natural group morphism of in Chapter 4 defined groups $G(h_0\,;\; A, E)$ to $G(H_0\,;\; A, E)$ is easy to derive from the listed properties, but the there proposed injectivity is unclear. Therefore we have revised the Lemma [**442**, lem. 3.8] in a very detailed technical Chapter 4 and have reformulated it as Theorem 4.4.6. It is in a sense a general tool for comparing sorts of *unsuspended but stable* E-theories with naturally corresponding KK-theories. This Theorem lists additional conditions, each of them equivalent to the injectivity of

[22] It suffices to check $\mathrm{K}_0(A \otimes A) = 0$, because one can replace A by $P(A \oplus (A \otimes \mathcal{P}_\infty)) \otimes B_0$.

the canonical epimorphism from $G(h_0\,;\; A, E)$ onto $G(H_0\,;\; A, E)$. An explicit (certainly very abstract !) example where the natural map is not injective only under the assumptions of the old Lemma [**442**, lem. 3.8] has not been found so far – but still could exist for some example that fits the general "axiomatic" assumptions of [**442**, lem. 3.8] ([23]).

The Lemma [**442**, lem.3.8] is here worked out in more detail and extended to Theorem 4.4.6 by adding a condition (DC), and we give a detailed proof of it in Chapter 4. But we have used/misused Chapter 4 to give also a very detailed account of sorts of calculations in K-theory of properly infinite unital C^*-algebras and of $\mathrm{K}_*(h_0(A)' \cap E)$ for "KK-theory-defining" morphism $h_0 \colon A \to E$, where $h_0(A)' \cap E$ contains a copy of $\mathcal{O}_2$ unitally as our minimal permanent assumption. It leads to groups $G(h_0\,;\; A, E)$ that must be understood in detail by the reader before he can understand the proofs in several other parts of this book entirely, e.g. the groups $\mathrm{Ext}(\mathcal{C}\,;\; A, B)$ in Chapter 5.

Fortunately we can generalize Kasparov's proof (and the way over the cobordism variant defined by J. Cuntz and G. Skandalis) of the identities $\mathrm{KK}_p(A, B) = \mathrm{KK}_c(A, B) = \mathrm{KK}_h(A, B)$, i.e., the proof of the homotopy invariance of KK-theory, to get that our cone-depending groups $\mathrm{KK}(\mathcal{C};\, A, B)$ are homotopy invariant. This $\mathcal{C}$-related result will be used to prove general decomposition theorems for strictly continuous paths of "deriving" unitaries, compare Section 5 in Chapter 8 for details. This decomposition results allow to proof that $\mathrm{Ext}(S\mathcal{C}\,;\; A, SB)$ – which is naturally isomorphic to $\mathrm{KK}(\mathcal{C}\,;\; A, B)$ – satisfies the assumptions of Theorem 4.4.6 in Chapter 4, in particular the – long time disputed – decomposition property (DC). It implies that the natural group *epimorphism* from the m.o.c. cone $\mathcal{C}$-equivariant unsuspended E-theory – the generalized Rørdam groups $\mathrm{R}(\mathcal{C};\, A, B)$ – onto the group $\mathrm{KK}(\mathcal{C};\, A, B)$ is an *isomorphism*. This is our base for isomorphism results, including the case of pi-sun A, B and $\mathcal{C} = \mathrm{CP}(A, B)$.

Has next blue part to be changed? Technics works?
Phillips method works?
Relation to KK-theory clear?

Independently from this result that completes of [**442**, lem. 3.8] we have in Section 3 of Chapter 9 also outlined a generalization of the arguments of N. Ch. Phillips in a way that they allow to show the homotopy invariance of m.o.c. cone $\mathcal{C}$-related unsuspended stable E theories – like our continuous variants $\mathrm{R}(\mathcal{C};\, A, B)$ of a kind groups that M. Rørdam and G. Elliott used in their proofs for the classification of certain Cuntz-Krieger algebras.

It is based on the homotopy invariance of the *Grothendieck group* of those kinds of semigroups – but that are not homotopy invariant as semigroups itself (sic !) – defined as unsuspended, but stable, variants of E-theory that satisfy asymptotically some additional relations, who's proof is essentially inspired by ideas

[23] A specific counter-example would be interesting for finding the *minimal necessary* assumptions for the axioms that make the surjective map from $G(h_0\,;\; A, E)$ onto $G(H_0\,;\; A, E)$ injective.

of N.Ch. Phillips in [**627**]. But we do not know if this can be used *to prove* in this special case the injectivity of $G(h_0\,;\ A, E) \to G(H_0\,;\ A, E)$, i.e., if two asymptotic morphisms $h_1 \colon A \to \mathrm{Q}(\mathbb{R}_+, B)$ and $h_2 \colon A \to \mathrm{Q}(R_+, B)$ are "stably homotopic" if h_1 and h_2 define the same element of $\mathrm{Ext}(S\mathcal{C}\,;\ A, SB)$ – with $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ generated by h_0.

`Above and below should be solved now at the end of Chapter 8 !!!`

It is also not clear how to produce an asymptotic homotopy between $k \oplus h_0$ and h_0 if there is strictly continuous path of unitaries $t \in [0, \infty) \mapsto U(t) \in \mathcal{M}(B)$ with $U(0) = 1$ and

$$t \in [0, \infty) \to U(t)^*(k \oplus H_0(a))U(t) - H_0(a) \in B\,,$$

(where $H_0 := \delta_\infty \circ h_0 = h_0 \oplus h_0 \oplus \cdots$) and

$$\lim_{t \to \infty} \| U(t)^*(k \oplus H_0(a))U(t) - H_0(a) \| = 0\,.$$

But please without (sic !) using the decomposition argument (DC) that we prove in Section 5 of Chapter 8, because this proves anyway the full Theorem 4.4.6 in Chapter 4, and factorize through the whole – most abstract – study of $\mathcal{C}$-related KK-theory in Chapter 8 to get the general (unrestricted) homotopy invariance of all this functors. It is a generalization of non-trivial observation of G. Kasparov (plus arguments of J. Cuntz and G. Skandalis).

But above needs the still not proven facts that $\mathrm{KK}(\mathcal{C}\,;\ A, B)$ is homotopy invariant with respect to B, and that it is isomorphic to the kernel of

$$\mathrm{K}_1\big(\pi_B(H_{\mathcal{C}}(A))' \cap \mathrm{Q}^{\mathrm{s}}(B)\big) \ \to \mathrm{K}_1\big(\mathrm{Q}^{\mathrm{s}}(B)\big)\,.$$

If one wants to conclude as in [**442**] then one needs as an additional information, e.g. the homotopy invariance of the Rørdam groups – a very special case of unsuspended but stable ideal-equivariant $\mathcal{E}$-theory introduced and studied in Chapters 7 and 9.

`But need also that the kernel of R-groups to KK`
`is` $\mathcal{E}$`-homotopy equivalent of` h_0`.  ?????`

But there is then needed an extra condition, ????? related to Kasparov's arguments ????, for the homotopy invariance of the groups $\mathrm{KK}(\mathcal{C};\,\cdot,\cdot)$ and $\mathrm{Ext}(\mathcal{C};\,\cdot,\cdot)$.

But finally the classification is given by a generalized Kasparov theory. In particular, $A \otimes \mathcal{O}_2 \cong B \otimes \mathcal{O}_2$ if A and B are separable stable nuclear C^*-algebras and have topologically isomorphic primitive ideal spaces.

Certainly, there is the still open question about the *explicit calculation* of our "generalized KK-invariants" given by

$$\mathrm{KK}_{\mathrm{nuc}}(X;\,\cdot,\cdot) := \mathrm{KK}(\mathcal{C}_X;\,\cdot,\cdot)$$

for the m.o.c. cone $\mathcal{C}_X := \mathrm{CP}^X_{nuc}$ of the X-equivariant residually nuclear c.p. maps, i.e., nuclear maps that are residually nuclear with respect to a given "action" of X. Notice that this is the open Question **(Q2)** in the special case where X is a point. But one can define generalizations of the UCT-class, e.g. with help of the "tautological" epimorphism and the 6-term exact sequence, cf. the proof of Theorem O in Chapter 12 for some simple example. Again, the non-trivial question is, which nuclear C^*-algebras are in this class.

Compare Theorem O for an example of some related difficulties in question.

Now for applications of the classification the most natural question is:

When does a separable nuclear C^*-algebra A absorb $\mathcal{O}_\infty$ tensorial, i.e., when $A \otimes \mathcal{O}_\infty \cong A$? (If such an isomorphism exist then there exists an other that is moreover an ideal-system preserving *-isomorphism.)

There are several necessary and sufficient conditions for A absorbing $\mathcal{O}_\infty$. We show – finally at the end of Chapter 10 and independently from the classification results and only from general properties of *strong pure infiniteness* and from the observation that $\mathcal{O}_\infty \cong \mathcal{D}_\infty := \mathcal{O}_\infty \otimes \mathcal{O}_\infty \otimes \cdots$ by an isomorphism that is unitarily homotopic to the embedding $a \in \mathcal{O}_\infty \mapsto a \otimes 1 \otimes \cdots \in \mathcal{D}_\infty$ –, that *a separable nuclear A is isomorphic to $A \otimes \mathcal{O}_\infty$ if and only if A is "strongly" purely infinite in the sense of the below given Definition 1.2.2* ([24]). The following definition is essentially the same as [**462**, def. 4.1].

Definition 1.2.1. We call a C^*-algebra A **purely infinite** if A has following properties (i) and (ii):

(i) A has no character, i.e., every irreducible representation of A has dimension > 1, and

(ii) For every $a \in A_+$ and every positive c in the closed ideal generated by a, and every $\varepsilon > 0$, there exists an element $d := d(a, c, \varepsilon) \in A$ such that

$$\| c - d^* a d \| < \varepsilon . \tag{2.1}$$

([**462**, def. 2.3] is a Defination of MvN-equivalence, with reference to G.K. Pedersen [**621**] that it is an equivalence relation on A_+.)

A C^*-algebra A is p.i. if and only if A has the – formally stronger – property that every nonzero $c \in A_+$ is properly infinite, cf. [**462**, lem. 4.2], or Corollary 2.5.6.

`To be checked:` or more directly:

because an element $a \in A$ is properly infinite in A, if and only if, $\pi_J(a)$ is infinite in A/J for *every* closed ideal $J \lhd A$ with $a \notin J$, cf. Part (v) of Lemma 2.5.3, and since properties (i) and (ii) of the definition pass to $\pi_J(a)$ for all quotients A/J of A with closed ideals $J \not\ni a$.

Implies ????

Definition 1.2.1 has not much to do with that for "pi-1" or "pi(1)" because Def. 1.2.1 includes simplicity ????

[24] In the case of stable or unital A we get this also from Theorem M in the same way as we can deduce $A \cong A \otimes \mathcal{O}_\infty$ from Theorem B in the case of pi-sun algebras A.

NO! So as it is now, it is exactly the same as pi(1) (up to that it is not required that $\ell_\infty(A)$ has no character!! But this can be shown in this case, because pi(1) and pi-1 are equivalent properties.

It is still an open question – also for *separable nuclear* non-simple C^*-algebras A – if purely infinite C^*-algebras are "strongly" purely infinite in sense of the following Definition 1.2.2. Our ideal-system equivariant $\mathrm{KK}(X;\cdot,\cdot)$-classification works only for separable nuclear C^*-algebras that are "strongly" purely infinite C^*-algebras in the sense of the following Definition 1.2.2.

DEFINITION 1.2.2. The non-zero C^*-algebra A is **strongly purely infinite** if A satisfies the following condition:
For every $a, b \in A_+$ and $\varepsilon > 0$ there exist elements $d := d(\varepsilon, a, b), e := e(\varepsilon, a, b) \in A$ such that

$$\| a^2 - d^* a^2 d \| < \varepsilon , \quad \|b^2 - e^* b^2 e\| < \varepsilon \ \text{ and } \ \|d^* abe\| < \varepsilon . \tag{2.2}$$

(We abridge 'purely infinite' by 'p.i.' and 'strongly purely infinite' by 's.p.i.')

It is easy to see that every non-zero *strongly* p.i. algebra is a purely infinite C^*-algebras in sense of Definition 1.2.1, indeed: Let $a := b := c^{1/2}$ in Definition 1.2.2 for $c \in A_+$, then Definition 1.2.2 shows that each non-zero $c \in A_+$ is a properly infinite element of A in the sense of [**462**, def. 3.2], cf. also Section 1 of Chapter 2.

If we use the isomorphism of C and $C \otimes \mathcal{O}_\infty \otimes \mathcal{O}_\infty \cdots$, then we can see that $A := B \otimes C$ is strongly p.i. for every (simple) pi-sun algebra C and every (non-zero) C^*-algebra B. We show moreover that $A := B \otimes \mathcal{Z}$ is s.p.i. if A (2-quasi-) traceless and $\mathcal{Z}$ denotes the Jiang-Su algebra, cf. also [**690**] in case of exact B.

If a C^*-algebra A has the WvN-property of Definition 1.2.3, then A has the property that for every self-adjoint $h^* = h \in \mathcal{M}(A \otimes \mathbb{K})_\omega$ there is a *-monomorphism $\lambda_h \colon C^*(h) \otimes \mathcal{O}_\infty \to \mathcal{M}(A \otimes \mathbb{K})_\omega$ with $\lambda(h \otimes 1) = h$. The latter implies that $\mathcal{M}(A)$ is purely infinite. (It is still an open question if the pure infiniteness of $\mathcal{M}(A)$ implies that A is strongly p.i., except some special cases as
e.g. ??? Even in case that ???? .)

M. Rørdam and the author have shown in [**463**] that strongly purely infinite C^*-algebras have the WvN-property, see Remarks 2.15.12 and 3.11.4 in Chapters 2 and 3 for an outline of the proof (including correction of typos in [**463**]).

It is still an *open question*, whether or not p.i. (or at least the existence of the above described *-monomorphisms λ_h in sufficiently general position) implies "strongly" p.i. in general.

By [**93**, thm.4.17], a *sufficient* condition for A being strongly p.i. is that every non-zero quotient A/J of A is p.i. in the sense of the definition of J. Cuntz [**172**, p. 186] (cf. Introduction to Chapter 2 and compare also [**169**, thm. 1.13, thm. 1.4] in the special cases of $A = \mathcal{O}_n$ for $n = 2, \ldots, \infty$), i.e., for every closed ideal $J \subseteq A$ holds that every non-zero hereditary C^*-subalgebra D of A/J contains a (non-zero) properly infinite projection $p \in D$.

In particular, if A has real rank zero, then A is strongly p.i., if and only if, each projection of A is infinite.

The algebra $\mathrm{C}_0((0,1],\mathcal{O}_2)$ is strongly p.i. but is not purely infinite in the sense of J. Cuntz. The unitization of $\mathcal{O}_2 \otimes \mathbb{K}$ has real rank zero and is purely infinite in the sense of J. Cuntz but is not p.i. in the sense of our Definition.

We list the needed results on purely infinite and strongly purely infinite non-simple C^*-algebras in Chapters 2 and 3 and outline the ideas for their proofs. This results are mainly joint work with M. Rørdam and E. Blanchard and we refer sometimes for details of the proofs to [**462**], [**463**] and [**93**].

`Begin of discussion of ''WvN-property'':`
`1) Has to be revised at several places.`

`2) Sort mentioned results for chapters, and formulate them there.`

`3) Where are Defs. of: ''residually nuclear maps'' ?.`
`In case of` $A \subseteq B$ `and` $V\colon A \to B$ `residually nuclear c.p. contraction ?.`
V `is ''1-step approximately inner'' c.f. Definition 3.10.1? Not a good place!`

We prefer to work in this book with the *WvN-property* of the following Definition 1.2.3 and, sometimes, even with additional assumptions as listed in Remark 3.11.1, because the WvN-property is, in a conceptional sense, a starting point for most of the proofs, and the strong pure infiniteness is a basic property for all of our constructions and its applications. It turns out in Chapter 12 as a result of ideal-system equivariant $\mathrm{KK}(X;\cdot,\cdot)$-classification that this two properties are equivalent.

DEFINITION 1.2.3. A C^*-algebra B has the **Weyl–von-Neumann property** – in short *WvN-property* – if for every σ-unital hereditary C^*-subalgebra $D \subseteq B$ and every C^*-subalgebra C of the multiplier algebra $\mathcal{M}(D\otimes\mathbb{K})$ of $D\otimes\mathbb{K}$, every *residually nuclear* completely positive contraction $V\colon C \to D \otimes \mathbb{K}$ can be approximated in point-norm by maps $C \ni c \mapsto d^*cd$ with contractions $d \in D \otimes \mathbb{K}$ ([25]).

We say that a C^*-algebra B has **residually nuclear separation** if, for every separable C^*-subalgebra $C \subseteq B$, every $a \in C_+$ and every $\varepsilon > 0$, there exists a residually nuclear contraction $V\colon C \to B$ such that $\|V(a) - a\| < \varepsilon$.

Notice that we can modify the residually nuclear contraction $V\colon C \to B$ in Definition 1.2.3 that it has in addition the property $V(C) \subseteq CBC$.

`Next should be part of a Proposition/ Theorem -- to be cited`

The WvN-property implies that B is purely infinite in the sense of Definition 1.2.1, that equivalently says that all elements of B_+ are properly infinite in B, i.e.,

[25] It implies that the c.p.c. V is "1-step approximately inner" in the sense of Definition 3.10.1.

B satisfies the equivalent properties **pi**(1) of Definition 2.0.4 and pi-1 of Definition **??**, cf. also [**462**, def. 3.2, def. 4.1, thm. 4.16].

`Give ref.s/not.cite for def.s and proofs`

`Shift details to other places?!!`

Moreover the WvN-property implies that for every separable C^*-subalgebra $D \subseteq B$ with the property that the inclusion map $\iota_D \colon d \to d$ is nuclear (which implies automatically that D is exact), there is a C^*-morphism $h\colon (D\otimes\mathbb{K})\otimes\mathcal{O}_\infty \to (B\otimes\mathbb{K})_\omega$ such that $h((d\otimes k)\otimes 1) = d\otimes k$ for $d \in D$, $k \in \mathbb{K}$ under the natural inclusion $B\otimes\mathbb{K} \subset (B\otimes\mathbb{K})_\omega$ of $B\otimes\mathbb{K}$ into the ultrapower $(B\otimes\mathbb{K})_\omega$. ([26]).

Indeed, let $C := D\otimes\mathbb{K}$, $s_1, s_2 \in \mathcal{M}(D\otimes\mathbb{K})$ isometries with $s_j^* s_k = \delta_{j,k}1$ the map $c \mapsto s_1 c s_1^* + s_2 c s_2^*$ is residually nuclear, thus is 1-step approximately inner in $B\otimes\mathbb{K}$ if B has the WvN-property.

And it shows that each element of $(B\otimes\mathbb{K})_+$ is properly infinite if B has the WvN-property.

`It seems (! open question?) that the WvN property also implies that` $\pi_B(D)' \cap \mathcal{M}(B)/B$ `contains a unital copy of` $\mathcal{O}_\infty$.
`Try to factorize the cone of` D `over` $\ell_\infty(B\otimes\mathbb{K})/c_0(B\otimes\mathbb{K})$ `???`

One can show ([27]) that a C^*-algebra B is strongly p.i. if B has both of the WvN-property and the residually nuclear separation property of Definition 1.2.3.

It is obvious that the WvN-property passes to hereditary C^*-subalgebras and is invariant under stabilization, hence is an invariant of Morita equivalence. The definition of the WvN-property says only something that one can limit the algebras C in the definition of the WvN-property to the case of separable C.

Moreover it is not difficult to see

`BY DEFINITION ??`

that B has the WvN-property if B_ω has the WvN-property.

Clearly the identity map $\mathrm{id}_B =: V$ on nuclear C^*-algebras B defines residually nuclear separation for each separable C^*-subalgebra C of B. Thus, for nuclear C^*-algebras B the WvN-property and strong pure infiniteness are the same.

Studies of primitive ideal spaces of nuclear C^*-algebras in combination with [**359**] and [**456**] lead to the observation that all stable separable C^*-algebras A have the (formally) stronger property of Abelian factorization, which obviously implies residually nuclear separation:

---

[26] We define the ultrapower A_ω of A by $A_\omega := \ell_\infty(A)/c_\omega(A)$ where $\omega \in \gamma(\mathbb{N}) := \beta(\mathbb{N}) \setminus \mathbb{N}$ is a point in the non-elementary part of the Stone-Čech compactification of $\mathbb{N}$.
Other authors use the notation A^ω for this algebra and then A_ω for the central sequence algebra $A' \cap A^\omega$.

[27] E.g. by ideas in the proof of [**463**, cor. 7.22] – that contains unfortunately some typos, see Chapters 2/3?? for corrected versions.

DEFINITION 1.2.4. A stable separable C^*-algebra A has the **Abelian factorization property** if there exists a locally compact Polish space P and non-degenerate *-monomorphisms $h\colon \mathrm{C}_0(P,\mathbb{K}) \to \mathcal{M}(A)$ and $k\colon A \to \mathcal{M}(\mathrm{C}_0(P,\mathbb{K}))$ such that the "C^*-correspondence" $\gamma := \mathcal{M}(h)\circ k\colon A \to \mathcal{M}(A)$ (– a special kind of Hilbert A-module with a left-sided action by A –) has the property

$$J = \gamma^{-1}\mathcal{M}(A,J) \quad \text{for all} \quad J \in \mathcal{I}(A)\,.$$

All simple stable C^*-algebras A have Abelian factorization by the trivial reason that one can take here for $P := \{p\}$ a point, i.e., $\mathrm{C}_0(P,\mathbb{K}) = \mathbb{K}$ and use that $A\otimes\mathbb{K} \cong A$ if A is stable, $h(T) := 1\otimes T \in \mathcal{M}(A\otimes\mathbb{K}) \cong \mathcal{M}(A)$ and let $k\colon A \to \mathcal{L}(\ell_2) \cong \mathcal{M}(\mathbb{K})$ any non-degenerate *-representation of A on ℓ_2.

It turns out that, if A has the Abelian factorization property, then the l.c. Polish space P and h can be chosen always such that P is 1-dimensional ([28]).

Therefore strong pure infiniteness and the WvN-property (?????? ref?) are now known to be equivalent for all C^*-algebras, because both have to be checked only on suitable sufficiently large separable C^*-subalgebras with one of this properties.

A proof of the Abelian factorization (see **??**) Definition in all generality uses a detailed study of the topology of second countable locally quasi-compact sober (= "point-complete") T_0 spaces (that we call "Dini spaces") and their "Dini functions", using the very last conclusions in Chapter 12. Therefore we have not included a proof here in the book. And we avoid to use Abelian factorization here directly. Instead we use methods that are still fairly elaborate but use formally weaker assumptions than the "residual factorization property" of A, (cf. Definition 1.2.3).

But in the special case of separable *exact* C^*-algebras, one can derive *residually nuclear separation*, defined in Definition 1.2.3 with help of Theorem K by the following construction:

Use Theorem K with $A\otimes\mathcal{O}_2\otimes\mathbb{K}$ in place of both A and B and with the natural "action" of $\mathrm{Prim}(A) = \mathrm{Prim}(B)$ on A for the proof of residually nuclear separation of separable exact A:

The resulting residually nuclear endomorphism h_0 has the property that its restrictions to commutative C^*-subalgebras C of A approximately dominates the inclusion map $C \hookrightarrow A$ in the sense of Definition 3.10.1. Thus, the point-norm closed matricial operator-convex cone generated by h_0 defines "residually nuclear separation" for A as defined in Definition 1.2.3. This argument works so simple only for separable exact C^*-algebras A. And, unfortunately, needs ultra-power constructions that we want not to bore the reader at the main parts of this books. So we make sometimes additional assumptions that we all replace in Chapter 12 by embeddings into suitable separable C^*-algebras in the ultrapower that have the required properties. Then we observe that this what we can do in the ultrapower

[28] But P is not something like a one-dimensional polyhedron. It is only some projective limit of such polyhedra.

"in one step" can be done approximately in the given algebra itself. Such a "fitting together" and approximation arguments in the earlier chapters can be applied to all studied cases in a controlled way.

Alternatively, mone can use a deeper result for separable exact C^*-algebras A: It says that $A \otimes \mathcal{O}_2$ contains a *regular* Abelian C^*-subalgebra C in the sense of Definition B.4.1. It implies that A has *Abelian separation* (in sense of: give reference here!) and follows also from Corollary 12.3.1 and applications of Theorem K and Corollary L in the remark following Corollary 12.3.1, and the corresponding result for nuclear C^*-algebras in [**464**] and [**359**]. But we should not get lazy and put non-trivial stuff simply in the assumptions: Applicability or Non-applicability depends mainly from the difficulty to observe the assumptions of some derived useful applications and conclusions (in the theorems). The study of assumptions and its interrelations, weaker properties and inducing properties is what a result makes a true invention.

Thus, we get finally that *an* exact *C^*-algebra A is strongly p.i., if and only if, A has the WvN-property.* But we can not use this simple (but not obvious) identity of two properties before the very end of Chapter 12!

But the reader should not forget that one first has to give a proof of Theorem K to get a base e.g. for the *deduction* of the permanently used and needed WvN-property, that we must derive from strong pure infiniteness to reach our applications.

We go along an alternative way as follows:

A C^*-algebra B is s.p.i. if and only if its ultra-power B_ω is s.p.i., cf. Proposition 2.16.8. A C^*-algebra B is weakly purely infinite if and only its ultra-power B_ω has "residually nuclear separation" in the sense of Definition 1.2.3 (and in a very "local" way), see also [**463**, prop. 7.13] ([29]).

`Next should be a Prop./Thm. in Chp.3 ?? Which section?`

More precisely:

If B is weakly purely infinite (i.e., B is n-pi for some $n \in \mathbb{N}$) and $A \subseteq B_\omega$ is a separable C^*-subalgebra of B_ω, $C \subseteq A$ an Abelian C^*-subalgebra of A then there exists a separable C^*-subalgebra $D \subseteq B_\omega$, an Abelian C^*-subalgebra $C_1 \subseteq D$ and a conditional expectation $E\colon D \to C_1$ such that $A \subseteq D$, $C \subseteq C_1$, and $E(D \cap J) \subseteq C_1 \cap J$ for each closed ideal of $J \lhd B_\omega$.

Moreover, one can find such a system $(D, E\colon D \to C_1 \subset D, D)$ for each given separable $A \subset B_\omega$ with this properties and with the additional property that E is an – inside D – approximately inner c.p. map. In particular, C_1 is a "regular" C^*-subalgebra of D.

---

[29] This property of B_ω is "natural" because B is *completely characterless* – i.e., no σ-unital hereditary C^*-algebra of B_ω has a non-zero character – if B weakly p.i.

Conversely, if B_ω has no irreducible representations that contain the compact operators in its image, and if in B_ω such systems $(D, E\colon D \to C_1)$ exists for each given $C \subseteq A \subset B_\omega$, then B is weakly purely infinite.

Since B is strongly p.i. if and only if B_ω is strongly p.i., it follows that B_ω has the WvN-property if B is strongly p.i.

In this way we obtain that *a C^*-algebra A is s.p.i. in the sense of Definition 1.2.2, if and only if, A_ω has the WvN-property of Definition 1.2.3.*

That the WvN-property of A_ω induces the WvN-property of A, can be shown also directly from the definition of the WvN-property. ???? Really ???? `Idea forgotten?` **??**

Thus, *every s.p.i. C^*-algebra A has the WvN-property.*

The converse direction – that the WvN-property of A implies that A is s.p.i.– is for the final proofs of theTheorems **??** and ????? important. ????

We need "nuclear separation" to establish the realizations of actions Ψ by the related cones $\mathcal{C}_\Psi$ of Ψ-equivariant residually nuclear maps.

Which proofs use "nuclear separation" and where is it defined?

Chp.2: residual nuclear separation and WvN-property imply strong p.i.

But for simple C^*-algebras there are many formally weaker – but for them equivalent – properties.

Chp.3: residually nuclear maps build the "minimal" ideal system invariant cone (the later needed property is that this cone is non-degenerate for separable stable C^*-algebras).

Chp.6: "nuclear separation" is – needed / required – to proof the "embedding theorem" (give references to def's and theorems !!!)

(Starting alone from any non-degenerate l.s.c. action of $\mathrm{Prim}(B)$ on separable exact A that is monotone upper s.c., it can be proved only fully after one has proven with help of this special case in chp.12 that the nuclear separation of the action can be proved with help of results in Chp. 7, 9 and 12).

Chp.12: // B separable and B stable, σ-unital, and $B \otimes \mathcal{O}_\infty \cong B$, show existence of separable stable C^*-subalgebras D with $B \subseteq D \subset \mathrm{Q}(\mathbb{R}_+, B)$, D stable, σ-unital, and $D \otimes \mathcal{O}_\infty \cong D$, with a regular Abelian subalgebra C (that separates the ideals of D).

Then finding for $A :=???$ c.p. maps $V\colon A \to C \subset D$ (that realize the action of $\mathrm{Prim}(B) = pi_B(\mathrm{Prim}(\mathrm{Q}(\mathbb{R}_+, B)))$ on A and with their help a nuclear embedding $k_1\colon A \otimes \mathcal{O}_2 \to D$ suitable (existing by the main embedding theorem) and realizing the action of $\mathrm{Prim}(D)$ on A. But $h_1 := k_1((\cdot) \otimes 1)$ is re-scaling invariant by Chapter 7. Thus, unitary equivalent to a "defining" nuclear embedding $A \to \mathcal{O}_2 \to B \otimes \mathcal{O}_\infty$.

In particular this implies that the given action of $\mathrm{Prim}(B)$ on A has nuclear separation.

This argument works only for separable exact C^*-algebras. Because for non-separable or non-exact C^*-algebras there does not exist an “embedding theorem”. (Into $\mathcal{O}_2$?)

The WvN-property of A implies always that A is p.i.

Since WvN-property implies p.i., it is also part (??) of the open problem if p.i. implies s.p.i.

It is unknown if p.i. implies s.p.i.

It is not unlikely that an elementary observation exists that shows that A with WvN-property is always s.p.i.

The results of this book allow to proof that for all separable stable A the natural action of $X := \mathrm{Prim}(A)$ on A – given by the natural isomorphism $\mathbb{O}X \cong \mathcal{I}(A)$ – has “residually nuclear” separation (i.e., this action is “induced” from the m.o.c. cone $\mathrm{CP}_{\mathrm{rn}}(A, A)$ of residually nuclear maps from A to A), but to carry the proof out one needs the possibly stronger – and not in this book proved – “Abelian separation” property for separable C^*-algebras.

```
 important???// This can be used for ????????
The QUESTION is/was:
Is there a simple way to derive directly
for separable *-algebras A from WvN-property of A
the STRONG pure infiniteness of A?
Or, -- equivalently -- from WvN-property of A
the WvN-property of A_ω.
```

The residual nuclear separation follows in case of separable exact C^*-algebras from Corollary L, it implies directly that every separable exact C^*-algebra A has the stronger property that $A \otimes \mathcal{O}_2$ contains a “regular” Abelian C^*-subalgebra that separates the ideals of A.

The existence of a regular Abelian C^*-subalgebra implies in particular the existence of an “Abelian factorization” for $A \otimes \mathbb{K}$, which is (formally) stronger than “residually nuclear separation”.

A more easy way to prove that the WvN-property implies strong pure infiniteness is not in sight yet.

Despite the rather involved result of existence of “Abelian factorization” it remains the more special and interesting *question*, whether $A \otimes \mathcal{O}_2$ contains a *regular* Abelian C^*-subalgebra in the sense of Definition B.4.1 *for every separable* C^*-algebra A. By Corollary 12.3.1 and [**464**, thm. 6.11] the latter is the case, if and only if, $A \otimes \mathcal{O}_2$ contains a regular exact C^*-subalgebra.

```
End discussion of ‘‘WvN-property’’. Still not well explained !
```

In special cases we obtain that “p.i.” implies “strongly p.i.”, e.g., for algebras of real rank zero, for algebras with Hausdorff primitive ideal space, or for separable

C^*-algebras with linearly ordered lattice of closed ideals. In particular, all *simple* purely infinite algebras are strongly purely infinite.

Why we consider different definitions of pure infiniteness?

One can only work with the property of strong pure infiniteness, but the others are usually easier to verify. We can then try to check additional properties of the studied algebras that allow to conclude strong pure infiniteness e.g. from (1-) pure infiniteness. But this is also an open problem for separable nuclear C^*-algebras B. There are only some sufficient conditions as e.g. B has Hausdorff primitive ideal space,

(of finite dimension ?),

$\mathcal{I}(B)$ is linearly ordered ideal lattice, and to "s.p.i." equivalent properties, as e.g. $B \cong B \otimes \mathcal{O}_\infty$ if B is nuclear. *Simple and exact* strongly purely infinite separable C^*-algebras B do not absorb $\mathcal{O}_\infty$ tensorial in general, as e.g. the example of the (strongly) purely infinite algebra $B := C^*_{reg}(F_2) \otimes \mathcal{R}$ shows, where $\mathcal{R}$ is the finite but not stably finite simple nuclear C^*-algebra of M. Rørdam [**687**] and $C^*_{reg}(F_2)$ is the (exact) regular group C^*-algebra of $C^*_{reg}(F_2)$. M. Rørdam itself denoted his algebra $\mathcal{R}$ by W.

At first we give some definitions concerning non-Hausdorff spaces, which are needed for suitable generalizations of the main results for simple p.i. algebras to non-simple p.i. algebras.

DEFINITION 1.2.5. A topological T_0-space X is **sober** if *every* prime closed subset of X is the closure of a point ([30]).

Here a closed subset $F \subseteq X$ is **prime**, if F is not the union $F_1 \cap F_2$ of two closed subsets F_1, F_2 of F that are both different from F.

Since, by results of J. Dixmier

citation? See also book of Pedersen ...

for a separable C^*-algebras A, closed prime ideals of A are primitive, the primitive ideal space $\mathrm{Prim}(A)$ of a separable C^*-algebra is a "sober" T_0-space (we call it "point-complete") with a countable base of its topology. The countable base can be described by the supports of the lower semi-continuous functions $J \in \mathrm{Prim}(A) \mapsto \|\pi_J(b_{n,k})\|$, where $b_{n,k} = (a_n - 1/k)_+$ for a sequence $a_1, a_2, \ldots$ which is dense in $\{a \in A_+ : \|a\| = 1\}$ and $n, k \in \mathbb{N}$.

In 2001 N. Weaver [**815**] published an example of non-separable prime C^*-algebras that is not non-primitive. Later T. Katsura [**411**] constructed examples of non-separable AF-algebras that are prime but not non-primitive.

[30] It is also called **point-complete** or **tidy**. Sober l.c. T_0-spaces are sometimes also called *spectral space* , but some authors define spectral spaces as point-complete T_0-spaces that have a base of the topology consisting of compact open subsets.

But it seems that one needs some set theory axiom that is stronger than the Axiom of choice?
But weaker than the Continuum Hypothesis??

DEFINITION 1.2.6. Let X be a sober T_0-space that is second countable, i.e., has a topology with a countable base.

We say that X **acts** on a C^*-algebra A, if there is given a monotone map Ψ from the lattice $\mathbb{O}(X)$ of open subsets Z of X to the closed ideals $\mathcal{I}(A)$ of a C^*-algebra A with $\Psi(\emptyset) = 0$ and $\Psi(X) = A$.

The action Ψ of X on A will be called **upper semi-continuous** , if, moreover,

(i) $\Psi(Z_1 \cup Z_2) = \Psi(Z_1) + \Psi(Z_2)$ for every pair of open subsets Z_1 and Z_2 of X, and
(ii) $\Psi(\bigcup Z_n)$ is the closure of $\bigcup \Psi(Z_n)$ if $Z_1 \subseteq Z_2 \subseteq \cdots$ is an increasing sequence of open subsets of X, i.e., Ψ is monotone.

The action Ψ is called **lower semi-continuous** if (instead of (i) and (ii)):

(iii) $\Psi(Z_1 \cap Z_2) = \Psi(Z_1) \cap \Psi(Z_2)$ for every pair of open subsets Z_1 and Z_2 of X, and
(iv) $\Psi(K) = \bigcap \Psi(Z_n)$, where K is the *interior* of $\bigcap Z_n$ in X, if $Z_1 \supset Z_2 \supset \cdots$ is a decreasing sequence of open subsets of X.

If the monotone map Ψ satisfies (i)–(iv), then we say that X acts on A **continuously**. (Or: Ψ **is continuous**).

It is **monotone continuous** if it satisfies only (ii)–(iv).

An example of a continuous action is the action of $Y := \text{Prim}(A)$ on A given by the one-to-one correspondence between the open subsets of $\text{Prim}(A)$ and closed ideals $\mathcal{I}(A)$ of A:

$$Z \in \mathbb{O}(Y) \mapsto \Psi_A(Z) := \bigcap \{J : J \in \text{Prim}(A) \setminus Z\} .$$

Note that $\Psi_A(\emptyset) = 0$ and that here we define $\Psi_A(Y) := A$.

If nothing is said about an action of $\text{Prim}(A)$ *on* A*, then this natural correspondence is used.*

Therefore, the monotonous maps Ψ from X to the closed ideals of A are in one-to-one correspondence to the monotonous maps from the open subsets of X into the open subsets of the primitive ideal space $Y = \text{Prim}(A)$ of A.

Check cite of Fell60 [296]!

By [**559**] and [**296**], if A is separable, then $\mathcal{I}(A)$ is naturally order anti-isomorphic (respectively the family $\mathbb{F}(\text{Prim}(A))$ of closed subsets of $\text{Prim}(A)$ is order isomorphic) to a closed subset Z_A of the Hilbert cube $[0, 1]^\infty$ with the coordinate-wise order: Take the map

$$J \in \mathcal{I}(A) \mapsto (\|\pi_J(c_n)\|)_{n=1}^\infty ,$$

where $c_1, c_2, \ldots$ is a dense sequence in $\{a \in A_+ \colon \|a\| = 1\}$. The induced Hausdorff topology on $\mathbb{F}(\mathrm{Prim}(A))$ is the **Fell-Vietoris topology**. The one-to-one map $F \in \mathbb{F}(\mathrm{Prim}(A)) \mapsto \mathrm{Prim}(A) \setminus F \in \mathbb{O}(\mathrm{Prim}(A)) \cong \mathcal{I}(A)$ defines on $\mathbb{O}(\mathrm{Prim}(A))$ a topology that is equal to the so-called **Lawson topology**.

Since the Dini-functions $\varphi\colon X \to [0,1]$ on the Dini spaces X (= point-complete second countable l.c. T_0-spaces) are naturally related to the ''way-below'' (= ''well-below'') continuous monotone functions on the continuous lattice $\mathbb{O}(X)$ into $[-\infty, \infty]$ if we take e.g. the strictly order-monotone homeomorphism $\psi\colon t \in [0,1] \mapsto [-\infty, +\infty]$ given by $\psi(t) := \tan(\pi(t-1/2))$.

Countably generated Continuous lattices Ω are in 1-1-correspondence with $\mathbb{O}(X)$ with -- up to homeomorphisms unique -- Dini space X.

There is a Theorem in lattice theory that gives the same embedding in a different formulation (Graetzer [332], Lattice Theory , Thm. 47 (of Larson), see also [321, thm. IV-3.20].

The set $Z_A \cong \mathcal{I}(A)$ contains zero $(0,0,\ldots) \leftrightarrow A$ and Z_A is preserved under forming of component-wise maxima: If $\alpha, \beta \in Z_A$, then $\max(\alpha,\beta) \in Z_A$. The points of $\mathrm{Prim}(A)$ can be found by considering the prime elements of Z_A with respect to the continuous "multiplication" given by $(\alpha,\beta) \mapsto \max(\alpha,\beta)$.

If we identify $\mathrm{Prim}(A)$ with this subset of prime elements in $Z_A \cong \mathcal{I}(A)$, then the closure of a set S in $\mathrm{Prim}(A) \subseteq Z_A$ is given by the hull-kernel operation $hk(S) := \{\alpha \in \mathrm{Prim}(A) \colon \alpha \leq \max S\}$.

A simple set-theoretical argument shows, that, for second countable sober (point-complete) T_0-spaces X, the above defined upper semicontinuity of a faithful and monotonous map $\Psi\colon \mathbb{O}(X) \to \mathcal{I}(A)$ which satisfies moreover (iii) and the non-degeneracy $\Psi(\emptyset) = 0$ and $\Psi(X) = A$, is equivalent to the existence of a (unique) continuous map p from $\mathrm{Prim}(A)$ into X such that $\Psi(Z)$ is the ideal corresponding to $p^{-1}(Z)$.

If Ψ is given by p^{-1}, then properties (i)–(iii), $\Psi(X) = A$ and $\Psi(\emptyset) = 0$ hold. The action Ψ is faithful, if and only if, $p(\mathrm{Prim}(A)) \cap (U \setminus V) \neq \emptyset$ for all open subsets $V \subset U \subseteq X$ with $V \neq U$. Then, furthermore, (iv) holds for Ψ, if and only if, p is "pseudo-open" (which is the same as "open" only if X is Hausdorff, see [**359**] for details).

Let us consider the *special case* where X is a locally compact *Hausdorff* space and Ψ is faithful and satisfies (i)–(iii) and $\Psi(\emptyset) = 0$, $\Psi(X) = A$. By Dauns-Hofmann theorem ([**402**, exercise 10.5.84], [**616**, cor. 4.4.8]) one gets that there is a unique C^*-morphism α from $\mathrm{C}_0(X)$ into the center of $\mathcal{M}(A)$ such that $\Psi(Z) = \alpha(\mathrm{C}_0(Z))A$

for every open subset Z of X. It is then easy to see, that A is C^*-bundle with base space X in the sense of [**471**] ([31]), if and only if, Ψ is non-degenerate and satisfies conditions (i)–(iv). Thus, the faithful continuous actions of locally compact Hausdorff spaces X on a C^*-algebra A are in natural one-to-one correspondence to the structures of C^*-bundles on A in the sense of [**471**]. It says that *our general theory contains those results for C^*-algebra bundles.*

In the case of continuous bundles, E. Blanchard [**89**] has found a special case of the below given "trivialization" Theorem K. The remaining points are, to give necessary and sufficient conditions on the bundle under which it is exact (this was done in [**471**]), and to give other conditions under which it is (strongly) purely infinite. See Chapter 2 for partial answers and related problems.

A C^*-algebra B defines on its multiplier algebra $\mathcal{M}(B)$ or, more generally, on the C^*-algebra $\mathcal{L}(E)$ of B-linear operators with bounded adjoints on a Hilbert B-module E, an action Ψ^{up} of $X = \mathbb{O}(\mathrm{Prim}(B)) \cong \mathcal{I}(B)$ as follows:

$$\Psi^{\mathrm{up}}\colon J \in \mathcal{I}(B) \mapsto \mathcal{M}(E, J) \in \mathcal{I}(\mathcal{L}(E))$$

where $\mathcal{M}(E, J) := \{T \in \mathcal{L}(E)\,;\; TE \subset EJ\}$. In the case where $E = B$ (considered as left B-module), we have $\mathcal{M}(B) = \mathcal{L}(E)$ and $\mathcal{M}(B, J)$ is the kernel of the natural C^*-morphism $\mathcal{M}(B) \to \mathcal{M}(B/J)$. Ψ^{up} satisfies (i), (iii) and (iv) if B is σ-unital and E is countably generated over B. But Ψ^{up} does not satisfy (ii) in general, e.g. in the case $B = c_0 \otimes \mathbb{K}$. If λ is an isometric B-module isomorphism from E_1 onto E_2, then $\lambda(\mathcal{M}(E_1, J)) = \mathcal{M}(E_2, J)$ for every closed ideal J of B.

How could the realization of a given action of $\mathrm{Prim}(B)$ on A look like?

Above we have defined the action $\Psi^{\mathrm{up}}\colon \mathcal{I}(B) \to \mathcal{I}(\mathcal{M}(B))$. In a more general setting we have:

Definition 1.2.7. Let $A \subseteq \mathcal{M}(B)$. One has two natural maps $\Psi^{A,B}_{\mathrm{down}}$ and $\Psi^{\mathrm{up}}_{B,A}$ from the open subsets $\mathbb{O}(\mathrm{Prim}(A)) \cong \mathcal{I}(A)$ of $\mathrm{Prim}(A)$ into $\mathcal{I}(B)$ (respectively from $\mathbb{O}(\mathrm{Prim}(B)) \cong \mathcal{I}(B)$ into $\mathcal{I}(A)$), given by:

$$\Psi^{A,B}_{\mathrm{down}}\colon K \in \mathcal{I}(A) \mapsto \overline{BKB} \in \mathcal{I}(B)\,,$$

respectively by

$$\Psi^{\mathrm{up}}_{B,A}\colon J \in \mathcal{I}(B) \mapsto A \cap \mathcal{M}(B, J) \in \mathcal{I}(A)\,.$$

Here $\overline{BKB}$ means the closure of the linear span of elements bac, where $a \in K$, $b, c \in B$

The corresponding actions of $\mathrm{Prim}(A)$ on B and of $\mathrm{Prim}(B)$ on A are increasing maps, the one corresponding to $\Psi^{A,B}_{\mathrm{down}}$ satisfies (i) and (ii) (but it is in general not faithful and has neither (iii) nor (iv)), and the one corresponding to $\Psi^{\mathrm{up}}_{B,A}$ fulfills (iii) and (iv) (but it is in general not faithful and has neither property (i) nor (ii)).

[31] I.e., A is the C^*-algebra of continuous sections in a continuous field of C^*-algebras $\{A_x\}_{x\in X}$, equipped with its $\mathrm{C}_0(X)$-module structure.

If $A \subseteq \mathcal{M}(B)$ satisfies $A \cap (I + J) = A \cap I + A \cap J$ for all closed ideals I, J of $\mathcal{M}(B)$ and if B is σ-unital, then $\Psi^{\mathrm{up}}_{B,A}$ satisfies (i).

In view of Theorem K, it is *important* that $\Psi^{\mathrm{up}}_{B,A}$ satisfies (ii) if $A \subseteq B$.

There are examples which show that

$$J \in \mathcal{I}(B) \mapsto \mathcal{M}(B, J) + B \in \mathcal{I}(\mathcal{M}(B)/B)$$

is in general neither lower semi-continuous nor upper semi-continuous, but satisfies (i) and (iii) if B is σ-unital. This causes a striking technical difficulty for proofs of generalized Weyl-von Neumann-Voiculescu theorems, cf. Chapter 5.

The results and methods of this monograph allow to prove
(but not here in this book because it requires in detail several
another hundert pages)
that each separable stable C^*-algebra A has
''Abelian factorization''.
This implies a proof of the n.c. Michael selection Conj.
and a proof that the MvN-property implies *strong* pure infiniteness

It remains the question if, for every separable C^*-algebra A,
the $\mathcal{O}_2$-stabilization $A \otimes \mathcal{O}_2$ contains a
''regular abelian C^*-algebra'' C in sense of Definition 1.2.9

The *non-commutative Michael selection Conjecture* 12.3.2 says that for separable stable C^*-algebras A and B and lower semi-continuous actions $\Psi \colon \mathcal{I}(B) \to \mathcal{I}(A)$ of $\mathrm{Prim}(B)$ on A there is a C^*-morphism $h \colon A \to \mathcal{M}(B)$ such that $\Psi = h^{-1}\Psi^{\mathrm{up}}_{B,h(A)}$, i.e., that $\Psi(J) = h^{-1}\mathcal{M}(B, J)$ for $J \in \mathcal{I}(B)$. Moreover, h should be weakly Ψ-residually nuclear in the sense of Definition 1.2.8. A proof of Conjecture 12.3.2 would imply that C^*-algebras with WvN-property in Definition 1.2.3 are strongly purely infinite, because Conjecture 12.3.2 implies the conjecture that every C^*-algebra has *residually nuclear separation* in sense of Definition 1.2.3.

Theorem 12.1.8 and the below stated Theorem K are partial results in the direction of the non-commutative Michael selection Conjecture 12.3.2. Theorem 12.1.8 (and Proposition 12.2.15) will be used for the proof of Theorem K.

DEFINITION 1.2.8. Suppose that X is a point-complete (also called "spectral", "sober" etc.) T_0-space with a countable base of its topology. Let Ψ_A and Ψ_B monotonous actions of X on C^*-algebras A and B. A completely positive map $V \colon A \to B$ is called **Ψ-equivariant** (or, more precisely, Ψ_A–Ψ_B-equivariant) if $V(\Psi_A(Z)) \subseteq \Psi_B(Z)$ for every open subset Z of X.

V is **Ψ-residually nuclear** (or, more precisely Ψ_A–Ψ_B-residually nuclear) if it is Ψ-equivariant and the class maps $[V] \colon A/\Psi_A(Z) \to B/\Psi_B(Z)$ are nuclear for every open subset Z of X.

A completely positive map T from A into $\mathcal{M}(B)$ will be called **weakly Ψ-equivariant** (respectively **weakly Ψ-residually nuclear**) if $V_b := b^*T(\cdot)b$ is Ψ-equivariant (respectively is Ψ-residually nuclear) for every $b \in B$.

We say that V is **residually nuclear** (respectively that T is **weakly residually nuclear**) in the special situation where $X = \mathrm{Prim}(B)$, $A \subseteq \mathcal{M}(B)$, Ψ_B is natural (i.e., $\Psi_B := \mathrm{id}_{\mathcal{I}(B)}$), $\Psi_A = \Psi^{\mathrm{up}}_{B,A}$ and V is Ψ-residually nuclear (respectively T is weakly Ψ-residually nuclear).

If A is exact, then V is Ψ-residually nuclear if V is Ψ-equivariant *and* is nuclear. But this is not true for arbitrary separable A (and arbitrary actions). If $A \subseteq B$ and $V : A \to B$

In Chapter 12 we finish the proof of the following embedding (or "sub-triviality") Theorem K which generalizes Theorem A and E. Blanchard's sub-triviality theorem for exact C^*-algebra bundles in [**89**].

THEOREM K (Embedding Theorem). *Suppose that A and B are separable and stable C^*-algebras, such that A is exact and B is strongly purely infinite.*

Let $\Psi_A : \mathbb{O}(X) \cong \mathcal{I}(B) \to \mathcal{I}(A)$ be a lower semi-continuous action of $X :=$ $\mathrm{Prim}(B)$ *on A which satisfies the "monotone upper semi-continuity" condition (ii) of Definition 1.2.6, together with the non-degeneracy condition*

$$\Psi_A(B) = \Psi_A(X) = A \text{ and } \Psi_A(\emptyset) = 0 .$$

*Then there exists a Ψ-residually nuclear *-monomorphism $h : A \otimes \mathcal{O}_2 \hookrightarrow B$ such that, for $h_0 := h((\cdot) \otimes 1)$ and every closed ideal J of B,*

$$h_0(\Psi_A(J)) = J \cap h_0(A) .$$

Moreover, h_0 is unitarily homotopic in the sense of Definition 5.0.1 to $h_0 \oplus h_0$.

*Every nuclear *-monomorphism h_1 from A into B, which is unitarily homotopic to $h_1 \oplus h_1$ and satisfies $h_1(\Psi_A(J)) = J \cap h_1(A)$ for $J \in \mathcal{I}(B)$, is unitarily homotopic to h_0.*

If $\Psi_A(J) = A$ always implies that $J = B$, then h can be found such that $h_0(A)B$ is dense in B.

A part of the proof of this Embedding Theorem is given in Chapter 6. It uses an additional assumption of a property of B: The existence of a "regular Abelian C^*-subalgebra" in $B \otimes \mathcal{O}_2$ in sense of Definition 1.2.9. From this property we derive the "Abelian factorization" property and the (for some arguments in our proof needed) "minimal" assumption of the "residual nuclear separation" property of B that we must require for the proof in Chapter 6. After that we can free the proof of the embedding theorem from the extra assumption of existence of "residually nuclear separation" by showing in Chapter 12 that we can find in the asymptotic corona $\mathrm{Q}(\mathbb{R}_+, B)$ of B a separable strongly purely infinite subalgebra F that contains B, contains a regular abelian C^*-subalgebra and has a monotone continuous action and upper s.c. action of $\mathcal{I}(A)$ on F that is compatible under rescaling automorphisms of $\mathrm{Q}(\mathbb{R}_+, B)$. The uniqueness up to unitary equivalence of the embedding of $A \otimes \mathcal{O}_2$ in $\mathrm{Q}(\mathbb{R}_+, B)$ gives that this is unitarily equivalent to an embedding from $A \otimes \mathcal{O}_2$ in B that fits into the given action of $\mathrm{Prim}(B)$ on A.

The results of this book (all together) lead to a proof that any separable stable C^*-algebra B has an Abelian factorization. The existence of regular Abelian C^*-subalgebras in $B \otimes \mathcal{O}_2$ follows for separable *exact* B from Corollary L given below. But despite of the not in this book proven existence of "Abelian factorization" for separable stable B, the *Question* about the existence of a regular Abelian C^*-subalgebra in $C^*_{max}(F_\infty) \otimes \mathcal{O}_2$ is still open. (If it exists, then $B \otimes \mathcal{O}_2$ contains a regular Abelian C^*-subalgebra $A_B \subseteq B \otimes \mathcal{O}_2$ for every separable C^*-algebra B.)

Why that? Give reason here, or reference to reasons given on other places!

Definition 1.2.9. We call an Abelian C^*-subalgebra $C \subseteq B$ of a C^*-algebra B **regular** in B if

(i) $(J + I) \cap C = (J \cap C) + (I \cap C)$ for all $I, J \in \mathcal{I}(B)$, and
(ii) C separates the lattice of ideals of B, i.e., $I \cap C = J \cap C$ implies $I = J$.

The additional assumption of the existence of a *regular* Abelian C^*-subalgebra C in $B \otimes \mathcal{O}_2$ will be removed finally in Chapter 12 by showing that the asymptotic corona $\mathrm{Q}(\mathbb{R}_+, B)$ contains a separable strongly purely infinite C^*-subalgebra $B_1 \subset \mathrm{Q}(\mathbb{R}_+, B)$ with the properties that $B \subset B_1$ and that $B_1 \otimes \mathcal{O}_2$ contains a regular Abelian C^*-subalgebra $C \subset B_1 \otimes \mathcal{O}_2$. The action Ψ of $\mathrm{Prim}(B)$ on A can be extended to an action Ψ_1 of $\mathrm{Prim}\, B_1$ on A by letting $\Psi_1(K) := \Psi(K \cap B)$ for $K \in \mathcal{I}(B_1)$. This extended action is invariant under "rescaling" (i.e., parameter change).

The uniqueness of the Ψ-preserving nuclear *-monomorphisms from $A \otimes \mathcal{O}_2$ in $\mathrm{Q}(\mathbb{R}_+, B)$ up to unitary homotopy (cf. Chapters 5, 7 and 9) leads to a "constant" nuclear embedding of $A \otimes \mathcal{O}_2$ into B itself that realizes the action Ψ.

With other words, under the above assumptions on A, B and Ψ_A, the action Ψ_A of $\mathrm{Prim}(B)$ on A can be realized as $h_0^{-1}\Psi^{\mathrm{up}}_{B,h_0(A)}$ for some non-degenerate nuclear *-monomorphism $h_0 \colon A \to B$ with $h_0 \oplus h_0$ unitarily homotopic to h_0. Moreover, then the nuclear *-monomorphism h_0 is uniquely determined, up to unitary homotopy, by Ψ_A and the property that $h_0 \oplus h_0$ is unitarily homotopic to h_0.

The existence and uniqueness of h_0 up unitary homotopy immediately implies the following Corollary L of Theorem K:

Corollary L. *Suppose that A and B are separable stable nuclear C^*-algebras and that γ is a topological isomorphism from* $\mathrm{Prim}(A)$ *onto* $\mathrm{Prim}(B)$.

*Then there is a *-isomorphism φ from $A \otimes \mathcal{O}_2$ onto $B \otimes \mathcal{O}_2$ that "realizes" γ, in the sense that $\varphi(J \otimes \mathcal{O}_2) = \gamma(J) \otimes \mathcal{O}_2$ for primitive ideals J of A.*

The isomorphism φ with this property is unique up to unitary homotopy.

MOVE TO PROOF of?

Notice, that the uniqueness up to unitary homotopy quoted in Corollary L is an "elementary" fact because $[\varphi_1 \oplus \varphi_2] = [\varphi_k]$ in $\mathrm{R}(\mathrm{Prim}(A); A \otimes \mathcal{O}_2, B \otimes \mathcal{O}_2)$ for $k \in \{1, 2\}$ for any two γ-equivariant φ_1, φ_2.

Another easy consequence of Theorem K is Corollary 12.3.1, that implies that *for every separable **exact** C^*-algebra A there exists a unique separable stable **nuclear** C^*-algebra B with the same primitive ideal space* $\mathrm{Prim}(A) \cong \mathrm{Prim}(B)$ *and with* $B \cong B \otimes \mathcal{O}_2$.

Such an algebra B and the homeomorphism γ from $\mathrm{Prim}(A)$ onto $\mathrm{Prim}(B)$ are unique up to algebraical and topological isomorphisms.

By Theorem K and with this properties the C^*-algebra B is unique up to isomorphisms that fix the given homeomorphism γ from $\mathrm{Prim}(B)$ onto $\mathrm{Prim}(A)$. There are γ-equivariant non-degenerate C^*-morphisms from B into A and from B into A.

We are now going to use the Theorem K and the there defined $h_0 \colon A \to B$ in the same way as we have used above Theorem A to obtain Theorem B.

For that we need to generalize Kasparov's $\mathcal{R}\,\mathrm{KK}^G(X;\,\cdot,\cdot)$ functor in some direction.

Definition 1.2.10. Let X be a point-complete ([32]) T_0-space with countable basis, and suppose that Ψ_A and Ψ_B are monotonous actions of X on A and B.

By $\mathrm{Hom}(X;\,A,B)$ – or more precisely by $\mathrm{Hom}(\Psi;\,A,B)$ – we denote the Ψ-equivariant C^*-morphisms from A to B. If the multiplier algebra of B contains a unital copy of $\mathcal{O}_2$, then the unitary equivalence classes $[h]$ of elements $h \in \mathrm{Hom}(X;\,A,B)$ are preserved under Cuntz addition and they constitute in a natural way an abelian semigroup.

By $\mathrm{Hom}_{\mathrm{nuc}}(X;\,A,B)$ we denote the Ψ-residually nuclear C^*-morphisms.

We define a **Ψ-equivariant Kasparov module** as a Kasparov (A,B)-module $\mathcal{E} = (E,\phi,F)$ (see e.g. Definition 8.2.1) which has the additional property that ϕ is Ψ_A-$\Psi^{\mathrm{up}} \circ \Psi_B$-equivariant. Or equivalently, for each $e \in E$, the completely positive map

$$V_e \colon a \in A \mapsto \langle \phi(a)e, e\rangle \in B$$

satisfies $V_e(\Psi_A(U)) \subseteq \Psi_B(U)$ for all open subsets $U \in \mathbb{O}(X)$. The class of Ψ-equivariant Kasparov (A,B)-modules is closed under direct sums of Kasparov modules and under unitary equivalence.

Let $\sim_{scp}$ denote the equivalence relation in the (A,B)-Kasparov modules given by unitary isomorphisms and compact perturbations (of F, cf. Section 1 of Chapter 8). The equivalence classes build a commutative semigroup $\mathbb{E}(A,B)/\sim_{scp}$, such that $\mathrm{KK}(A,B) := \mathrm{Gr}(\mathbb{E}(A,B)/\sim_{scp})$.

If $(E_1,\phi_1,F_1) \sim_{scp} (E,\phi,F)$ and (E,ϕ,F) is Ψ-equivariant, then (E_1,ϕ_1,F_1) is so.

We define the **Ψ-equivariant KK-group** $\mathrm{KK}(X;\,A,B)$ as the Grothendieck group of the sub-semigroup $\mathbb{E}(X;\,A,B)/\sim_{scp}$ of the $\sim_{scp}$ classes of Ψ-equivariant

[32] Also called "*spectral*" or "*sober*".

(A, B)-Kasparov modules in $\mathbb{E}(A, B)/\sim_{scp}$. The induced equivalence-relation on the Ψ-equivariant (A, B)-Kasparov modules implies the equivalence $\sim_c$ of "cobordism" or "homology" (but is build *inside* the semigroup of unitary equivalence classes of Ψ-equivariant Kasparov modules, cf. Chapter 8).

Give precise references and def's !!!

A Ψ-equivariant Kasparov module $\mathcal{E} = (E, \phi, F)$ is called **Ψ-nuclear** if for every $e \in E$ the completely positive map $a \mapsto \langle \phi(a)e, e \rangle$ from A to B is *Ψ-residually nuclear*. If a Kasparov module is $\sim_{scp}$ equivalent to a Ψ-nuclear Kasparov module, then it is itself Ψ-nuclear. The Ψ-nuclear $\sim_{scp}$ classes are closed (i.e. "invariant") under direct sums and unitary equivalence.

Thus, the $\sim_{scp}$ equivalence classes of Ψ-nuclear Kasparov (A, B)-modules build a sub-semigroup $\mathbb{E}_{\text{nuc}}(X;\, A, B)/\sim_{scp}$ of the semigroup $\mathbb{E}(A, B)/\sim_{scp}$ of $\sim_{scp}$ equivalence classes of Kasparov modules.

We define the **Ψ-nuclear** KK-group $\text{KK}_{\text{nuc}}(X;\, A, B)$ as the *Grothendieck group* of the sub-semigroup $\mathbb{E}_{\text{nuc}}(X;\, A, B)/\sim_{scp}$ of the semi-group $\mathbb{E}(A, B)/\sim_{scp}$.

More generally, we consider in Chapters 8 and 9 the groups $\text{KK}(\mathcal{C};\, A, B) := \text{Gr}(\mathbb{E}(\mathcal{C};\, A, B)/\sim_{scp})$ where $\mathcal{C} \subseteq \text{CP}(A, B)$ is a point-norm closed operator-convex cone of completely positive maps, and $\mathbb{E}(\mathcal{C};\, A, B)/\sim_{scp} \subseteq \mathbb{E}(A, B)/\sim_{scp}$ denotes the semigroup of $\sim_{scp}$-equivalence classes of $\mathcal{C}$-compatible Kasparov modules (E, ϕ, F) (i.e., of the modules with the property that for every $e \in E$ the completely positive map $a \mapsto \langle \phi(a)e, e \rangle$ is in $\mathcal{C}$). Notice that almost nothing is changed in Kasparov's theory except that we restrict the constructions to more special classes of A-B-modules that produce automatically the desired equi-variances.

In this more systematic approach the old non-equivariant theory is still contained and can be seen by considering $\text{KK}(A, B) = \text{KK}(\mathcal{C};\, A, B)$ for $\mathcal{C} := \text{CP}(A, B)$, and $\text{KK}(X;\, A, B) = \text{KK}(\mathcal{C};\, A, B)$ for the m.o.c. cone $\mathcal{C}$ of with respect to $\mathbb{O}(X)$-action equivariant elements in $\text{CP}(A, B)$ ...

An adaptation of the proofs in usual KK-theory shows that $\text{KK}(X;\, \cdot, \cdot)$, $\text{KK}_{\text{nuc}}(X;\, \cdot, \cdot)$ and the most general $\text{KK}(\mathcal{C};\, A, B)$ behave analogously to KK:

There is a natural semigroup morphism

$$[h] \in [\text{Hom}(X;\, A, B)] \mapsto [h - 0] := [\mathcal{E}_h] \in \text{KK}(X;\, A, B),$$

for stable separable A and B, where the Kasparov B-module $\mathcal{E}_h$ is given by $\mathcal{E}_h := (B, h, 0)$ and $[h]$ denotes the unitary equivalence classes by unitaries in $\mathcal{M}(B)$.

The usual KK-groups can be rediscovered from our general approach by $\text{KK}(A, B) = \text{KK}(\{\text{point}\};\, A, B)$.

One can prove the existence of Kasparov products $x \otimes_B y \in \text{KK}(X;\, A, C)$ for $x \in \text{KK}(X;\, A, B)$ and $y \in \text{KK}(X;\, B, C)$ in the same way as for ordinary KK-theory. There is a natural bi-additive map

$$\text{KK}(X;\, A, B) \times \text{KK}(C, D) \to \text{KK}(X;\, A \otimes C, B \otimes D),$$

that is induced by tensor products of modules (if C and D are nuclear), where the action of X on the tensor products, e.g. on $A\otimes C$, is given by

$$\mathbb{O}(X)\ni Z\mapsto \Psi_A(Z)\otimes C\in\mathcal{I}(A\otimes C)\,.$$

If we fix X, then $\mathrm{KK}(X;\,A,B)$ is a bi-functor in the category of Ψ-equivariant C^*-morphisms. The bi-functor $\mathrm{KK}(X;\,\cdot,\cdot)$ is *homotopy invariant* for Ψ-equivariant homotopy, has Bott periodicity in each variable, and has six-term exact sequences in each variable on Ψ-equivariant (and Ψ-equivariant semi-split) short exact sequences of separable algebras,

where we suppose that the actions Ψ of X on A and B satisfy some regularity conditions expressed by the related m.o.c. cone $\mathcal{C}(X,\Psi_A,\Psi_B;A,B)$.

`Exactly which ''regularity conditions'',`
`Where mentioned?`

If X is Hausdorff and the actions on A and B are continuous, then $\mathrm{KK}(X;\,A,B)$ is the same as Kasparov's $\mathcal{R}\,\mathrm{KK}^G(X;\,A,B)$ for the trivial group $G=\{e\}$, even if differently defined.

The functor $\mathrm{KK}_{\mathrm{nuc}}(X;\,A,B)$ has similar properties, but $\mathrm{KK}(X;\,\cdot,\cdot)$-equivalence does not necessarily imply $\mathrm{KK}_{\mathrm{nuc}}(X;\,\cdot,\cdot)$-equivalence. If A or B is nuclear, then the natural morphism from $\mathrm{KK}_{\mathrm{nuc}}(X;\,A,B)$ into $\mathrm{KK}(X;\,A,B)$ is an isomorphism.

Consider e.g. $X=\{0,1\}$ with topology $\mathbb{O}(X)=\{\emptyset,\{0\},\{0,1\}\}$. Then the elements of $\mathrm{KK}(X;\,A,B)$ give invariants for transformations between extension $0\to I\to A\to A/I\to 0$ into $0\to J\to B\to B/J\to 0$, if the Busby invariants of the extensions dominate the zero representation (cf. Section 8 of Chapter 5).

We define in Chapter 5 weakly nuclear extension groups $\mathrm{Ext}_{\mathrm{nuc}}(X;\,A,B)$ – and more general $\mathrm{Ext}(\mathcal{C}\,;\,A,B)$ for countably generated operator convex cones $\mathcal{C}\subseteq\mathrm{CP}(A,B)$. The analog of Kasparov's proof for the isomorphism $\mathrm{Ext}_{\mathrm{nuc}}(A,SB)$ and $\mathrm{KK}_{\mathrm{nuc}}(A,B)$ shows also that $\mathrm{Ext}_{\mathrm{nuc}}(X;\,A,SB)$ is naturally isomorphic to $\mathrm{KK}_{\mathrm{nuc}}(X;\,A,B)$, see Chapter 8.

If B is σ-unital and stable, then a kind of Weyl–von-Neumann–Voiculescu theorem for the class of weakly residually nuclear maps $V\colon C\subseteq\mathcal{M}(B)\to\mathcal{M}(B)$ holds if and only if B has the **WvN-property** of Definition 1.2.3.

Moreover, B_ω (respectively $\mathrm{Q}(\mathbb{R}_+,B)$) has the WvN-property, if and only if, B is "strongly purely infinite" in the sense of Definition 1.2.2. Therefore all proofs, mapping cone constructions and difference constructions carry over to this new category, cf. Chapters 5, 7, 8 and the proofs of Theorems B and M in Chapter 9.

Now we make, for the next Theorem M, the following assumptions (1)-(3) on A, B, $N\subseteq B$, $X:=\mathrm{Prim}(N)$ and the actions of X on A and B:

(1) *Suppose that A is separable, stable and exact, B is σ-unital, and N is a strongly purely infinite separable stable C^*-subalgebra of B such that NB is dense in B.*
(2) *Let $X:=\mathrm{Prim}(N)$, and let X act on B by $\Psi_B:=\Psi^{N,B}_{\mathrm{down}}$.*

(3) *Further, suppose that X acts lower semi-continuously on A, such that, moreover, $\Psi_A(X) = A$, $\Psi_A(\emptyset) = 0$, $\Psi_A(Z) = A$ implies $Z = X$, and such that Ψ_A satisfies (ii) of Definition 1.2.6,* i.e., the action Ψ_A of A on A is non-degenerate and monotone continuous.

We can apply Theorem K to the action of $\mathrm{Prim}(N)$ on A, and get a non-degenerate nuclear *-monomorphism $h_0 \colon A \to N \subseteq B$, such that h_0 is unitarily homotopic to $h_0 \oplus h_0$, and $h_0(\Psi_A(J)) = h_0(A) \cap J$ for $J \in \mathcal{I}(N)$. Note, that h_0 is determined by this properties up to unitary homotopy as a nuclear C^*-morphism from A into N.

Is the following intermediate action not contained
in the general type of $\mathcal{C}$- or Ψ-equivariant actions?

Theorem M. *Suppose that A, B, $N \subseteq B$, X, and the actions Ψ_B, Ψ_A satisfy the above assumptions* (1)-(3).

*Let $h_0 \colon A \to N \subseteq B$ be the *-monomorphism given by Theorem K, let $[h] \in [\mathrm{Hom}_{\mathrm{nuc}}(X;\, A, B)]$ denote the unitary equivalence class of h, and let $[h - 0] \in \mathrm{KK}_{\mathrm{nuc}}(X;\, A, B)$ be the difference construction for $h \in \mathrm{Hom}_{\mathrm{nuc}}(X;\, A, B)$.*

(i) *The map*

$$\alpha \colon\, [\mathrm{Hom}_{\mathrm{nuc}}(X;\, A, B)] \ni [h] \;\mapsto\; [h - 0] \in \mathrm{KK}_{\mathrm{nuc}}(X;\, A, B)$$

is a semigroup epimorphism.

(ii) *$[h - 0] = [k - 0]$ in $\mathrm{KK}_{\mathrm{nuc}}(X;\, A, B)$ if and only if $h \oplus h_0$ and $k \oplus h_0$ are unitarily homotopic.*

(iii) *If, moreover, B is itself strongly purely infinite and Ψ_B is an isomorphism, i.e., comes from an isomorphism of $\mathrm{Prim}(N)$ onto $\mathrm{Prim}(B)$, then $h \oplus h_0$ is unitarily homotopic to h for every *-monomorphisms $h \colon A \hookrightarrow B$ which satisfies $h(\Psi_A(Z)) = h(A) \cap \Psi_B(Z)$ for open subsets $Z \subseteq X$.*

Notice that Ψ_B is an isomorphism, if and only if, Ψ_B defines an isomorphism of $\mathrm{Prim}(N)$ onto $\mathrm{Prim}(B)$ – and is defined by such an isomorphism.

The proof of Parts (i) and (ii) will be given together with the proof of Parts (i) and (ii) of Theorem B. But we assume there the existence of the nuclear *-monomorphism $h \colon A \otimes \mathcal{O}_2 \hookrightarrow N$ with the properties listed in Theorem K for N (in place of B). Theorem K will be proven independently in Chapter 12, based on a partial result in Chapter 6. The important absorption result (iii) of Theorem M is shown in Chapter 7.

$\mathrm{KK}(X;\, \cdot, \cdot)$ classifies all separable stable nuclear C^*-algebras up to $\mathcal{O}_\infty$-stable isomorphisms by the following generalization of Corollary C.

Corollary N. *Suppose that A and B are separable, stable and nuclear C^*-algebras, and that there is a topological isomorphism γ from $\mathrm{Prim}(A)$ onto $\mathrm{Prim}(B)$. Let Ψ_B denote the continuous action of $X := \mathrm{Prim}(A)$ on B defined by γ.*

If $z \in \mathrm{KK}(X;\, A, B)$ is a $\mathrm{KK}(X;\,\cdot,\cdot)$-equivalence between A and B, then there is a Ψ-equivariant isomorphism φ from $A \otimes \mathcal{O}_\infty$ onto $B \otimes \mathcal{O}_\infty$

*It seems only true that there are X-equivariant *-monomorphisms $h\colon A \to B$ and $k\colon B \to A$ such that $k \circ h$ is unitarily homotopic to id_A and $h \circ k$ is unitarily homotopic to id_B such that $[\varphi - 0] = z$.*

There is only one isomorphism φ with this property up to unitary homotopy.

The proof follows from Theorem M in the same way as the proof of Corollary C follows from Theorem B (see the arguments above Corollary C).

As in the case of simple nuclear algebras, the C^*-algebras A and B absorb $\mathcal{O}_\infty$ tensorial if A and B are moreover strongly p.i.

BEGIN: discussion of homotopy invariance.
The example in detail should be moved to some suitable chapter.

It should be noted that homotopy invariance of the isomorphism classes of strongly purely infinite separable stable nuclear C^*-algebras does not follow, even if we assume in addition that the ideal structure is preserved on the way of the homotopy and can be "corrected" to an ideal system fixing path of full endomorphisms by adding the non-degenerate "zero" endomorphism h_0 to this path.

This can be illustrated transparently by separable nuclear s.p.i. algebras that ??????

For example, consider the half-open interval $X_0 := (0,1]_{\mathrm{lsc}}$ with the "lower semi-continuity"-describing T_0-topology given by the intervals $(r,1]$ $(r \in [0,1))$ and $\emptyset$ as open sets, see also [**359**, thm. 1.4].

By [**559**] (see also [**689**]), there is a canonical way to produce a separable nuclear C^*-algebra C with $\mathrm{Prim}(C) = X_0 = (0,1]_{\mathrm{lsc}}$ that is "locally purely infinite" in a rather weak sense of Definition 2.0.3.

It implies by Corollary 2.6.6 that C is strongly p.i. , which implies $C \cong C \otimes \mathcal{O}_\infty$ by Theorem **??**.

There exist separable nuclear C^*-algebras D with $\mathrm{Prim}(D) := (0,1]_{\mathrm{lsc}}$ that are not purely infinite. Since C is separable, purely infinite and has no unital quotient it is stable. Thus, there is a unital copy of $C^*(s_1, s_2) \cong \mathcal{O}_2$ in its multiplier algebra $\mathcal{M}(C)$. This shows $C \cong C \otimes \mathcal{O}_\infty \cong C \otimes \mathcal{O}_\infty \otimes \mathbb{K}$, and that there exists an ideal system preserving non-degenerate *-monomorphism $h_0\colon C \otimes \mathcal{O}_2 \cong C \otimes \mathcal{O}_2 \otimes \mathbb{K} \to C$, by using a non-degenerate C^*-morphism $\mathcal{O}_2 \otimes \mathbb{K} \to \mathcal{O}_\infty \otimes \mathbb{K}$.

Question: Are all approximate to id unitary equivalent isomorphisms of separable $\mathbb{K} \otimes A \otimes \mathcal{O}_2$ unitary homotopic to id?
Here the question could be how near the unitaries $U_n^* U_{n+1}$ of such approximate unitary equivalence defining unitaries can be taken to the unitary group $\mathcal{U}(A \otimes \mathcal{O}_2 + 1_{\mathcal{M}(A)} \otimes \mathcal{O}_2)$.

This group of isomorphisms is not studied well until yet.

We can build the Cuntz sum $\mathrm{id}_C \oplus_{s_1,s_2} h_0 \colon C \to C$ that is unitarily homotopic to id_C because id_C asymptotically dominates h_0 by Corollary **??**.

This unitary homotopy – in sense of Definition 5.0.1 – defines a point-norm continuous path $\psi_t \colon C \to C$ with $\psi_0 = \mathrm{id}$ and $\psi_t(c) = u(t)^* c u(t)$ and $\psi_1(c) = \mathrm{id}_C \oplus h_0$. Moreover, since C is σ-unital and stable, there is a norm-continuous path of unitaries $t \in [0,1) \mapsto u(t) \in \mathcal{M}(C)$ such that $\lim_{t\to 1} u(t)^* s_2 c s_2^* u(t) = c$ for all $c \in C$, i.e., id_C and $0 \oplus_{s_1,s_2} \mathrm{id}_C$ are unitarily homotopic, in particular $0 \oplus_{s_1,s_2} h_0$ is ideal system preserving homotopic to h_0.

If we combine the above defined paths of endomorphisms then we find a *-monomorphism from $\varphi \colon C \to \mathrm{C}([0,1], C)$ that is ideal system preserving, thus defines an element of $\mathrm{KK}(\mathrm{Prim}(C)\,; C, \mathrm{C}([0,1], C))$ and satisfies $\pi_0 \circ \varphi = \mathrm{id}_C$ and $\pi_1 \circ \varphi = h_0$. If we apply the above arguments in a bit more general situation (with obvious generalization), we get the following corollary of the classification:

COROLLARY 1.2.11. *If A is a separable nuclear strongly purely infinite C^*-algebra that admits a ideal system preserving zero homotopy, then A is stably isomorphic to $A \otimes \mathcal{O}_2 \otimes \mathbb{K}$, i.e., $A \otimes \mathbb{K} \cong A \otimes \mathcal{O}_2 \otimes \mathbb{K}$.*

It follows that the homeomorphism class of the primitive ideal space is the only invariant of the isomorphism class of $A \otimes \mathcal{O}_2 \otimes \mathbb{K}$. And it is not difficult to see that $\mathrm{Prim}(A)$ must by homeomorphic to $(0,1]_{\mathrm{lsc}} \times \mathrm{Prim}(A)$.

Indeed, let $a_1, a_2, \ldots$ a dense sequence in the positive contractions of A and let $b := \sum_n 2^{-n} a_n$. Then, clearly, $\|\pi_I(b)\| \leq \|\pi_J(b)\|$ for $J \subseteq I$. The equation $\|\pi_I(b)\| = \|\pi_J(b)\|$ implies that $J = I$.

`Give a transparent proof:`

The latter, because in case $J \neq I$ (and $J \subset I$) there exists a pure state ρ on A with $\rho(J) = \{0\}$ but $\rho(I) \neq \{0\}$ ...

(All non-empty open sets are prime and there is a countable sequence of open subsets V_n of $\mathrm{Prim}(A)$ that build a base of the topology of $\mathrm{Prim}(A)$. If we take for each of this a strictly positive contraction $a_n \in J_n$ for the corresponding ideal and let $b := \sum_n 2^{-1} a_n$. If $\|\pi_{J_k}(b)\| = \|\pi_{J_\ell}(b)\|$ and $J_k \subseteq J_\ell$ ...????

`Check cite/ref and explain`

A modification of the construction in ???

[**816**, ????] **??** ????

`It seems not to be the right class`
`Perhaps Rørdam's paper [689] seems to be nearer to the idea.`
`reference to his Israel J. Math. paper?`

allows to construct $C \cong C \otimes \mathcal{O}_\infty$ in a manner, that it has an explicit ideal-preserving zero-homotopy, this is a C^*-morphism $\gamma \colon C \to \mathrm{C}((0,1], C)$ with $\gamma_t \cong \pi_t \circ \gamma \colon J(s,1] \to J(ts,1]$,

where we ?????????????? and ???????????

Notice that $J(t,1] \subset J(s,1]$ and $\bigcap_{t\in(0,1]} J(t,1] = \{0\}$, i.e., there is a point-norm continuous path $\{\gamma_t\,;\ t\in[0,1]\}$ of endomorphisms $\gamma_t\colon C\to C$ such that $\gamma_1 = \mathrm{id}$, $\gamma_0 = 0$ and $\gamma_t(J)\subseteq J$ for every closed ideal J of C and every $t\in[0,1]$, cf. [**464**, prop. 6.1].

`Give the path explicit ?!!`

`Check cite !! ??`

It follows that the (non-zero) strongly purely infinite algebra $A := C \oplus (\mathcal{O}_2 \otimes \mathbb{K})$ is homotopic to $B := \mathcal{O}_2 \otimes \mathbb{K}$ in a Ψ-equivariant manner,

but the algebras have primitive ideal spaces that are not homotopic.

`Check: Are` $Z := X_0 \uplus \{-1\}$ `with ''open''` $\{-1\}$ `and the space` $\{-1\}$ `NOT homotopic??`
`Let` $\psi(t)(s) := t\cdot s$ `and` $\psi(t)(-1) = -1$.
`Is each` $\psi(t)$ `continuous on` Z?
`Is` $\psi(t)$ `globally continuous?`
`Is` X_0 `via` $\psi(t)$ `homotopic to` $\emptyset$?

Clearly, this phenomenon can not appear if A and B are replaced by *simple* (p.i.) C^*-algebras.

Now let, more generally, C an arbitrary strongly purely infinite stable separable nuclear C^*-algebra (in particular $C\cong C\otimes\mathcal{O}_\infty\otimes\mathbb{K}$), and let $\gamma_t\colon C\to C$ an ideal system preserving homotopy between id and 0 (like in the special case above). Then we can (Cuntz-)add to the morphisms γ_t the mono-morphism h_0, and get that $\gamma_t\oplus h_0\colon C\to C$ defines a Ψ-equivariant homotopy from $\mathrm{id}_C\oplus h_0$ to the monomorphism $0\oplus h_0$. In this special case it is equivalent to the property that $(\gamma_t\oplus h_0)(J)$ generates J for each $J\in\mathcal{I}(C)$.

They must define the same element of $\mathrm{KK}(X; C, C)$ by homotopy invariance of $\mathrm{KK}(X;\cdot,\cdot)$. Both satisfy the assumptions of Part (iii) of Theorem M. It follows, that $h_0\colon C\to C$ is unitarily homotopic to id_C, which implies that

$$C\ni c\mapsto c\otimes 1\in C\otimes\mathcal{O}_2$$

is an $\mathrm{KK}(X_0,\cdot,\cdot)$-equivalence. Thus, $C\ni c\mapsto c\otimes 1\in C\otimes\mathcal{O}_2$ is approximately unitary equivalent to an isomorphism from C onto $C\otimes\mathcal{O}_2$. This shows:

If a strongly purely infinite separable nuclear C^*-algebra C admits an ideal-system preserving zero homotopy, then C absorbs $\mathcal{O}_2$ tensorial, i.e., $C\cong C\otimes\mathcal{O}_2$.

See the paper [**464**] for a more detailed study of this class of nuclear C^*-algebras:
It turns out that they are all AH-algebras with building blocks $M_n(\mathrm{C}_0(P,p_\infty))$ where (P,p_∞) are certain pointed one-dimensional finite CW-complexes P with each point connected to $p_\infty\in P$.

`Give precise conditions on` P!

The converse does not hold, e.g. $\mathcal{O}_2 \otimes \mathbb{K}$ tensorial absorbs $\mathcal{O}_2$ but is not homotopic to zero: No (non-zero) simple C^*-algebra A is zero-homotopic, [**175**], because $A \otimes \mathcal{O}_2$ has real rank zero for simple A, cf. Theorem E.

It follows that one has necessarily to consider a sort of more special Ψ-equivariant homotopy, that ensure that also the corresponding primitive ideal spaces are *homeomorphic*.

DEFINITION 1.2.12. Suppose that $\Psi_A\colon \mathbb{O}(X) \to \mathcal{I}(A)$ and $\Psi_B\colon \mathbb{O}(X) \to \mathcal{I}(B)$ are actions of a T_0 space X on A respectively B.

Let $k_0, k_1\colon A \to B$ be Ψ_A-Ψ_B–equivariant C^*-morphisms (respectively Ψ-residually nuclear C^*-morphisms, respectively $k_0, k_1 \in \mathcal{C} \subseteq \mathrm{CP}(A,B)$).

We say that k_0 and k_1 are **Ψ-homotopic** ,

if ????? and ??? `how to avoid singularities?`,

if there is is a point-norm continuous path $[0,1] \ni t \mapsto \gamma_t$ in the Ψ_A-Ψ_B–equivariant C^*-morphisms (respectively Ψ-residually nuclear C^*-morphisms, respectively $\gamma_t \in \mathcal{C}$ is $\mathcal{C}$-compatible for $\mathcal{C} \subseteq \mathrm{CP}(A,B)$) $\gamma_t\colon A \to B$ such that $\gamma_0 = k_0$ and $\gamma_1 = k_1$.

The family $\{\gamma_t\}$ is an **equivariant homotopy**, respectively is a **$\mathcal{C}$-compatible homotopy**.

The Ψ-equivariant homotopy γ_t between k_0 and k_1 will be called **full** if, for each $U \in \mathbb{O}(X)$, $\gamma_t(\Psi_A(U))$ generates for every $t \in [0,1]$ the same ideal $\Phi(U) := \overline{Bk_0(\Psi_A(U))B} \subseteq \Psi_B(U)$ of B.

`Check homotopy statements`
`above and from here to next label !   : ??`

The homotopy invariance of $\mathrm{KK}(X;\, A,B)$ and of $\mathrm{KK}_{\mathrm{nuc}}(X;\, A,B)$ ensures that Ψ-homotopic k_0 and k_1 have the same $\mathrm{KK}(X;\, A,B)$-class, respectively same $\mathrm{KK}_{\mathrm{nuc}}(X;\, A,B)$-class.

On the other hand, we can find (by Corollary N) a Ψ-equivariant isomorphism from $A \otimes \mathcal{O}_\infty$ onto $B \otimes \mathcal{O}_\infty$, if we consider only those **homotopy equivalences** which are given by $h\colon A \to B$, $k\colon B \to A$, $p(t)\colon A \to A$ and $q(t)\colon B \to B$, which satisfy $kh = p(0)$, $p(1) = \mathrm{id}_A$, $p(t)(A) \cap J = p(t)(J)$ and $Ap(t)(J)A$ dense in J for every $J \in \mathcal{I}A$ and every $t \in [0,1]$, and $hk = q(0)$, $q(1) = \mathrm{id}_B$, $q(t)(B) \cap J = q(t)(J)$ and $Bq(t)(J)B$ is dense in J for every $J \in \mathcal{I}B$ and every $t \in [0,1]$. It means that we require that $p(t)$ induces the identity map of the lattice $\mathbb{O}(\mathrm{Prim}(A)) \cong \mathcal{I}(A)$ for each $t \in [0,1]$ (and same for $q(t)$ and $\mathbb{O}(\mathrm{Prim}(B))$).

The latter (strong) non-degeneracy condition for an Ψ-equivariant homotopy can be arrived by replacing h by $h \oplus h_0^{A,B}$ (respectively k by $k \oplus h_0^{B,A}$, p_t by $p_t \oplus h_0$ and q_t by $q_t \oplus h_0$).

This strong conditions on the homotopy imply in particular that $\mathrm{Prim}(A)$ and $\mathrm{Prim}(B)$ are homeomorphic. If then $h\colon A \to B$ and $k\colon B \to A$ define an equivariant homotopy with respect to the natural actions of $\mathrm{Prim}(B)$ (respectively of $\mathrm{Prim}(A)$)

of the *above stronger type*, then $[h] \in \mathrm{KK}(\mathrm{Prim}\, B;\, A, B)$ is a $\mathrm{KK}(\mathrm{Prim}\, B;\, \cdot, \cdot)$-equivalence, and $h \oplus h_0$ is unitarily homotopic to an isomorphism from A onto B ([33]).

Check above formula! And next statement on ??????

Thus, *a strongly p.i. separable stable nuclear C^*-algebra A is isomorphic to $A \otimes \mathcal{O}_2$ if it is homotopic to zero in a* Prim(A)*-equivariant manner.*

(For example, $C \cong C \otimes \mathcal{O}_2$ if C is the above considered algebra with ideal system preserving zero homotopy). The *converse does* not hold as the example $A := \mathcal{O}_2 \otimes \mathbb{K}$ shows. But one has, for s.p.i. separable nuclear stable algebras A, that $A \otimes \mathcal{O}_2 \cong A$ if and only if $\mathrm{KK}(\mathrm{Prim}(A);\, A, A) = 0$. (Use almost verbatim the same arguments as for Part (iv) of Corollary F.)

Partly mentioned further above? What? ??

END: discussion of homotopy invariance.

Corollary L tells us nothing about the structure of the primitive ideal spaces of separable nuclear C^*-algebras A. A pure topological description of the primitive ideal spaces of nuclear C^*-algebras A is given in [**359**], that uses results of [**464**] and of Chapters 3 and 12.

It would be desirable to know under which conditions on A the algebra $D = A \otimes \mathcal{O}_2 \otimes \mathbb{K}$ is the inductive limit of C^*-algebras $\mathrm{C}_0(Y_n, \mathcal{O}_2 \otimes \mathbb{K})$ for Polish l.c. spaces Y_n. This is the case, e.g. , if $\mathcal{I}(A)$ is linearly ordered (by inclusion of ideals).

Unfortunately there are also examples where D can not be expressed as such an inductive limit, e.g. , if $A := \{f \in \mathrm{C}([0,1], M_2) \colon f(1) \in \Delta\}$ where Δ denotes the subalgebra of diagonal matrices in M_2. (In fact, for the last example A, the algebra D can not be any inductive limit of C^*-algebras with Hausdorff primitive ideal spaces, cf. Remark B.12.1.)

All strongly purely infinite separable nuclear C^*-algebras A that admit an ideal-system preserving homotopy beween id_A and 0 satisfy $A \cong A \otimes \mathcal{O}_2 \otimes \mathbb{K}$ and are inductive limits of algebras $A_1 \subseteq A_2 \subseteq \cdots$ with A_n isomorphic to $\mathrm{C}_0(\Gamma, p) \otimes M_{k_n}$, where Γ is a finite connected graph and $\mathrm{C}_0(\Gamma, p)$ denotes the algebra of continuous functions on Γ that vanish at a distinguished point $p \in \Gamma$, cf. [**464**].

It is still an *open question* whether, for every separable stable nuclear C^*-algebra B, the C^*-algebra $D := B \otimes \mathcal{O}_2$ is an inductive limit of C^*-subalgebras of D that are isomorphic to C^*-algebras $A \otimes \mathcal{O}_2$, where A is of type I.
One can show that D is a crossed product of an inductive limit of algebras of the form $\mathrm{C}_0(P_n \backslash \{q_n\}, M_n)$ with $\mathbb{Z}$, where P_n denotes a connected finite one-dimensional polyhedron and q_n is a point of P_n, cf. [**464**].

It implies that for every nuclear separable C^*-algebras A the algebra $A \otimes \mathcal{O}_2$ contains an Abelian C^*-subalgebra $C \subset A \otimes \mathcal{O}_2$ that is "regular" in the sense of Definition 1.2.9.

[33] Notice here that $h_0^{A,B} \circ h_0^{B,A}$ is unitarily homotopic to $h_0^{A,A}$.

It follows that for the T_0 space $Y := \mathrm{Prim}(A)$ of a separable exact C^*-algebra A there exist a locally compact Polish space X ([34]) and a continuous map $\psi\colon X \to Y$ that is "pseudo-open" and "pseudo-surjective" in the sense of Definitions **??** and **??**. In fact, then $C := \mathrm{C}(X)$ can be embedded by Theorem **??** into $A \otimes \mathcal{O}_2$ such that $\varphi\colon C \to A \otimes \mathcal{O}_2$ induces ψ^{-1}.

Conversely, for any locally quasi-compact sober T_0 space Y with the property that such a continuous map $\psi\colon X \to Y$ exists for some locally compact Polish space X there exists a separable nuclear C^*-algebra A such that $\mathrm{Prim}(A) \cong Y$ by [**359**, thm. 1.4].

`Next must be changed drastically, because of New results ??`

Which New results?? Give Ref's or Cite !!!

Let us consider an other aspect of the the "UCT":

M. Dadarlat published in [**193**, sec. 3] an example (based on an observation in [**369**]) of a continuous field $(A_x)_{x\in Q}$ of C^*-algebras A_x over the **Hilbert cube** $Q := [0,1]^\infty$ that has fibers $A_x \cong \mathcal{O}_2$ and that its C^*-algebra of continuous sections $\mathcal{A}$ has non-trivial $\mathrm{K}_1(\mathcal{A}) \neq 0$. If one tensors with $\mathcal{P}_\infty$ then one gets an example with $A_x \cong \mathcal{O}_2$ but $\mathrm{K}_0(\mathcal{A}) \neq 0$.

In particular, $(A_x)_{x\in Q}$ can't be locally trivial. One can see (e.g. from the construction of Dadarlat) that the nuclear algebra $\mathcal{A}$ is strongly purely infinite (i.e., absorbs $\mathcal{O}_\infty$ tensorial) and satisfies the UCT.

Let $(A_x)_{x\in Q}$ an arbitrary continuous field over $Q := [0,1]^\infty$ with all fibers isomorphic to $\mathcal{O}_2$.

Is the C^*-algebra $\mathcal{A}$ of continuous sections in the field $(A_x)_{x\in Q}$ always in the UCT-class?

This kind of algebras $\mathcal{A}$ are all "locally" purely infinite in the sense of Definition 2.0.3. Are this algebras $\mathcal{A}$ purely infinite (weakly purely infinite, strongly purely infinite)? Counterexamples? What are reasonable invariants to distinguish them? It leads to the question of classification of the isomorphisms from $\mathcal{O}_2 \otimes \mathcal{O}_2$ onto $\mathcal{O}_2$ by a suitable "classifying space".

`Next comes some old stuff. Partly to be removed!! ??`

Let Y a (not-necessarily Hausdorff) sober T_0-space. We use for an action $\Psi\colon \mathbb{O}(Y) \to \mathcal{I}(A)$ of a topological space Y on A the notation $A|Z := \Psi(U)/\Psi(U) \cap \Psi(U \setminus Z)$ if Z is a closed subset of an open subset $U \subseteq X$. We say that X acts on A *continuously* if Ψ is a lattice *monomorphism* and is both "upper semi-continuous" and "lower semi-continuous" in the sense of Definitions **??**.

[34] i.e., X is a locally compact second countable Hausdorff space, or equivalently expressed: X is homeomorphic to a separable complete metric space that is in addition locally compact. The complete metric is not uniquely determined by this property of X.

THEOREM O. *Let X a second countable locally quasi-compact point-complete T_0 space, and let G a second countable l.c. group that acts continuously on X by $\mu\colon G \to \mathrm{Homeo}(X)$.*

Then holds:
If X acts continuously on a stable separable nuclear C-algebra A and $\alpha\colon G \to \mathrm{Aut}(A)$ is an action on A with $\alpha(g)(\Psi(U)) = \Psi(\mu(g)(U))$ for all $g \in G$, then there exists a unique separable stable purely infinite nuclear C*-algebra B with a continuous action $\beta\colon G \to \mathrm{Aut}(B)$, an isomorphism $\lambda\colon X \to \mathrm{Prim}(B)$ from X onto $\mathrm{Prim}(B)$, an X-equivariant monomorphism $\varphi\colon A \to B$ and a new action $\alpha'\colon G \to \mathrm{Aut}(A)$, such that*

α' is (exterior equivalent ?? or weakly?? outer) 1-cocycle conjugate to α ?

only 2-cocycle conjugate ????

??

$\varphi \circ \alpha'(g) = \beta(g) \circ \beta(g)$

$\beta(g)(B|\lambda(U)) = B|\lambda(\mu(g)(U))$

$[\varphi] \in \mathrm{KK}(X; A, B)$ *is a* $\mathrm{KK}(X; \cdot, \cdot)$*-equivalence.*

B is determined up to unitary homotopy and X-equivariant isomorphisms.

Moreover, TFAE:

(i) *If A is nuclear and separable,* $\mathrm{Prim}(A) \cong X$, *and* $A/J \cong (A/J) \otimes \mathcal{O}_2$ *for every* primitive *ideal, then* $A \cong A \otimes \mathcal{O}_2$.
(ii) *If X acts on separable nuclear C*-algebras A and B continuously, and if $\psi\colon A \to B$ is an X-equivariant *-monomorphism such that, for each $x \in X$, the induced morphism $A|\overline{\{x\}} \to B|\overline{\{x\}}$ defines a* $\mathrm{KK}(\overline{\{x\}}; A|\overline{\{x\}}, B|\overline{\{x\}})$ *equivalence,*
then ψ defines a $\mathrm{KK}(X; A, B)$ equivalence.
(iii) *more?* $\dim(X) < \infty$*?*
(iv) *more?*

In the meantime Dadarlat [**192**] has shown that $A \cong \mathrm{C}_0(X, \mathcal{O}_2)$ (respectively $A \cong \mathrm{C}_0(X, \mathcal{O}_\infty)$) if A is separable and unital, $X := \mathrm{Prim}(A)$ is a a *finite-dimensional* Hausdorff space and if every primitive quotient of A is isomorphic to $\mathcal{O}_2$ (respectively $\mathcal{O}_\infty$).

Is some local triviality needed?

He shows also that $\mathcal{O}_2$ and $\mathcal{O}_\infty$ are the only pi-sun algebras B with the property $A \cong \mathrm{C}(X, B)$ for all compact metric spaces X of finite dimension, and all $\mathrm{C}(X)$-algebras A with fibers $A_x \cong B$.

(We did not check if here only the UCT class has been studied !!!)

It follows that X satisfies (i) of Theorem O if X has a decomposition series X_γ with $X_{\gamma+1} \setminus X_\gamma$ is a finite-dimensional Hausdorff space, `Def. of strong UCT-class for` $\mathrm{KK}(X;\cdot,\cdot)$ given by suitable actions of X on Polish l.c. spaces Y or on separable type one C^*-algebras.

HERE we should also list the new defined basic properties for the classification and its terminology.

Riesz decomposition property, "strongly self-absorbing" C*-algebras, Completely positive maps of order zero, QDQ vs. UCT, Decomposition rank (of subhomogenuous C*-algs), pure C*-algebras, Nuclear dimension, Covering dimension for nuclear C*-algebras, locally finite decomposition rank, Controlled KK-theory, property A, Watatani Index for C*-algebras, slice maps, nonc. Weyl - von Neumann theorem, Elliott invariant, Flat dimension growth for C*-algebras, Nonstable K-Theory, corona factorisation property,

3. Background and some basic ideas in proofs

The conceptional background of our proofs of Parts (i) and (ii) of Theorems B and M can be described as follows:

If we have "actions" $\Psi_A\colon \mathbb{O}(X)\to\mathcal{I}(A)$ and $\Psi_B\colon \mathbb{O}(X)\to\mathcal{I}(B)$ of spaces X on C^*-algebras A and B, then we can select suitable matrix operator-convex cones $\mathcal{C}\subseteq \mathrm{CP}(A,B)$ of c.p. maps V that are equivariant with respect to the actions, i.e., $V(\Psi_A(U))\subseteq \Psi_B(U)$ for $U\in\mathbb{O}(X)$, and satisfy like-wise additional conditions, e.g. that V is residually nuclear for the ideal systems selected via the actions Ψ_A and Ψ_B.

This procedure is almost equivalent to a functorial selections of subsemigroups of the semigroups of unitary equivalence classes of Kasparov A-B-modules.

We define in Chapters 5 and 8 groups $\mathrm{Ext}(\mathcal{C};\,A,B)$ and $\mathrm{KK}(\mathcal{C};\,A,B)$, depending on non-degenerate operator-convex cones $\mathcal{C}\subseteq\mathrm{CP}(A,B)$ in a functorial way, such that e.g. $\mathrm{KK}(A,B)=\mathrm{KK}(\mathrm{CP}(A,B);\,A,B)$ or $\mathrm{KK}_{\mathrm{nuc}}(A,B)=\mathrm{KK}(\mathrm{CP}_{nuc}(A,B);\,A,B)$ if A is separable and B is σ-unital (see Chapters 5, 8, 9). Our extension groups $\mathrm{Ext}(\mathcal{C};\,A,B)$ will be defined by relations that are similar to relations given for $\mathrm{KK}^1(A,B)\cong\mathrm{Ext}(A,B)$ for trivially graded stable σ-unital A and B, the difference is that the generalized morphisms (ψ,P) of the Cuntz-Kasparov picture – cf. [**73**, 17.6.4] – are required to fulfill the extra condition that $b^*\psi(\cdot)b\in\mathcal{C}$ for each $b\in B$. We prove and apply that

$$\mathrm{KK}(\mathcal{C};\,A,B)\cong\mathrm{Ext}(\mathcal{C}(\mathbb{R});\,A,\mathrm{C}_0(\mathbb{R},B))$$

to bring $\mathcal{C}$-compatible asymptotic morphisms and KK-groups together.

The functorial construction $(\mathcal{C};\,A,B)\mapsto\mathrm{KK}(\mathcal{C};\,A,B)$ is homotopy invariant inside the – chosen/allowed – matricial operator-convex cones (defined and partly studied in Chapter 3) and there is a natural isomorphism $\mathrm{Ext}(\mathcal{C}(\mathbb{R});\,A,\mathrm{C}_0(\mathbb{R},B))\cong\mathrm{KK}(\mathcal{C};\,A,B)$, where $\mathcal{C}(\mathbb{R})\subseteq\mathrm{CP}(A,\mathrm{C}_0(\mathbb{R},B))$ denotes the operator-convex cone of c.p. maps $V\colon A\to\mathrm{C}_0(\mathbb{R},B)$ with $V(\cdot)(t)\in\mathcal{C}$ for all

$t \in \mathbb{R}$. Moreover, $\mathrm{Ext}(\mathcal{C}(\mathbb{R}); A, \mathrm{C}_0(\mathbb{R}, B))$ *is naturally isomorphic to the kernel of*

$$\mathrm{K}_1\left(\pi_B(H_0(A))' \cap \mathrm{Q}^s(B)\right) \to \mathrm{K}_1\left(\mathrm{Q}^s(B)\right) .$$

(Here $H_0 \colon A \to \mathcal{M}(B)$ is a non-degenerate *-morphism with infinite repeat $\delta_\infty \circ H_0$ unitarily equivalent H_0, such that the c.p. maps $A \ni a \mapsto b^* H_0(a) b \in B$ are dense in $\mathcal{C}$.)

The results will be used in Chapter 9 to prove with help of Theorem A (respectively Theorem K) the following result that is more general than Parts (i) and (ii) of Theorems B and M:
Let A and B stable C^*-algebras, where A is separable and B is σ-unital, and let $h_0 \colon A \hookrightarrow B$ a non-degenerate *-monomorphism such that $h_0 \oplus h_0 = h_0$. Let $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ denote the point-norm closed matrix operator-convex cone generated by h_0. Then,
the difference construction $h \mapsto [(B, h, 0)] =: [h - 0]$ *defines an additive map from* $\mathrm{Hom}(A, B) \cap \mathcal{C}$ onto $\mathrm{KK}(\mathcal{C}; A, B)$ *such that* $[h - 0] = [k - 0]$ *if and only if* $h \oplus h_0$ *and* $k \oplus h_0$ *are unitarily homotopic.*
Here the addition on $\mathrm{Hom}(A, B)$ is given (up unitary equivalence in $\mathcal{M}(B)$) by the Cuntz addition with a copy of $\mathcal{O}_2$ that unitally contained in $\mathcal{M}(B)$.

If we use the non-degenerate monomorphism $h_0 \colon A \otimes \mathbb{K} \to B \otimes \mathbb{K}$, from Theorems A and K, then we get Parts (i) and (ii) of Theorems B and M. With this general result in hand, the hard work reduces to the proof of Theorems A and K.

On the way to the proofs of Theorems A and K we obtain and use (among others) a sufficient criteria for *existence of an X-equivariant lift*:

`Next must be a Prop/Thm in Chap. 5. Check!` ?? Suppose that A and B are stable C^*-algebras, where A is separable B is σ-unital, and that $H_0 \colon A \hookrightarrow \mathcal{M}(B)$ and $\varphi \colon A \hookrightarrow \mathrm{Q}(B) = \mathcal{M}(B)/B$ are nuclear *-monomorphisms with the properties that $H_0(A)B$ is dense in B and, for every $a \in A$, $\pi_B(H_0(a))$ and $\varphi(a)$ generate the same closed ideal of $\mathrm{Q}(B)$. Then, *there is a unitary* $U \in \mathcal{M}(B)$ *such that* $\varphi = \pi_B(U^* H_0(\cdot) U)$, *if one of the following conditions (i) or (ii) is satisfied:*

(i) There exists a C^*-algebra C such that $B \cong C \otimes \mathcal{O}_2 \otimes \mathcal{O}_2 \otimes \cdots$, or
(ii) $\pi_B^{-1}(\varphi(A))$ is *stable*, and there are C^*-morphisms $H \colon A \otimes \mathcal{O}_2 \hookrightarrow \mathcal{M}(B)$ and $\Phi \colon A \otimes \mathcal{O}_2 \hookrightarrow \mathrm{Q}(B) = \mathcal{M}(B)/B$ with $H_0(a) = H(a \otimes 1)$ and $\varphi(a) = \Phi(a \otimes 1)$ for $a \in A$.

It has to be emphasized that much of the machinery needed for this work was already present in the literature (at least implicitly), especially done in the works of J. Cuntz, J. Glimm, G. Kasparov and D. Voiculescu until mid of the eighties of last century (cf. Chapters 2, 4. 5 and 8). Our viewpoints are inspired by early work of Elliott and Rørdam on the classification of Cuntz-Krieger algebras.

Our proofs of Theorem A and of Theorem B need old results of J. Cuntz concerning the realization of K_0 and K_1 for purely infinite C^*-algebras in [**172**], our characterization of exact C^*-algebras [**438**], some basic results of Kasparov theory [**405**], and improvements of Kasparov's Proof by Cuntz and Skandalis and others, see [**73**] and the "nuclear" variant of Kasparov theory given by Skandalis [**726**].

Additional background basic material can be found in textbooks [**73**], [**616**], [**810**], and in the articles [**172**] and [**726**].

Generalizations of results from Glimm's early work are important technical tools. This gives a way of approximating nuclear maps by maps of the form $x \mapsto c^* x c$ (under certain additional assumptions). It leads us in Chapter 5 to a generalized Weyl–von-Neumann–Voiculescu theorem, by modifying and using ideas of Kasparov [**404**].

The results of Chapters 2, 3, 4, 5 and 7 are fundamental and each is crucial for the proofs in the following Chapters. Chapter 6 contains the proof of Theorem A. Its method will be explored to prove Theorem 6.3.1, which is a special case of Theorem K, but Theorem K without any extra technical assumption will be finally proved in Chapter 12 with help of a sort non-commutative variant of the Michael selection theorem.

4. On J. Elliott's Classification Programm and Conjectures

Section to be rewritten/shorten:
Short cut, and outline some new results.
But only as summary e.g. following ICM lectures?
Don't forget the stable projection-less case
My (in-adequate?) remarks could be moved in Appendix A or B?

The below formulated Elliott classification conjecture is now verified for all simple separable nuclear C^*-algebras A that tensorial absorb the Jiang-Su algebra $\mathcal{Z}$ and satisfy the Universal Coefficient Theorem (UCT) for its KK-theory. The latter means that there exists a separable commutative C^*-algebras C that is KK-equivalent to A.

The classification of the "elementary" cases, e.g. $\mathrm{K}_*(A) = 0$ could perhaps also replace the UCT by other asymptotic equivalence..???

But it gives not an essentially simpler proof for the above considered case of (simple) pi-sun C^*-algebras. And the methods used in the case where e.g. A is stably projection-less is a bit away from the methods developed and used here. In particular, stably projection-less simple nuclear C^*-algebras have automatic one or more quasi-traces (cf. E.K. paper cited ???), and are in a sense the opposite of the pi-sun C^*-algebras.

The complete data are the ordered K-theory, – with K_0 pointed and scaled by a possible unit element –, and the cone of l.s.c. traces and its pairing with K_0.

It seems that the case of stably projection-less C^*-algebras is not completely studied, e.g. it could be that most of them are mostly crossed products of stable purely infinite algebras by some $\mathbb{R}$-action.

An inspiring role for this development of this final results was the idea of "decomposition rank" and to use the "balancing" role of tensorial absorption of the Jiang-Su algebra $\mathcal{Z}$, that spells out many in early study unexpected difficulties. The cases of AF-algebras, special study on AH-algebras and ASH-algebras did pave the way, also the in this book considered special case of nuclear purely infinite algebras related to graphs did play an inspiring role on the way to the success until now.

Partial results on stably projection-less nuclear C^*-algebras do also exist, but have until now no systematic description of all possible cases with given trace cone, or has not appeared until now. For example, stably projection-less C^*-algebras A remain stably projection-less if we tensor them with the Jiang-Su algebra $\mathcal{Z}$ (or other ASH-algebras). All simple separable nuclear stably projection-less C^*-algebras have densely defined (e.g. on the positive part of the Pedersen algebra) additive traces that play a role for the classification.

It should be emphasized that the, up to tensorial $\mathcal{Z}$ stably isomorphic, classes of simple nuclear C^*-algebras A can have different $\mathrm{K}_0(A)_+$, e.g. the embedding $a \mapsto a \otimes 1$ defines a natural isomorphism $\mathrm{K}_*(A) \cong \mathrm{K}_*(A \otimes \mathcal{Z})$ but the ordered "cones" $\mathrm{K}_*(A)_+$ and $\mathrm{K}_*(A\otimes\mathcal{Z})_+$ of the stable equivalence classes of idempotents in $(A\otimes\mathbb{K})_+$ (respectively in $(A\otimes\mathcal{Z}\otimes\mathbb{K})_+$) are in some cases different. This can happen also for simple ASH-algebras A, because there are examples of unital simple ASH-algebras where the ordered semigroup $\mathrm{K}_0(A \otimes \mathbb{K})_+$ is not "weakly unperforated", but it is known (!!!!! find citation / reference !!!!!) that $\mathrm{K}_0(A \otimes \mathcal{Z} \otimes \mathbb{K})_+$ is weakly unperforated for every C^*-algebra A.

It has to do – and in the "locally" purely infinite case that is our minimal assumption – with properties of the "large" version of the Cuntz semi-group $\mathrm{Cu}(A)$, that reduces to the set of Dini-functions on $\mathrm{Prim}(A)$ in the cases that $A \cong A \otimes \mathcal{O}_\infty$ as it happens in the case that we consider.

We restate a *special case* of the original Classification Conjecture of G. Elliott in a way that allows the reader to see, how our viewpoints and the results of N.Ch. Phillips and the author in the special case of separable simple unital amenable C^*-algebras are related to it, and which questions – namely $(Q1)$ and $(Q2)$ concerning the classification of simple purely infinite algebras remain open.

It is possible that one has answers if one requires additional properties, as e.g. the CFT property or infinitesimally properties.

Before we begin with this we want to acknowledge with congratulation the important almost final result for the classification of unital simple C^*-algebras:

If A_1, A_2 are a separable unital simple nuclear C^*-algebra that are KK-equivalent to separable Abelian C^*-algebra C_1, C_2 and tensorial absorb the

Jiang-Su algebra $\mathcal{Z}$ in the sense $A_k \otimes \mathcal{Z} \cong A_k$, then A_1 and A_2 are isomorphic if and only if A_1 and A_2 the same Elliott invariant (as defined below **??**).

Since A and $A\otimes\mathcal{O}_\infty$ are isomorphic for all strongly purely infinite separable nuclear algebras (and since for simple A pure infiniteness and strong pure infiniteness are the same) $A \cong A \otimes \mathcal{Z}$ follows from $\mathcal{O}_\infty \otimes \mathcal{Z} = \mathcal{O}_\infty$.

(But I do not know if also for the stably projection-less separable simple nuclear C^*-algebras A with $A \cong A \otimes \mathcal{Z}$ the classification in the UCT class becomes now complete.

An interesting question is if they all come from crossed products $A \rtimes \mathbb{R}$ of stable pi-sun algebras A by an action of the real numbers $\mathbb{R}$, or as crossed product by an action of the semigroup $\mathbb{R}_+ = [0, \infty)$, or by $(0, \infty)$.

`Next is a bit out of discussion and perhaps not related.`

We define a Z_2-graded group $\mathrm{K}_*(A) := \mathrm{K}_0(A) \oplus \mathrm{K}_1(A)$, and a pre-order on $\mathrm{K}_0(A)$ by the subsemigroup $\mathrm{K}_0(A)^+ := \{[p] \in \mathrm{K}_0(A) \colon p \in \mathrm{Proj}(A \otimes \mathbb{K})\}$.

Let A be a C^*-algebra and let $T^+(A)$ denote the locally compact cone of non-negative (additive) traces on the Pedersen ideal of $A\otimes\mathbb{K}$. There is a natural pairing $\langle \cdot, \cdot \rangle$ between $\mathrm{K}_0(A)$ and $T^+(A)$, defined by $\langle z, \tau \rangle := \tau(p - q) \in \mathbb{R}$ for $z \in \mathrm{K}_0(A)$ and $\tau \in T^+(A)$.

`Is next correct?` Here p, q are projections in $\widetilde{A} \otimes \mathbb{K}$ such that $z = [p] - [q]$, $p - q$ is in the Pedersen ideal of $A \otimes \mathbb{K}$, and $\widetilde{A}$ is the unitization of A.

Suppose that A and B are simple, separable and nuclear C^*-algebras, and that $\sigma_0 \colon \mathrm{K}_0(A) \to \mathrm{K}_0(B)$ and $\sigma_1 \colon \mathrm{K}_1(A) \to \mathrm{K}_1(B)$ are group isomorphisms from the K-groups of A onto the K-groups of B such that $\sigma_0(\mathrm{K}_0(A)^+) = \mathrm{K}_0(B)^+$. Let $\sigma^T \colon T^+(B) \to T^+(A)$ be a continuous additive isomorphism from $T^+(B)$ onto $T^+(A)$, such that they have the coherence properties $\langle z, \sigma^T(\tau)\rangle = \langle \sigma_0(z), \tau\rangle$ for all $z \in \mathrm{K}_0(A)$ and $\tau \in T^+(B)$.

If σ_1, σ_2 and σ_T are given, then a variant of the **Conjecture of Elliott** `Cite source for Elliott invariant !!!` can be reformulated in an equivalent way as follows:

There exists an isomorphism ψ from $A \otimes \mathbb{K}$ onto $B \otimes \mathbb{K}$ such that

$$\sigma_* = \mathrm{K}_*(\psi) \qquad \text{and} \qquad \sigma^T(\tau) = \tau \circ \psi \quad \forall\, \tau \in T^+(B)\,.$$

If A and B are unital and $\sigma_0([1]) = [1]$ then one *requires* in addition that the isomorphism σ can be chosen such that, $\psi(1 \otimes p_{11}) = 1 \otimes p_{11}$.

If one of the algebras A or B is not known to be of real rank zero, then sometimes additional invariants have been introduced to verify the Elliott conjecture even only in very special cases. The now most prominent one is tensorial absorption of the Jiang-Su algebra $\mathcal{Z}$, cf. [**391**], because $A\otimes\mathcal{Z}$ and A have "almost" the same Elliott invariants. This excludes also the cases where one of A or B is "elementary", i.e., is stably isomorphic to the compact operators $\mathbb{K}$, e.g. to distinguish $\mathbb{C}$ and the Jiang-Su algebra $\mathcal{Z}$, or where one of the algebras is unital and finite but is not stably finite, or [**687**].

And ??????????????

??

([35]),

extra requirements on the stable rank, on the real rank, or the decomposition rank ... weakly unperforated perforated $\mathrm{K}_0(A)_+$ etc. ??? .

`It happens if one tensors by Jiang-Su algebra as shown by Rørdam ‘‘strongly` K_1`-surjective’’ [690, def. 6.1]????.`

An example of a property that is perhaps not encoded in the Elliott invariants is the *local* K_1*-surjectivity*:
We say that a *simple* C^*-algebra A is **locally K_1-surjective** , if for every *non-zero* projection $p \in A \otimes \mathbb{K}$ and every $x \in \mathrm{K}_1(A)$ there exists a projection $q \in A \otimes \mathbb{K}$ such that

(i) $[p] = [q]$ in $\mathrm{K}_0(A)$, and
(ii) x is in the image of the natural C^*-morphism from the unitary group of $q(A \otimes \mathbb{K})q$ into $\mathrm{K}_1(A)$.

This condition is trivially satisfied for all stably projection-less C^*-algebras A. The property of local K_1-surjectivity has an explanation with help of the graded K_*-groups: There is a natural isomorphism

$$\mathrm{K}_*(A) := \mathrm{K}_0(A) \oplus \mathrm{K}_1(A) \cong \mathrm{K}_0(\mathrm{C}(S^1, A)),$$

cf. [**73**, sec.9.4.1], and one can use this isomorphism to introduce an pre-order structure $\mathrm{K}_*(A)_+$ on $\mathrm{K}_*(A)$ by the sub-semigroup $\mathrm{K}_0(\mathrm{C}(S^1, A))^+$ of $\mathrm{K}_0(\mathrm{C}(S^1, A))$.

One can see that this semigroup consists of the elements $([p], [u]) \in \mathrm{K}_*(A)$, where $p \in A \otimes \mathbb{K}$ is a projection and $u \in \mathcal{U}(p(A \otimes \mathbb{K})p)$ is a unitary (that has to be extended to a unitary in the unitization $(A \otimes \mathbb{K})^{\sim}$ by $u \mapsto u + (1 - p)$).

Indeed, if $P = \{p(e^{2\pi it}) \in M_n(A)\,;\ t \in [0, 1]\}$ is a projection in $\mathrm{C}(S^1, M_n(A)) \subseteq \mathrm{C}(S^1, A \otimes \mathbb{K})$ then there exists a continuous path $t \in [0, 1] \to v(t) \in \mathcal{U}(M_n(A + \mathbb{C} \cdot 1))$ with $v(0) = 1$ and $v(t)^* p(1) v(t) = p(e^{2\pi it})$.

Then $u := pv(1)p \in \mathcal{U}(p(A \otimes \mathbb{K})p)$ for $p := p(1)$. The element $[p] \in \mathrm{K}_0(A)$ is the image of $[P]$ under the map $[\lambda]_0\colon \mathrm{K}_0(\mathrm{C}(S^1, A)) \to \mathrm{K}_0(A)$ induced by $\lambda\colon f \in \mathrm{C}(S^1, A \otimes \mathbb{K})) \mapsto f(1) \in A \otimes \mathbb{K}$. This attaches to P a pair (p, u) with $u \in \mathcal{U}(p(A \otimes \mathbb{K})p)$ and $p = \lambda(P)$.

[35] The semigroup of all Murray–von-Neumann equivalence classes of projections in $\mathcal{M}(A \otimes \mathbb{K})$, or the infimum of the dimensions of the maximal ideal spaces of the family of Abelian Kadison-Singer-type C^*-subalgebras of A (i.e., with unique pure states extension property), or comparison properties (certain sub-semigroups of) the Cuntz semigroup of $A \otimes \mathbb{K}$.

Let $([q],[w]) \in \mathrm{K}_*(A)$ with $q \in A\otimes\mathbb{K}$ and $w \in \mathcal{U}(q(A\otimes\mathbb{K})q)$. Then $w\oplus_{s,t}(w^*) \in \mathcal{U}_0((q\oplus_{s,t}q)(A\otimes\mathbb{K})(q\oplus_{s,t}q))$ and if $w(t) \in \mathcal{U}_0((q\oplus_{s,t}q)(A\otimes\mathbb{K})(q\oplus_{s,t}q))$ is a path with $w(0) = q\oplus_{s,t} q$ and $w(1) = w\oplus_{s,t} w^*$, then $P(e^{2\pi it}) := w(t)(q\oplus_{s,t}0)w(t)^*$ is a projection in $(q\oplus_{s,t}q)(A\otimes\mathbb{K})(q\oplus_{s,t}q)$ with $p := \lambda(P) = q\oplus_{s,t}0$ and $pw(1)p = w\oplus_{s,t}0 \in \mathcal{U}(p(A\otimes\mathbb{K})p)$. more details???? **??**

All simple stably infinite C^*-algebras A are locally K_1-surjective, and for them holds $\mathrm{K}_0(A)^+ = \mathrm{K}_0(A)$ and $\mathrm{K}_*(A)^+ = \mathrm{K}_*(A)$, because for each projection $p \in A\otimes\mathbb{K}$ there exists a full and properly infinite projection $q \in A\otimes\mathbb{K}$ with $[q] = [p]$ in $\mathrm{K}_0(A)$, cf. Lemma 4.2.6(ii) (compare also classical work of J.Cuntz [**172**] !). Then there are natural isomorphisms $\mathrm{K}_1(A) \cong \mathrm{K}_1(A\otimes\mathbb{K}) \cong \mathrm{K}_1(E)$ for the unital C^*-algebra $E := q(A\otimes\mathbb{K})q$, and E has a properly infinite unit q, which implies that E is K_1-surjective, i.e., that $u \in \mathcal{U}(E) \to [u] \in \mathrm{K}_1(E)$ is surjective, cf. Lemma 4.2.6(v).

If A is simple and *stably finite*, then it is easy to see that A is locally K_1-surjective, if and only if,

$$\mathrm{K}_*(A)^+ = \{(0,0)\} \cup \big((\mathrm{K}_0(A)^+ \setminus \{0\}) \oplus \mathrm{K}_1(A)\big)\,,$$

where $\emptyset\oplus\mathrm{K}_1(A) := \emptyset$, e.g. stably projection-less A are locally K_1-surjective because $\mathrm{K}_*(A)^+ = 0\oplus 0 = \{(0,0)\}$.

Simple unital *locally* K_1-surjective algebras A *with cancellation property* (for the semi-group $V(A) = [\mathcal{P}_\infty(A)]$) are necessarily K_1-*surjective* in the sense that $u \in \mathcal{U}(A) \to [u] \in \mathrm{K}_1(A)$ is a surjective map.

Unital simple C^*-algebras A with *stable rank one* are locally K_1-surjective ([36]). Unital simple C^*-algebras that are inductive limits of homogeneous algebras have in general stable rank > 1, cf. Villardsen [**797**], [**795**].

QUESTION 1.4.1. Can methods of [**797**] and [**795**] help to construct a unital simple ASH algebra that is not locally K_1-surjective?

Even for simple nuclear C^*-algebras of real rank zero it is not known if they are locally K_1-surjective (but they are K_1-injective, cf. [**525**, cor.4.2.10]).

The Conjecture of Elliott has been confirmed in many cases, but always under strong restrictions on A and B, e.g. that they are inductive limits of certain special sub-homogenous algebras A_n and B_n ([37]), or, in some very special cases, where A and B are stably isomorphic to (cocycle) crossed products of such inductive limits by outer actions of $\mathbb{Z}$, $\mathbb{Z}_n$ or by $\mathbb{R}$. Until now, on has not found a method to deduce this required properties of A and B from conditions of K-theoretic nature alone, or from "general defining relations" of A and B given by non-commutative polynomials.

---

[36] Apply Gauss algorithm to invertible matrices in $M_n(pAp)$ that have invertible entries.

[37] The primitive ideal spaces $\mathrm{Prim}(A_n)$ and $\mathrm{Prim}(B_n)$ contain only Hausdorff subspaces X with "small" dimension in comparison with the *minimal* dimension of its irreducible representations

Stably projection-less simple exact C^*-algebras A have always non-zero *additive* traces (cf. e.g. [**441**]), i.e., $T^+(A) \neq 0$. There exist inductive limits A of sub-homogenous algebras such that A is stably projection-less *and* $\mathrm{K}_*(A) = 0$. It is then not difficult to see that they satisfy $T^+(A) \neq 0$. The existence of such algebras A can be seen from [**259**, thm. 3.2, thm. 5.2], that shows that the possible Elliott invariants $(G_0^+, G_0, G_1, T^+, \langle \cdot, \cdot \rangle)$, with the additional conditions $T^+ \neq 0$ and that $\langle z, \tau \rangle > 0$ (for all $\tau \in T^+$) implies $z \in G_0^+$, are exhausted by the invariants of simple inductive limits A of sub-homogenous algebras A_n that are extensions of sums of sub-homogenous algebras with at most 2-dimensional Hausdorff subspaces of primitive ideal spaces ([38]).

Let us consider from now on only the the Elliott invariant $(\mathrm{K}_*(A)^+ \subseteq \mathrm{K}_*(A))$ of *simple separable nuclear C^*-algebras A with* $T^+(A) = 0$:

A combination of works of Blackadar, Cuntz [**78**] and Haagerup [**342**] shows that, for *simple and exact* C^*-algebras A, the equation $T^+(A) = 0$ holds, if and only if, A is not stably finite (cf. B.4.5 or [**441**]). If, in addition, A is separable then there is a simple unital C^*-algebra B with properly infinite unit (in fact we find then B that contains a copy of $\mathcal{O}_2$ unitally) such that $A \otimes \mathbb{K} \cong B \otimes \mathbb{K}$.

Thus, if $T^+(A) = 0$, then $\mathrm{K}_0(A)^+ = \mathrm{K}_0(A)$ by [**172**], *and* $A \otimes \mathbb{K}$ contains a properly infinite projection, which implies e.g. that $A \otimes \mathbb{K}$ can not be the inductive limit of type-I C^*-algebras ([39]). Every *simple* inductive limit A of type-I C^*-algebras has a non-zero positive trace on its minimal dense ideal $\mathrm{Ped}(A)$. More generally, a simple C^*-algebra A without a densely defined 2-quasi-trace can't be a subalgebra of an ultra-product

$\prod_\omega (B_1, B_2, \ldots)$ of a sequence $B_1, B_2, \ldots$ of type-I algebras, which involves a striking difference between the class of stable infinite nuclear simple C^*-algebras and all classes of algebras that can be described as inductive limits of type-I C^*-algebras. This sorts of inductive limits contain strictly all other sorts of algebras that have been successfully classified up to isomorphisms by its Elliott invariant until so far.

If $\mathrm{K}_0(A) \neq 0$ *and* $\mathrm{K}_0(A)_+ = \mathrm{K}_0(A)$, or if $\mathrm{K}_0(A) = 0$ *and* $A \otimes \mathbb{K}$ contains a non-zero projection, then A is stably infinite and $T^+(A) = 0$. So we see that the equation $T^+(A) = 0$ for simple nuclear A describes the stably infinite algebras among the simple nuclear C^*-algebras A. For them, *the invariants of Elliott reduce only to* K_0 *and* K_1. M. Rørdam has constructed in [**687**] a simple, separable, unital, and nuclear C^*-algebra $\mathcal{R}$ that is finite but is stably infinite.

[38] They are defined by a generalized mapping torus construction A_n (a special difference construction) for pairs of morphisms between sums of sub-homogenous algebras with primitive ideal spaces such that the Hausdorff parts have dimension ≤ 2. See [**273**, appendix] for an alternative proof, where the building blocks A_n are sub-homogenous algebras with at most 1-dimensional Hausdorff subspaces of its primitive ideal spaces.

[39] Moreover, there is a finite subset X of A such that $1/2 \leq \max\{\mathrm{dist}(x, B)\,;\ x \in X\}$ for *every* type-I C^*-subalgebra B of A^{**}.

In particular, $\mathcal{R}$ is not purely infinite in the sense of Definition 1.2.1, given below. The algebra $\mathcal{R}$ is stably isomorphic to the crossed product of a certain type I C^*-algebra C by an endomorphism λ of C, thus, $\mathcal{R}$ is stably isomorphic to a crossed product $D \rtimes_\mu \mathbb{Z}$ by an automorphism μ of $D := \lim_{n\to\infty} \lambda_n : C_n \to C_{n+1}$ with $C_n := C$, and $\lambda_n := \lambda$. The algebra $\mathcal{R}$ has *not* real rank zero, but contains "small" projections, cf. [**691**] and $\mathrm{K}_*(\mathcal{R}) = \mathrm{K}_*(\mathrm{C}(X))$ for $X := S^2 \times S^2 \times \cdots$ where S^2 means here the 2-dimensional sphere. In fact it is stably isomorphic to the generalized Fock-Toeplitz algebra (and to the Cuntz-Pimsner algebra) of some Hilbert $\mathrm{C}(X, \mathbb{K})$–bi-module.

Its K_*-groups are both isomorphic to $\mathbb{Z}\oplus\mathbb{Z}\oplus\cdots$, i.e., $\mathrm{K}_*(\mathcal{R}) \cong \mathrm{K}^*(S^1 \times S^1 \times \cdots)$.

Let us say some words about the *general* classification problem for non-p.i. algebras and its connection with the Rørdam groups $\mathrm{R}(\mathcal{C};\, A, B)$ that we introduce in Chapter 7.

`to be filled in: overview! and Rordam groups` ??

`update:` (Now 2021 ???): The classification covers now all – unital? – separable simple nuclear C^*-algebras that absorb the Jiang-Su algebra tensorial and are in the UCT-class?)

Some of the proofs of Elliott's Conjecture work well for inductive limits $A := \mathrm{indlim}_n A_n$ of sub-homogenous algebras A_n, e.g. provided that A is of *real rank zero* and that there is some bound $\infty > \Gamma \geq D_n/R_n$ for the ratio between the supremum D_n of the dimensions of the Hausdorff subspaces of $\mathrm{Prim}(A_n)$ and the infimum R_n of the dimensions of the irreducible representations of the A_n's, or that A is simple and the A_n's are extensions of finite dimensional algebras C_n by suspensions SB_n of finite dimensional algebras B_n, i.e., if there are exact sequences $0 \to SB_n \to A_n \to C_n \to 0$.

No description of this additional assumptions in terms of the K-theory has been found yet.

E.g. it is even an open problem whether a simple separable unital nuclear C^*-algebra A of real rank zero with unique trace state and with the pre-ordered K- and KK-groups of the CAR algebra M_{2^∞} is stably isomorphic to M_{2^∞}. In particular suppose that $A \otimes \mathcal{O}_\infty \cong M_{2^\infty} \otimes \mathcal{O}_\infty$ and that $(\mathrm{K}_0(A), [1_A], \mathrm{K}_0(A)_+)$ and the Elliott invariant of the UHF-algebra M_{2^∞} are order isomorphic by an isomorphism that is compatible with the – by $\mathcal{O}_\infty$-stable isomorphism – given isomorphism of $\mathrm{K}_0(A)$ with $\mathrm{K}_0(M_{2^\infty})$.

Question: Is A stably isomorphic to M_{2^∞} ?

This should be the case if A is in the UCT-class ... ???

The true problem is here if such A must automatic tensorial absorb the Jiang-Su algebra $\mathcal{Z}$. Or at least if $F(A) := A' \cap A_\omega$ has no character ... ??????

It is even not clear if there exists a simple unital nuclear C^*-algebra C of real rank zero with the Elliott invariant $(\mathbb{Z}, \mathbb{Z}_+, 1)$ and unique trace state, but (!) such that $F(C)$ has a character.

(I want to see how it is constructed as an inductive limit of finite-dimensional C^*-algebras A_n by completely positive contractions, because all separable nuclear C^*-algebras A are such inductive limits up to completely positive and completely isometric isomorphisms.)

Forgive me, if I want to see pi-sun algebra with trivial K-theory that is not isomorphic to $\mathcal{O}_2$, which is simply generated by two isometries $s_1, s_2 \in \mathcal{L}(\ell_2(\mathbb{N}))$ with

$$1 = s_1^* s_1 = s_2^* s_2 = s_1 s_1^* + s_2 s_2^* .$$

Perhaps it is e.g. the case if C has not the "corona factorization property" (CFP).

One can see here that ??????? CFP is very necessary and excludes cases that have not CFP (or satisfy not the UCT ?). Therefore we write here all at a constructive and elementary level that shows where we suddenly this additional properties UCT or CFP need.

Moreover it is even unknown whether pre-ordered KK-invariants and trace invariants are enough to characterize the CAR algebra among the simple separable nuclear quasi-diagonal C^*-algebras in the UCT-class with real rank zero and stable rank one. (Please don't misunderstand me: Here we should start with data from the ordered K_*-theory and *not* from the methods to construct them from inductive limits of (many step) extensions of stabilized sub-homogenous algebras combined with semi-direct products by semigroups or quantum groups. The question should be: how many pairwise stably non-isomorphic simple nuclear C^*-algebras have the same invariants, and how look the amenable C^*-algebras in those classes of partially ordered K_*-theory that are NOT in (some sort of) the UCT-class.

Is "seems" that the (non-zero) separable, unital, nuclear (= amenable), purely infinite, and simple C^*-algebras A with $A \cong A \otimes \mathcal{Z}$ are all contained in the UCT-class.

But no proof or counter examples have been found yet (end of 2021?). Notice here that all pi-sun A satisfy $A \cong A \otimes \mathcal{O}_\infty$ (give references here) and that $\mathcal{O}_\infty \cong \mathcal{O}_\infty \otimes \mathcal{Z}$.

Next has to be edited !!! `update:`

The latter follows (not simply) from the fact that $\mathcal{O}_\infty$, $\mathcal{Z}$ and $\mathcal{O}_\infty \otimes \mathcal{Z}$ are all nuclear, simple, separable, unital and are in the UCT class, and that $\mathcal{O}_\infty$ and $\mathcal{O}_\infty \otimes \mathcal{Z}$ are strongly purely infinite (because are p.i. and simple).

In the case of simple separable nuclear projection-less stable algebras there are only some interesting examples studied so far.

One of it is given by a crossed product of $\mathcal{O}_2$ with an irreducible circle action, ????? In the case of a unital C^*-algebra without non-trivial projections there is e.g. the open question if the Jiang-Su algebra $\mathcal{Z}$, [**391**], is the only tensorial self-absorbing separable unital C^*-algebra $A \neq \mathbb{C}$ in the UCT-class that has the same Elliott invariant as $\mathbb{C}$.

Since W. Winter has shown that all separable tensorial self-absorbing unital C^*-algebras with approximately inner flip absorb the Jiang-Su algebra $\mathcal{Z}$, and since the class of $\mathcal{Z}$-absorbing unital simple nuclear stably finite C^*-algebras in the UCT-class are classified by its Elliott invariant it follows that tensorial $\mathcal{Z}$-absorbing and a kind of ordered $(\mathrm{K}_0(A), \mathrm{K}_0(A)_+, 1_A)$ is then a complete invariant.

The big open problem is: Can we escape from the very serious additional assumption that A is in the UCT-class for the classification of pi-sun algebras A?

More generally is $A \otimes \mathcal{O}_\infty$ (or $A \otimes \mathcal{Z}$) for all amenable separable A in the UCT class?

Is the UCT property equivalent to the Corona factorization property?

"Sudden" Question:

Consider the universal C^*-algebra $A_n = C^*(a, d_k, 1, s, t)$ given for $a \geq 0$, $d_1, \ldots, d_n, 1, s, t$ by the relations $\sum_k d_k^* a d_k = 1$, $s^* t = 0$, $s^* s = 1$, $t^* t = 1$.

(It implies that A_n contains a copy of $\mathcal{O}_\infty$. Let $t_1, t_2, \ldots$ natural generators build from s and t.)

$X := \sum_k t_k a^{1/2} d_k$ satisfies $X^* X = 1$.

Is $a \otimes 1$ properly infinite in $A_n \otimes \mathcal{Z}$?

I.e., does there exist $g \in A_n \otimes \mathcal{Z}$ with $g^*(a \otimes 1) g = 1 \otimes 1$?

It is enough to find $h \in A \otimes \mathcal{Z}$, and non-zero $b \in \mathcal{Z}_+$ with $h^*(a \otimes 1)h = 1 \otimes b$, because $\mathcal{Z}$ is simple, $\mathcal{O}_\infty \otimes \mathcal{Z} \cong \mathcal{O}_\infty$ and $1_A \in \mathcal{O}_\infty \subseteq A$.

Take elements b and $x_1, \ldots, x_n \in \mathcal{Z}$ with $x_k^* x_\ell = \delta_{k,\ell} b$ (e.g. coming from an n-homogenous element $\psi\colon \mathrm{C}_0(0,1] \otimes M_n \to \mathcal{Z}$ $b = \psi(f_0 \otimes p_{11})$).

Then $g := \sum_k d_k \otimes x_k$ has this property.

In [**467**] it is shown that the (CFP) is valid if $F(A) = (A' \cap A_\omega)/\operatorname{Ann}(A, A_\omega)$ has no character.

Theorem 4.3. (of [**467**]):

Let A be a unital separable C^*-algebra such that the central sequence algebra $F(A)$ has no characters. Then A has the Strong Corona Factorization Property (s CFP ? SCFP ?).

"Strong" Corona Factorization Property for semigroups, cf. citation [18, Definition 2.12] (in [**467**] ??? what is 18??):

For every $x', x, y_1, y_2, y_3, \ldots$ in $\mathrm{Cu}(A)$ and $m \in \mathbb{N}$ such that $x' << x$ and $x \leq m y_n$ in $\mathrm{Cu}(A)$ for all $n \geq 1$, there exists $k \geq 1$ such that $x' \leq y_1 + y_2 + \ldots + y_k$ in $\mathrm{Cu}(A)$.

The (strong) Corona Factorization Property can therefore be viewed as a weak comparability property for $\mathrm{Cu}(A)$.

It is not known how the Rørdam semi-groups $\mathrm{SR}(A, B)$ of Chapter 7 play together with (versions of) the Cuntz semigroups, even not in the important case, where A and B tensorial absorb the Jiang-Su algebra $\mathcal{Z}$.

This shows that we can't present here an idea for answering classification questions in full generality if other types of algebras or additional structure like group actions have to be studied. We develop in this book a method to reduce some classification problems to questions on the realization of KK-theory with help of generalized Weyl–von-Neumann–Voiculescu theorems. The main tools are continuous modifications of the Rørdam groups $\mathrm{R}(A, B)$, as defined in Chapter 7. They play a role in several generalizations, e.g. to the non-simple case as described above, or others, as mentioned in the remarks of Chapter 7. Some of the known stable invariants for simple separable nuclear C^*-algebras are the same for $\mathrm{R}(\cdot, \cdot)$-equivalent C^*-algebras A and B (e.g. they are KK-equivalent, $F(A)$ and $F(B)$ contain, up to isomorphisms, the same simple separable C^*-subalgebras, the stable rank, the real rank and decomposition rank are the same). A part of further study on classification could be the study of the consequences of $\mathrm{R}(\cdot, \cdot)$-equivalence. Partial results in this direction are Theorems B and M and its Corollaries C and N above. Above where? Above where? Give references !!

5. The way to here. Acknowledgements

This book is a very expanded and generalized version of the preprint of December 1994 (3rd draft) with the same title “Classification of purely infinite C*-algebras using Kasparov's theory”. In the original 1994-preprint a simpler “discrete” asymptotic theory using $\mathrm{EK}_\omega(A, B)$ has been taken to eliminate some technical difficulties arising in the continuous case. Now we have replaced the discrete asymptotic methods (working with sequences) by their technically more involved continuous versions (working with paths going to infinity). This more elaborate theory allows to see more clearly where we have homotopy-invariant results. Now they are all integrated into our newest version that rigorously uses matricial operator-convex cones, because, up to the – not here – discussed group- or quantum-group equivariance.

A pre-version (of some sections concerning basics on purely infinite simple algebras) partly has been written in 1998 by postdoc students of the Fields Institute year on C^*-algebras. It was based on a seminar which was organized and held by postdoc students, but was supported by several lectures, consultations, e-mails and outlines from the author. The sections concerning simple algebras in the new presentation reflects a compromise between their detailed and elementary approach and the authors new insights, that changed during more then three decades considerably.

More details and background are given. In fact, the exposition is sometimes very detailed. But here we are running into a problem: half of the technical lemmas are folklore trivialities for those readers coming from the theory of exact C^*-algebras, tensor products and operator spaces. The other half is trivial for readers who have a clear understanding how different variants of KK-theories and K-theories can be constructed, and how they can be compared. But both is presented here at an elementary level, – so far as it is really used for the proof of our theorems. Only textbook material is omitted or is only sketched ([40]).

The old and sketchy proof of the natural isomorphism of the Grothendieck group $\mathrm{R}(A, B)$ of $[\mathrm{Hom}_{\mathrm{nuc}}(A \otimes \mathbb{K}, \mathrm{Q}(\mathbb{R}_+, B \otimes \mathbb{K}))]_u$ with $\mathrm{KK}_{\mathrm{nuc}}(A, B)$ from the Appendix A of the Dec 94 preprint is now explained in a more transparent manner, by an axiomatic study of the semigroups of morphisms which are dominated by a fixed morphism (see Theorem 4.4.6, Proposition 7.2.13 and Chapter 9). But, up to using a technical framework that divide the arguments into smaller steps and offer more details, we use the same idea as in the proof outlined in the Appendix A of the Dec 94 preprint. Now it becomes visible that the ideas in the preprint apply also to the semigroups $\mathrm{SR}(X;\, A, B) := [\mathrm{Hom}_{\mathrm{nuc}}(X;\, A, \mathrm{Q}(\mathbb{R}_+, B))]$ and to the even more general semigroups $\mathrm{SR}(\mathcal{C};\, A, B)$ for (non-simple) stable separable exact A and arbitrary σ-unital stable strongly purely infinite B, and, more generally, to the semigroups $\mathrm{SR}(\mathcal{C};\, A, B)$ for in a "functorial way" selected matrix operator-convex cones $\mathcal{C} \subseteq \mathrm{CP}(A, B)$. But one needs to use the homotopy invariance of the generalized m.o.c. cone equivariant Kasparov groups $\mathrm{KK}(\mathcal{C};\, A, B)$ to get the basic ingredient for the proof that the natural group epimorphism from the $\mathcal{C}$-controlled unsuspended-but-stable E-theory groups $\mathrm{R}(\mathcal{C};\, A, B)$ onto $\mathrm{KK}(\mathcal{C};\, A, B)$ is also injective.

Notice that E. Blanchard [**89**] has extended Theorem A to C^*-algebra bundles. He uses Theorem A and Rørdam's proof of $\mathcal{O}_2 \cong \mathcal{O}_2 \otimes \mathcal{O}_2 \otimes \cdots$ (cf. [**678**]). This was done independent by N. Ch. Phillips [**?**] and the author with other methods and applications.

Also, there is an alternative proof of Part (i) of Theorem A and Parts (ii) and (iii) of Corollary F, given by N. Ch. Phillips and the author [**?**], that does *not* use a generalized Weyl–von-Neumann–Voiculescu theorem, that we, here in this book, prove and use.

N. Ch. Phillips [**627**] gave a shorter proof of Corollary C based on the observations given here in Parts (ii) and (iii) of Corollary F above (as in the beginning of the authors Dec 94 preprint). His proof uses $\mathcal{E}$-theory and deep results of M. Dadarlat, N. Higson, A. Loring, H. Lin and M. Rørdam.

One can proceed in the non-simple case along a way similar to the approach of N.Ch. Phillips with a generalized ideal lattice-equivariant version of E-theory in the non-simple case, after one has proved Theorem K (= non-simple variant of

[40] Some knowledge on Cuntz-Krieger algebras is useful for considering examples. But the most basic examples are discussed here in the Appendix A.

Theorem A). In fact, some results of N. Higson, J. Cuntz and others indicate that every sort of an KK-theory is functorial equivalent to a “liftable” (or “semi-split”) variant of some E-theory. We are quite happy to find a convincing proof in our case of $\mathrm{KK}(\mathcal{C};\, A, B)$ and the related stable but unsuspended version of E-theory, here realized by the generalization $\mathrm{R}(\mathcal{C};\, A, B)$ of Rørdam's sequence groups.

This can be made precise in analogy with our natural isomorphisms

$$\mathrm{R}(\mathcal{C};\, A, B) \cong \mathrm{Ext}(\mathcal{C};\, A, SB) \cong \mathrm{KK}(\mathcal{C};\, A, B)\,,$$

where A and B are stable and separable and $\mathcal{C} = \mathcal{C}(h_0)$ for some non-degenerate *-morphism $h_0\colon A \to B$ that is unitarily homotopic to $h_0 \oplus h_0$. That means: We show that in the considered cases there is a bijection between certain m.o.c. cones and such morphisms h_0.

If one imposes into the *definitions* directly some sort of homotopy-equivalence then the above considered isomorphisms are “almost evident”. Then the isomorphisms are much easier to derive than our “constructive” results in Chapters 8 and 9 that give really unitary homotopy rather than general homotopy equivalence. But general homotopy equivalences are useless for our purpose. In fact, – at least in view of our applications –, the great invention of Kasparov was the observation that the groups $\mathrm{Ext}(A, B)$ with its fairly *algebraic* definition – see Chapter 5 – are naturally isomorphic to the homotopy invariant groups $\mathrm{KK}(A, SB)$, cf. Chapters 5 and 8 for more details and Section 5 for the most important implication of this homotopy invariance. We need a more “constructive” proof of the isomorphism $\mathrm{Ext}(\mathcal{C};\, A, SB) \cong \mathrm{KK}(\mathcal{C};\, A, B)$ than those proofs given usually, because it becomes an important ingredient of our proof of the isomorphism $\mathrm{R}(\mathcal{C};\, A, B) \cong \mathrm{Ext}(\mathcal{C};\, A, SB)$ at the very end of Chapter 9. The reader also should observe that some technical preparation for the proofs of above isomorphisms contain new results, that we have formulated and established in much more generality than actually used here in the book for proofs of the main topics.

The author has outlined proofs of Theorem A(i), Corollary F(iii) and Corollary G (and of the result that a pi-sun algebra has a central sequence of unital copies of $\mathcal{O}_\infty$) in his talk on the ICM-satellite conference in Geneva in August 1994. The idea of the proofs of Theorem I and Corollary J has been outlined in the authors talk in Rome, July 1996, at the conference on Operator Algebras and Quantum Field Theory.

In 1995-1998 we have extended the results, except Corollary H, to continuous bundles of C^*-algebras with finite dimensional metrizable compact base, in the sense of [**471**]. One only has to replace $\mathrm{KK}_{\mathrm{nuc}}(\cdot,\cdot)$ by a “nuclear” version of the Kasparov functor $\mathcal{R}\,\mathrm{KK}^G(X;\,\cdot,\cdot)$ for the base space X (where here $G := \{e\}$ is the trivial group!), and the sub-triviality theorem of E. Blanchard [**89**] replaces Theorem A.

In the period from March to September 1998 we arrived at a complete classification of all stable separable nuclear C^*-algebras that tensorial absorb $\mathcal{O}_\infty$ up to ideal system preserving isomorphisms by their $\mathrm{KK}(X; \cdot, \cdot)$-class.

Theorem M has been presented in the authors talk in Copenhagen, August 1998. A talk about Theorem K was given in Münster, March 1999. An overview of the main results of this book was given in [**442**], including outlines of some proofs. In the meantime many new results have appeared, and our new exposition should allow the reader to see that several fundamental observations can be derived also by our approach. The more general viewpoint using operator-convex cones in Chapters 3, 5, 7, 8 and 9 has been worked out in 2001–2006, and was outlined in conference and workshop talks in 2007 and 2008. Among the applications are ??????

`list some applications of classification` ??????? **??**

The author likes to thank R. Bhat, S. Friese, P. Friis, T. Häberlen, H. Harnisch, H. Osaka and G. Vaillant. They have helped to prepare versions of parts of the early 1994 preprint and/or have worked out a more detailed version of parts of it.

Inspiring, helpful and sometimes (with any right !) critical remarks came from C. Anantharaman-Delaroche, D. Bisch, B. Blackadar, E. Blanchard, U. Bunke, J. Cuntz, M. Dadarlat, G. Elliott, U. Haag, G. Kasparov, M. Rørdam, V. Voiculescu, A. Wassermann, S. Wassermann, J. Weidner and W. Werner. They also have suggested improvements that I tried to follow on.

J. Cuntz, J. Elliott and M. Rørdam have supported the work of the author on this monograph several times.

6. To do: Unify NOTATION in all Chapters!

Use $\approx$ (Cuntz equiv.) and $\sim_{MvN}$ (Murray–von-Neumann equiv.)

`Adjust in all chapters of the book the use of` $\sim$ `and` $\approx$

And the same with $[a]_\sim$, $\langle a\rangle_\sim$, $[a]_\approx$, $\langle a\rangle_\approx$.

Put it in the Index list. Decide where a reminder is necessary... **??**.

CHAPTER 2

Basics on purely infinite C^*-algebras

We consider here several properties that cause pure infiniteness of simple or non-simple C^*-algebras. It requires to discuss first the relations between the different definitions of infiniteness and the related terminology for C^*-algebras. The three Sections 2, 3 and 4 consider mainly the case of simple algebras. But the later considered pure infiniteness of non-simple algebras play also for the classification of simple C^*-algebras an important role. It causes a partly study of the huge variety of definitions of sorts of "infiniteness" for non-simple C^*-algebras or of elements in them. Then some of the later used permanence properties will be studied here in this chapter.

The last three Sections 16, 17 and 18 study properties of strong purely infinite C^*-algebras in sense of Definition 1.2.2, and some constructions that lead to strong p.i. C^*-algebras. Before and in-between there is the study of general observations needed in the proofs of results in later chapters, where sometimes only locally some sort of infiniteness plays a role for the applications.

The inventor – and pioneer of the study – of "purely infinite simple C^*-algebras" was Joachim Cuntz. He introduced in [**172**, p. 186] a notion of pure infiniteness in case of *simple* C^*-algebras using his observation in below given Lemma 2.1.6 for simple C^*-algebras:
A C^*-algebra A is said to be **purely infinite** – in the sense of J. Cuntz – if *every non-zero hereditary C^*-subalgebra D of A contains an infinite projection $p \in D$,* $p \neq 0$, i.e., a non-zero projection p that is *Murray–von-Neumann equivalent* to a proper sub-projection of itself in the sense of following definition:

Definition 2.0.1. Elements $a, b \in A_+$ are **Murray–von-Neumann equivalent** (short: **MvN-equivalent**) in A if there exists $d \in A$ with $d^*d = a$ and $dd^* = b$. The relation will be denoted by $a \sim_{MvN} b$ or simply by $a \sim b$.

The MvN-equivalence class of $a \in A_+$ will be denoted by $[a]_{MvN}$ – or simply by $[a]$ if there is no danger to be mixed up with the considerably "bigger" class $[a]_{\approx}$ of all $b \in A_+$ that are Cuntz–equivalent to a (cf. Definition 2.5.1).

Basic examples of purely infinite *simple* algebras are the Cuntz algebras $\mathcal{O}_{\mathrm{n}}$, $n = 2, 3, \ldots,$ that are the universal unital C^*-algebras generated by elements $s_1, \ldots, s_n$ with defining relations $s_j^* s_k = \delta_{j,k} 1$ for $j, k \in \{1, 2, 3, \ldots, n\}$ and $\sum_{k=1}^{n} s_k s_k^* = 1$, respectively the Cuntz algebra $\mathcal{O}_\infty$ generated by a sequence of elements $s_1, s_2, \ldots$ with relations $s_j^* s_k = \delta_{j,k} 1$ for $j, k \in \mathbb{N}$, cf. [**169**]. In particular, J. Cuntz studied and confirmed in early work some related conjectures of J. Dixmier (1964) in [**214**] concerning $\mathcal{O}_2$.

Some properties of $\mathcal{O}_\infty$ and $\mathcal{O}_2$ did play a fundamental role for the proofs of the classification results for pi-sun algebras both in the approach of N. Ch. Phillips and in the the approach of the author of this book. Therefore, we list some properties of Cuntz-algebras $\mathcal{O}_{\rm n}$ and $\mathcal{O}_\infty$ in Section 1 of Appendix A and outline there elementary proofs for this properties, – but only so far as they do not follow immediately from some of the very basic observations in Chapters 2, 3 and 4. Moreover, we give in Section 1 of Appendix A some additional informations on the algebras $\mathcal{O}_{\rm n}$ that will be used often in proofs, applications and examples.

Our "long" Proposition 2.2.1 says that on the class of *simple* C^*-algebras pure infiniteness in the sense of J. Cuntz is equivalent to each of the local, weak or strong pure infiniteness defined below, and to many other properties that are useful for several applications useful. But there are examples of amenable (= nuclear) separable unital simple C^*-algebras that are (quasi-) trace-less but are not purely infinite in the sense of any here given and considered definitions, cf. the example of M. Rørdam [**687**] ([1]).

It has been shown in [**462**, prop. 4.7], [**463**, cor. 6.9] and [**93**, thm. 4.17], – cf. also our Proposition 2.6.5 –, that in case of C^*-algebras A of *real rank zero* all of our below given definitions of pure infiniteness of simple C^*-algebras A coincide.

Unfortunately, this is not the case for non-simple A. ????

`Next blue/red text has to be verified, is ''under observation":`
More generally, equivalence of *all* definitions of pure infiniteness (– except possibly *strong* pure infiniteness! –) for C^*-algebras holds for all C^*-algebras with the property that

for every closed ideal $J \neq A$ of A and every non-zero hereditary C^*-subalgebra D of A/J there exists a non-zero projection $p \in D$,

i.e., where A is "rich of projections" in the sense of our Definition 2.6.1: If C^*-algebras A with this property has our "weakest" property of infiniteness, – i.e. the "local pure infiniteness" (l.p.i) of Definition 2.0.3 – then it turns out that A is purely infinite in the sense of Definition 1.2.1.

This class of C^*-algebras A contains the class given by the property that

every non-zero hereditary C^*-subalgebra $D \subseteq A/J$ of any quotient A/J of A contains a non-zero infinite projection $p \in D$,

– i.e., those where all quotients are purely infinite in the sense of the above quoted

---

[1] Since a long time it seems to be still (January 2022) an open question if there exists a simple nuclear C^*-algebra of "real rank zero" that is stably infinite but is not purely infinite, cf. Question (Q1) in Chapter 1. This cited famous example of M. Rørdam has *not* this properties. Such an example (of real rank zero), – if it exists –, can be modified to produce a unital simple algebra A with real rank zero, that contains no infinite projection, but $M_2(A)$ contains a copy of $\mathcal{O}_2$ unitally. Even if this exists, then the question is: Can such kind of A be a *nuclear* C*-algebra with all this properties?

definition of J. Cuntz in [**172**] ([2]) –,
are purely infinite in sense of Definition 1.2.1.

We do not know if purely infinite C^*-algebras A, that are "rich of projections", in sense of our Definition 2.6.1, are moreover *strongly purely infinite* in sense of Definition 1.2.2, – our so far strongest infiniteness property of a C^*-algebra that is "rich of protections".

`We need only a kind of semi-splitting`
`(in cases where we can reduce all arguments to the separable case`
`by considering suitable` $C*$`-subalgebras` E `if possible):`
An element $b \in E_+$ with $\overline{bEb} \subseteq A$ with $b \approx (b \oplus b)$ and a non-zero element $c \in E_+$ orthogonal to b, i.e., $cb = 0$ and $\pi_A(c) \neq 0$.
Can only work if $A(??)$ is not "essential"???...
But it could be that all non-zero projections of cEc are contained in cAc ...?
No progress ... !!!
To find b, c one could take a strictly positive element of $a \in A_+$, i.e., $A = \overline{aEa}$.
Try to use the projectivity of $C_0((0,1], M_2)$, and consider $M_2 \subseteq E/A$ ...
It gives positive contractions $c, d \in E_+$ with $cd = 0$, $\pi_A(c) = p_{11}$, $\pi_A(d) = p_{22}$.
Then try to modify $a + d$ ...

NO PROGRESS !!!

One *question* is, if in case of separable σ-unital A, where A is an ideal of E, that is "rich of projections" and is purely infinite ($\Leftarrow$ HERE: A or E ?), has the property that an exact sequence $0 \to A \to_\eta E \to_\pi \mathcal{O}_2 \to 0$ must split, i.e., that there exists a C^*-morphism $\phi \colon \mathcal{O}_2 \to E$ with $\pi \circ \phi = \mathrm{id}_{\mathcal{O}_2}$ for the quotient epimorphism $\pi \colon E \to \mathcal{O}_2$ with kernel $\eta(A)$ for the inclusion morphism $\eta \colon A \to E$ onto an ideal of E if E has real rank zero.

(Questions: Is this splitting necessary for E being s.p.i.? Or is "semi-splitness" enough?)

Because then it would be the same as our Definition 2.6.1 (but with property l.p.i. added as additional property) if we could show that each copy of $\mathcal{O}_2$ can be lifted for a strongly p.i. ideal with many projections. Here we can reduce all to the separable case, and build later inductive limits of them.

In general the question is:

Does there exists a separable p.i. C^*-algebra A such that *every* non-zero hereditary C^*-subalgebra D of A is *not* strongly p.i.?

There exists D that contains may nonzero n-homogenous C^*-subalgebra $E_n := F_n \otimes M_n$ with $E_{n+1} \subseteq E_n$.

(The injections ??????? .)

If such example *not* exists, then every p.i. algebra is s.p.i. !!!

[2]... defined there mainly for the study of simple Cuntz-Krieger algebras!

(Where are the proofs of this?)

Thus, it suffices to consider suitable separable C^*-subalgebras of ultrapowers of p.i. algebras ... ???

But if A has real rank zero then local pure infiniteness of A implies strong pure infiniteness of A, because it is a special case of the following result:

If A satisfies the stronger condition that, – for every hereditary C^*-subalgebra $D \subseteq A$ and pure state ρ on A with $\rho|D \neq 0$ – , there exists a projection $p \in D$ with $\rho(p) \neq 0$ ([3]), then A is strongly purely infinite in sense of Definition 1.2.2 if A is locally purely infinite in sense of Definition 2.0.3 .

So far we don't have seen any example of a purely infinite separable C^*-algebra A that satisfies the properties in Definition 2.6.1 of C^*-algebras with "many projections", but is not strongly purely infinite.

`Check, compare and relate this blue part to above to the written text. Remove repeats in blue parts!!!`

`The two next discussed cases seem not to be equivalent! Check again!`

`Merge below and above text about special cases!`
`Look more to applications than to`
`problems with very weak definitions!`

`THIS is somewhere in the proof:`

It implies immediately that every $\pi_J(a) \in A/J$ is infinite for each $a \in A_+$ and closed ideal J of A with $a \notin J$, if one takes $D := \overline{\pi_J(a)(A/J)\pi_J(a)}$. Thus, each non-zero element of A is infinite.

Suppose that each non-zero element of A_+ is infinite, is then each non-zero element of A_+ properly infinite?

??? lem:2.infinite.elem ??? cf. Lemma **??**(v) and discussion of case of algebras that are "rich of projections" ...

Definition 2.6.1

Propositions on generalized Cuntz def. **??** and **??**

[prop:2.Cases.where..Cuntz.pi..implies..l.p.i]

[prop:2.cases.where..l.p.i..implies..p.i.?]

`Refs.: proof of cases where l.p.i implies p.i.`
`e.g. tensor ‘‘q-traceless’’ with Jiang-Su algebra`
`linear ordered lattice of ideals leads to s.p.i.`
`being ‘‘rich of projections’’ ...` ???????

... then A is moreover strongly purely infinite in sense of Definition 1.2.2. (Really???)

---

[3] Equivalently expressed: For every $a \in A_+$ with $\|a\| = 1$ and pure state ρ on A with $\rho(a) = 1$ there exists a projection $p \in \overline{aAa}$ with $\rho(p) > 1/2$.

It seems that this class of C^*-algebras (with real rank zero or at least with many projections) and the class of C^*-algebras A with the property that the ideal-lattice of A is linear ordered, are the only cases where we can show so-far that the properties (l.p.i.) and (s.p.i) coincide.

Then the permanence properties for the class of strong purely infinite C^*-algebras allows to define from this classes other classes of C^*-algebras where (l.p.i.) and (s.p.i) coincide.

But until now (Jan 2022) we have seen no example of a C^*-algebra A that is locally or weakly purely infinite but is not strongly purely infinite ... but, unfortunately, some proofs and most interesting applications require strong pure infiniteness. END OF BLUE DISPUT TEXT. ????

On the other hand, the algebra $\mathcal{O}_2 \otimes \mathbb{K} + \mathbb{C} \cdot 1$ (with unit $1 := 1_{\mathcal{O}_2} \otimes id_{\ell_2}$) has real rank zero and is purely infinite in the sense of the above mentioned definition of J. Cuntz [**172**, p. 186], but is even not locally p.i. in the weakest sense: the "local pure infiniteness" of Definition 2.0.3, because its unit element 1 is not *properly* infinite (inside the multiplier algebra $\mathcal{M}(\mathcal{O}_2 \otimes \mathbb{K})$ of $\mathcal{O}_2 \otimes \mathbb{K}$. The algebra $\mathrm{C}_0((0,1], \mathcal{O}_2)$ is strongly p.i. in the sense of our Definition 1.2.2, but is not purely infinite in sense of the definition in [**172**], because it is stably projection-less.

Therefore, it is necessary to underline that we use or consider the original definition of J. Cuntz *only in case of simple* C^*-algebras A:

The Definition 1.2.2 of *strongly* purely infinite algebras is better applicable to non-simple C^*-algebras, and has nice functorial properties, e.g. passes to quotients, extensions (see Section 17) and to tensorproducts with exact C^*-algebras ([4]).

One can even work with the below given (possibly weaker) definitions, that are both equivalent to strong pure infiniteness in particular cases, e.g. where A has *real rank zero*, or is *simple*, or has a *Hausdorff* primitive ideal space $\mathrm{Prim}(A)$ *of finite dimension*, or where the lattice $\mathcal{I}(A)$ of closed ideals of A is *linearly ordered*.

What about examples or counter examples?

But here is good news for readers that feel disturbed by the "zoological garden" of definitions of pure infiniteness of non-simple C^*-algebras A and their still incomplete list of permanence properties:

If one tensors a C^*-algebra $A \neq \{0\}$ with the Jiang-Su algebra $\mathcal{Z}$ then all our definitions of pure infiniteness become the same, i.e., $A \otimes \mathcal{Z}$ is "locally purely infinite" in sense of Definition 2.0.3 if and only if $A \otimes \mathcal{Z}$ is *strongly purely infinite* as defined in Definition 1.2.2.

It implies immediately that $A \otimes \mathcal{O}_\infty$ is s.p.i. for every C^*-algebra $A \neq \{0\}$, because $\mathcal{O}_\infty \cong \mathcal{O}_\infty \otimes \mathcal{Z}$.

[4] Despite we haven't seen so far a, – necessarily non-simple –, example of a weakly p.i. C^*-algebra that is not strongly p.i. It is related to the more general open question if non-zero elements have good approximate Glimm halving in non-simple residually anti-liminary C^*-algebras, cf. Section 7.

Give cite or ref for isomorphism $\mathcal{O}_\infty \cong \mathcal{O}_\infty \otimes \mathcal{Z}$!

(Must show KK-equivalence ??? of $\mathcal{Z}$ to $\mathbb{C}$ or $\mathcal{O}_\infty$)

Moreover this is even the case if $A \otimes \mathcal{Z}$ has no non-trivial 2-quasi-trace. Here "trivial" means that the 2-quasi-trace takes only the values $\{0, +\infty\}$ on $(A \otimes \mathcal{Z})_+$.

(All quasi-traces on C*-algebras A are automatically 2-quasi-traces if A is both simple and exact ... ?

"Prime" C*-algebras with non-trivial l.s.c. 1-quasi-traces can exist. The full free group C*-algebra $C^*(F_\infty)$ has all sorts of quasi-traces, among them those that are not 2-quasi-traces.)

Moreover $A \otimes \mathcal{Z}$ is strongly purely infinite if each lower semi-continuous 2-quasi-trace $\tau \colon A_+ \to [0, \infty]$ takes only the values 0 and $+\infty$, i.e., if each τ is "trivial" in the following sense:

`Compare and choose from the kernel descriptions!!`

A lower semi-continuous 2-quasi-trace $\tau \colon A_+ \to [0, +\infty]$ is called *trivial* if τ takes only values in $\{0, +\infty\}$, and is defined by its closed kernel ideal $\tau^{-1}(0) =: J \subseteq A$.

"Trivial" lower semi-continuous 2-quasi-traces $\tau \colon A_+ \to \{0, +\infty\}$ correspond naturally to closed ideals J_τ defined by $(J_\tau)_+ := \tau^{-1}(0)$, and, conversely, τ_J is defined from a closed ideals $J \lhd A$ by $\tau_J(a) := 0$ if $a \in J_+$ and by $\tau_J(a) := +\infty$ for $a \in A_+ \setminus J$.

If A is an exact C^*-algebra, then $A \otimes \mathcal{Z}$ is s.p.i., if and only if, A_+ has no non-trivial additive trace.

Why we need here that A is exact? Has to do with the additivity of of 2-quasi-traces (are they natural extendable to $M_2(A)_+$ etc. ...) ???

Give exact citation !!!

Corollary 3.12 of the authors Abel Proc. paper – submitted in 2005! (or 2004?) – says moreover:

$A \otimes \mathcal{Z}$ is s.p.i. if every l.s.c. 2-quasi-trace on A_+ is trivial.

(It is (= seems to be) clear that $A \otimes \mathcal{Z}$ has no non-trivial 2-quasi-trace if A has no non-trivial 2-quasi-trace.

Thus, the point in the proof is: If $A \otimes \mathcal{Z}$ has no non-trivial 2-quasi-trace, then $A \otimes \mathcal{Z}$ is s.p.i.

(All s.p.i. C*-algebras have no traces ... A bit imprecise expressed:

The traces on B_+ a C*-algebra B can be extended to and calculated from the "open" projections in W*-algebra $(B \otimes \mathbb{K})^{**}$. The natural order and equivalence will be respected ... If they are approximated from below by stable projections then only the values 0 and $+\infty$ can appear.)

The point seems to be that we have to consider the corresponding "dimension functions" on the open projections. They must be trivial in sense that only 0 and $+\infty$ can appear.

Definition: Pedersen Ideal := The ideal of B that is generated by the elements $(b - \varepsilon \cdot 1)_+$ with $b \in B_+$ and $\varepsilon \in (0, \|b\|)$ and $1 \in \mathcal{M}(B)$.

Does this arguments use that $\mathcal{Z} \cong \mathcal{Z} \otimes \mathcal{Z}$?)

This has been proven by M. Rørdam, first in the special case of nuclear C^*-algebras A in [**690**, thm.5.2], – where one can use the result of U. Haagerup [**342**] that all 2-quasi-traces are additive on exact C^*-algebras – and later in [**690**, thm.5.?2?] for all A. We give a different proof in Section **??**, that is a modification of the authors original proof in ?? Abel proc...??? ... ??????

?????? Kirchberg ???

More important for our more special applications is that the tensor products $A \otimes \mathcal{O}_\infty$ of any non-zero C^*-algebra A with the Cuntz algebra $\mathcal{O}_\infty$ is strongly purely infinite (= s.p.i.) in sense of Definition 1.2.2.

Only in the very special case of separable *nuclear* C^*-algebras A we have always the strong conclusion: Separable nuclear C^*-algebras A are strongly purely infinite, if and only if, $A \cong A \otimes \mathcal{O}_\infty$. For general exact and separable C^*-algebras A this seems to be `Give reference to this isomorphism, it is likely in Chapter 11?`

EXAMPLE 2.0.2. `!!! Adjust my notation for` $\mathcal{R}$ `by notion` W`,`
`because M. Rørdam called it` W `in [467].`
`Then change it also on other places,` e.g. `in the Introduction Chapter 1`
`Also in the Introduction where it is mentioned!!`
`Where is written that this` A `has the property`
`(CFP) (= Corona Factorization property ) and where that`
$F(A)$ `has a character ?`
`Where is` $F(A)$ `defined ???? Give Ref's !!!`
`No-Where! But` W `and` $C^*_{red}(F_2)$ `have the properties`
`that` $F(W)$ `and` $F(C^*_{red}(F_2))$ `have characters,`
`It is not known if` $F(A)$ `has a character.`
`There is a claim that some conjectures related to (CFP) would be`
`destroyed if` $F(A)$ `has a character.`

Let $W := \mathcal{R}$ denote the unital simple separable nuclear C^*-algebra W with $\mathrm{K}_*(W) \cong \mathrm{K}_*(S^2 \times S^2 \times \cdots)$ constructed by M. Rørdam in [**687**] that is finite but is not stable finite, where S^2 denotes here the 2-dimensional unit sphere in $\mathbb{R}^3$.

Where is the existence of a character on $F(W)$ proven? Or a general theorem that says: $F(A)$ without character implies that A is not stably finite ...

The simple, separable, unital and *exact* C^*-algebra $A := C^*_{red}(F_2) \otimes \mathcal{R}$ is purely infinite by Theorem E. Hence, it is also strongly purely infinite by simplicity of this

A. But this C^*-algebra A does not absorb tensorial any amenable C^*-algebra $\neq \mathbb{C}$. ([5]).

Moreover, the algebras $B := C^*_{red}(F_2)$ and $C := \mathcal{R}$ ($= W$) have both the property that the unital C^*-algebra $F(B)$ and $F(C)$ have a character.

(Where are W and $\mathcal{R}$ defined, and described. In a paper of Rørdam. The W seems to be)

In case of $C^*_{red}(F_2)$ this follows from the classical observation that the commutant $vN(F_2)' \cap vN(F_2)^\omega$ of the von-Neumann algebra $vN(F_2)$ in its von-Neumann algebra ultrapower $vN(F_2)^\omega$ has a character, because it is simply $\mathbb{C} \cdot 1$.

Notice that $vN(F_2)^\omega$ is the adjoint of the Banach space $(vN(F_2)_*)_\omega$ (in our terminology). There is a natural unital C^*-morphism from $C^*_{red}(F_2)_\omega$ into the von-Neumann algebra $vN(F_2)^\omega$. It maps $C^*_{red}(F_2)' \cap C^*_{red}(F_2)_\omega$ into $vN(F_2)' \cap vN(F_2)^\omega$, because $\|[a,u]\| + \|[a,v]\| \geq \|[a,u]\|_2 + \|[a,v]\|_2$ and the unit ball of $C^*_{red}(F_2)$ is dense in the unit ball of $vN(F_2)$, – with respect to the ℓ_2-norm on $C^*_{red}(F_2) \subset \ell_2(F_2)$.

`This seems TO BE WRONG and has not been claimed in [467]!!:` A has perhaps the (then rather surprising) property that the central sequence algebra $F(A) := A' \cap A_\omega$ has a character, see [**467**, ex. 4.6].

NO? that above is still not proven! But is a question how near an operator $\sum_{g \in X} L_g \otimes c_g$ is to $1 \otimes \mathcal{R}$ (now denoted by $1 \otimes W$?) if it commutes almost with the generators of F_2 .

??? Next also still to check:
This example could show also that simple separable unital exact C^*-algebras A with the Corona Factorization Property (CFP)

Give reference to Def. of (CFP) !!!

exist ??? with the property that the invariant

$$F(A) := A' \cap A_\omega / \operatorname{Ann}(A, A_\omega)$$

has a character ???

Seems not clear if this example has a character!, All simple purely infinite exact C^*-algebras should have always the (CFP)? Or not?? Some answer ???

All σ-unital *simple* purely infinite C^*-algebras A are unital or stable.

Citation of Prop./Cor.?

This will be shown for separable A, but carries automatically over to σ-unital simple purely infinite C^*-algebras A, because they can be considered as an limit of an directed net $\{A_\tau\}$ of separable simple purely infinite C^*-subalgebras of A that contain a strictly positive element of A.

[5] It is not shown there that $A \not\cong A \otimes M_n$, but that follows for this A from the fact that there exist non-zero $[p] \in \mathrm{K}_0(A)$ with the property that there does not exist $[q] \in \mathrm{K}_0(A)$ with $[p] = n[q]$, i.e., $[p]$ is not "divisible" inside $\mathrm{K}_0(A)$ by some $n \in \mathbb{N}$.

If A is then stable, then $\mathcal{M}(A)/A$ is simple and purely infinite. This could/should imply the *corona factorization property* (CFP) ???

Above was not proven! Ref. to Def?

If a simple separable and exact C^*-algebra A has the property that $F(A)$ has *not* a character then one has always that (simple ?) A has property (CFP).

?? Above and below the same ??

But it is also known that if A is separable and $F(A)$ has no character then A has corona factorization property (CFP), cf. [**467**, thm. 4.3].

Our study starts with a variety of helpful weaker properties that are related to pure infiniteness but are often easier to verify than pure infiniteness itself, e.g. for C^*-bundles (i.e., C^*-algebras of bounded continuous sections in continuous fields of C^*-algebras), or for C^*-algebras with linearly ordered ideal lattice.

The property that an element $a \in A$ with $a \neq 0$ is "infinite" in A has been defined by J. Cuntz by the requirement that there exists non-zero element $b \in A$ such that

$$b \oplus a \precsim a\,.$$

See Definitions 2.0.3 **??** and **??**.

Among the almost "weakest" definition of pure infiniteness of C*-algebras is that of "local pure infiniteness":

Check blue text, refs and labels of l.p.i
Check/COMPARE other places of Def. ?? ??? with next blue.
Move equivalent formulations to places where they are used.

The local stability is perhaps a very rare property! Have to find other types of elements to work with.

DEFINITION 2.0.3. A non-zero C^*-algebra A is **locally purely infinite** (**l.p.i.**) if, for every non-zero $a \in A_+$ and pure state ρ on A with $\rho(a) > 0$, there exists a stable C^*-subalgebra $D \subseteq \overline{aAa}$ with $\rho(D) \neq \{0\}$.

Later the Lemma 2.7.15 says that we can replace in Definition 2.0.3 the "pure state" simply by "state", and get therefore a formally stronger definition than that formulated in Definition 2.0.3.

(That definition could be "incorrect" for a suitable version of "local pure infiniteness", because "infinite" is not necessarily "stable" ... Moreover, it should be called "locally stable" !!! But a stable C^*-algebra D is isomorphic to $D \otimes \mathbb{K}(\ell_2)$, i.e. $D \cong D \otimes \mathbb{K}$ and contains a σ-unital stable separable C^*-subalgebra $E \subseteq D$ with the property that there exists a non-zero epimorphism from $F := \mathrm{C}_0(0,1] \otimes \mathbb{K}$ onto E. But the diagonal compact operator $f := (1, 1/2, 1/4, \ldots, 2^{-n} \ldots)$ is properly infinite operator in $\mathbb{K}$, in the sense that there exist sequences of elements (a_n) and (b_n) such that

$$f \otimes 1_2 = \lim_n [a_n, b_n]^* [f a_n, f b_n]$$

in $M_2(\mathbb{K}) \cong \mathbb{K}$ This implies that F and E contain a strictly positive contraction that is properly infinite.

Or is it somewhere shown that for p.i. elements $a \in A_+$ the algebra $\overline{aAa}$ contains a non-zero stable C^*-subalgebra $D \subseteq \overline{aAa}$?

If a is "infinite", then (perhaps ??????) some element $e \in \overline{aAa}_+$ with $\|e\| = 1$ exists that is infinite in sense $(e-t)_+ \oplus (e-t)_+ \precsim (e-t)_+$ for suitable $t \in (0,1)$.

Perhaps ... this implies that $\overline{aAa}_+$ contains a (non-zero) stable C^*-algebra?

$\Leftarrow$ Would be important and interesting to know!

But stability $D \cong D \otimes \mathbb{K}$ of D implies natural pure infiniteness of each strictly positive elements $a \in D_+$, i.e. with $D = \overline{aDa}$.

Suppose that B is "purely infinite" ... (says that $b \oplus b \precsim b$ for all $b \in B_+$)

... or suppose something weaker ???, this could be that every element of B is "infinite" in the sense, that – for each non-zero $b \in B_+$ – there exits a non-zero $c_b \in B_+$ with $c_b \oplus b \precsim b$ ... ??? It is known that those elements c_b build the positive part $J(b)_+$ of some closed ideal $J(b)$ of B. And one knows that the element $\pi_{J(b)}(b) := b + J(b)$ of $B/J(b)$ is finite in $B/J(b)$ ... (Give References ! the strict finiteness of).

It implies: If every non-zero positive element of every quotient of B/J is infinite, then each element $b \in B_+$ is properly infinite, i.e. $b \oplus b \precsim b$.

Moreover, suppose that B is σ-unital, non-unital, and each (non-zero) quotient B/J has no unit element.

Is B then itself stable? (Stability Question: $B \otimes \mathbb{K} \cong B$?)

Look to Rordam paper ... ???

Ref.? Big question: to what kind of "purely infinite" C^*-algebras.!!)

" Zhang's Dichotomy ":

A σ-unital, purely infinite (!!!), simple C*-algebra is either unital or stable. (Reference/Cite ???).

What kind of definition of "pure infiniteness" is used for "Zhang's Dichotomy"?

[**688**, prop. 5.4] Rordam, Japan 2004 (or 2003),

Definition 6.10.? of this Rordam paper (defines Property: "regular")

A C*-algebra I is called "regular" if every full, hereditary sub-C*-algebra of I, that has no unital quotients and no bounded traces, is stable.

(E.K.: $I := \mathbb{K}$ – of $\ell_2(\mathbb{N})$ – is not regular ????) Every non-zero hereditary C*-subalgebra D of $\mathbb{K}$ is "full" in $\mathbb{K}$? because each nonzero element x of $\mathbb{K}_+$ generates $\mathbb{K}$ as the closed ideal of $\mathbb{K}$ that is generated by x. The D is given by a positive compact operator (by taking one of its strictly positive contractions in it). Alternatively it is given as $P\mathbb{K}P$ for some orthogonal projection P on $\ell_2(\mathbb{N})$. $P\mathbb{K}P$

has finite dimension, if and only if, $P\ell_2(\mathbb{N})$ is finite-dimensional (and has a faithful trace). Otherwise $P\mathbb{K}P$ is stable.

Thus, each $D := P\mathbb{K}(\ell_2)P$ satisfies the definition of a regular hereditary sub-C*-algebra of $\mathbb{K}(\ell_2)$ (given by M. Rørdam for all hereditary C*-subalgebras of $\mathbb{K}(\ell_2)$.

(Check this again !!!)

[**688**] Proposition 6.12. (of Rordam [**688**] ???) Let $0 -- > I -- > A -- > B -- > 0$ be a short exact sequence of separable C*-algebras and suppose that I is regular. Then A is stable, if and only if, I and B are stable.

Question 6.5. of Rordam [**688**]:

Does every (separable) C*-algebra A have a greatest stable ideal (i.e., a stable ideal that contains all other stable ideals)?

(Is a the closure of an upward directed family of stable ideals of A a stable ideal of A?)

Equivalently: Let A be the sum of two stable ideals $A = J + I$. Is A stable?

Is $\mathrm{C}_0(0,1]\otimes\mathbb{K}$ ($= C_0((0,1],\mathbb{K})$??) semi-projective ?.

`compare next blue with Lemma 2.7.15!`

If each stable C^*-subalgebra $D \subseteq \overline{aAa}$ satisfies $\rho(D) = \{0\}$, then ρ is zero on the hereditary C^*-subalgebra E of $\overline{aAa}$ that is generated by all stable elements in $\overline{aAa}$.

DEFINITION (cite/ref: where first def.?) of "stable" elements $b \in A_+$: $\overline{bAb}$ is stable, i.e. $\overline{bAb} \cong \overline{bAb} \otimes \mathbb{K}$.

Equivalently: $b \in A_+$ is a stable element, if and only if, there exists a C^*-homomorphism $\psi\colon \mathrm{C}_0(0,1]\otimes\mathbb{K} \to A$ such that $b = \psi(f_0 \otimes (t_1, t_2, \ldots))$, for $(t_1, t_2, \ldots) \in c_0 \subset \mathbb{K}$ with $1 \geq t_1 \geq t_2 \geq \cdots$, and all $t_n > 0$.

(First one has to find an isomorphism $\overline{bAb} \cong \overline{bAb} \otimes \mathbb{K}$ and then ???? use ???? that b is there approximately equivalent to $b \otimes c_0$, (or simply replace b by $b \otimes c_0$ ...).

But E is invariant under automorphisms of D, in particular E is a closed ideal of D, i.e., in general the hereditary C^*-subalgebra E of D generated by the convex combinations of all positive "stable" elements in D is an ideal of D. The E must be equal to D if A is locally purely infinite in sense of Definition 2.0.3.

If a hereditary C^*-subalgebra E of D is invariant under conjugation by certain unitary elements in the multiplier algebra $\mathcal{M}(D)$ ... ?

It follows that ??????

The following Definition is equivalent to Definition [**93**, def. 1.2].

DEFINITION 2.0.4. We call a C^*-algebra A **n-purely infinite** (or: A is **pi(n)**) for some fixed $n \in \mathbb{N}$ if A satisfies that

(i) for every nonzero $a \in A_+$, positive b in the closed ideal $J(a)$ of A generated by a, and every $\varepsilon > 0$, there exists $d_1, \ldots, d_n \in A$ such that

$$\| b - \sum_{1 \leq k \leq n} d_k^* a d_k \| < \varepsilon ,$$

and

(ii) every quotient C^*-algebra $\neq 0$ of $\ell_\infty(A)$ has (linear) dimension $> n^2$.

The Part (ii) says here that $\ell_\infty(A)$ has no irreducible *-representation on a Hilbert space $\mathbb{H}$ of dimension $k \leq n$.

Why we use here in Part (ii) of Definition 2.0.4 the huge $\ell_\infty(A)$ in place of A? Is there an example where (ii) for A (in place of $\ell_\infty(A)$) is not enough?

Is not clear if we can prove that $\ell_\infty(A)$ has no irreducible representation on a Hilbert space of dimension $k \leq n$ if A has no irreducible representation on a Hilbert space of Dimension $k \leq n$ ...

Use projectivity of $M_k(\mathrm{C}_0(0,1])$ ...

But there are more general and precise observations needed ...

... because this "proof" gives only a sequence of (needed) positive functions

$$f_m \colon (0,1] \to (0,1]$$

with $f_m(1/m, 1] = 1$ and $f_{m+1} f_m = f_m$, and that have the property that a convex combination a_k of $n+1$-homogenous contractions in $\ell_\infty(A)$ exist that are ... (!!! check hand-written papers for an idea of proof ... but seems not complete ...).

If we can use only the following weaker requirement in Part (ii*) of Definition 2.0.5 in place of Part (ii) of Definition 2.0.4 then it is not clear if the two Definitions 2.0.4 and 2.0.5 are really equivalent, or if Definition 2.0.4 is strictly stronger than Definition 2.0.5 ...

Definition 2.0.5. Let A a C*-algebra. Then A is called (n-step) "locally purely infinite" (or "A is pi(n)") if

(i*) Each element $a \in A_+$ is n-step infinite in the sense:
For each elements $c_1, \ldots, c_{n+1} \in A$ and $\varepsilon > 0$ there exist $d_1, \ldots, d_n \in A$ such that

$$\| \sum_{1 \leq j \leq n+1} c_j^* a c_j - \sum_{1 \leq k \leq n} d_k^* a d_k \| < \varepsilon ,$$

and

(ii*) A has no irreducible representation on a Hilbert space $\mathbb{H}$ of dimension $k \leq n$.

We say that A is **weakly purely infinite** (for short **w.p.i.**) if A is pi(n) for some $n \in \mathbb{N} = \{1, 2, \ldots\}$.

The property (i*) in Definition 2.0.5 implies that for a C*-algebra A with this property implies that the property (ii*) is equivalent to each of the following properties (ii*,1)–(ii*,4?) for its elements and irreducible representations:

(ii*,1) No hereditary C*-subalgebra D of A has a (non-zero) character.

(ii*,2) No hereditary C*-subalgebra D of A has a (non-zero) finite-dimensional quotient D/J. (Here one can take a closed ideal I of A and consider $J := I \cap D$, because for each closed ideal J of a hereditary C^*-subalgebra D of A the closed ideal J of A generated by I, i.e., the closure I of the linear span of $A \cdot J \cdot A$, satisfies $J = I \cap D$, because $DAJAD \subseteq I$.)

(ii*,3) No irreducible representation $\rho(A)$ of A contains a (non-zero) compact operator in its image.

(ii*,4) No closed ideal J of A has an irreducible representation $\rho\colon J \mapsto \mathcal{L}(\mathcal{H})$ with $\rho(J) = \mathbb{K}(\mathcal{H})$.

It is not difficult to see that the Part (i) of Definition 2.0.4 and

??????

are equivalent to Part (i*) of Definition 2.0.5.

It follows that A is *purely infinite* in the sense of Definition 1.2.1, if and only if, A is pi(1) in the sense of Definition 2.0.4, but pi(1) follows from the formally weaker requirements (i) for $n := 1$ and (ii*) that A has no character (instead to require moreover that $\ell_\infty(A)$ has no character !).

The conjecture (!) is that the same holds for the requirement (ii) for pi(n), i.e., that it is enough to require that

(ii*) A (itself) has no irreducible representation of dimension $\leq n$.

But until now (2022) no general argument for a proof of this has been found. But properties (i) and (ii*) imply together that all (non-zero) n-homogenous elements of A are properly infinite, cf. Proposition ??? **??**. And this implies that all non-zero n-homogenous elements of $\ell_\infty(A)$ and of A_ω are properly infinite...

But this argument does not exclude the existence of irreducible representations of dimension $< n$ on A_ω or $\mathcal{M}(A)$... ??? Examples ?? for this phenomenon ??

Part (ii) says that $\ell_\infty(A)$ has no irreducible representation $d\colon \ell_\infty(A) \to \mathcal{L}(\mathcal{H})$ with $\mathrm{Dim}(\mathcal{H}) \leq n$. Since $\mathcal{M}(A)$ is a unital C^*-subalgebra of $\ell_\infty(\mathcal{M}(A))$ and $\ell_\infty(A)$ is an essential ideal of $\ell_\infty(\mathcal{M}(A))$, it would be stronger to require that $\mathcal{M}(A)$ has no irreducible representation of dimension $\leq n$. It is not known, even in the case where A is separable, if $\mathcal{M}(A)$ can have an irreducible representation of dimension $\leq n$, but its sequence algebra $\ell_\infty(A)$ has no irreducible representation of dimension $\leq n$. (But $\ell_\infty(\mathcal{M}(A))$ has then a C^*-epimorphism onto $\ell_\infty(M_k)$ for some $k \leq n$.)

It has to do with the more general question if $\ell_\infty(A)$ is again residual antiliminary if a C^*-algebra A is residually antiliminary, cf. the discussions below Definition 2.7.2 of residual antiliminary C^*-algebras.

The Definition 2.0.4 is an equivalent formulation of [**93**, def. 1.2]. It was used in [**93**] for some results on pure infiniteness of C^*-bundles (:= algebras of continuous sections vanishing at ∞ in continuous fields of C^*-algebra).

An alternative description of weak pure infiniteness is given in the following definition of a perhaps stronger property "pi-n" defined in [**463**, def. 4.3].

`This is mentioned below a second time (with footnote?). Compare it and remove one of them:`

The pi(n) C^*-algebras have the formally stronger property pi-m of Definition 2.0.6 for suitable (but still unknown) $m \in \mathbb{N}$ with $n \leq m$.

DEFINITION 2.0.6. We say that a C^*-algebra A has **property pi-n** (or: A is pi-n) if, for each non-zero $a \in A$, the n-fold direct sum $a \oplus a \oplus \cdots \oplus a = a \otimes 1_n$ is properly infinite in $M_n(A)$, if considered as a diagonal matrix in $M_n(A)$.

If A has the property of Definition **??** then no (non-zero) hereditary C^*-subalgebra D of A has a character and any n-homogenous positive contraction $a \in A$ is properly infinite in A.

The Definition 1.2.1 and the above given Definitions 2.0.3, 2.0.4, and **??** of local or weak pure infiniteness coincide in case of simple C^*-algebras, cf. Proposition 2.2.1.

In Section 12 of this chapter it is shown that property pi-n implies property pi(n) on non-simple A.

Conversely, if A has property pi(m) for some m then there exists $n \geq m$ such that A has property pi-n, but no general function $f\colon \mathbb{N} \to \mathbb{N}$ is known yet (Febr.2022) with the property that $n \leq f(m)$. Moreover, there exists, for every factorial state ρ on A, a closed ideal J of A with the properties

(i) $\rho|J \neq 0$,
(ii) J is "essential" in A, i.e., $a \in A$ and $a \cdot J = \{0\}$ implies $a = 0$, and
(iii) the ideal J has property pi-n (if A has property pi(n)).

Moreover, if A has property pi(m) then there exists $n \geq m$ such that A has property pi-n. But until now (Febr 2022 ?) no estimating function $f(m) \in \mathbb{N}$ is known with the property that A is pi-$f(m)$ and $f(m) \geq m$ if A has property pi(m). It seems that such estimating functions $m \to f(m)$ depend from topological properties of Prim(A).

We give an overview about the known results and open questions concerning non-simple (locally, weakly or strongly) purely infinite algebras in Section 11 of this chapter – with some parts of the needed proofs postponed to later sections and chapters, because there are then the needed observations available for the reader.

By Definition 1.2.1 in the Introduction Chapter 1, a C^*-algebra A is *purely infinite*, if and only if, A has a property that is formally weaker than the Property pi(1) of Definition 2.0.4: But it suffices to require that A has no non-zero character

– instead to require the additional property that $\ell_\infty(A)$ has no character as it is extra required in Definition 2.0.4.

We give later in Proposition **??** a list of order between infiniteness.

In fact, – without (!) some sort of infiniteness –, there *could be* examples of separable (non-simple?) C^*-algebras A that have no irreducible representations of finite dimension but that $\ell_\infty(A)$ has a non-zero character. Then $\mathcal{M}(A)/A$ has a character ??? and, for all $b \in A$, the sequence $(b, b, \ldots) \in \ell_\infty(A)$ is in the kernel ideal of this representation.

It is related to questions about the ultrapowers of states on A and finite dimensional quotients of $\mathcal{M}(A)/A$.

`What about` $A := M_{2^\infty} \otimes \mathbb{K}$`?`
`Why` $\mathcal{M}(A)/A$ `should have a "character"?` Reference ?? The question if this A has no character is equivalent to the questions: Has $\mathcal{M}(A)$ a character ?? Has $\mathcal{M}(A)$ a trace?

It turns out that A is purely infinite in sense of Definition 1.2.1, if and only if, each non-zero element $a \in A$ is properly infinite in the sense of Definition 2.1.1. But this says that A has Property pi-1 of Definition 2.0.6. See Corollary 2.5.6 for a proof of this equivalences based on a more engaged discussion of the variety of notions of “infinity” of elements and of pure infiniteness of C^*-algebras. It is still not known (2022 ?) what happens in case $n = 2$, e.g. even in case of $\mathrm{C}([0,1], A)$ for non-simple properly infinite C^*-algebras A. Up to some special cases, it is not known (Jan 2022 ?) if Property pi-1 implies that A is *strongly purely infinite* in sense of Definition 1.2.2, except in some very particular cases, e.g. if A contains “many projections” in a sense perhaps equivalent to A having “real rank zero”, or where the lattice of closed ideals of A is linear ordered ...

Recall that a non-zero element $a \in A_+$ is called *n-homogenous* if there exists a (non-zero) C*-algebra morphism $\psi : \mathrm{C}_0((0,1]) \otimes M_n \mapsto A$ with $a = \psi(f_0 \otimes 1_n)$, where $f_0(t) := t \in (0,1]$. With other words: There exists a non-zero positive contraction $b \in A_+$ (e.g. with $b := \psi(f_0 \otimes e_{1,1})$ and elements $c_2, \ldots, c_n \in A$ with $c_j^* c_j = b$, $c_j^* b = 0$ and $c_j^* c_k = 0$ for $j \neq k$, $j, k \in \{2, \ldots, n\}$. Then the n-homogenous $a \in A$ becomes $a = b + c_2(c_2^*) + \cdots + c_n(c_n^*)$.

The comparison between the definitions should be reached with the formulations with help of the J. Cuntz semigroup and by absence of traces ! No (non-zero) hereditary quasi-traces

Let us finish all this possible ideas concerning pure infiniteness of C*-algebras A by the following (until here weakest) definition of pure infiniteness:

We say that a C^*-algebra A has **property pi-n** (or: A is pi-n) if, for each non-zero $a \in A$, the n-fold direct sum $a \oplus a \oplus \cdots \oplus a = a \otimes 1_n$ is properly infinite in $M_n(A)$, if considered as a diagonal matrix in $M_n(A)$.

There is a relation between the two definitions:

Above pi-n says that $a \otimes 1_n$ is s.p.i. in $M_n(A)$ for all $a \in A$. It is not obvious that this implies that $a = b + c_2(c_2^*) + \cdots + c_n(c_n^*)$ (like in Definition 2.0.7) is properly infinite. But the diagonal matrices with diagonals $(a, 0, 0, ..., 0)$, $(b, c_2c_2^*, ..., c_n(c_n^*))$ and $(b, b, ..., b)$ are equivalent in $M_n(A)$. The diagonal matrix $(b, b, ..., b) = b \oplus b \oplus \cdots \oplus b$ is p.i. in $M_n(A)$ if A has the property pi-n of Definition 2.0.6. This matrix is MvN-equivalent to $(a, 0, ..., 0) = a \oplus 0 \oplus \cdots \oplus 0$ in $M_n(A)$. Thus, the Property pi-n of Definition 2.0.6 implies the formally weaker Property "pi-n" of Definition 2.0.7.

It is now the question: What happens with the others: pi-n, pi(n), ...?

Definition 2.0.7. We say that a C^*-algebra A is "*locally n-purely infinite*" if

(i) No (non-zero) hereditary C^*-subalgebra D of A has a (non-zero) character.
(ii) Each (non-zero) n-homogenous positive contraction $a \in A$, $a := b + c_2(c_2^*) + \cdots + c_n(c_n^*)$ with $c_k^* c_j = \delta_{j,k} b$, has the property that $a \oplus c \precsim a$ for each $c \in J_+$, where $J \subseteq A$ is the closed ideal generated by b (that contains the element a).

In particular Part(ii) implies that any n-homogenous positive contraction $a \in A$ is properly infinite in A. And Part(i) is equivalent to the property that no irreducible representation of A has a non-zero compact operator in its image.

Below part of old text ?? Begin of change?

property pi-n (or: A is pi-n) if, for each non-zero $a \in A$, the n-fold direct sum $a \oplus a \oplus \cdots \oplus a = a \otimes 1_n$ is properly infinite in $M_n(A)$.

We define in the next section a formally (much?) weaker property of pure infiniteness on C^*-algebras in Definition **??**. weak.p.i. ? Each ?????

1. Infinite elements, factorization and transitivity

This section collects basic definitions concerning infiniteness and some needed technical lemmata that are interesting in itself and play a role in several poofs in the other chapters. But some of those proofs will be postponed and then given or outlined in the Appendices A and B, simply to run not too far away from the main topic of this chapter: A small portion of many ideas for non-commutative versions of “infiniteness”.

We recall first our later often used definitions of *infinite*, *properly infinite*, *stable*, *n-infinite*, *n-properly infinite* and *n-homogenous* positive elements of a C^*-algebra A, and some equivalents of it. Notice that we have changed and refined them for our applications, because those given by other authors have only applications to very special types of C^*-algebras. See e.g. some remarks below and in other chapters on this differences.

New way:

All the variants of infiniteness imply the last n-homogenous variant.

(THAT is not clear now! And, if it is so, then the reachability in n-steps shows only that all $(n+1)$-homogenous elements are properly infinite. It requires the additional assumption that no hereditary C*-subalgebra D of A has a character.

But it is, in case of non-simple separable C*-algebras A, not enough to show that all non-zero elements $a \in A_+$ are infinite – but for each pure state ρ on $D := \overline{aAa}$ there exists an in D non-zero "infinite" element $d \in D_+$ with $\rho(d) > 0$.)

It is important to consider those definitions that carry over to suitable separable C*-sub-algebras of A ...

The minimal requirement should be that for every hereditary C*-subalgebra $D \subseteq A$ and every pure state ρ on D there exists an infinite positive contraction $d \in D$ with $\rho(d) > 2/3$. "Infinite" means here that there exists non-zero $e \in D_+$ with $e \oplus d \precsim_D d$ ...

No!!! We must require that the ideal J of D generated by the elements $e \in D_+$ with the property $e \oplus d \precsim_D d$ contains d, i.e., $d \oplus d \precsim_D d$ and d is properly infinite. This means that we have to find $e \in D_+$ with $e \oplus d \precsim_D d$ and $\rho(e) > 0$.

How is this related to:

1) No hereditary C*-subalgebra $D \subseteq A$ has a character

(i.e. equivalently (!): no irreducible representation ρ of A contains the compact operators in its image.),

and

2) There exists (general and fixed) $n \in N$ with the property that, for each $a \in A_+$, $b \in A_+$ with b in the closed ideal J_a of A generated by a, and $\varepsilon \in (0, \|a\|)$, there exists $d_1, \ldots, d_n \in A$ with $\sum_{k=1}^{n} d_k^* a d_k = (b - \varepsilon)_+$.

(Can we here replace this by $n := f(m)$ for a suitable function f and the requirement that $a \otimes 1_m$ is properly infinite in $M_m(A)$?)

!!! But it is not clear if we must require (below, later or here) that there exists suitable $e \in D_+$ with $\rho(e) > 1/2$ and $e \oplus d \precsim_D d$. !!!

If we require here that there exists $e \in D_+$ with $\rho(e) \neq 0$ and $e \oplus d \precsim_D d$, then this would show that d itself must satisfy $d \oplus d \precsim_D d$, i.e. that d is p.i. (and not only infinite).

The point in the case of separable C*-algebras A is that in each non-zero hereditary C*-subalgebra D of a quotient A/J there exists a properly infinite element in D. This generates "maximal" properly infinite elements in the quotients hereditary C*-sub-algebras of A.

If one has then an extension theorem (that is yet not available) for (rather special) extensions of separable C*-algebras with p.i. strictly positive elements. Then one can try to find out if the extension has also a p.i. strictly positive element.

The problem is then to show that every separable subset X of A is contained in a separable C*-sub-algebra B of A, that is again suitably generated by infinite elements ..., has again this (given) local pure infiniteness ... :

In particular it says: $c \oplus b \precsim_B b$ if $b, c \in B \subseteq A$ and $c \oplus b \precsim_A b$.

Requirements:

(1) No non-zero hereditary C*-sub-algebra D of A has a character. (This is equal to the property that for every irreducible representation ϕ of A does not intersect the algebra of compact operators.)

(2) if D is a non-zero σ-unital hereditary C*-sub-algebra of A, and $J \neq A$ a closed ideal of A, such that D is not contained in J, then (the requirement is that) $E := D/(D \cap J) \subseteq A/J$ contains an infinite element, i.e. there exists non-zero elements $f, g \in E_+$ with $g \oplus f \precsim_E f$.

But we need the stronger property: For every $a \in A_+$ and every closed ideal J of A with $a \notin J$ there exists a non-zero element $b \in (A/J)_+$ with $b \oplus \pi_J(a) \precsim_{A/J} \pi_J(a)$.

It says a is contained in the closed ideal J_a of A defined by: $e \in J_a$, if and only if, $e \oplus a \precsim_A a$. The element $\pi_{J_a}(a)$ is always finite in A/J_a.

Thus $a \in A$ is properly infinite

(or is "purely infinite" ??)

in A, i.e., $a \oplus a \precsim_A a$) if and only if, for every closed ideal J of A $\pi_J(a)$ is infinite in A/J or $a \in J$ (i.e., that $\pi_J(a) = 0$).

(This relation in $M_2(E)$ for $E := D/(D \cap J)$ is here the same as the relation $g \oplus f \precsim_{A/J} f$ in $M_2(A/J)$. One should require more precise that ?????

The point is:

So far, we can all reduce to the separable case (– depending much from the chosen definition of "locally infinite" elements! –), then we can reduce our study to separable A, and then for given $d \in A_+$ and let $D := \overline{dAd}$ there exists a "maximal" closed ideal $J := \overline{eAe} = \overline{eDe}$ of D with the property that $e \in D_+$ is

(1.) strictly positive in J and

(2.) e is properly infinite in D,

This maximality comes in the case of separable D from the fact that there exists an extremal closed ideal J of D such that J the strictly positive elements $e \in J$ of J are all properly infinite, i.e. $e \oplus e \precsim_J e$.

This existing ($\approx$-) maximal p.i. contraction $e \in D_+$ should turn out (by a suitable proof) to be strictly positive in D, i.e. $J = \overline{eAe}$ and $e \oplus e \precsim_J e$.

The proof is likely indirect:

(1.) We have to show that for each closed ideal of J of D with $D \neq J$ that each non-zero σ-unital hereditary sub-algebra E of D/J exists a (non-zero) infinite element $e \in E_+$.

that is ????

We could pass to $F := \{a \in D; \pi_J(a) \in E\}$. Then $J \subseteq F \subseteq D$ and F is hereditary in D and in A. Moreover, $J \subseteq F$ is a closed ideal of F.

If J is σ-unital then F is again σ-unital (as D by definition).

Since one can all reduce to the separable case (by preserving $\precsim$ with some care !) we can always suppose and use that all is σ-unital.

It is necessary and sufficient to consider the case of hereditary C*-sub-algebras D of separable C*-algebras A ... Each closed ideal J of D is the intersection $J = I \cap D$ of a closed ideal I of A with D.

This implies that ?????.

and D/J contains again a properly infinite element $f \in D/J$ ... ...)

All can be reduced to a suitable separable C*-sub-algebra B of A that contains a given separable subspace X of A and satisfies that $b_1 \precsim_{M_n(B)} b_2$ for $b_1, b_2 in M_n(B)$ if and only if $b_1 \precsim_{M_n(A)} b_2$.

(THAT IS NOT obvious ...)

All are compatible with inductive limits (of this separable subspaces).

In this sense:

It is likely that many p.i.-elements appear in the separable case:

There, in hereditary $D \subseteq A$, are (inside D) extremal (!) positive p.i. elements $d \in D_+$, in the sense that for every p.i. element $e \in D_+$ with $d \in \overline{eDe}$ holds that $e \precsim_D d$ (and automatically $d \precsim_D e$). The separability of A (and then that of D) secure that the closed ideal $J \supseteq D$ of D generated by d has the property that a strictly positive contraction of $f \in J_+$ has the property that $d \approx f$. It implies that there are elements $a_n, b_n \in A$ with $a_n^* d a_n = (f - 2^{-n})_+$ (by proper infiniteness of d) and $b_n^* f b_n = (d - 2^{-n})_+$. It shows that for the corresponding open projections $p, q \in A^{**}$ that define D and J are equal, i.e. we get that $D = J$.

(In fact then $J := \overline{dDd}$ is for such $d \in D_+$ is always an ideal of D by the maximality and this could give then also uniqueness! ???).

(NEXT: try to use this to show that "p.i." implies "s.p.i." ??? Find it in the appendix ??? !!!!!!)

SOME TECHNICAL CONSIDERATIONS:

Let $a, b \in A_+$ with $\|a\| \leq 1$ and $\|b\| \leq 1$, then straight calculation shows that

$$2(a - (a - b)_+) = (a + b) - \sqrt{(a - b)^2}.$$

Notice here that $\sqrt{(a - b)^2} = |a - b|$.

$a - (a - b)_+$ and $b - (b - a)_+$ have norms $\leq 2\|ab\|$

Pedersen book: Proposition 1.3.8.: If $0 < \beta \leq 1$ the function $t \mapsto t^\beta$ is operator monotone for each $t \in [0, \infty)$.

I.e. in a C*-algebra A, then $a, b \in A_+$, $0 < \beta \leq 1$, $a \leq b$ implies $a^\beta \leq b^\beta$.

(we need case $\beta = 1/2$).

Does it follow that $\|b^\beta - a^\beta\| \leq \|b - a\|^\beta$, at least for $\beta = 1/2$?

(cite here Pedersen book ...?)

The relevant formula for the needed decompositions by the estimate for contractions $a, b \in A_+$ is given by some estimate like (?? upper next is not really checked !)

$$\|(a + b) - |a - b|\| \leq 2\|ab\|,$$

or $\leq (2\|ab\|)^{1/2}$ and the (correct !) equation:

$$2(a - (a - b)_+) = (a + b) - \sqrt{(a - b)^2}.$$

Notice here that $\sqrt{(a - b)^2} = |a - b|$.

Needs study of operator-monotone function:

Something like $\|x - y\| \leq \|x^2 - y^2\|^{1/2}$ for $x, y \in A_+$??? or equivalently $\|a^{1/2} - b^{1/2}\| \leq \|a - b\|^{1/2}$ for $a, b \in A_+$ by operator-monotony of the map $a \in A_+ \mapsto a^{1/2}$.

SEE APPENDIX "C" !!! for more.

DEFINITION 2.1.1. An element $a \in A_+$ is **infinite** if there exists *non-zero* $b \in A_+$ such that, for every $\varepsilon > 0$, there exist $d_1, d_2 \in A$ (depending on ε) with

$$\|d_1^* a d_1 - a\| < \varepsilon, \quad \|d_2^* a d_2 - b\| < \varepsilon \quad \text{and} \quad \|d_1^* a d_2\| < \varepsilon\,. \tag{1.1}$$

Expressed by use of the Cuntz semigroup as: $a \oplus b \precsim_A a$ in $\mathcal{C}\sqcap(A)$.

A non-positive element a in $\mathrm{Ped}(A)$ is called "infinite" if $a^* a$ is infinite.

The element $a \in A_+$ is **properly infinite** if we can take $b := a$ in the second of the Inequalities (1.1).

Thus $a \in A$ and $a \oplus a \precsim_A a$ says that a is a properly infinite element of A.

We call a non-zero element $a \in A$ **stable** if the σ-unital hereditary C^*-subalgebra $\overline{a^* A a}$ is a stable C^*-subalgebra of A.

Notice here that $\overline{a^* A a}$ is stable, if and only if, $\overline{a A a^*}$ is stable. Following Lemma shows that Property pi-n of Definition **??** implies Property pi(n) of Definition 2.0.4.

LEMMA 2.1.2. *Let A denote a C^*-algebra and let $a \in A$ a non-zero element in A. Suppose that there exist $\ell \in \mathbb{N}$ sequences of elements $D_\ell, E_\ell \in M_{n+1}(A)$ with*

$$\lim_{\ell \to \infty} D_\ell \,\mathrm{diag}(a, \ldots, a, 0) E_\ell = \mathrm{diag}(a, \ldots, a, a)\,. \tag{1.2}$$

Then $1_n \otimes a$ is properly infinite in $M_n(A) \cong M_n \otimes A$, and, for each element $b \in J(a)$ in the closed ideal $J(a)$ of A generated by a and $\varepsilon > 0$, there exists $f_1, \ldots, f_n, g_1, \ldots, g_n$ with $\|b - \sum_{k=1}^n f_k a g_k\| < \varepsilon$. If a and b are positive then one can find here the elements $f_k, g_k \in A$ with $f_k = g_k^*$.

Let $a, b_1, b_2, \ldots \in A_+$ *contractions with the properties that* $(a-\varepsilon)_{\otimes}1_n$ *and* $(b_k - \varepsilon)_+ \otimes 1_n$ *are properly infinite in* $M_n(A)$ *or zero for each* $\varepsilon \in (0,1]$*.*

Then $b := (b_1, b_2, \ldots) \in \ell_\infty(A)$*, (respectively* $b := (a, a, \ldots)$*) has the property that* $h(b) \notin \mathbb{K}(\mathcal{H})$ *for every irreducible representation* $h \colon \ell_\infty(A) \to \mathcal{L}(\mathcal{H})$*, i.e.,* $h(b)$ *is not compact if* $h(b) \neq 0$*.*

In particular, if $a \otimes 1_n$ *is properly infinite in* $M_n(A)$ *for each non-zero element* $a \in A_+$*, then* $\ell_\infty(A)$ *has no irreducible representations that contains compact operators in its image.*

Especially $a \in A$*, respectively* $(a, a, \ldots)$ *and* $(b_1, b_2, \ldots)$ *in* $\ell_\infty(A)$ *are contained in the kernel of all irreducible representations of finite dimension of* A*, respectively of* $\ell_\infty(A)$ *.*

PROOF. The equations 1.2 say that $1_{n+1} \otimes a \precsim 1_n \otimes a$ in the $\precsim$-terminology of J. Cuntz, or, even more abstractly expressed, that $(n+1)[a] \leq n[a]$, in the pre-ordered "large" Cuntz semi-group $\mathrm{Cu}(A)$, cf. Section 5 in Appendix A, our definitions in Section

section 2.infinitesimal **??**

and Definition 2.5.1.

We can repeat the approximation by suitable choice of *new* operators $D_{\ell,m}, E_{\ell,m} \in M_{n+m}(A)$ beginning with $D_{\ell,1} := D_\ell$, $E_{\ell,1} := E_\ell$ and the suitable products $D_{\ell,m} := \mathrm{diag}(1_m, D_\ell) \in M_{m+k}(A)$ and $E_{\ell,m} := \mathrm{diag}(1_m, D_\ell) \in M_{m+k}(A)$ to get that $1_{n+m+1} \otimes a$ is the limit of $D_{\ell,m}((1_{n+m} \otimes a) \oplus 0)E_{\ell,m}$ for $\ell \to \infty$.

The following uses that generally $\mathrm{diag}(h(b), \ldots, h(b)) \cong (h \otimes \mathrm{id}_n)(b \otimes 1_n)$ is properly infinite in $C \otimes M_n$ if $h(b) \neq 0$ and $b \otimes 1_n$ is properly infinite in $B \otimes M_n$, for each given C^*-morphism $h \colon B \to C$.

Notice here that positive compact operators $c \in \mathbb{K}(\mathcal{H})_+ \subseteq \mathcal{L}(\mathcal{H})$ have the property that $((c \otimes 1_n) - \varepsilon)_+ = (c - \varepsilon)_+ \otimes 1_n$ is finite or zero for each $\varepsilon > 0$, – because they have finite rank in $\mathbb{K}(\mathcal{H}) \otimes M_n \cong \mathbb{K}(\mathcal{H} \otimes \ell_2(n))$. In particular, $c = 0$ if $c \geq 0$, $c \otimes 1_n \in \mathbb{K}(\mathcal{H}) \otimes M_n$ and $((c \otimes 1_n) - \varepsilon)_+ = (c - \varepsilon)_+ \otimes 1_n$ is properly infinite or zero for each $\varepsilon > 0$.

Let $B := \ell_\infty(A)$ and $b := (b_1, b_2, \ldots)$ or $b := (a, a, \ldots)$ in B_+, respectively $B := A$ and $b := a \in A$, with the property that $(b - \varepsilon)_+ \otimes 1_n$ is zero or properly infinite in $B \otimes M_n$.

Suppose that there exists irreducible representation $h \colon B \to \mathcal{L}(\mathcal{H})$ such that $h(b)$ is a non-zero compact operator on $\mathcal{H}$.

Let $h \colon B \to \mathcal{L}(\mathcal{H})$ an irreducible representation, and suppose that $h(b)$ is compact, i.e., $h(b) \in \mathbb{K}(\mathcal{H})$. Then, for $\iota := \mathrm{id}_{M_n}$, $(h \otimes \iota)(b \otimes 1_n) \in \mathbb{K}(\mathcal{H}) \otimes 1_n \subseteq \mathbb{K}(\mathcal{H} \otimes_2 \ell_2(n))$ and $(h \otimes \iota)((b - \varepsilon)_+ \otimes 1_n) = ((h(b) \otimes 1_n) - \varepsilon)_+$. Thus, $(h \otimes \iota)((b - \varepsilon)_+ \otimes 1_n)$ has non-zero finite rank in the Hilbert space $\mathcal{H} \otimes_2 \ell_2(n)$ for $\varepsilon \in (0, \|b\|)$, or $((h(b) \otimes 1_n) - \varepsilon)_+ = 0$. But, by assumption, $(b - \varepsilon)_+ \otimes 1_n$ is properly infinite if $\varepsilon \in (0, \|b\|)$. It follows that $((h(b)\otimes 1_n) - \varepsilon)_+$ is properly infinite or zero, and that $((h(b)\otimes 1_n) - \varepsilon)_+$ has finite rank. Thus, $((h(b)\otimes 1_n) - \varepsilon)_+ = 0$ for every $\varepsilon > 0$, i.e., $h(b) = 0$. It says $h(b) = 0$ if $h(b) \in \mathbb{K}(\mathcal{H})$.

Thus, the images of irreducible representations of A and $\ell_\infty(A)$ can not contain compact operators. In particular, they have no irreducible representations that contain non-zero compact images in its images. □

If we use Lemma 2.1.9, then we can see that an element $a \in A_+$ is *infinite* if there exists non-zero $b \in A_+$ with the property that for every $\varepsilon > 0$ there exists $\delta \in (0, \varepsilon)$ and $d := d(a, b, \varepsilon, \delta) \in M_2(A)$ such that

$$d^*\big((a-\delta)_+ \oplus 0\big)d \;=\; (a-\varepsilon)_+ \oplus (b-\varepsilon)_+\,.$$

Clearly the element $a \in A_+$ is *properly infinite* if we find for each $\varepsilon > 0$ some $\delta > 0$ and $d := d(a, \varepsilon) \in M_2(A)$ such that

$$d^*\big((a-\delta)_+ \oplus 0\big)d \;=\; (a-\varepsilon)_+ \oplus (a-\varepsilon)_+\,.$$

It is not difficult to obtain from Definition 2.1.1 that positive $a \in A_+$ is *properly* infinite *inside* the hereditary C^*-subalgebra $D := \overline{aAa}$ of A if and only if a is properly infinite in A, cf. the arguments in the proof of Proposition 2.2.5(i).

It implies that every stable element is properly infinite. But (non-zero) properly infinite *projections* are obviously not stable.

Sometimes it is useful to allow also $a = 0$ to be "properly infinite" (respectively "stable") in the formulation of some results, but notice that 0 is not an infinite element by *our* Definition 2.1.1.

But the Definition 2.1.1 of (non-properly infinite but) infinite elements allows to conclude only that a is infinite in A if (and only if) a^*a is infinite inside the hereditary C^*-subalgebra $D := \overline{a^*Aa} = \overline{(a^*a)A(a^*a)}$. Therefore $a \in A$ is infinite in A if and only a is infinite inside the closed ideal $J(a) := \overline{\mathrm{span}(AaA)}$ of A generated by a, cf. the "compression" arguments in the proof of Proposition 2.2.5(i).

By Lemma 2.5.3(v), a non-zero $a \in A_+$ is properly infinite if (and only if) $\pi_J(a)$ is zero or infinite in A/J for every closed ideal J of A. It implies e.g. that all non-zero elements in A_+ are properly infinite in A if A is purely infinite in the sense of Definition 1.2.1, which is, almost verbatim, equal to the below considered property pi(1) in Definition 2.0.4, and this turns later out to be equal to property pi-1 of Definition 2.0.6, and says that each non-zero $a \in A_+$ is properly infinite.

But the "property pi-1" defined in Definition 2.0.7 seems to be different. because it requires that a is 2-homogenous. ???

We ask here for some care, because different definitions of infiniteness of elements in some publications do not imply infiniteness in the sense of our Definition 2.1.1, e.g. H. Lin and Sh. Zhang gave in [**532**, def. 1.1] the following definition for positive elements a in the Pedersen ideal $\mathrm{Ped}(A)$:

An element $a \in \mathrm{Ped}(A)_+$ is called *infinite* in [**532**], if there are nonzero positive elements b and c in $\mathrm{Ped}(A)_+$ such that $bc = cb = 0$, and there exist sequences (x_n) and (y_n) in A such that $b+c = \lim_n x_n^* c x_n$, and $c = \lim_n y_n^* a y_n$. In our terminology, this property of $a \in \mathrm{Ped}(A)_+$ is equivalent to $c \precsim a$ and is slightly stronger than $b \in I_A(c)$, i.e., c is infinite and a majorize c. And, in our terminology, this implies that $[a] \geq [c]$ in $\mathrm{Cu}(A)$ and that c is infinite. Lemma 2.1.6 shows that in case of *simple* C^*-algebras A the definition [**532**, def. 1.1] of infinite elements is equivalent to our notion of *infinite elements* given in our Definition 2.1.1. The existence of a nonzero element $b \in A_+$ with $bc = 0$ and $b + c \precsim c$ inside A is not *equivalent* to infiniteness of c if the C^*-algebra A is not simple. But it is a *sufficient* condition for being infinite in non-simple C^*-algebras, cf. Lemma 2.5.4.

This definitions of proper infiniteness are not the same in case of non-simple C^*-algebras A:

Let A here denote the unitization of $\mathrm{C}_0(0,1] \otimes \mathcal{O}_2$: Then $1 \otimes 1 \geq f_0 \otimes 1$ and the element $f_0 \otimes 1 \sim_{MvN} f_0 \otimes (s_1 s_1^*)$ is properly infinite in A in the sense of definition [**532**, def. 1.1], because $f_0 \otimes (s_1 s_1^*)$ is orthogonal to the element $f_0 \otimes (s_2 s_2^*)$. But $1 \otimes 1$ is finite, because a non-unitary isometry can not be homotopic to 1 in $\mathcal{O}_2$ inside the class of isometries. We don't know if the above cited definition of Lin and Zhang of infinite elements are equivalent to our definition at least for non-simple A with *real rank zero*, (but didn't see a counterexample). Consider the unitization of $\mathrm{C}_0(X, \mathcal{O}_2)$ for $X := C \cap (0,1]$, where $C \subset [0,1]$ is the Cantor subset. The unit is infinite but is not properly infinite: It can't be properly infinite because restriction to a zero-sequence in X shows this by observing that $(1,1,\ldots)$ is not properly infinite in $c_0(\mathcal{O}_2) + \mathbb{C} \cdot (1,1,\ldots) \subset \ell_\infty(\mathcal{O}_2)$.

Let $A \subset \ell_\infty(\mathcal{O}_2)$ denote the C^*-algebra generated by $c_0(\mathcal{O}_2)$ and the unit element $(1,1,\ldots) \in \ell_\infty(\mathcal{O}_2)$, then each element of A is infinite, but $(1,1,\ldots)$ is not *properly* infinite in A. This A has real rank zero and each projection is infinite, but only the elements of $c_0(\mathcal{O}_2)$ are properly infinite.

But for *projections* a, b, c in a C^*-algebra A of real rank zero the projection a is infinite in sense of our Definition 2.1.1 if one restricts the definition of Lin and Zhang only to projections $a, b, c \in A$. It says then only that each non-zero projection a that satisfies their conditions has the property that $a = p + q$ with p an infinite projection.

We have to consider also several non-simple C^*-algebras with non-zero real rank if we study general purely infinite C^*-algebras.

Some conditions allow only to see that diagonal elements $\mathrm{diag}(a, a, \ldots, a) = a \otimes 1_n \in M_n(A) \cong A \otimes M_n$ are infinite or properly infinite for some unknown (!) fixed $n \in \mathbb{N}$, e.g. this is the case where one can show only that $\ell_\infty(A)$ has no non-trivial quasi-trace. We are forced to variate and refine the Definition 2.1.1 in the following manner:

DEFINITION 2.1.3. An element $a \in A_+$ is **n-infinite** (respectively is **n-properly infinite**), if $a \otimes 1_n$ is infinite (respectively is properly infinite) in $A \otimes M_n$.

An element $a \in A_+$ is **n-stable** if the hereditary C^*-subalgebra $D := \overline{(a \otimes 1_n)(A \otimes M_n)(a \otimes 1_n)}$ of $A \otimes M_n$ contains a stable hereditary C^*-subalgebra E that is *full* in D.

Notice that here n-stability of $a \in A_+$ only means that the stable $E \subseteq D$ generates the same ideal of $A \otimes M_n$ as D does.
Important warning: 1-stable elements $a \in A_+$ are not necessarily stable elements in the sense of Definition 2.1.1.

If each element $a \in A_+$ is n-infinite (or n-properly infinite), then at least every n-homogenous element $a \in A_+$ is infinite (respectively n-properly infinite) in A, and it is always contained in the kernel of every irreducible representation of A of dimension $< n$. It is also contained in the kernel of Of all irreducible representations od dimension n if a is n-properly infinite.

We remind the definition of n-homogenous positive elements:

DEFINITION 2.1.4. An element $a \in A_+$ is called **n-homogenous**, if there exists a C^*-morphism $\rho\colon \mathrm{C}_0(0,1] \otimes M_n \to A$ with $\|a\| \cdot \rho(f_0 \otimes 1_n) = a$ for the generator $f_0(t) = t$ of $\mathrm{C}_0(0,1]$.

The proof of Proposition A.8.4. or [**538**, prop. 2.7], give the following equivalent description of an n-homogenous element $a \in A_+$: There exist – *not uniquely determined* – contractions $z_2, \ldots, z_n \in A$ with properties $z_k z_j^* = 0$ for $j \neq k$, $z_j z_k = 0$ for $j, k = 2, \ldots, n$ and $z_j^* z_j = z_2^* z_2$ for $j = 3, \ldots, n$, such that $a = \|a\| \cdot (z_2^* z_2 + \sum_{k=2}^n z_k z_k^*)$.

A C^*-morphism $\rho\colon \mathrm{C}_0(0,1] \otimes M_n \to A$ with $\|a\| \cdot \rho(f_0 \otimes 1_n) = a$ is then defined by $\{z_2, \ldots, z_n\}$ and the assignments

$$\rho\colon\ f_0 \otimes p_{k,1} \ \mapsto\ z_k\,.$$

By Remark 2.1.16, a C^*-algebra A contains an n-homogenous element $a \in A_+$ with $\|a\| = 1$ if A is not a k-sub-homogenous C^*-algebra for some $k < n$.

Recall that C^*-algebra A is **k-sub-homogenous** if A is isomorphic to a C^*-subalgebra of $M_k(C)$ for some *commutative* C^*-algebra C. This happens, if and only, if all irreducible representations of A have dimension $\leq k$. All *separable* k-sub-homogenous C^*-algebras are C^*-subalgebras of $M_k \otimes \ell_\infty = \ell_\infty(M_k)$.

Our notions of n-homogenous and of n-stable positive elements have nothing in common, because n-stable elements $a \in A_+$ have the property that $a \otimes 1_n$ is properly infinite in $M_n(A)$, but n-homogenous $a \in A_+$ have not necessarily this property, as e.g. $a := 1_n \in M_n$.

Sometimes we use following important property of n-homogenous elements: If $a \in A_+$ is n-homogenous, then $a \otimes p_{11} \in A \otimes M_n$ is MvN-equivalent to $b \otimes 1_n$ in $M_n(A) \cong A \otimes M_n$ for suitable $b \in \overline{aAa}_+$ that commutes with a in A.

We allow only in some exceptional cases for all the above given definitions of properties of elements $a \in M_n(A)$ that $a = 0$, then just to simplify the formulation of conditions or of results.

Remark 2.1.5. Some authors prefer to use (completely positive) "order-zero morphisms" $\psi \colon C \to A$ from C to A instead of C^*-algebra homomorphisms $h \colon \mathrm{C}_0((0,1], C) \to A$. Those ψ are often used in cases where $C = M_n$ (and more generally if C is of finite dimension).

The order-zero morphisms ψ are defined as completely positive linear maps $\psi \colon C \to A$ with $\|\psi\| \leq 1$ and the property that $\psi(c)\psi(d) = 0$ for all $c, d \in C_+$ with $cd = 0$. In particular, $\psi(c) := h(f_0 \otimes c)$ is an order-zero morphism if $h \colon \mathrm{C}_0((0,1], C) \to A$ is a C^*-algebra homomorphism.

We modify in Section 9 of Appendix A arguments in the proofs of [**838**, thm.2.3] of M. Wolff and of W. Winter and J. Zacharias in [**836**], where they show that for each completely positive order-zero map $\psi \colon C \to A$ there exists a unique C^*-algebra homomorphism $h \colon \mathrm{C}_0((0,1], C) \to A$ with $h(f_0 \otimes c) = \psi(c)$ for all $c \in C$.

In fact we need for our recovery of h from ψ only the 2-positivity of the linear map ψ and the orthogonality property of ψ on C_+, i.e., that $\mathrm{id}_{M_2} \otimes \psi$ is positive and that $\psi(c)\psi(d) = 0$ for $c, d \in C_+$ for $cd = 0$. to obtain the latter, cf. Section 9 of Appendix A.

A crucial starting point for the study of simple purely infinite C^*-algebras was observed first by J. Cuntz. It is the nice observation stated in the following Lemma 2.1.6. Its proof should be an exercise, – e.g. by using an argument that is a bit more elementary than using properties of the general Cuntz relation $\precsim$ on elements of $A \otimes \mathbb{K}(\ell_2)$.

Lemma 2.1.6. *Suppose that A is a* simple *C^*-algebra. Let $a, b \in A_+$. If $a \leq b$ and a is infinite in A, then a and b are both* properly *infinite in A, and a is properly infinite inside the hereditary C^*-subalgebra $\overline{aAa}$ of A.*

This Lemma does not apply to non-simple C^*-algebras, cf. Example 2.5.13, but it is also a very special case of Lemma 2.5.3(i) on the Cuntz majorization $\precsim$ in arbitrary C^*-algebras.

Another often used fact is Part (ii) of the following Lemma 2.1.7 concerning stably generated ideals, and ideals generated by ideals of C^*-subalgebras. The first statement in each item plays a particular role `Consider blue changes! Give new proofs?// Consider also the remark before proof!// Compare with Lemma 2.7.3!!`

LEMMA 2.1.7. *Let A a C^*-algebra, $B \subseteq A$ a C^*-subalgebra, and let J the closed ideal of A that is generated by B, i.e., J is the closed linear span of the set of products $A \cdot B \cdot A$.*

(o) *The* set $B \cdot A \cdot B$ *of products $b_1 a b_2$ with $b_1, b_2 \in B$ and $a \in A$ is the same as the hereditary C^*-subalgebra $E := \overline{\text{span}(BAB)}$ of A generated by B, where* span$(\,\cdot\,)$ *denotes the linear span, i.e., no addition operations or approximations are needed to get* all *elements of the hereditary C^*-subalgebra E from the set of products $b_1 a b_2$.*

In particular, B is hereditary in A, if and only if, the set $B \cdot A \cdot B$ *is equal to B.*

(i) *If the unit $1_{\mathcal{M}(B)}$ is properly infinite in $\mathcal{M}(B)$, then the hereditary C^*-subalgebra $E = B \cdot A \cdot B$ of A contains a* stable *hereditary C^*-subalgebra D of A that generates the same closed ideal J of A as generated by B (also generated by E).*

(ii) *If the unit $1_{\mathcal{M}(B)}$ is properly infinite in $\mathcal{M}(B)$, and $a_1, a_2, \ldots \in J_+$ is any sequence in J, then there exists a sequence $d_1, d_2, \ldots \in A$ with the properties $d_j^* d_k = \delta_{jk} a_k$ and $d_k d_k^* \in D \subseteq E$.*

(iii) *In particular, if $p \in \mathcal{M}(A)$ is a non-zero* properly *infinite projection, then pAp contains a* stable *hereditary C^*-algebra D such that the ideal J generated by D contains pAp.*

(iv) *If, moreover, B is stable then $1_{\mathcal{M}(B)}$ is properly infinite and the hereditary C^*-algebra $E = BAB$ itself is stable.*

(v) *(Ideal-separation and ideals of hereditary C^*-subalgebras)*

Let $B \subseteq A$ a C^*-subalgebra of A and denote by $J_B := \overline{\text{Span}(ABA)}$ the closed ideal of A generated by B.

Consider the maps $\Phi \colon Y \mapsto \overline{\text{Span}(AYA)}$ from the family of all subsets $Y \subseteq A$ of A into the family closed ideals of A, and the map $\Psi \colon I \mapsto I \cap B$, from the family of closed ideals I of A into the closed ideals J of B.

Then, $\Phi(\Psi(I)) = I \cap J_B$ for each closed ideal I of A, if and only if, the elements of B separate the closed ideals of the hereditary C^*-subalgebra BAB of A.

If,– in addition –, each closed ideal of J of B is the intersection $J = I \cap B$ of a closed ideal $I \subseteq A$ with B then the restriction $\Phi | \mathcal{I}(B)$ of Φ to the family of closed ideals J of B is the inverse map of the map $I \mapsto B \cap I$, i.e., $\Psi(\Phi(J)) = J$ each for each closed ideal J of B.

Thus, then $J = B \cap \overline{\text{Span}(AJA)}$ for all ideals $J \in B$ and $I = \overline{\text{Span}(A(B \cap I)A)}$ for all closed ideals | of A.

In particular, for all hereditary C^*-subalgebras D of A and every closed ideal I of A, the closed ideal $D \cap I$ of D generates the closed ideal $I \cap J_D$ of A and each closed ideal K of D is the intersection $K = D \cap I$ of the closed ideal I of A generated by K.

PROOF. (o): Let $E := \overline{\text{span}(B \cdot A \cdot B)}$ the closed linear span of the elements $b_1 a b_2 = (b_2^* a^* b_1^*)^*$ with $a \in A$ and $b_1, b_2 \in B$.

Clearly, $E \subseteq A$ is a hereditary C^*-subalgebra of A, and E is a non-degenerate left and right B-module. Moreover for every countable subset X of E there exists a sequence of positive contractions $b_1, b_2, \ldots \in B_+$ such that $x = \lim_n b_n x = \lim_n x b_n$ for all $x \in X$. If we let $d := \sum_n 2^{-n} b_n$, then

$$X \subseteq \overline{d \cdot E \cdot d} \subseteq \overline{d \cdot A \cdot d} \subseteq E\,.$$

We can apply the factorization theorem of G.K. Pedersen [**621**, thm. 4.1] to the non-degenerate $C^*(d)$-bimodule $\overline{d \cdot E \cdot d} \subseteq E$, cf. also our special version in Theorem A.11.1. This allows to see that for each finite sequence $e_1, \ldots, e_n \in \overline{d \cdot E \cdot d} \subseteq E$ there exists a positive contraction $d_0 \in C^*(d)_+ \subseteq B_+$ and elements $f_1, \ldots, f_n \in E$ such that $e_k = d_0 f_k d_0$ for $k = 1, \ldots, n$. In particular, E is identical with the set $B \cdot A \cdot B$ of products $b_1 a b_2$ with $a \in A$ and $b_1, b_2 \in B$.

(i): The non-degenerate *-monomorphism defined by the inclusion $B \hookrightarrow E := B \cdot A \cdot B$ defines a unital *-monomorphism $\mathcal{M}(B) \hookrightarrow \mathcal{M}(E)$.

By assumptions, there are isometries $s, t \in \mathcal{M}(B) \subseteq \mathcal{M}(E)$ with orthogonal ranges. Then $s_1 := s$, $s_n := t^{n-1}s$ for $n = 2, 3, \ldots$ correspond to a unital C^*-morphism from $\mathcal{O}_\infty$ into $\mathcal{M}(E)$.

Thus, $\mathcal{M}(E)$ has a properly infinite unit, i.e., contains a copy of $\mathcal{O}_\infty := C^*(s_1, s_2, \ldots\,;\ s_j^* s_k = \delta_{jk} 1)$ unitally. The C^*-subalgebra D of E generated by $\{s_k e s_j^*\,;\ j, k \in \mathbb{N}, e \in E\}$ is a stable C^*-subalgebra of E because D is the closure of $\bigcup_{m,n} s_m E s_n^*$, which implies that $D \cong E \otimes \mathbb{K}$, e.g. via the isomorphism ψ given by $\psi(e \otimes p_{kj}) = s_k e s_j^*$ for the matrix units p_{jk} of $\mathbb{K}$.

The D is full in E and is hereditary in E, because it is the closure of the union of the increasing family of split corners $P_n E P_n$ of E with $P_n := s_1 s_1^* + \cdots + s_n s_n^*$, $s_1 E s_1^* \subset P_n E P_n \subset E$, and $s_1 e s_1^* \sim_{MvN} e$ inside E for each $e \in E_+$.

Hence, D, E and B generate the same closed ideal $J := \overline{\operatorname{span}(ABA)}$ of A.

(ii): By Part (i), D is isomorphic to $E \otimes \mathbb{K}$ via natural transformation with help of the isometries $s_1, s_2, \ldots \in \mathcal{M}(E)$. (But the s_n are not necessarily in $\mathcal{M}(D)$.)

If we use that $\mathbb{K} \otimes \mathbb{K} \cong \mathbb{K}$ we get isometries $T_n \in \mathcal{M}(\mathbb{K})$ with $T_j^* T_k = \delta_{jk} 1$ such that $\sum_k T_k T_k^*$ strictly converges to the unit $1_{\mathcal{M}(\mathbb{K})}$. It follows that the isometries $S_k := 1 \otimes T_k$ are isometries in $\mathcal{M}(E) \otimes \mathcal{M}(\mathbb{K}) \subseteq \mathcal{M}(E \otimes \mathbb{K})$ such that $\sum_k S_k S_k^*$ converges strictly to 1 in $\mathcal{M}(E \otimes \mathbb{K})$. The isomorphism ψ from D onto $E \otimes \mathbb{K}$ extends to a strictly continuous *-isomorphism $\mathcal{M}(\psi)$ from $\mathcal{M}(D)$ onto $\mathcal{M}(B \otimes \mathbb{K})$. Then the sequence $t_1, t_2, \ldots \in \mathcal{M}(D)$ of isometries $t_k := \mathcal{M}(\psi)^{-1}(S_k)$ has the property that $t_j^* t_k = \delta_{jk} 1$ and that $\sum_k t_k t_k^*$ converges in $\mathcal{M}(D)$ strictly to 1.

It is enough to show that for each $a \in J_+$ there exists an element $h \in J$ with $h^* h = a$ and $hh^* \in D$ to obtain the requested elements $d_n \in D$:
Indeed, we find for the given sequence $a_1, a_2, \ldots \in J_+$ a sequence $h_1, h_2, \ldots \in J_+$ with $h_k^* h_k = a_k$ and $h_k h_k^* \in D$. Then the elements $d_k := t_k h_k$ satisfy $d_j^* d_k = \delta_{jk} a_k$ and $d_k d_k^* \in D$.

Let $a \in J_+$ where $J := \overline{\operatorname{span}(A \cdot D \cdot A)}$, and let $\varepsilon > 0$.

Then D is full in J, and there are $e_1,\ldots,e_m \in D_+$ and $f_1,\ldots,f_m \in J$ with $\|a-b\| < \varepsilon$ for $b := \sum_j f_j^* e_j f_j$.

If we use Lemma 2.1.9, then we find $c \in A$ such that $g_1 := f_1c,\ldots,g_m := f_nc \in A$ with $\sum_j g_j^* e_j g_j = (a-\varepsilon)_+$. The element $x := \sum_j t_j(e_j)^{1/2} g_j \in A$ satisfies $x^*x = (a-\varepsilon)_+$ and $xx^* \in D$. The latter uses that D is hereditary and $t_je_jt_j^* \in D$. In particular $x \in J$. Let $\nu(t) := (t-\varepsilon-\delta)_+/(t-\varepsilon)_+$, the element $y := x(1-\nu(a))^{1/2}$ satisfies $y^*y = (a-\varepsilon)_+ - (a-\varepsilon-\delta)_+$.

In this way, we find $y_1, y_2, \ldots \in J$ with $y_ny_n^* \in D$, $y_1^*y_1 = (a-1/2)_+$, $y_n^*y_n = (a-2^{-n})_+ - (a-2^{2-n})_+$ for $n>1$. Then $h := \sum_n t_ny_n$ is an element of the requested type, because the series is absolutely convergent by

$$\|t_ny_n\| \leq \|y_n\| \leq \|(a-2^{-n})_+ - (a-2^{-(n-1)})_+\|^{1/2} \leq 2^{-n/2} \quad \text{for} \quad n>1,$$

$h^*h = \sum_n y_n^*y_n = a$ and $hh^* = \lim_{n\to\infty}(\sum_{j,k\leq n} t_jy_jy_k^*t_k^*) \in D$.

(iii): There are partial isometries $u, v \in A$ with $u^*u = v^*v = p$ and $uu^*+vv^* \leq p$. Let $B = C^*(u,v)$. Then $\mathcal{M}(B) = B$ and $1_{\mathcal{M}(B)} = p$ is properly infinite, $E = pAp$ and D is the closure of $\bigcup_{m,n} s_mEs_n^*$, where here $s_n := u^{n-1}v$ for $n = 1,2,\ldots$ and $u^0 := p$. Notice that $ps_np = s_n$ and $s_j^*s_k = \delta_{jk}p$.

(iv): The C^*-algebra B is stable, if and only if, its multiplier algebra $\mathcal{M}(B)$ contains a sequence $t_1, t_2, \ldots$ of isometries with mutually orthogonal ranges, such that the sum $\sum_n t_nt_n^*$ converges to $1_{\mathcal{M}(B)}$ in the strict topology of $\mathcal{M}(B)$, cf. Remark 5.1.1(8) for more about "stability".

The natural map $\iota\colon \mathcal{M}(B) \to \mathcal{M}(E)$ is injective, unital and strictly continuous for $E = BAB$. Therefore $s_1 := \iota(t_1)$, $s_2 := \iota(t_2)$, $\ldots \in \mathcal{M}(E)$ satisfy again $\sum_n s_ns_n^* = 1$. Thus, E is stable if B is a stable.

(v): The subsets $\Phi(Y) := \overline{\mathrm{Span}(AYA)}$ of A are the closed ideals of A generated by non-empty subsets Y of A, in particular $J_B := \Phi(B)$ is the smallest closed ideal of A with $B \subseteq J_B$. Notice that $\Phi(I\cap B) \subseteq I \cap J_B$ for all closed ideals of I of A, and $\Phi(\Phi(Y)) = \Phi(Y)$ for all non-empty subsets $Y \subseteq A$ of A.

Let I a closed ideal of A. Recall that $\Psi(B\cap I)$ is the closed ideal of A generated by $B\cap I$. Since $B\cap I$ is contained in the ideal $J_B\cap I$, it follows that

$$\Psi(B\cap I) \subseteq J_B \cap I.$$

And it implies that $B\cap \Psi(B\cap I) = B\cap I$, because $B\cap I \subseteq \Psi(B\cap I)$ and $B\cap(J_B\cap I) = B\cap I$ by $B\subseteq J_B$.

The above equations show that $B\cap(J_B\cap I) = B\cap\Psi(B\cap I)$, which is equivalent to $B\cap(D\cap I) = B\cap(D\cap\Psi(B\cap I))$ for the hereditary C^*-subalgebra $D := B\cdot A\cdot B$, cf. Part (i).

It follows: The C^*-subalgebra B of A separates the closed ideals of $D := B\cdot A\cdot B$, if and only if, B separates the ideals of J_B, if and only if, the ideal $J_B\cap I$ of J_B that is generated by $B\cap I$ for all closed ideals I of J_B, i.e., each closed ideal of J_B is determined by its intersection with B.

Thus, always $B \cap \Psi(I \cap B) = B \cap I$, or B does not separate the closed ideals of BAB, respectively of J_B.

It follows then that $I \cap B = \Psi(I \cap B) \cap B$ for all closed ideals I of A. Thus, if B is separating for the ideals of J_B (or – equivalently – for the ideals of $D := B \cdot A \cdot B$) then this says that $\Psi(I \cap B) = I \cap J_B$ for all closed ideals I of A.

But the ideals $I \cap B$ are not all ideals of B if B is not hereditary in A. There are examples of finite-dimensional C^*-algebras A where B can have much more closed ideals than the special ideals $I \cap B$ for ideals I of A. □

EXAMPLE 2.1.8. The stable C^*-subalgebra D defined in the proof of Lemma 2.1.7 is not necessarily equal to E, because $B := A := \mathcal{O}_\infty$ satisfy our assumptions, but $E := \mathcal{O}_\infty$ and $J = \mathcal{O}_\infty$ are not stable.

The behaviour of the isometries and elements constructed during the proof has to be considered with some care because they are usually not in $\mathcal{M}(A)$:
Consider the C^*-algebra $A := \mathcal{O}_\infty \otimes \mathbb{K}$, and a pure state ρ on $\mathcal{O}_2$. Let $L := \{c \in \mathcal{O}_2\,;\ \rho(c^*c) = 0\}$ the closed left-ideal corresponding to ρ and $B := (L^* \cap L) \otimes p_{11} \subset A$. Then B is a full stable hereditary C^*-subalgebra of A, and the algebras $B \subseteq A$ satisfy with $E = B = D$ and $J = A$ all the assumptions of Lemma 2.1.7, where here B itself is full, stable and hereditary, but the in the proof of Lemma 2.1.7(i) defined and used isometries and projections $s_n, P_n \in \mathcal{M}(B) \subseteq \mathcal{M}(E)$ are *not* elements of $\mathcal{M}(J) = \mathcal{M}(A)$. But there exists an element $X \in A$ with X^*X strictly positive in A and XX^* strictly positive in B that creates an almost canonical isomorphism from $\mathcal{M}(B) \subset B^{**} \subset A^{**}$ onto $\mathcal{M}(A) \subseteq A^{**}$ by the isometry $V \in A^{**}$ given by the polar decomposition $X = V(X^*X)^{1/2}$.

Beginning of transport back from Appendix A:
Replace e.g. all ‘‘Lemma lem:A.old.2.5 (iv)’’ by Remark 2.1.16

The following often used Lemma is [**463**, lem. 2.4(iii)]. We give here a different proof that is short, elementary and does not use results about operator monotone functions. The self-adjoint operator $a_+ - a_-$ is the polar decomposition of $a^* = a$.

LEMMA 2.1.9. *Suppose that $a \in \mathcal{M}(A)$, $b \in A$ and $\gamma \in [0, \infty)$ satisfy in $\mathcal{M}(A)$ that*

$$0 \leq b \leq a + \gamma \cdot 1 .$$

Then, for every $\varepsilon > \gamma$, there exists $d := d(\varepsilon) \in \overline{bC^*(a,b)b} \subseteq A$ with

$$\|d\| \leq 1 \qquad \text{and} \qquad d^*\, a_+\, d = (b - \varepsilon)_+ .$$

In particular, there exists $d \in A$ with $\|d\| \leq 1$ and $d^* a_+ d = (b - \varepsilon)_+$ if $a^* = a \in A$ and $b \in A_+$ satisfy $\|b - a\| < \varepsilon$.

PROOF. Let $\varphi(t) := \big((t-\gamma)_+^{-1}(t - (\varepsilon+\gamma)/2)_+\big)^{1/2}$ and $g := \varphi(b) a_+ \varphi(b)$.

The function $\varphi(t)$ is zero on $[0, \mu]$ for $\mu := (\varepsilon + \gamma)/2 > \gamma$ and is a non-negative continuous function on $[\mu, \infty)$. It is increasing because $\varphi(t)^2 = 1 - (\mu - \gamma)(t-\gamma)^{-1}$

for $t \in [\mu, \infty)$. This and the inequalities $0 < \gamma < \mu < \varepsilon$ imply $(t-\gamma)_- \cdot \varphi(t) = 0$, $\varphi(t) \in [0,1)$, $0 \le \varphi(b) \le \varphi(\|b\|) \cdot 1$. Recall that $(b-\varepsilon)_+ \le (b-\mu)_+$ for $0 \le \mu \le \varepsilon$.

Then $\|\varphi(b)\| < 1$, $\varphi(b) \cdot (b-\gamma)_- = 0$ and

$$(b-\varepsilon)_+ \le (b-\mu)_+ = \varphi(b)(b-\gamma)\varphi(b) \le g\ . \tag{1.3}$$

We define d as the norm-limit of the elements $d_n := \varphi(b)(g+1/n)^{-1/2}(b-\varepsilon)_+^{1/2}$:

The $d_n \in A$ are contractions and the sequence $(d_1, d_2, \ldots)$ converges in A, because $\|\varphi(b)\| \le 1$ and Inequality (1.3) imply $\|d_n^* d_n\| \le 1$ and, by monotony of the C^*-norms on the cone of positive operators, that

$$\|d_n - d_m\|^2 \le \| g(g+1/n)^{-1} - g(g+1/m)^{-1} \| \le 2/\min(n,m)\,.$$

It is obvious from the definition of the d_n that $(b-\varepsilon)_+ = \lim_n d_n^* a_+ d_n$, – and this convergence is independent from the above shown convergence for the sequence (d_n).

If $a^* = a \in A$ and $b \in A_+$ satisfy $\gamma := \|b-a\| < \varepsilon$, then $b \le a + \gamma$. □

Remark 2.1.10. It seems to be well-known folklore that matrices $a = [a_{j,k}] \in M_n(A)$ have operator norm estimates

$$\|a\| \le n \cdot \max\{\|a_{j,k}\|\,;\ 1 \le j,k \le n\}\,.$$

Moreover, one gets the better estimate

$$\|a\| \le (n-1) \cdot \max\{\|a_{j,k}\|\,;\ 1 \le j,k \le n\}\,.$$

if the "diagonal" sub-matrix $\mathrm{LR}(n) = \mathrm{diag}(a_{1,1}, a_{22} \ldots, a_{n,n})$ of $[a_{j,k}]$ has only zero entries,.

The estimate follows from the choice of n sub-matrices $\mathrm{LR}(\ell)$, $\ell \in \{1,\ldots,n\}$, each with at most n non-zero suitably chosen entries $a_{j,k}$, e.g. with $(k-j)\mathrm{mod}\ell$ for $\ell \in \{1,\ldots,n\}$ in $\mathbb{Z}/n\mathbb{Z}$, and the property that $\mathrm{LR}(\ell)^*\mathrm{LR}(\ell)$ is a diagonal matrix. Thus, the norm of $\mathrm{LR}(\ell)$ is given exactly by the maximum of the norms of the entries of $\mathrm{LR}(\ell)$. Then $\|a\| \le$ the sum of the norms of this sub-matrices.

See Section 18 in Appendix B for more details on such sub-matrices.

An immediate consequence of Lemma 2.1.9 is the following observation:

Lemma 2.1.11. *Let $e_1, e_2, \ldots, e_n \in A$ and $\gamma > (n-1) \cdot \|e_j^* e_k\|$ for all $j > k$. Then there exists a contraction $D = [d_{j,k}] \in M_n(A)$ such that $f_j^* f_k = \delta_{j,k}(e_k^* e_k - \gamma)_+$ for the elements $f_k := e_1 d_{1,k} + e_2 d_{2,k} + \ldots + e_n d_{n,k}$ with $k \in \{1,2,\ldots,n\}$.*

Proof. Consider the matrices $a, b \in M_n(A)_+$ defined by

$$a := [e_1,\ldots,e_n]^* \cdot [e_1,\ldots,e_n] \quad \text{and} \quad b := \mathrm{diag}(e_1^* e_1, \ldots, e_n^* e_n)\,.$$

The matrix $a - b \in M_n(A)$ has zero diagonal elements, Remark 2.1.10 applies and says that

$$\|a-b\| \le (n-1) \cdot \max\{\|e_j^* e_k\|\,;\ 1 \le j < k \le n\}\,.$$

Lemma 2.1.9 provides a matrix $D = [d_{jk}] \in M_n(A)$ that satisfies $D^*aD = (b-\gamma)_+$ and hast norm $\|D\| \leq 1$. $\square$

We need in Chapter 3 and other places the equivalences for a given element $h \in A_+$ listed in the following Lemma:

LEMMA 2.1.12. *Let A a C^*-algebra, $h \in A_+$ and $2 \leq q \in \mathbb{N}$.*

The following properties (a, i)–(a,iii) *of h are equivalent:*

(a, i) *For every $\varepsilon > 0$, there exist $e_1, e_2, \ldots, e_q \in A$ with $\|e_j^* e_k - \delta_{j,k} h\| < \varepsilon$ for $j, k \in \{1, 2, \ldots, q\}$.*

(a, ii) *For each $\gamma > 0$ and $\psi \in \mathrm{C}_0(0, \|h\|]_+$ with $\psi|[0,\gamma] = 0$ there are elements $e_1, \ldots, e_q \in A$ with $e_j^* e_k = \delta_{jk} \cdot \psi(h)$ for $j, k \in \{1, \ldots, q\}$.*

(a,iii) *Each element $g \in \overline{hAh}_+$ satisfies the property in part* (a, i) *– with g in place of h.*

The following, considerable stronger, properties (b, i)–(b,iv) *of $h \in A_+$ and the closed ideal $J := J(h) \subseteq A$, generated by h, are equivalent to each other:*

(b, i) *For every $a \in J_+$ and $\varepsilon > 0$ there exist elements $e_1, e_2 \in A$ with*

$$\|e_j^* e_k - \delta_{jk} a\| < \varepsilon \quad \text{for } j, k \in \{1, 2\}.$$

(b, ii) *For each $n > 1$ and $\varepsilon > 0$ there exist elements $e_1, \ldots, e_n \in A$ with*

$$e_j^* e_k = \delta_{jk}(h - \varepsilon)_+ \quad \text{for } j, k \in \{1, 2, \ldots, n\}.$$

(b,iii) *For every $a \in J_+$, $n \in \mathbb{N}$ and $\varepsilon > 0$ there exist $d_1, \ldots, d_n \in J$ such that*

$$d_j^* d_k = \delta_{jk}(a - \varepsilon)_+ \quad \text{for } j, k \in \{1, 2, \ldots, n\}.$$

(b,iv) *$A_\infty := \ell_\infty(A)/c_0(A)$ contains a stable hereditary C^*-subalgebra D such that the element $\Delta(h) := (h, h, \ldots) + c_0(A)$ is contained in the closed ideal of A_∞ generated by D.*

We do not require in part (a, i) that $e_j e_j^* \in \overline{hAh}$, e.g. the case $A = M_2$, $q = 2$ and $h = p_{11}$ shows that the properties (a, i) and (b, i) are very different.

The property (b, i) in Lemma 2.1.12 applies to all $a \in A_+$ e.g. if the unit element of $\mathcal{M}(A)$ is properly infinite, or if – more general – A contains an approximate unit consisting of positive contractions e_σ that are M-vN equivalent to two orthogonal pairs of contractions, e.g. there are $f_\sigma, g_\sigma \in A$ with $f_\sigma^* g_\sigma = 0$, $f_\sigma^* f_\sigma = e_\sigma$ and $g_\sigma^* g_\sigma = e_\sigma$.

PROOF. All items are equivalent if $h = 0$. It suffices to consider on all places the cases where $\|h\| = 1$, $\|g\| = 1$ respectively $\|a\| = 1$, because otherwise we can rescale the $\varepsilon > 0$, $\gamma > 0$, and change the function $\psi \in \mathrm{C}_0(0, \|h\|]_+$ in a suitable manner.

Equivalence of (a, i), (a,ii) *and* (a,iii):

(a,iii) $\Rightarrow$ (a, i): $h \in C^*(h^3)_+ \subseteq \overline{hAh}_+$.

(a, i) $\Rightarrow$ (a,iii): Let $\|h\| = 1 = \|a\|$, $g \in \overline{hAh}_+$ with $\|g\| = 1$, $\varepsilon \in (0, 1/2)$ and $\gamma := \varepsilon/7$. There exists $a \in A$ with $a^* = a$ and $\|g^{1/2} - h^{1/2}ah^{1/2}\| < \gamma$, because $\overline{hAh} = \overline{h^{1/2}Ah^{1/2}}$. Then $\|g - h^{1/2}ahah^{1/2}\| < (2+\gamma)\gamma < \varepsilon/2$.

Let $\mu := \varepsilon/(1 + 2\|a\|^2)$, then $\|ah^{1/2}\|^2 \cdot \mu \leq \mu\|a\|^2 < \varepsilon/2$.

By assumption there exists elements $e_1, e_2, \ldots, e_q \in A$ with $\|e_j^* e_k - \delta_{j,k} h\| < \mu$ for $j, k \in \{1, \ldots, q\}$. Let $f_k := e_k a h^{1/2}$. Then $\|f_j^* f_k - \delta_{j,k} h^{1/2}ahah^{1/2}\| < \mu \cdot \|ah^{1/2}\|^2 \leq \mu\|a\|^2 < \varepsilon/2$. Hence, $\|f_j^* f_k - \delta_{j,k} g\| < \varepsilon$.

(a,ii) $\Rightarrow$ (a, i): Let $\varepsilon > 0$ and take $\delta := \varepsilon/2$ and $\psi(t) := \max(0, t - \delta)_+$.

(a, i) $\Rightarrow$ (a,ii): It follows from the special case where $\psi := \varphi_\gamma$ for $\gamma > 0$ and $\varphi_\gamma(t) := \max(0, t - \gamma)$. Indeed, if $\psi \in \mathrm{C}_0(0, \|h\|]_+$ with and $\psi|[0, 2\gamma] = 0$ is given, and $d_1, \ldots, d_q \in A$ exists with $d_j^* d_k = \delta_{jk} \cdot \varphi_\gamma(h)$, then the elements $e_k := d_k a$ satisfy $e_j^* e_k = \delta_{jk} \cdot \psi(h)$ for $a := \lambda(h)$ with $\lambda(t) := \big(\max(0, t-\gamma)^{-1}\psi(t)\big)^{1/2}$.

In the special case $\varphi_\gamma(h) = (h - \gamma)_+$ we can apply Lemma 2.1.11 to the situation in Part (a, i):
Let $\mu := \gamma/(q+1)$, and find $f_1, \ldots, f_q \in A$ with $\|f_j^* f_k - \delta_{j,k} h\| < \mu$. By Lemma 2.1.9 there exist contractions $g_k \in A$ with $g_k^* f_k^* f_k g_k = (h - \mu)_+$. It follows that still $\|g_j^* f_j^* f_k g_k\| \leq \|f_j^* f_k\| < \mu$ for $j \neq k$. The inequality $q \cdot \mu < \gamma$ allows to apply Lemma 2.1.11 and obtain $e_1, \ldots, e_q \in A$ with $e_j^* e_k = \delta_{jk} \cdot (h - \gamma)_+$ for $j, k \in \{1, \ldots, q\}$.

Equivalence of (b, i)–(b, iv):

We use the equivalence of (a, i)–(a,iii) to prove equivalence of (b, i)–(b,iv).

The implications (b,iii) $\Rightarrow$ (b, i) and (b,iii) $\Rightarrow$ (b, ii) are obvious. We show the implications (b, i) $\Rightarrow$ (b,iii), (b,ii) $\Rightarrow$ (b,iv) and (b,iv) $\Rightarrow$ (b, i).

(b, i)$\Rightarrow$(b,iii): The equivalence of (a, i) and (a, ii), applied to $a \in J_+$ in place of h and $q := 2$, shows that the property in Part (b, i) is equivalent to the property that, for every $a \in J_+$ and every $\varepsilon > 0$, there exist elements $e_1, e_2 \in A$ with $e_j^* e_k = \delta_{j,k}(a - \varepsilon)_+$, for $j, k \in \{1, 2\}$. Notice that all $e_1, e_2 \in A$ with this property are automatically in J.

We proceed by induction over $n \geq 2$ and suppose that we have shown that for every $a \in A_+$ and every $\varepsilon > 0$ there exist elements $e_1, e_2, \ldots, e_n \in A$ – depending from a and ε – that satisfy the following equations 1.4:

$$e_j^* e_k = \delta_{j,k}(a - \varepsilon)_+ \qquad \text{for } j, k \in \{1, 2, \ldots, n\}. \tag{1.4}$$

The assumptions in (b, i) allow to find $n + 1$ elements $e_1, \ldots, e_n, e_{n+1} \in A$ that satisfy Equation (1.4):

Let $\varepsilon > 0$, $a \in J_+$ and $\gamma := \varepsilon/3$ and $2 \leq n \in \mathbb{N}$. There exists $d_1, d_2, \ldots, d_n \in A$ with with $d_j^* d_k = \delta_{j,k}(a - \gamma)_+$ by induction assumption. This implies that $d_k \in J$, $d_k d_k^* \in J_+$ and $d_j^* d_k = 0$ for $j, k \in \{1, 2, \ldots, n\}$. Let $b := \sum_{k=1}^n d_k d_k^* \in J_+$. $(b - \gamma)_+ = \sum_{k=1}^n (d_k d_k^* - \gamma)_+$ because $d_j^* d_k = 0$ for $j \neq k$.

By assumptions in Part (b, i), there exists $f_1, f_2 \in A$ with $f_j^* f_k = \delta_{j,k}(b - \gamma)_+$.

The orthogonality of the $f_k f_k^*$, uniqueness of polar decomposition allow to show with functional calculus that $(b-\gamma)_+^{1/2} d_k = (d_k d_k^* - \gamma)_+^{1/2} d_k = d_k (d_k^* d_k - \gamma)_+^{1/2} = d_k (a-2\gamma)_+^{1/2}$. Thus, $(f_\ell d_j)^* f_\ell d_k = \delta_{j,k}(a-2\gamma)_+(a-\gamma)_+$. Recall that $\varepsilon = 3\gamma$ and (well-) define a function $\varphi \in \mathrm{C}_0(0, \|a\|]_+$ by

$$\varphi(t) := \big((t-\varepsilon)_+ \,/\, ((t-2\gamma)(t-\gamma)) \big)^{1/2} .$$

Then $e_k := f_1 d_k \varphi(d_k^* d_k)$ for $k \in \{1, \ldots, n\}$ and $e_{n+1} := f_2 d_1 \varphi(b)$ satisfy $e_j^* e_k = \delta_{j,k}(b-\varepsilon)_+$ for $j,k \in \{1, \ldots, n, n+1\}$.

(b,ii)⇒(b,iv): By assumptions of Part (b,ii) we can find $e_{k,n} \in A$, $k \in \{1, \ldots, n\}$ with the property

$$e_{j,n}^* e_{k,n} = \delta_{j,k}(h - 2^{-n})_+ \quad \text{for } j,k \in \{1, \ldots, n\} .$$

Define $e_{k,n} := 0$ for $k > n$, and elements $R_k \in A_\infty := \ell_\infty(A)/c_0(A)$ by

$$R_k := (e_{k,1}, e_{k,2}, \ldots, e_{k,n}, e_{k,n+1}, \ldots) + c_0(A) .$$

Then $R_j^* R_k = \delta_{j,k} \cdot \Delta(h)$ for all $j,k \in \mathbb{N}$. Thus, the closed linear span of the elements $R_j R_k^* \in A_\infty$ for $j,k \in N$ generate a stable hereditary C^*-subalgebra D of A_∞ ([6]). The $\Delta(h)$ is contained in the closed ideal of A_∞ that is generated by D.

(b,iv)⇒(b, i): Let $D \subseteq A_\infty$ a stable hereditary C^*-subalgebra of $A_\infty := \ell_\infty(A)/c_0(A)$ and let $I \subseteq A_\infty$ the closed ideal of A_∞ that is generated by D. If $(h,h,\ldots) + c_0(A) =: \Delta(h) \in I$ then $\Delta(a) \in I$ for each $a \in J = \overline{\mathrm{span}(AhA)}$.

By Lemma 2.1.7(ii), there exist for each element $b \in I_+$ elements $c_1, c_2 \in I$ with $c_1^* c_2 = 0$ and $c_1^* c_1 = c_2^* c_2 = b$. If we apply this to $b := \Delta(a)$ and take, for $k \in \{1,2\}$, elements $(d_1^{(k)}, d_2^{(k)}, \ldots) \in \ell_\infty(A)$ with norms $= \|c_k\|$ and $(d_1^{(k)}, d_2^{(k)}, \ldots) + c_0(A) = c_k$ then

$$\lim_{n\to\infty} \|(d_n^{(j)})^* d_n^{(k)} - \delta_{j,k} b\| = 0 \quad \text{for } j,k \in \{1,\, 2\} .$$

Thus, the inequality in Part (b, i) is satisfied if we let $e_1 := d_n^{(1)}$ and $e_2 := d_n^{(2)}$ for suitable $n \in \mathbb{N}$. □

Remark 2.1.13. It is not clear if the equivalent properties in Parts (b,i)–(b,iv) of Lemma 2.1.12 are also equivalent to the following version of "local stability":

For every $\varepsilon > 0$ there exists a stable hereditary C^*-subalgebra D_ε of A such that $(h-\varepsilon)_+$ is in the closed ideal of A generated by D_ε. ([7])

Remark 2.1.14. The implication (b, ii) ⇒ (b,iii) in Lemma 2.1.12 was very indirectly obtained in the proof of Lemma 2.1.12 by the row of implications:
(b, ii) → (b,iv) → (b, i) → (b,iii).
Here is an alternative direct proof for the implication (b, ii) ⇒ (b,iii):

Let $a \in J_+$, $n \in \mathbb{N}$ and $\varepsilon > 0$. Since a is a positive element in the ideal generated by h, there exist $m \in \mathbb{N}$ and elements $g_1, \ldots, g_m \in A$ and $\gamma \in (0, \varepsilon/2)$

[6] This D is isomorphic to $\mathbb{K} \otimes C^*(h)$

[7] It could be that this can be translated into a question about the existence of a full stable hereditary C^*-subalgebra in a certain hereditary C^*-subalgebra of an infinite *amalgamated free product*.

such that $\|a - \sum_{j=1}^{m} g_j^*(h-\gamma)_+ g_j\| < \varepsilon/2$. Let $q := mn$. By Part (b, ii) there exists q elements $e_{j,k} \in A$ with $e_{j,k}^* e_{j,k} = (h-\gamma)_+$ $(1 \le j \le m,\ 1 \le k \le n)$. The elements $f_k := \sum_{j=1}^{m} e_{j,k} g_j$ have the properties $f_\ell^* f_k = 0$ for $\ell \ne k$ and $\|a - f_k^* f_k\| < \gamma$ for $\ell, k \in \{1, \ldots, n\}$.

By Lemma 2.1.9 there exists contractions $d_k \in A$ with $d_k^* f_k^* f_k d_k = (a-\varepsilon)_+$. Thus, $e_j^* e_k = \delta_{j,k}(a-\varepsilon)_+$ for $e_k := f_k d_k$ and $j, k \in \{1, \ldots, n\}$.

Lemma 2.1.15 `covert by new lem:2.advance.Kadison.transit exhausting old:  lem:A.old.3.4b or lem:2.6-1`

The Part (i) of the following Lemma 2.1.15 is one of the possible characterization of projections in the "socle" of bi-duals A^{**} ([8]). The observation that they are "closed" projections imply a very important and often used "excision" result.

Lemma 2.1.15 (Generalized Kadison transitivity and Excision).

Let A a C^*-algebra and $p \in A^{**}$ a non-zero projection.

(i) *The W^*-subalgebra $pA^{**}p$ of A^{**} has finite dimension, if and only if, there are pairwise inequivalent irreducible representations $D_k \colon A \to \mathcal{L}(\mathcal{H}_k)$ and projections $q_k \in \mathcal{L}(\mathcal{H}_k)$* of finite rank *such that for the natural normal (and unital) extensions of D_k to A^{**} satisfy*

$$(D_1 \oplus \ldots \oplus D_n)(pap) = q_1 D_1(a) q_1 \oplus \ldots \oplus q_n D_n(a) q_n$$

for $a \in A$ and that $(D_1 \oplus \cdots \oplus D_n)|pA^{**}p$ is faithful on $pA^{**}p$ ([9]).

(ii) (Generalized Kadison transitivity.) *If $p \in A^{**}$ is a projection such that $M := pA^{**}p$ is finite-dimensional, then the natural C^*-morphism π from $\{p\}' \cap A$ into $pA^{**}p$, given by $a \mapsto ap$, is an* epimorphism, *and there exists a C^*-morphism*

$$\psi \colon\ \mathrm{C}_0((0,1], M) \to \{p\}' \cap A$$

such that $\pi(\psi(f)) = \psi(f)p = f(1)$ for all $f \in \mathrm{C}_0((0,1], M)$.

(iii) (Generalized Excision Lemma.) *Suppose that $M := pA^{**}p$ is finite-dimensional, $\Omega \subseteq A$ is a compact subset of A and*

$$\psi \colon\ \mathrm{C}_0((0,1], M) \to \{p\}' \cap A$$

[8] "socle" is french, but the english translation "base" does not fit here.

[9] Our notation does not distinguish between a representation D of A and its normal extension to A^{**}, given by $\Pi \circ D^{**}$ via the natural normal *-epimorphism $\Pi \colon \mathcal{L}(\mathcal{H})^{**} \to \mathcal{L}(\mathcal{H})$.

is any C^**-morphism such that*

$$\pi(\psi(f)) = \psi(f)p = f(1) \qquad \textit{for all } \; f \in \mathrm{C}_0((0,1], M)\,. \tag{1.5}$$

Then there exists a positive contraction $g \in A_+$ *with* $gp = p$ *such that*

$$\lim_{n\to\infty} \|g^n\big(a - \psi(f_0 \otimes pap)\big)g^n\| = 0 \quad \textit{for all } \; a \in \Omega\,, \tag{1.6}$$

where $f_0(t) := t$*, i.e.,* $(f_0 \otimes pap)(t) = t \cdot pap \in pA^{**}p$ *for* $t \in [0,1]$*.*

We can Ω replace by the compact set $\Omega \cup \{\psi(f_0 \otimes c)\,;\; c \in M, \|c\| \le 1\}$, without change of other assumptions or conclusions in Part (iii).

Notice that $b - \psi(f_0 \otimes pbp) \in L^* + L$ for all $b \in \Omega$, because $L^* + L$ is the kernel of $A \ni a \mapsto pap$, where $L \subseteq A$ denotes the closed left-ideal

$$L := \{a \in A\,;\; p(a^*a)p = 0\,\}\,.$$

A suitable decomposition of Ω could help / can help / to give a proof of Parts (ii) and (iii). See the arguments for the special case where L is a left-kernel of a pure state on A.

Proof. (i): If one does not go the “rigorous” way mentioned in our Remark 2.1.19 and use instead e.g. G.K. Pedersen’s improved version [**616**, thm. 2.7.5] of the Kadison transitivity theorem, then we have to show before at least the (almost obvious?) existence of some normal unital representation $H\colon A^{**} \to \mathcal{L}(\mathcal{H})$ with the property that the restriction to $pA^{**}p$ is faithful and that $H(p)$ has finite rank in $\mathcal{L}(\mathcal{H})$, i.e., it is necessary to show first that H can be selected with the additional property $H(p) \in \mathbb{K}(\mathcal{H})$. The following is such an elementary argument that shows the existence of H with this for the application of [**616**, thm. 2.7.5] very needed properties:

Let $p^*p = p \in A^{**}$ nonzero. Suppose that $pA^{**}p$ has finite (linear) dimension. Then there are projections $q_1, \ldots, q_n$ in the center of $pA^{**}p$ such that $q_kA^{**}q_k = q_kpA^{**}p \cong M_{n_k}$ and $q_1 + \ldots + q_n = p$. We find “minimal” projections $0 \ne e_k \le q_k$ with $e_kA^{**}e_k = \mathbb{C} \cdot e_k$. It implies that central projections $Q \in Z(A^{**})$ can only satisfy one of $Qq_k = q_k$ or $Qq_k = 0$. Moreover, $Qe_k = 0$ implies $Qq_k = 0$. Let R_k the maximal central projection with $R_ke_k = 0$ and let $Q_k := 1 - R_k$. The $Q_k \in Z(A^{**})$ is the central support projection of e_k and $A^{**}Q_k$ is a type-I-factor. By definition of the Q_k holds $pQ_k = q_k$, $Q_kQ_j = 0$ for $k \ne j$ and $p(Q_1 + \ldots + Q_n) = p$. Thus, there are Hilbert spaces $\mathcal{H}_k$ and normal *-isomorphisms $d_k\colon A^{**}Q_k \to \mathcal{L}(\mathcal{H}_k)$ from $A^{**}Q_k$ onto $\mathcal{L}(\mathcal{H}_k)$. Let $D_k(a) := d_k(aQ_k)$ for $a \in A$. Here we identify A with its natural image in the W*-algebra A^{**}. Clearly the restrictions $D_k|A$ to A of the normal *-representations D_k of A^{**} are pairwise non-equivalent irreducible representations of A and the normalization D of the direct sum $(D_1|A) \oplus \cdots \oplus (D_n|A)$ of this irreducible representations is identical with

$$D_1 \oplus \cdots \oplus D_n\colon\; A^{**} \to \mathcal{L}(\mathcal{H}_1 \oplus_2 \cdots \oplus_2 \mathcal{H}_n)\,.$$

Moreover $D(p)$ is a projection of finite rank $\mathrm{Rk}(p) \le \mathrm{Dim}(pA^{**}p)$.

Conversely, suppose that $p \in A^{**}$ is a projection and that pairwise inequivalent irreducible representations $D_k \colon A \to \mathcal{L}(\mathcal{H}_k)$, $k = 1, \ldots, n$ and projections $q_k \in \mathcal{L}(\mathcal{H}_k)$ of finite rank exist such that, for $a \in A$ and the normal extensions of D_k to A^{**} (again denoted by D_k), holds

$$(D_1 \oplus \cdots \oplus D_n)(pap) = q_1 D_1(a) q_1 \oplus \cdots \oplus q_n D_n(a) q_n$$

and that $(D_1 \oplus \cdots \oplus D_n)|pA^{**}p$ is faithful on $pA^{**}p$. Now use that irreducible *-representations are always non-degenerate, direct sums of non-degenerate *-representations are non-degenerate, and that normalizations of non-degenerate *-representations are unital. It follows that the direct sum $D := D_1 \oplus \cdots \oplus D_n$ of the normal extensions of D_k to A^{**} is unital, satisfies $D(p) = q_1 \oplus \ldots \oplus q_n$, – i.e., $D(p)$ has finite rank – and $D|pA^{**}p$ is faithful. Thus, $pA^{**}p$ has finite linear dimension (equal to sum of squares of the ranks $\sum_k \mathrm{Rk}(q_k)^2$). This properties show that the above selected representation $D \colon A \to \mathcal{L}(\mathcal{H})$ satisfies all assumptions of [**616**, thm. 2.7.5].

(ii): With Part(i) in hand, we are in position to use [**616**, thm. 2.7.5] and get the desired *surjectivity* of the natural C^*-morphism $\pi \colon \{p\}' \cap A \mapsto pA^{**}p$ with $\pi(a) := ap = pap$ for $a \in \{p\}' \cap A$.

Alternatively, – but with some in Remark 2.1.18 given *necessary additional* observations –, one could use also [**400**, thm. 5.4.5] and its generalization by S. Sakai [**704**, thm. 1.21.16] to derive this surjectivity.

In fact we decide here to use Part(i) to obtain – from the assumption that $pA^{**}p$ is of finite dimension – the following special kind of *-representation D exists:
Let D a normal unital *-representation of A^{**} onto a von-Neumann algebra in some $\mathcal{L}(\mathcal{H})$ and $p \in A^{**}$ is a projection such that $D|pA^{**}p$ is faithful and $D(p)$ is of finite rank, i.e., $\mathrm{Dim}(D(p)\mathcal{L}(\mathcal{H})) < \infty$. Then there exists a central projection $Q \in Z(A^{**})$ with $Qp = p$ such that $D|QA^{**}Q$ is faithful (and again unital).

Thus, the natural C^*-morphism $(\{p\}' \cap A) \ni a \mapsto pa \in pA^{**}p$ is surjective by this observation and [**616**, thm. 2.7.5].

(See Remark 2.1.18 or Remark 2.1.19 for alternative proofs of this surjectivity.)

Let π denote the natural *-epimorphism from $A_0 := \{p\}' \cap A$ onto $M := pA^{**}p$, and let $J := \ker(\pi)$, and consider the evaluation map $\eta \colon CM \to M$ given by $f \mapsto f(1) =: \eta(f)$ from $CM := \mathrm{C}_0((0,1], M)$ onto M. By Proposition A.8.4, the cone $CM := \mathrm{C}_0((0,1], M)$ is projective. Thus, there exist a C^*-morphism $\psi \colon CM \to A_0 \subseteq A$ with $\pi \circ \psi = \eta$.

(iii): Recall that $M := pA^{**}p$ and $CM := \mathrm{C}_0((0,1], M)$. By Part(ii), there exists a C^*-morphism $\psi \colon CM \to A_0 := \{p\}' \cap A$ that satisfies $\pi(\psi(f)) = f(1) = pf(1)p$ for all $f \in CM$.

The separable case has to do with Proposition A.15.2 and the determination of the multiplicative domain of $\pi_{L^*+L} \colon A \to A/(L^* + L)$ considered in Theorem A.16.5(iii). ?????

The excision result needs Lemma A.21.1 on peak elements.

The non-separable case can then be considered by selecting a suitable separable C^*-subalgebra B of A that contains $\psi(CM)$ and the given separable subset. This can be done with help of the separable selection Lemma B.14.1 and Proposition A.15.2.

Later ??? bring ??? Proposition A.21.4 back to Chapter 2.???

Or refers in place of his proof to here???

To get more precise in calculations we discuss some topics ... with help of listed below/above.. ???

Here, $p \in A^{**}$ is a projection such that $M := pA^{**}p$ is a C^*-algebra of finite (linear) dimension, π denotes the restriction to A_0 of the completely positive contraction $V_p(a) := pap$ for $a \in A^{**} \supseteq A$.

The C^*-subalgebra B_0 of A_0 generated by $\psi(CM)$ is separable and $B_0/(B_0 \cap J) = A_0/J \cong M$ is unital, where $J \subset A_0$ is the kernel of π.

Obviously (why ???) $J = D := A \cap ((1-p)A^{**}(1-p))$ is a hereditary C^*-subalgebra of A and is equal to the kernel ideal of $\pi\colon a \in A_0 \mapsto pa = pap \in A^{**}$.

$L := A \cap (A^{**}(1-p))$, $A =? = L^* + L + A_0$, $D = L^* \cap L = J$, $A_0 = B_0 + D = \mathcal{N}(A, D)$.

By Proposition A.15.2, $L^* + L$ is a closed linear subspace of A and the natural map $A/(L^*+L) \to pA^{**}p$ induced by $\pi\colon A \ni a \mapsto pap \in pA^{**}p$ defines a completely isometric isomorphism from $(A/(L^*+L))^{**}$ onto $pA^{**}p =: M$. Since $\pi(\psi(CM)) = M$ It follows that $A = L^*+L+\psi(CM)$. Let A_1 denote the separable C^*-subalgebra of A generated by $\Omega \cup \psi(CM)$. By Lemma B.14.1, there exists a separable C^*-subalgebras B of A with the property that $A_1 \subseteq B$ and $B \cap (L^* + L) = (B \cap L)^* + (B \cap L)$ and the natural map from $B/\big((B\cap L)^* + (B \cap L)\big)$ to $A/(L^*+L)$ is completely isometric and completely positive.

Since $A/(L^*+L) \cong M$ and $\pi_{L^*+L} \circ \psi = \mathrm{id}_M$ it follows that we can repeat the above consideration in case for separable A now for B and $\Omega \cup \psi(CM)$.

```
    Here possible end of proof,
if separable case is before completely shown.
Or is it below?
```

The crucial points of the proof are to show that the projection p is closed, and that the open support projection $q_D \in A^{**}$ of D is equal to $1-p$ and $J = D = L^* \cap L$.

Then $e \in A_+$ with $\|e\| = 1$, $e(1-e) \in D$, $ep = p$ and $e(1-e)$ strictly positive in D exists. By separability of D (if A is separable) and p is the unit of $M = pA^{**}p$.

Apply the Lemma A.21.1 to $E := \pi^{-1}(\mathbb{C} \cdot p) \subseteq A_0$ and J to get a positive contraction $g \in E$ with the properties that $\pi(g) = p$ and $g - g^2 \in J_+$ is strictly positive in J.

Then g is strictly positive in A and has the excision property of Equation (1.6).

(1) in case where A is separable, that $A = A_0 + DA + AD$ and that there exists $g \in (A_0)_+$ with $\|g\| = 1$, $\pi(g) = p$ and $g - g^2$ strictly positive in D. (Because then g has obviously the in (iii) proposed properties ????

$A_0 = \mathcal{N}(A, D) = D + \psi(CM)$???

(2) Reduction of the general case to the separable case if A is non-separable:

Find (!!!) separable C^*-subalgebra B of A with $\psi(CM) \cup \Omega \subseteq B$ such that $F := B \cap D$ satisfies $B = BF + FB + \psi(CM)$ and $B/(BF + FB) \cong M$ naturally.

(The point is to manage that $\mathcal{N}(B, F) \subseteq A_0$ and $BF = B \cap (AD)$.???)

Could it be that $\mathrm{dist}(b, BF) = \mathrm{dist}(b, AD)$ for all $b \in B$ is sufficient?

Notice that $\psi(CM) \cap D$ is an ideal of $\psi(CM)$.

Then apply above arguments to separable B (in place of A).

The argument works well if $D = J$ is σ-unital. Reduce to this case !!! ???

```
Next to be filled in / corrected !?
It is necessary to use characterizations of open and closed
projections -- as considered in Appendix A.
Take better all to there.
```

And $1 - p \in A^{**}$ is the "open" support projection of D, i.e., $D^{**} \cong \mathrm{wcl}(D) = (1 - p)A^{**}(1 - p)$.

We consider first the case where A is separable:

Cite here the Prop. ?? on closed/open projection!!!
Existence of contraction $e \in A_+$ with $pep = p$ has to be deduced!!!

There exists $e \in A_+$ with $pep = p$ and $\|e\| \leq 1$ by Part (ii), e.g. $e := \psi(f_0 \otimes 1_M)$.

Let $f \in D_+$ a strictly positive contraction for $D := L^* \cap L$, where $L := A \cap (A^{**}(1 - p))$.

Then $D = A \cap (1 - p)A^{**}(1 - p)$ is the kernel of the C^*-morphism $A_0 = \{p\}' \cap A \to pA^{**}p$, because $a \in \{p\}' \cap A$, if and only if, $a \in A \cap (pA^{**}p + (1 - p)A^{**}(1 - p))$. And $pap = 0$ if and only if $a \in (1 - p)A^{**}(1 - p))$.

We get for the above taken $e, f \in A_+$ that $e, f \in \{p\}' \cap A = \mathcal{N}(A, D)$, and that there exists $g \in (\{p\}' \in A)_+$ with $\|g\| \leq 1$, $pgp = p$ and $g(1 - g)$ is strictly positive in D.

Build g from e and f. !!!!!!

$a \mapsto pap = V(a)$ has kernel $A \cdot D + D \cdot A$???? $V(a - \psi(f_0 \otimes V(a))) = V(a) - pV(a) = 0$???

$g^n d, dg^n \to 0$ for all $d \in D$, because $g(1 - g)$ is strictly positive in D.

Way of arguments:

1) p is closed,

2) the open $1-p$ is the right support projection of the closed left ideal $L := A \cap A^{**}(1-p)$. (Thus $L^{**} = A^{**}(1-p)$.)

3) $pA^{**}p = pAp \cong A/(R+L)$ for $R := L^* := \{a^* ; \ a \in L\}$

4) $\{p\}' \cap A = \mathcal{N}(A, R \cap L)$

5) The completely positive map $V(a) := pap$ from A onto $pA^{**}p$ has kernel $L^* + L$?, i.e., $((1-p)A^{**} + A^{**}(1-p)) \cap A = L^* + L$, for $L := A \cap (A^{**}(1-p)) = \{a \in A ; \ ap = 0\}$ by p closed?

6) Cite here definition of $\mathcal{N}$?????

$A = L^* + L + \mathcal{N}(A, L^* \cap L)$

7) $D := L^* \cap L$ is ideal of $\mathcal{N}(A, D)$, $\mathcal{N}(A, D) = \{p\}' \cap A$.

8) ($M := pA^{**}p \neq \{0\}$ is finite-dimensional) $\Omega \subseteq A$ The compact subset Ω of A and the image of $\psi \colon \mathrm{C}_0((0,1], M) \to A$ generate a separable C^*-subalgebra B of A.

9) Can enlarge B to a separable C^*-subalgebra C of A such that $B \subseteq C$, $C \cap (R+L) = (C \cap R) + (C \cap L)$, $(C \cap D) \cdot C = L \cap C$, $\mathcal{N}(C, C \cap D) + C \cap (R+L) = C$,

$\{p\}' \cap C = \mathcal{N}(C, C \cap D)$

$(C \cap R) + (C \cap L)$ is always closed. See Appendices ??? behind Reduction to separable.

More ??

Now proceed as in case of separable A.

Fact list:

1. p is a closed projection with

$$p \in \mathrm{wcl}(\{p\}' \cap A) \cong \{p\}' \cap A^{**} = (1-p)A^{**}(1-p) + pA^{**}p$$

Needs that $pa^*ap = 0$ if and only if $a \in A^{**}(1-p)$.

π extends to the c.p. contraction $V \colon A \ni a \mapsto pap \in pA^{**}p$

i.e., $\{p\}' \cap A$ is the multiplicative domain of V.

1a.

$J :=$ kernel of π is the same as $D := A \cap (1-p)A^{**}(1-p)$, because $D \subseteq A_0$ and $D \subseteq J$. $a \in J \subseteq A_0$ implies $pa = ap = 0$, thus $a \in A$ and $a = (1-p)a(1-p)$.

and

1b.

$1 - p \in A^{**}$ is the open support projection of D,

???? Needs $pA^*p \cong (pA^{**}p)_*$ is $\sigma(A^*, A)$-closed ???

Unit ball of pA^*p is equal to unit ball of $X^\top$, for $X := \{a \in A ; \ v(a) = 0, \ v \in pA^*\}$???

because $J = D \subseteq (1-p)A^{**}(1-p)$ and the open support projection $q_D \in A^{**}$ of D is contained in the weak closure of of A_0 in A^{**} by $J = D$ and satisfies $q_D + p \leq 1$, i.e., $(1 - q_D) \geq p$. If $(1 - q_D) - p \neq 0$, then

$A_0/J \cong M = pA^{**}p$ via implies that $\mathrm{wcl}(A_0)/(q_D A^{**} q_D) \cong M$.

Needs $q_D A^{**} q_D = \mathrm{wcl}(D) \subseteq (1-p)A^{**}(1-p)$

The map $(1-q_D)A^{**}(1-q_D) \to pA^{**}p$ given by $(1-q_D)a(1-q_D) \mapsto pap$ is surjective, and is multiplicative for a in the weak closure of A_0 in A^{**}.

because p is a closed projection ????

why it is closed??? $pAp = pA^{**}p$ – confirmed in Part (ii).

1c.

The set $L := A \cdot D$ of products $a \cdot d$ is a closed left ideal of A, because the closed linear span of L is obviously contained in A and $L = L \cdot D$ by Cohen factorization.

(The arguments for this are similar to those in Part (o) in proof of Lemma 2.1.7.)

with $A/(L^* + L) \cong M$???

To be shown.

$D := L^* \cap L = L^* \cdot L$ is kernel of $\pi\colon \{p\}' \cap A \to M$. $D = ((1-p)A^{**}(1-p)) \cap A$? by $L = (A^{**}(1-p)) \cap A$

Needs: p closed, and $1 - p$ support of D.

$q \in A^{**}$ open then $qAq \subseteq A$

??? (If A is unital, then this is wrong in general, because then this implies $pinA$

$L = \overline{A \cdot D}$?

The C^*-morphism ϕ defines a linear map λ from A into $L^* + L$ given by $\lambda(a) := a - \phi(V(a))$.

Let $\{d_n\} \in D_+$ an approximate unit of D given by contractions

The rest is reduction to separable case.

We enlarge B_0 to the still separable C^*-algebra $B_1 := C^*(\Omega \cup B_0)$. The natural map $b \mapsto pbp$ is a completely positive contraction that maps the unit-ball of B_1 onto the unit ball of $pA^{**}p$ and maps $\phi(f_0 \otimes x)$ to $x \in pA^{**}p$.

But this is not enough to find in B_1 the desired positive contraction g. ....????

Let J the kernel ideal of $\{p\}' \cap A \to M := pA^{**}p = pAp$. Then one can show that $L := A \cdot J$ is a closed left ideal of A such that $L^{**} = A^{**}(1-p)$ (by noticing that p is a closed projection and $1-p$ is an open projection), that $\phi\colon A \ni a \mapsto pap \in M$ satisfies $\phi^{-1}(0) = L^* + L$ and defines a completely positive and completely isometric isomorphism from the C^*-system $A/(L^* + L)$ onto M.

If B is some separable C^*-subalgebra of A such that ϕ maps the closed unit-ball of B onto the closed unit-ball of M, then this does not imply that $B/(\phi^{-1}(0) \cap B)$ is completely isometric to M.

We must do a careful selection of a bigger separable C^*-algebra $B_e \supseteq B$ of A such that the kernel ideal I of $\pi|B_e \colon \{p\}' \cap B_e \to M$ defines a closed left-ideal $L_e := B_e \cdot I$ with the property that the natural map from $B_e/(L_e^* + L_e)$ onto M is completely positive and completely isometric.

The key for this inductive selection is the Lemma B.14.1.

We get from Lemma B.14.1 a separable C^*-subalgebra $B_e \supseteq B$ such that $B_e \subseteq \overline{BAB}$, $(B_e \cap L)^* + (B_e \cap L)$ is closed in B_e, that it is the same as $B_e \cap (L^* + L)$ and that the natural map from $B_e/(B_e \cap (L^* + L))$ to $A/(L^* + L) \cong pA^{**}p$ defines a surjective completely positive complete isometry from $(\{p\}' \cap B_e)/(J \cap B_e)$ onto $pA^{**}p$.

NOTICE 31.12. 2017:

If $B \subseteq A$ is a C^*-subalgebra of A and $L \subseteq A$ is a closed left ideal and $R \subseteq A$ is a closed left ideal, then $R + L$ is a closed subspace of A by Part (iv) of Proposition A.15.2.

This implies that $B \cap (R + L)$, $B \cap R$ and $B \cap L$ are closed linear subspaces of A. Thus, $B \cap R$ and $B \cap L$ are closed right and left ideals of B. Again, by Part(iv) of Proposition A.15.2, $(B \cap R) + (B \cap L)$ is a closed linear subspace of B, obviously contained in the closed linear subspace $B \cap (R + L)$ of B.

By our pre-assumption that $(B \cap R) + (B \cap L)$ is dense in $B \cap (R + L)$, we get the equality

$$B \cap (R + L) = (B \cap R) + (B \cap L)\,.$$

(Without this "density assumption" the formula would be wrong: $A : \mathbb{C} \oplus \mathbb{C}$, $B := \mathbb{C} \cdot (1,1)$, $L := \mathbb{C} \oplus 0$, $R := 0 \oplus \mathbb{C}$. $A = L + R$, $B \cap L = 0$, $B \cap R = 0$ and $B \cap (L + R) = B$.)

But requires an additional selection process that also shows that

$$B/(B \cap (R + L)) \to A/(R + L)$$

is isometric, respectively, is completely isometric, by tensoring all with M_n ...

Needs to show that $\operatorname{dist}(b, R + L) = \operatorname{dist}(b, B \cap (R + L))$ ...

This seems to work only with a suitable iteration process, until $B \otimes \mathbb{K} \subseteq A \otimes \mathbb{K}$ is relatively weakly injective.

But above procedure has to be suitably changed to an inductive procedure that allows to construct a suitable separable C^*-subalgebra $B \subseteq C \subseteq A$ by Corollary A.15.3.

Moreover it hold then that the natural C^*-monomorphism $\{p\}' \cap B_e \to \{p\}' \cap A$ is surjective by separability of $A/(R + L)$.

???? WHERE it is SHOWN ????

$L \cap B_e = B_e \cdot (J \cap B_e)$.

Recall here that $J \subseteq \{p\}' \cap A$ is the kernel of the surjective C^*-morphism $\{p\}' \cap A \to pA^{**}p$.

This implies that $B_e \cdot (J \cap B_e) = L \cap B_e$, $B_e/(L \cap B_e + L^* \cap B_e) \cong M$. and $B_e/(J \cap B_e) \cong M$, with all isomorphisms canonical.

It follows that the separable C^*-algebra $J \cap B_e$ contains a strictly positive contraction and the C^*-subalgebra $\pi^{-1}(\mathbb{C} \cdot 1_M) \subseteq (\{p\}' \cap B_e)$ contains a positive contraction a_0 with $\pi(a_0) = 1_M$ and $(1 - a_0)a_0$ strictly positive in $J \cap B_e$.

Here the set $\Omega \subseteq A$ is not considered.

Consider e.g. the separable C^*-subalgebra $A_1 := C^*(\Omega, B_0) \subseteq A$.

It it a question if A_1 has to be suitably enlarged (still separable and "suitable").

This bigger separable C^*-algebra B_e should have the property that B_e plays the same role as A.

Say, A itself is separable. $M := A/(L^* + L)$, $D := L^* \cap L$, $\mathcal{N}(A, D)/D \cong M$,

$\{p\}' \cap A? =? \mathcal{N}(A, D)$??

Then $L_1 := A_1 \cap (A^{**}(1 - p))$ is a closed left-ideal of A_1, $D_1 := L_1^* \cap L_1$ is a hereditary C^*-subalgebra and

????

$A_1/(L_1^* + L_1) \cong pA_1p \cong M$.

????

$\mathcal{N}(D_1, A_1) \supseteq A_1 \cap \{p\}'$ contains $\phi(CM)$ and is (in ???) the multiplicative domain of $a \in A_1 \mapsto pap \in pA^{**}p$.

$\mathcal{N}(D_1, A_1)/D_1 \cong pA^{**}p$? $p(a - \phi(f_0 \otimes pap))p = 0$ for all $a \in A$.

Need $g \in A_1 \cap \{p\}'$ with $g \geq 0$, $\|g\| = 1$, $pg = p$, $g(1 - g)$ strictly positive in D_1.

Then $g^n(X - \phi(f_0 \otimes pXp))g^n \to 0$ for $X \in A_1$ and $n \to \infty$.

Needs that kernel of $A_1 \to pA^{**}p$ is equal to sum $L_1^* + L_1$????

Needs to construct a "regular" separable enlargement of A_1 by "reduction to separable case".

???? By Lemma A.21.1 there exists ????

`Next is OLD version?????`

The proof refines the proofs of Lemmas 2.1.7 or **??** and Remark 2.1.16

Let $M := pA^{**}p$ of finite linear dimension, $C := \{p\}' \cap A$ and $\pi\colon f \in C \to fp \in M$ the C^*-morphism from C into M considered in Part (ii). Then π is an epimorphism by (ii). We define $\varphi\colon \mathrm{C}_0((0, 1], M) \to M$ by $\varphi(f) := f(1)$ for $f \in \mathrm{C}_0((0, 1], M)$.

By Proposition A.8.4, $\mathrm{C}_0((0,1],M)$ is projective. It says that there exists a C^*-morphism $\psi_0\colon \mathrm{C}_0((0,1],M)\to C$ with $\pi\circ\psi=\varphi$, i.e., $\psi(f_0\otimes a)p=a$ for all $a\in M$.

The convex set $S_p(A)$ $(=C_p(A^{**}))$ of positive functionals $\rho\in A^*=(A^{**})_*$ with $\rho(p)=\|\rho\|$ is $\sigma(A^*,A)$-closed, because this set is naturally isomorphic to the *compact* quasi-state space of $M=pA^{**}p$. Thus, the projection $p\in A^{**}$ is closed, and there is a closed left-ideal $L\subseteq A$ such that $q:=1-p$ is the open support projection of L in A^{**}, i.e., $A^{**}q$ is the weak*-closure of L in A^{**}.

It follows, that $\|pap\|=\mathrm{dist}(a,qA^{**}+A^{**}q)=\mathrm{dist}(a,L^*+L)$. In particular, L^*+L is the kernel of the c.p. map $a\in A\to pap\in M$. We get $a-\psi_0(f_0\otimes pap)\in L^*+L$, because $a-\psi_0(f_0\otimes pap)\in A$ and $p(a-\psi_0(f_0\otimes pap))p=0$ for all $a\in A$.

More ????????

Since Ω is a compact subset of A, there is a separable C^*-subalgebra E_0 of A with $\Omega\cup\psi_0(\mathrm{C}_0((0,1],M))\subseteq E_0$.

Since E_0 is separable, there exist a separable C^*-subalgebra $E_1\subseteq A$ with $E_0\subseteq E_1$, $a-\psi_0(f_0\otimes pap)\in(E_1\cap L)^*+(E_1\cap L)$ and $\|pap\|=\mathrm{dist}(a,(E_1\cap L)^*+(E_1\cap L))$ for all $a\in E_0$.

Next (commented?) comes also from Lemma B.14.1.

to be filled in

Part(iii) of Lemma 2.1.15, ??

If $\gamma\colon M_{n_k}\cong Mq_k$ is a *-isomorphism from M_{n_k} onto Mq_k, then there is a natural *-isomorphism τ from F_k onto $F_{k,1}\otimes M_{n_k}$ such that $F_{k,1}=\overline{yEy}=\overline{y(F_k)y}$ for $y:=\psi_0(f_0\otimes\gamma(p_{11}))$ and $\tau(\psi_0(f_0\otimes\gamma(\alpha)))=y\otimes\alpha$ for $\alpha\in M_{n_k}$.

Step ?:
(Recall here that $q:=1-p$ is the above defined open support projection of a hereditary C*-subalgebra of A.)

Text/Statement:

For every separable C^*-subalgebra $C\subseteq A$, there exists a positive contraction $g\in\{p\}'\cap A$ with $gp=p$ and $\lim_n\|g^ncg^n\|=\|pcp\|$ for all $c\in C$.

It is important that $p\in A^{**}$ is "closed", – in the sense that $1-p\in A^{**}$ is the "open" support projection of a hereditary C^*-subalgebra $D\subseteq A$ of A.

Step ?:
More general case:

If $J\lhd B$ contains a strictly positive element $e\in J_+$, and if the C^*-morphism

$$\varphi\colon\ \mathrm{C}_0((0,1],M)\to B/J$$

has kernel $\ker(\varphi)=\mathrm{C}_0((0,1),M)$, – i.e., there is a *-monomorphism $\lambda\colon M\to B/J$ with $\varphi(f)=\lambda(f(1))$ for $f\in\mathrm{C}_0((0,1],M)$ –, then the homomorphic lift $\psi\colon\mathrm{C}_0((0,1],M)\to B$ of φ can be chosen such that $\lim\|g^ne\|=0$ for $g:=\psi(f_0\otimes 1_M)$, where $f_0\in\mathrm{C}_0(0,1]$ is given by $f_0(t):=t$. □

REMARK 2.1.16. The Parts (i,ii) of Lemma 2.1.15 show that there exist a non-zero C^*-morphism $\psi\colon\ \mathrm{C}_0((0,1], M_n) \to A$ if a C^*-algebra A has an irreducible representation $\rho\colon A \to \mathcal{L}(\mathcal{H})$ of dimension $\geq n$. If we let $f_k := \psi(f_0^{1/2} \otimes p_{k,1})$, $e := \psi(f_0 \otimes p_{11})$ with $f_0(t) = t$ for $t \in [0,1]$, we get the following Part (i) and its consequences in Parts (ii), (iii) and (iv):

(i) If A has an irreducible representation of dimension $\geq n$ then there exist elements $e \in A_+$ and $f_1, \ldots, f_n \in A$ that satisfy the relations $\|e\| = 1$ and $f_j^* f_k = \delta_{j,k} e$ for $j, k = 1, \ldots, n$.

(ii) In particular, if $a \in A$ and a^*Aa is not a commutative algebra, then there exists $b \in a^*Aa$ with $b^2 = 0$ and $\|b\| = 1$. (Local Glimm halving Lemma, cf. [**616**, lem. 6.7.1]).

(iii) If each non-zero hereditary C^*-subalgebra D of A has no character, then for every $n \in \mathbb{N}$ and non-zero hereditary C^*-subalgebra D of A we find $e, f_1, \ldots, f_n \in D$ with the relations listed in Part (i).

(In particular, if A is antiliminary, then each non-zero hereditary C^*-subalgebra D of A is also antiliminary, and the D contain a copy of $M_n \otimes \mathrm{C}_0(0,1]$ for each $n \in \mathbb{N}$.)

(iv) If, moreover, A is *strictly antiliminary* (also called *residually antiliminary*, cf. Definition 2.7.2) in the sense that each non-zero quotient A/J of A is antiliminary in the sense of [**616**, sec. 6.1.1], then for every non-zero hereditary C^*-subalgebra D of A, every pure state ρ on D and every $n \in \mathbb{N}$ there exists a C^*-morphism $\psi\colon\ \mathrm{C}_0((0,1], M_n) \to D$ with

$$\rho(\psi(f_0 \otimes p_{11})) = 1\,.$$

(And this is equivalent to the property that no hereditary C^*-subalgebra of A has a non-zero character.)

Indeed, the Parts (i,ii) of Lemma 2.1.15 apply to all non-zero hereditary C^*-subalgebras $D \subseteq A$, because the property that *each D has no character* implies that all non-zero hereditary C^*-subalgebras $D \neq \{0\}$ of A can not have any irreducible representation of finite dimension (even can not contain non-zero compact operators in its images).

LEMMA 2.1.17. *Let ρ a pure state on a C^*-algebra A. We denote the corresponding irreducible representation with cyclic vector ξ_ρ by $D_\rho\colon A \to \mathcal{L}(L_2(A,\rho))$.*

Then there exists for each $a \in A_+$ and $\varepsilon > 0$ a contraction $g := g(a,\varepsilon) \in A$ such that

$$\|D_\rho(a)\| \,<\, \varepsilon \,+\, \rho(g^*ag)\,. \tag{1.7}$$

In particular, for each (fixed) pure state ρ on a simple *C^*-algebra A,*

$$\|a\|^2 \;=\; \sup\{\,\rho(g^*(a^*a)g)\,;\; g \in A,\ \|g\| \leq 1\}\,.$$

Here $L_2(A,\rho) := A/L_\rho$ with $L_\rho := \{a \in A\,;\; \rho(a^*a) := 0\,\}$. It satisfies for all $a \in A$ that $\rho(a) \;=\; \langle D_\rho(a)\xi_\rho, \xi_\rho\rangle$.

More precisely there exists $h^* = h \in A$ with $\|h\| \leq \pi$ such that $\exp(ih) \in A + \mathbb{C} \cdot 1 \in A^{**}$ satisfies Inequality (1.7) with $\exp(ih)$ in place of g. One can find a contraction $f \in A_+$ such that $D_\rho(f)\xi_\rho = \xi_\rho$. Then $g := \exp(ih)f \in A$ satisfies Inequality (1.7).

PROOF. The connected component $\mathcal{U}_0(\widehat{A})$ of 1 in the unitary group $\mathcal{U}(\widehat{A})$ of the unitization

$$\widehat{A} := A + \mathbb{C} \cdot 1 \subseteq \mathcal{M}(A) \subseteq A^{**}$$

operates transitive on the unit sphere of the Hilbert space $\mathcal{H} := L_2(A, \rho) = D_\rho(A)x_\rho$, because the (reformulated) Kadison transitivity in Lemma 2.1.15(ii,iii) implies that for every $y \in \mathcal{H}$ the natural c.p. contraction

$$V : a + \xi 1 \mapsto p(D_\rho(a) + \xi 1)p$$

maps the multiplicative domain of V onto $p\mathcal{L}(\mathcal{H})p$, where $p \in \mathcal{L}(\mathcal{H})$ is the orthogonal projection onto the complex linear span of $\{y, \xi_\rho\}$, i.e., $p\mathcal{H}$ is 1-dimensional or is 2-dimensional. If it is one-dimensional, then $y = \alpha \cdot \xi_\rho$ with $\alpha = \exp(i\gamma)$ for some $\gamma \in [0, 2\pi)$.

If $\|y\| = 1$ and $U \in p\mathcal{L}(\mathcal{H})p \cong M_2(\mathbb{C})$ is (partial) unitary with $U^*U = p = UU^*$ and $U(\xi_\rho) = y$, then U is an exponential in $p\mathcal{L}(\mathcal{H})p$, because all unitaries in $M_2(\mathbb{C})$ are exponentials, i.e., $U = p\exp(ik)p = \exp(ik)p$ for some $k^* = k \in p\mathcal{L}(\mathcal{H})p$ with $\|k\| \leq \pi$.

By Part (ii) of Lemma 2.1.15 there exists $h^* = h \in \{p\}' \cap A$ with $pD_\rho(h) = k$. It follows for $T := D_\rho(h)$ in $\mathcal{L}(\mathcal{H})$ that

$$\exp(iT)p = p\exp(iT) = \exp(ik)p = \exp(ik) - (1 - p).$$

In particular, $\exp(iT)(\xi_\rho) = \exp(ik)(\xi_\rho) = y$.

If we extend D_ρ naturally to a *-representation of $A + \mathbb{C} \cdot 1 \subseteq \mathcal{M}(A)$ then this says that $D_\rho(\exp(ih))\xi_\rho = y$. If we use that $b\exp(ih) \in A$, then we get that $D_\rho(b\exp(ih))(\xi_\rho) = D_\rho(b)(y)$, and – therefore – that

$$\rho(\exp(ih)^* b^* b \exp(ih)) \;=\; \|D_\rho(b)y\|^2 .$$

We apply this precise general observation to get the desired more relaxed estimate:

Given $0 \neq a \in A_+$ and $\varepsilon \in (0, 1/2)$ we let $\delta := \varepsilon/\mu$ with $\mu := 2(1 + \|a\|^{1/2})$. Then $\delta^2 + 2\delta\|a\|^{1/2} < \varepsilon$.

There exists $y \in \mathcal{H}$ with $\|y\| = 1$ and $\|D_\rho(a^{1/2})\| \leq \delta + \|D_\rho(a^{1/2})y\|$. It implies

$$\|D_\rho(a)\| < \varepsilon + \langle D_\rho(a)y, y\rangle .$$

As we have seen above, there exists $h^* = h \in A$ with $\rho(\exp(ih)^* a \exp(ih)) = \|D_\rho(a^{1/2})y\|^2$. Thus,

$$\|D_\rho(a)\| \;<\; \varepsilon \;+\; \rho(\exp(ih)^* a \exp(ih)) .$$

We get the "relaxed" Inequality (1.7) for $g := f_\delta(a)\exp(ih)$, where $f_\delta(t) := \min(1, \delta^{-1}\max(t-\delta, 0))$ with sufficiently small $\delta \in (0, 1/4)$. □

REMARK 2.1.18. There are several other methods to prove the surjectivity of $\pi\colon (\{p\}' \cap A) \ni a \mapsto pa \in pA^{**}p$ for "closed" projections $p \in A^{**}$, e.g. by modifying the original Kadison transitivity theorem [**400**, thm. 5.4.3, thm. 5.4.5], or – more comfortable – its generalization by S. Sakai [**704**, thm. 1.21.16], but one can directly use the far more general results mentioned in below given Remark 2.1.19.

`Give here also reference to Appendix A!!!`

Here is one of the very elementary ways: A closer inspection of there original proofs shows that both cited original results (of Kadison or Sakai) did prove only that the map

$$(\{p\}' \cap (A + \mathbb{C}\cdot 1)) \ni a \mapsto pa \in pA^{**}p$$

is surjective for $A + \mathbb{C}\cdot 1 \subseteq A^{**}$.

`Check this critics on the citations to Kadison or Sakai again! Simply to avoid a mistake!`

But a simple trick shows that one can replace here $A + \mathbb{C}\cdot 1$ by A itself ([10]):

Let $D_k\colon A^{**} \to \mathcal{L}(\mathcal{H}_k)$ normal and surjective with supports $Q_k \in Z(A^{**})$ and let $p_k := D_k(p) = D_k(Q_k p)$, – as considered in Lemma 2.1.15(i).

Further let D_0 denote the restriction of $D_1 \oplus \cdots \oplus D_n$ to $pA^{**}p$. Consider a unitary $w \in pA^{**}p$ of $pA^{**}p$ and define $u_k := D_k(w) \in p_k\mathcal{L}(\mathcal{H}_k)p_k$.

The advanced forms of the Kadison transitivity theorem [**704**, thm. 1.21.16], (that follows also directly from [**400**, thm. 5.4.5] or [**616**, thm. 2.7.5]) applied to the unitization $\widehat{A} = A + \mathbb{C}\cdot 1 \subseteq A^{**}$ of A and to the pairwise inequivalent irreducible representations $D_k\colon \widehat{A} \to \mathcal{L}(\mathcal{H}_k)$ show the following: There is a unitary $U \in \widehat{A}$ with $p_k D_k(U) p_k = u_k$ for $k = 1, \ldots, n$.

Thus $D_0(pUp - w) = 0$ for the above defined D_0. Since $D_0|pA^{**}p$ is faithful, we get $pUp = w$. It implies $pU^*pUp = p = pUpU^*p$, $pU(1-p) = 0 = (1-p)Up$ and $(pU - Up) = 0$. It shows that the C^*-morphism $\psi\colon a \in C_1 \mapsto ap \in pA^{**}p$ is a *-epimorphism from $C_1 := \{p\}' \cap (A + \mathbb{C}1)$ onto $pA^{**}p$.

On the other hand, by $1\cdot p = p = p\cdot 1$, $C_1 = C + \mathbb{C}1$ for $C := \{p\}' \cap A$ and $C = C_1$ or $C_1/C \cong \mathbb{C}$. Obviously, in the second case $\psi(C)$ is a closed ideal of $pA^{**}p$ of co-dimension *at most* one!

If we use that $pA^{**}p$ has finite linear dimension, then the latter implies that $pA^{**}p$ has a character, given by a central projection q of $pA^{**}p$.

Now comes the "dirty trick": We replace A by $A \otimes M_2$ and p by

$$p \otimes 1_2 \in A^{**} \otimes M_2 \cong (A \otimes M_2)^{**}.$$

Then $(p \otimes 1_2)(A \otimes M_2)^{**}(p \otimes 1_2) \cong pA^{**}p \otimes M_2$ has no character anymore.

[10] This trick was *not* observed or precisely mentioned in any of the 3 above cited books.

Above considerations (applied to $A \otimes M_2$ instead on A) show that the image of the natural C^*-morphism

$$\eta\colon \{p \otimes 1_2\}' \cap (A \otimes M_2) \to pM^{**}p \otimes M_2$$

is an ideal of $pA^{**}p \otimes M_2$ of co-dimension ≤ 1. But $pM^{**}p \otimes M_2$ has no character. Thus, η must be surjective.

The surjectivity of η implies the surjectivity of the map π defined by $\pi(a) := ap$ for $a \in \{p\}' \cap A$. Indeed: Let $x \in pA^{**}p$. There exists $b \in \{p \otimes 1_2\}' \cap A \otimes M_2$ with $b \cdot (p \otimes 1_2) = x \otimes e_{11}$. It follows that there is $a \in A$ with $(1 \otimes e_{11})b(1 \otimes e_{11}) = a \otimes e_{11}$ and $ap = x$, where $e_{11} \in M_2$ is the upper-left matrix unit. Moreover,

$$[a, p] \otimes e_{11} = (1 \otimes e_{11})[b, p \otimes 1_2](1 \otimes e_{11}) = 0\,.$$

This proves that the C^*-morphism $\pi\colon \{p\}' \cap A \to pA^{**}p$ is surjective. It will be used in the proof of Lemma 2.1.15(ii), by appying first one of the cited (older) textbook versions of the Kadison transitivity theorem.
HERE ends Remark 2.1.18

REMARK 2.1.19. One can shorten the proof of all Parts of Lemma 2.1.15 considerably by using more general results that we anyway have to use for our embedding results in Chapter 5.

First check that each projection $p \in A^{**}$ of finite rank (in the sense that $pA^{**}p$ has finite dimension) is a "closed" projection in A^{**}, i.e., $(1-p)$ is the supremum of an upward directed net of positive contractions in A, or equivalently:
The closed left ideal $L := A \cap (A^{**}(1-p))$ of A has an open right support projection that is equal to $1-p$. This means that the weakly closed left ideal $A^{**}(1-p)$ of A^{**} is the bi-polar of a closed ideal $L := A \cap (A^{**}(1-p))$ of A (that is, in our here considered special case, the intersection of finitely many left-kernels $L_\rho := \{a \in A\,;\ \rho(a^*a) = 0\}$ of pure states ρ on A).

This idea has been used in the proof of [**704**, thm. 1.21.16] ([11]), but in the there considered special case it was not completely proved that the natural C^*-morphism

$$\mathcal{N}(A, L^* \cap L) \to (A/(L^* + L)) \cap \mathcal{M}(A/(L^* + L)) \subseteq pA^{**}p$$

by using the natural isomorphism $pA^{**}p \cong A^{**}/((1-p)A^{**} + A^{**}(1-p))$, is a *surjective C^*-morphism* with kernel $\operatorname{Ann}(A, L^* \cap L)$ – that is a closed ideal of $\mathcal{N}(A, L^* \cap L)$.

The reason for the surjectivity of the map from normalizers onto the multiplier algebra of the quotient C^*-space is that the closed unit ball of A maps *onto* the closed unit ball of $A/(R+L)$ if R is a closed right-ideal of A and L is closed left-ideal of A.

`It should be shortened by reference to the appendices`

It comes by using the bipolar theorem for

?????

[11] Rewritten here in our notation / terminology – and not as in [**704**]

those convex subsets of Banach spaces that are closures of its *open* (again convex) interiors and there bi-duals from the more universal (and almost trivial) *perturbation property* of maps $a \in M \mapsto paq \in pMq$ for projections p, q in W*-algebras M:
If $a, b \in M$ satisfy $\|a\|, \|b\| < 1$ and $\|paq - pbq\| < \varepsilon$ then there is $c \in M$ with $\|c\| < 1$, $pbq = pcq$, and $\|a - c\| \leq \varepsilon + \sqrt{2\varepsilon}$.

(A study of $\|a\|\, u_1$ and $\|b\|\, u_2$ in place of a and b defined by suitably "iterated" construction of "Halmos" unitaries ([12]) $u_1, u_2 \in M_3(M)$ leads to an idea of proof of this non-obvious fairly sharp inequality.)

In the very special case considered in Lemma 2.1.15(iii) we have the particular situation that $\mathcal{M}(A/(L^* + L)) = pA^{**}p + (1-p)A^{**}(1-p)$ where $L := A \cap (A^{**}(1-p))$ is nothing else the intersection of the "left"-kernels of finitely many pure states on A. The C^*-subalgebra $B := \{p\}' \cap A$ of A maps always onto $\mathcal{M}(A/(L^* + L)) \cap pAp$, which is in this special situation equal to $pA^{**}p$ because p is a closed projection.

We can then simply consider the multiplier algebra $\mathcal{M}(A//E) \cong pA^{**}p$ of the unital operator system $A/(L^* + L) =: A//E$ for $E := L^* \cap L$ to get the desired "precise" variant of an "advanced" Kadison transitivity theorem by the projectivity of cones over C^*-algebras of finite dimension.
HERE ends Remark 2.1.19
More precise and short references to the Appendix Section would be useful.

In the three following lemmata $\mathbb{C}^n$ denotes the complex Hilbert space $\ell_2(n)$ of dimension $n \in \mathbb{N}$. Next one uses an extension that reduce all to the until case:

Lemma 2.1.20. *Let C a unital C^*-algebra, $B \subseteq C$ a C^*-subalgebra and $V \colon B \to M_n = \mathcal{L}(\mathbb{C}^n)$ a c.p. contraction.*

There exists a unital c.p. map $U \colon C \to M_n$ and a positive contraction $d \in (M_n)_+$ with $V(b) = dU(b)d$ for all $b \in B$.

Moreover, $d = V^{**}(1)^{1/2}$ for $1 \in B^{**}$.

Proof. The "Stinespring" dilation of the c.p. map V is given by some Hilbert space $\mathcal{H}_0$, a *-representation $\rho \colon B \to \mathcal{L}(\mathcal{H}_0)$ and a linear map $g \colon \mathbb{C}^n \to \mathcal{H}_0$ such that $V(b) = g^* \rho(b) g$.

We can suppose here that ρ is non-degenerate, i.e., $\mathcal{H}_0 = \overline{\rho(B)\mathcal{H}_0}$, because otherwise we can replace g by $q \cdot g$ and ρ by $\rho(b)|q\mathcal{H}_0$, where q is the orthogonal projection from $\mathcal{H}_0$ onto the closure of the linear span of $\rho(B)\mathcal{H}_0$. Then the normalization $\overline{\rho} \colon B^{**} \to \mathcal{L}(\mathcal{H}_0)$ satisfies $\overline{\rho}(1) = \mathrm{id}_{\mathcal{H}_0}$ and the second conjugate V^{**} of $V \colon B \to M_n$ is given by $V^{**} = g^* \overline{\rho}(\,\cdot\,) g$. It implies $V^{**}(1_{B^{**}}) = g^* g$.

There exist a unital *-representation $D \colon C \to \mathcal{L}(\mathcal{H})$ and an isometry $I \colon \mathcal{H}_0 \to \mathcal{H}$ such that $\rho(b) = I^* D(b) I$ for all $b \in B$. This can be shown e.g. by using extension

[12] See Remark 4.2.4 for the definition of Halmos unitaries.

of positive functionals, cf. [**616**, prop. 3.1.6]. The map $W(c) := I^*D(c)I$ is a unital c.p. map $W\colon C \to \mathcal{L}(\mathcal{H}_0)$ with $W|B = \rho$.

Let $p \in M_n$ denote the support projection of $g^*g \in M_n$. There is partial isometry $z \in \mathcal{L}(\ell_2(n), \mathcal{H}_0)$ with $z(g^*g)^{1/2} = g$ and $z^*z = p$. Let $d := (g^*g)^{1/2}$. We can define a c.p. contraction $U_0\colon C \to M_n$ by $U_0(c) := z^*W(c)z$ with $U_0(1) = p$. Then $V(b) = g^*\rho(b)g = dz^*W(b)zd = dU_0(b)d$. Let $\mu\colon C \to \mathbb{C}$ a state on C and define $U_1(c) := \mu(c)\cdot(1-p)$. The sum $U := U_0 + U_1$ is a c.p. map from C into M_n with $U(1_C) = 1_n$ and $dU(b)d = V(b)$.

If $1_C \in B$ then $V^{**}(1_C) = dU^{**}(1_C)d = dU(1_C)d = d^2$.

If $1_C \notin B$ then the C^*-subalgebra $B + \mathbb{C}\cdot 1_C$ of C has a non-zero character χ with $\chi(B) = 0$. It extends to a state μ on C with $\mu(B) = \{0\}$. If we define U_1 with this state μ, then we get $U(b) = U_0(b)$ for $b \in B$ and $dU(b)d = V(b) = g^*\rho(b)g$.

Now observe that $V^{**}(x) = g^*\overline{\rho}(x)g$ for $x \in B^{**}$. It follows $V^{**}(1_{B^{**}}) = g^*g = d^2$, because $V^{**}(x) = dU_0^{**}(x)d$ for $x \in B^{**}$. □

The following "existence" Lemma 2.1.21 is needed, because we consider e.g. in Proposition 2.2.1 non-separable purely infinite simple C^*-algebras, and then non-separable ultra-powers and corona algebras. It requires to check some cases for non-separable behavior.

Recall that the projections $P = P^* = P^2$ with separable $P\mathcal{H}$ generate (– in a pure algebraic manner! –) a non-unital simple closed ideal J of $\mathcal{L}(\mathcal{H})/\mathbb{K}(\mathcal{H})$ if the Hilbert space $\mathcal{H}$ is not separable. In case $n = 1$ the assumptions of next Lemma allow that λ is a state on $\mathcal{L}(\mathcal{H})$ with $\lambda|\pi_{\mathbb{K}}^{-1}(J) = 0$, then λ is zero on $P\mathcal{L}(\mathcal{H})P$. It is one of the reasons for our "local redefining" of λ on separable C^*-subalgebras B of $\mathcal{L}(\mathcal{H})$ like in next Lemma ...

LEMMA 2.1.21. *Let $\mathcal{H}$ a non-separable Hilbert space, $B \subseteq \mathcal{L}(\mathcal{H})$ a separable C^*-subalgebra, $Q \in \mathcal{L}(\mathcal{H})$ an orthogonal projection onto a separable subspace of $\mathcal{H}$ and $\lambda\colon \mathcal{L}(\mathcal{H}) \to M_n$ a c.p. map with $\lambda(\mathbb{K}(\mathcal{H})) = 0$.*

Then there exists an orthogonal projection $P \in \mathcal{L}(\mathcal{H})$, a (new) unital c.p. map $\rho\colon P\mathcal{L}(\mathcal{H})P \to M_n$ and an element $g \in (M_n)_+$, such that $P\mathcal{H}$ is separable, $PQ = Q$, $Pb = bP$ for all $b \in B$, and with $\lambda(b) = g\rho(Pb)g$, for all $b \in B$, and $\rho(P\mathbb{K}P) = \{0\}$.

PROOF. Still to be checked again:

Consider the separable C^*-subalgebra C of $\mathcal{L}(\mathcal{H})$ generated by $\{1, Q, R\} \cup B$, where R denotes the orthogonal projection onto $(B \cap \mathbb{K})\cdot\mathcal{H}$ and let $1 := \mathrm{id}_{\mathcal{H}}$. ([13])

The subspace $R\mathcal{H}$ is separable because $B \cap \mathbb{K}$ is separable and, therefore, contains an in $B \cap \mathbb{K}$ strictly positive compact operator b_0. It has has above defined R as its support projection in $\mathcal{L}(\mathcal{H})$. The C^*-algebra C is unital and $1 \in C$. Take a sequence $c_1, c_2, \ldots$ in C that is dense in the unit-ball of C, and find finite-dimensional subspaces $X_n \subseteq \mathcal{H}$ with the property that $\|c_k|X_n\| + 2^{-n} \geq \|c_k\|$ for

[13] Here the notation is different from that in the proof of Lemma 2.1.20.

$k \leq n$. Let X_∞ denote the separable linear span of the X_n and of $Q\mathcal{H}$. Now take the smallest C-invariant closed subspace $\mathcal{H}_0$ of $\mathcal{H}$ containing X_∞. It is separable by separability of C and X_∞. Then $Q\mathcal{H} \subseteq \mathcal{H}_0$ and the restriction $c|\mathcal{H}_0$ of the elements $c \in C$ is a faithful unital C^*-algebra morphism D from C into $\mathcal{L}(\mathcal{H}_0)$ given by $D(c) := c|\mathcal{H}_0 = (c \cdot P)|\mathcal{H}_0$, where we denote by P the orthogonal projection from $\mathcal{H}$ onto $\mathcal{H}_0$.

Then $\mathbb{K}(\mathcal{H}_0) = P\mathbb{K}(\mathcal{H})P$, and

$$\|\pi_{\mathbb{K}(\mathcal{H}_0)}(D(c))\| = \|\pi_{\mathbb{K}(\mathcal{H})}(c)\| \quad \forall\ c \in C\,,$$

because $D(c) \in \mathbb{K}(\mathcal{H}_0)$, if and only if, $c \in \mathbb{K}(\mathcal{H})$.

Since C is a separable C^*-algebra, the closed ideal $C \cap \mathbb{K}$ of C contains a strictly positive contraction $e \in C_+$ that is a strictly positive element of $C \cap \mathbb{K}$, and the support projection of e is equal to P and commutes with C.

It holds

$$D(C) \cap \mathbb{K}(\mathcal{H}_0) = D(C \cap \mathbb{K})\,,$$

and, for $c \in C$, $D(c) = (c \circ P) \in P\mathbb{K}P \cong \mathbb{K}(\mathcal{H}_0)$ if and only if $c \in \mathbb{K}$. And this implies that $\|\pi_{\mathbb{K}}(c)\| = \|\pi_{\mathbb{K}(\mathcal{H}_0)}(D(c))\|$ for all $c \in C$.

Thus, $C/(C \cap \mathbb{K}) \cong (C + \mathbb{K})/\mathbb{K} \subseteq \mathcal{L}(\mathcal{H})/\mathbb{K}(\mathcal{H})$ and $D(C)/(D(C) \cap \mathbb{K}(\mathcal{H}_0)) \cong (D(C) + \mathbb{K}(\mathcal{H}_0))/\mathbb{K}(\mathcal{H}_0)$ are isomorphic C^*-algebras, and up to natural isomorphisms, $C/(C \cap \mathbb{K}) \subseteq \mathcal{L}(\mathcal{H})/\mathbb{K}(\mathcal{H})$ and $D(C)/(D(C) \cap \mathbb{K}(\mathcal{H}_0))$ contained in $\mathcal{L}(\mathcal{H}_0)/\mathbb{K}(\mathcal{H}_0)$.

Because $\lambda\colon \mathcal{L}(\mathcal{H}) \to M_n$ is a c.p. map with $\lambda(\mathbb{K}(\mathcal{H})) = 0$, the restriction to $C + \mathbb{K}(\mathcal{H})$ defines a c.p. map from $C + \mathbb{K}$ to M_n with kernel $\mathbb{K}$. Let $[\lambda]\colon (C + \mathbb{K})/\mathbb{K} \to M_n$ the c.p. map with $\lambda = [\lambda] \circ \pi_{\mathbb{K}}$ The above discussed isomorphism $[D]$ from $(D(C) + \mathbb{K}(\mathcal{H}_0))/\mathbb{K}(\mathcal{H}_0)$ onto $(C + \mathbb{K})/\mathbb{K}$ allows to define a c.p. map ??????

$C/(C \cap \mathbb{K}) \cong D(C)/(D(C) \cap \mathbb{K})$ to M_n and then from ?????

....The $\rho\colon \mathcal{L}(\mathcal{H}_0) \to M_n$ comes ... later ... as unital c.p. map $\rho(T) :=$????? by use of Lemma **??** extension ... of the

Then P commutes with the elements of $b \in C$ and $\mathrm{dist}(\mathbb{K}, b) = \mathrm{dist}(\mathbb{K}, P \cdot b)$ for $\mathbb{K} = \mathbb{K}(\mathcal{H})$. This distance is also identical with $\mathrm{dist}(P\mathbb{K}P, b)$ and with $\|\pi_{\mathbb{K}}(b)\| = \|\pi_{C \cap \mathbb{K}}(b)\|$ for $b \in C$. Moreover $C \cap \mathbb{K} = C \cap P\mathbb{K}P$, $C/C \cap \mathbb{K}$ is natural isomorphic to $(C + \mathbb{K})/\mathbb{K}$ and is isomorphic to $\pi(D(C) + \mathbb{K}(\mathcal{H}_0))/\mathbb{K}(\mathcal{H}_0)$.

The point for the latter is: 1) $b \to bP$ is a C^*-morphism, that is faithful on B? and $\mathbb{K} \cap (B \cdot P) = (B \cap \mathbb{K}) \cdot P$?

??? We can now the restriction λ to $b \in B$ of λ given by $\rho(Pb) =: \lambda(b)$, extend to $\mathcal{L}(P\mathcal{H})$ with $\rho(\mathbb{K} \cap \mathcal{L}(P\mathcal{H})) = \{0\}$ because $\mathbb{K} \cap \mathcal{L}(P\mathcal{H}) = P\mathbb{K}P \cong \mathbb{K}(P\mathcal{H})$ and $\lambda(B) \cap (P \cdot \mathbb{K} \cdot P) = \lambda(B \cap \mathbb{K})$

$\lambda|(B \cap P \cdot \mathbb{K} \cdot P)$

????

Or extend $\rho(Pb)$ to $P\mathcal{L}(\mathcal{H})P \cong \mathcal{L}(P\mathcal{H})$ with $\rho(P\mathbb{K}(\mathcal{H})P) = \{0\}$???

Here is used that $\rho(\mathbb{K}) = 0$ ... ???

To be filled in !! ?? □

The below given Lemma 2.1.22 and its proof shows that the generalizations of the classical Weyl–von-Neumann Theorem along the lines of D. Voiculescu is in fact a very special case of Proposition 5.4.1 that generalizes the Weyl–von-Neumann Theorem in an m.o.c. cone equivariant manner, – in particular in an ideal-system preserving manner if those m.o.c. cones are suitably chosen.

The space $\mathbb{C}^n$ means the n-dimensional complex Hilbert space $\ell_2(n)$ in next Lemma 2.1.22. Similar results can be shown also in the real case with almost obvious modifications here and in Lemma 2.1.20.

Lemma 2.1.22 (J. Glimm, D. Voiculescu). *Suppose that $A \subseteq \mathcal{L}(\mathcal{H})$ is a C^*-algebra and that $S\colon A \to M_n = \mathcal{L}(\mathbb{C}^n)$ is a completely positive contraction that annihilates $A \cap \mathbb{K}(\mathcal{H})$, i.e., satisfies $S(A \cap \mathbb{K}(\mathcal{H})) = \{0\}$.*

Then for every compact subset $\Omega_1 \subseteq A$, every compact subset $\Omega_2 \subseteq \mathcal{H}$ and every $\varepsilon > 0$, there is a linear isometry ?? perhaps only: contraction ?? $v\colon \mathbb{C}^n \to \mathcal{H}$ such that, for all $a \in \Omega_1$, $y \in \Omega_2$ and $x \in \mathbb{C}^n$ holds:

$$\|S(a) - v^*av\| < \varepsilon \qquad \textit{and} \qquad |\langle v(x), y\rangle| < \varepsilon\|x\|\,. \tag{1.8}$$

If, moreover, $\mathrm{id}_{\mathcal{H}} \in A + \mathbb{K}(\mathcal{H})$ and $S(a) = 1_n$ for all $a \in A$ with $a \in \mathbb{K}(\mathcal{H}) + \mathrm{id}_{\mathcal{H}}$, or if $\mathrm{id}_{\mathcal{H}}$ is not contained in $A + \mathbb{K}(\mathcal{H})$, then there exists an isometry *$v\colon \mathbb{C}^n \cong \ell_2(n) \to \mathcal{H}$ that satisfies the inequalities* (1.8).

What are the differences between this *isometries*? check the proof again!

Notice that $\mathrm{id}_{\mathcal{H}} \notin A + \mathbb{K}(\mathcal{H})$ if $A + \mathbb{K}(\mathcal{H})$ is *not* unital. In particular $A + \mathbb{K}(\mathcal{H})$ is not unital if A is stable or if $A \subseteq \mathbb{K}(\mathcal{H})$.

Here $\mathbb{C}^n$ is the n-dimensional complex Hilbert space $\ell_2(n)$, and $1_n \in M_n \cong \mathcal{L}(\ell_2(n))$ is then the identity map of $\mathbb{C}^n$. It is crucial for applications that the map v can be chosen always as a contraction, respectively as an isometry in the mentioned two special cases.

Proof of Lemma 2.1.22. We use Lemma 2.1.20 for the reductions to the unital case and (later) reduction to the unital separable case for a unital c.p. map $T\colon (A + \mathbb{K} + \mathbb{C} \cdot \mathrm{id}_{\mathcal{H}})/\mathbb{K} \to M_n$. Here $\mathcal{H}$ is not necessarily separable, but restriction to separable C^*-subalgebras of A and then to separable subspaces of $\mathcal{H}$ allows a reduction to separable closed subspaces of $\mathcal{H}$. This reductions to the separable case allows to use (and cite) then several places where this cases are considered (with slightly different proofs).

The original S is then obtained by "compression" as in the Lemma 2.1.20, that leads to the case where $v\colon \mathbb{C}^n \to \mathcal{H}$ is then only a contraction.

In the following, $\mathbb{K}$ means $\mathbb{K}(\mathcal{H})$ and $1 := \mathrm{id}_{\mathcal{H}}$. If 1 is not contained in $A+\mathbb{K}$ then $A+\mathbb{K}$ is a closed ideal of the C^*-algebra $A+\mathbb{K}+\mathbb{C}\cdot 1 \subseteq \mathcal{L}(\mathcal{H})$, and $A\cap\mathbb{K}$ is a closed ideal of A and is also a closed ideal of $A+\mathbb{K}$ with $(A+\mathbb{K})/\mathbb{K} \cong A/(A\cap\mathbb{K})$.

Thus, $S\colon A\to M_n$ with $S(A\cap\mathbb{K}) = \{0\}$ can be considered as a completely positive contraction $T\colon (A+\mathbb{K})\to M_n$ with $T(\mathbb{K}) = 0$.

If $1\in A+\mathbb{K}$, i.e., there exists $a\in A$ with $a\in\mathbb{K}+1$ and $S(a) = 1_n$ for all $a\in A$ with $a\in\mathbb{K}+1$, then T is unital.

If 1 is not contained in $A+\mathbb{K}$, then $A+\mathbb{K}$ is an essential ideal of $A+\mathbb{K}+\mathbb{C}\cdot 1$, and the minimal extension T_e of $T\colon A+\mathbb{K}\to M_n$ to a positive map from $A+\mathbb{K}+\mathbb{C}\cdot 1$ to M_n is given by the restriction to $A+\mathbb{K}+\mathbb{C}\cdot 1\subseteq (A+\mathbb{K})^{**}$ of the bi-adjoint $T^{**}\colon (A+\mathbb{K})^{**}\to M_n$ of T.

??? Compare Lemma 2.1.20 !!!

$1\in A+\mathbb{K}(\mathcal{H})$ and $S(a) = 1_n$ for all $a\in A$ with $a\in\mathbb{K}(\mathcal{H})+\mathbb{C}\cdot 1$

???

that annihilates $A\cap\mathbb{K}(\mathcal{H})$, i.e., satisfies $S(A\cap\mathbb{K}(\mathcal{H})) = \{0\}$.

The Stinespring dilation of $S\colon A\to M_n\cong\mathcal{L}(\ell_2(n))$ with ?????

We use here the notation $\mathbb{C}^n := \ell_2(n)$, i.e., $\mathbb{C}^n$ is equipped with the norm $\|(\alpha_1,\ldots,\alpha_n)\|_2 := (\sum_k |\alpha_k|^2)^{1/2}$. And "c.p." means "completely positive".

The estimates in the inequalities (1.8) have to be shown only for the compact subsets $\Omega_1\subseteq A$ and $\Omega_2\subseteq\mathcal{H}$, and for given $\varepsilon>0$. It implies that it suffices to *consider* in place of A and $\mathcal{H}$ the separable C^*-subalgebra $C^*(\Omega_1)\subseteq A$ and the closed separable subspace $\mathcal{H}_0\subseteq\mathcal{H}$ that contains Ω_2 and is invariant under $C^*(\Omega_1)$. They satisfy $C^*(\Omega_1)\cap\mathbb{K}(\mathcal{H}_0)\subseteq A\cap\mathbb{K}(\mathcal{H})$, i.e., we can suppose that A and $\mathcal{H}$ *are separable from now on.* But there are critical points here: Possibly we have to enlarge the separable closed subspaces $\mathcal{H}_0\subseteq\mathcal{H}$ and the separable C^*-algebra $A_0\subseteq A$ with $A_0\mathcal{H}_0\subseteq\mathcal{H}_0$ in the cases where $\mathrm{id}_{\mathcal{H}}\in A+\mathbb{K}(\mathcal{H})$ to get that $\mathrm{id}_{\mathcal{H}_0}\in A_0+\mathbb{K}(\mathcal{H}_0)$. We find $k\in\mathbb{K}(\mathcal{H})$ and $a_1\in A$ with $k+a_1 = \mathrm{id}_{\mathcal{H}}$ ...

Then we can ...

In case that ...

and to check that we can select the new separable C^*-algebra A_0 (in place of A) and , such that the new Hilbert space $\mathcal{H}_0$ and the C^*-algebra A_0 is chosen big enough ...

that in the cases where $\mathrm{id}_{\mathcal{H}}\in A+\mathbb{K}(\mathcal{H})$ and $S(a) = 1$ for all $a\in A$ with $a\in\mathbb{K}(\mathcal{H})+\mathrm{id}_{\mathcal{H}}$, or where $\mathrm{id}_{\mathcal{H}}$ is not contained in $A+\mathbb{K}(\mathcal{H})$,

the new $A_0|\mathcal{H}_0\subseteq\mathcal{L}(\mathcal{H}_0)$ given now by

again satisfies $\mathrm{id}_{\mathcal{H}_0}\in A_0+\mathbb{K}(\mathcal{H}_0)$ and $S(a) = 1$ for all $a\in A_0$ with $a\in\mathbb{K}(\mathcal{H}_0)+\mathrm{id}_{\mathcal{H}_0}$, respectively again satisfies

????????????

and

Details ?????.

Reduction of the general case to the case where A and $\mathcal{H}$ are separable:
The compact sets $\Omega_1 \subset A$ and $\Omega_2 \subset \mathcal{H}$ generate a separable C^*-subalgebra B of A and a B-invariant separable closed subspace $\mathcal{H}_1$ of $\mathcal{H}$ such that $\Omega_2 \subset \mathcal{H}_1$ and $\psi\colon b \in B \mapsto b|\mathcal{H}_1$ is a faithful C^*-morphism and $\psi(B \cap \mathbb{K}(\mathcal{H})) = \psi(B) \cap \mathbb{K}(\mathcal{H}_1)$.

If $\mathrm{id}_{\mathcal{H}} \in A + \mathbb{K}(\mathcal{H})$ and $S(a) = 1$ for all $a \in A$ with $a \in \mathbb{K}(\mathcal{H}) + \mathrm{id}_{\mathcal{H}}$,

or if $\mathrm{id}_{\mathcal{H}}$ is not contained in $A + \mathbb{K}(\mathcal{H})$, ...

Notice that Ω_1 and Ω_2 contain for each ε finite subsets X_1 and X_2 such that the $\varepsilon/3$ balls around them cover all of Ω_1, respectively Ω_2. Then all predicted conclusions

(still to be proved !)

are reduced to the study of the case where the algebra A and the Hilbert space $\mathcal{H}$ are *separable* and the subsets $\Omega_1 \subset A$ and $\Omega_2 \subset \mathcal{H}$ are finite sets.

Further reductions of the general case with separable A and $\mathcal{H}$:

We start with a reduction of all cases to the case where $\mathrm{id}_{\mathcal{H}} \in A + \mathbb{K}(\mathcal{H}) = A$, $S(\mathrm{id}_{\mathcal{H}}) = 1_n$ and $S(\mathbb{K}(\mathcal{H})) = \{0\}$.

`Next step not done yet !!!`
`but cited 3 places where it was done for separable` C^*`-subalgebras of the Calkin algebra.`

Below ????

Then we can give references to different nice proofs of this very special case, i.e., where A is separable, $\mathrm{id}_{\mathcal{H}} = 1_A$ and $S(\mathrm{id}_{\mathcal{H}}) = 1$, i.e., where $n = 1$ and S is the restriction to A of a state on the Calkin algebra $\mathcal{L}(\mathcal{H})/\mathbb{K}(\mathcal{H})$.

It says essentially that the restriction of a state S on the Calkin algebra to a separable C^*-subalgebra of $A \subseteq \mathcal{L}(\mathcal{H})$ is a point-wise limit on A of a net of vector states that converges on $\mathbb{K}(\mathcal{H})$ point-wise to zero.

The reduction to the special separable unital case uses Lemma 2.1.20.

`Refer to above Lemma ???`

The following observation is easy to verify:
If D and E are (arbitrary) C^*-algebras, $T\colon D \to E$ a c.p. map and $J \subseteq D$ closed ideal with $T(J) = \{0\}$, the the class-map $[T]_J\colon D/J \to E$ is a c.p. map.

We apply this observation and Lemma 2.1.20 to $C := \mathcal{L}(\mathcal{H})/\mathbb{K}$, $B := (A + \mathbb{K})/\mathbb{K} \cong A/(A \cap \mathbb{K})$ and the quotient map $V := [S]\colon B \to M_n$.

This reduces all cases to the special case where $1 := \mathrm{id}_{\mathcal{H}} \in A + \mathbb{K}$ and $S(a) = 1_n$ for all $a \in 1 + \mathbb{K}$, and then to $\mathcal{H} \cong \ell_2(\mathbb{N})$ and separable A. Now we can cite textbooks and papers for the ???? remaining two steps: ???? Which steps???

The proof for this special case reduces to the well-known more special case where A and $\mathcal{H}$ are separable and $n = 1$:

Each of [**798**](1976), [**43**](1977) or [**207**, lem. II.5.2](1996) give a reduction of the unital separable case with $n > 1$ to the case $n = 1$.

Then all is reduced to the case of unital separable A and $n = 1$, i.e., where $M_n = \mathbb{C}$ and S is a state on A that annihilates $A \cap \mathbb{K}(\mathcal{H})$. This is the basic case, that has been shown in each of the references Glimm [**323**](1960), Dixmier [**217**, lem. 11.2.1](1969), [**123**] (1976), or [**207**, lem. II.5.1](1996) with slightly different proofs requiring different basic knowledge. □

`Next: Still to be checked:`

Remark 2.1.23. The Part(iii) of Lemma 2.1.15 and Lemma 2.1.22 and 2.1.15 imply together in the special case of a non-elementary simple C^*-algebra A the following observation:

Let $V\colon A \to M_n$ a completely positive contraction. Then, for every compact subset $\Omega \subseteq A$, pure state ρ on A and $\varepsilon > 0$, there exist contractions $e, b_1, \ldots, b_n \in A$ with the properties $b_j^* b_k = \delta_{j,k} e$, $\rho(e) = 1$ and

$$\|b_j^* a b_k - V(a)_{j,k} e\| < \varepsilon \quad \text{for} \quad j,k \in \{1,\ldots,n\} \text{ and all } a \in \Omega .$$

`!!! Wanted result:`

There exists contractions $b_1, \ldots, b_n \in A$ and $e \in A_+$ with $\|e\| = \rho(e) = 1$, $b_j^* b_k = \delta_{jk} e$ such that $\|\Delta(a)\| < \varepsilon$ for $a \in \Omega$ where

$$\Delta(a) := [b_1, \ldots, b_n]^* a [b_1, \ldots, b_n] - V(a) \otimes e \in M_n(A) .$$

It is equivalent to:

$$\|V(a)_{j,k} e - b_j^* a b_k\| < \varepsilon/(n+1) \quad \text{for all } j,k \in \{1,\ldots,n\},\ a \in \Omega .$$

(Here one can take partial isometries b_k and a projection $e \in A$ if A is simple and has *real rank zero*.)

Indeed:

Let $d_\rho\colon A \to \mathcal{L}(\mathcal{H})$ the irreducible representation corresponding to some pure state ρ on A.

The simplicity of A allows us to identify the elements $a \in A$ with $d_\rho(a) \in \mathcal{L}(\mathcal{H})$ for $\mathcal{H} := A/L_\rho$. Then $d_\rho(A) \cap \mathbb{K}(\mathcal{H}) = \{0\}$, because A is non-elementary by assumption.

We ?? get ?? by Lemma **??** ???

Let V be a completely positive contraction $gW(\cdot)g$ from $\mathcal{L}(\mathcal{H})$ to M_n, where W is unital and $0 \le g \le 1$ in $g \in (M_n)_+$, $\|g\| \le 1$.

The Lemma 2.1.22 implies the existence of an isometry $I\colon \mathbb{C}^n \to \mathcal{H}$ with the property that $\|I^* d_\rho(a) I - V(a)\| < \varepsilon/3$ for all $a \in \Omega$.

Let $x_j := Ie_j \in A/L_\rho$ for the canonical ONB of $\mathbb{C}^n = \ell_2(n)$ with norm $\|(\alpha_1, \ldots, \alpha_n)\|^2 = \sum_j |\alpha_j|^2$. The Lemma 2.1.15 gives for the irreducible representation d_ρ the existence of contractions $b_1, \ldots, b_n \in A$ with $b_j + L_\rho = x_j$, $\|b_1\| = 1$ and $b_j^* b_k = \delta_{j,k} b_1^* b_1$, $j, k \in \{1, \ldots, n\}$, such that $\rho(b_1^* b_1) = 1$.

The quotient map $A \to A/L_\rho$ has the property that the closed unit-ball of A maps onto the closed unit-ball of the Hilbert space A/L_ρ , cf. Remark **??**.

The point is here:
We find a C^*-morphism $\psi\colon \mathrm{C}_0((0,1], M_n) \to A$ such that $d_\rho(\psi(f_0 \otimes 1_n)) = P_n$ for the orthogonal projection onto the linear span of $x_1, \ldots, x_n$, and

$$\rho(f_0 \otimes p_{j,j}) = Ie_j = x_j \ \ ???$$

Take $b_k := f_0^{1/2} \otimes p_{k,1}$. Could replace f_0 by f_0^n with the property that

$$\rho(\psi(f_0^m \otimes 1_n) a (f_0^m \otimes 1_n)) - \rho(a) \otimes 1_n$$

becomes small ?? ??????

2. Characterizations of simple purely infinite algebras

Among the simple C^*-algebras, the purely infinite C^*-algebras can be characterized in terms of fairly different criteria but those turn out to be equivalent in this special case. The most useful and applicable criteria are the more complicate looking once. We provide a selection of those criteria in the Proposition 2.2.1 without claiming completeness or originality. The list of this equivalent properties is the work of many hands. We tried to find the most simple explanations for this equivalences. But notice that we give later several other different criteria that also characterize pure infiniteness of *simple* C^*-algebras A, see e.g. Proposition 2.2.5(iv), Corollary 2.4.6, Corollary 2.2.11, Corollary 3.2.16(ii) in conjunction with Remark 3.2.17, and, last but not least, the most important for our applications:
a simple non-elementary C^*-algebra A has the WvN-property – given in Definition 1.2.3 –, if and only if, A is purely infinite, cf. Chapters 3 and 5 for basic applications of the WvN-property (= *Weyl – von Neumann Property*).

There exist fairly different properties that also characterize separable non-elementary simple purely infinite *nuclear* C^*-algebras A by simplicity of $F(A) := (A' \cap A_\omega)/\operatorname{Ann}(A, A_\omega)$ in [**448**, thm. 2.12], or by the “unrestricted” validity of an analog of the Weyl–von-Neumann–Voiculescu theorem, cf. Corollary 5.7.3.

Most of the criteria in the parts of Proposition 2.2.1 itself do *not* imply simplicity, only the properties in Parts (ii), (iv), (vi), (vii), (xv) and (xvi) of Proposition 2.2.1 imply also that A is simple. Therefore we prefer to add here the requirement that A is simple and non-zero.

What about Part (ix)? (Same number now???)

The properties in Parts (iv), (vii) and (viii) are only equivalent if A is simple, because weakly purely infinite C^*-algebras are not necessarily simple.

But (iv) and (vii) both imply simplicity ... Are (iv) and (vii) “formally” equivalent? Formally (iv) implies (vii), and (vii) implies (viii). ...

They are almost obviously the same in case of simple C^*-algebras, but (vii) (and (iv)?) imply the simplicity of A. ?????

Several of those properties are not equivalent to each other if the C^*-algebra A is *not* simple as e.g. those in Parts (i) and (ii).

Part(ii) of Proposition 2.2.1 expresses only the Definition 1.2.1 of not necessarily simple purely infinite C^*-algebras in the special case of simple C^*-algebras – in a way that this new definition of a “simple purely infinite” C^*-algebras A contains also the simplicity of A and is clearly not equivalent to the property in Part(x) that works also for non-simple C^*-algebras A.

This many equivalent properties allow to say: If A is simple and has one of the properties listed in Proposition 2.2.1, then A has each of the listed properties, e.g. if A is p.i. in sense of J. Cuntz, then it has also all the properties listed e.g. in (vi), (ix), (x) and (xvi). For example, by Parts (ix) *and* (x), a non-zero simple C^*-algebra A is p.i. if and only if every σ-unital hereditary C^*-subalgebra D of A is stable or has a properly infinite unit $1_D := p$, i.e., $D = pAp$ with in A properly infinite projection p.

We say that a simple C^*-algebra A is **non-elementary** if A is not isomorphic to the algebra of compact operators $\mathbb{K}(\mathcal{H})$ on a Hilbert space $\mathcal{H}$ of finite or infinite dimension, in particular $A \ncong \mathbb{C}$.

`Needed for Citation ?:` Which parts show directly that
Property pi(1) [pi(n) $\Leftarrow$ (iv)] is equal to Property *pi*-1 $\Leftarrow$ (ii);
pi-n $\Leftarrow$ (xi), (xiv)?, **??**
What about (x), (xii), (xiii)?

PROPOSITION 2.2.1. *Suppose that A is a (non-zero)* simple *C^*-algebra. Then the following possible properties* (i)–(xvii) *of A are equivalent to each other:*

(i) *A is purely infinite in the sense of J. Cuntz* [**172**, p. 186]*, i.e., every non-zero hereditary C^*-subalgebra D of A contains an infinite projection $p \in D$* ([14]).
(ii) *A is purely infinite in the sense of Definition 1.2.1, i.e., $A \neq \mathbb{C}$, and for each $a, b \in A_+$ with $\|a\| = \|b\| = 1$ and $\varepsilon > 0$, there exists $c \in A$ with $\|b - c^*ac\| < \varepsilon$* ([15]).
(iii) *A is* locally *purely infinite in the sense of Definition 2.0.3, i.e., every non-zero hereditary C^*-subalgebra E of A contains a non-zero stable C^*-subalgebra $B \subseteq E$.*

[14] The projection p is then *properly* infinite by simplicity of A, cf. Lemma 2.1.6. In particular, A has the ”small projections” property (SP) that says that every non-zero hereditary C^*-subalgebra D of A contains a non-zero projection.

[15] There is $c \in A$ with $\|c\| = 1$ and $\|b - c^*ac\| < \varepsilon$, cf. Proof of (iv)$\Rightarrow$(ii) or Proof of (iii)$\Rightarrow$(ii).

(iv) *The algebra A is non-elementary and, for every $b \in A_+$ with $\|b\| = 1$ and every $\varepsilon > 0$, there exists a number $m := m(b, \varepsilon) \in \mathbb{N}$ (allowed here to depend on both of b and ε) such that, for every $a \in A_+$ with $\|a\| = 1$, there exist elements $c_1, \ldots, c_m \in A$ (depending on a, b, ε) that satisfy $\|b - \sum_{j=1}^{m} c_j^* a c_j\| < \varepsilon$.* [16]

(v) *A is* strongly *purely infinite in the sense of Definition 1.2.2, i.e., for every $a_1, a_2 \in A_+$ and $\varepsilon > 0$ there exist $d_1, d_2 \in A$ with $\|d_i^* a_i a_j d_j - \delta_{ij} a_i a_j\| < \varepsilon$ for $i, j = 1, 2$.*

(vi) *A is algebraical simple in the sense that $A \neq \mathbb{C}$ and for every $a, b \in A$ with $a \neq 0$ there are $x, y \in A$ with $xay = b$.*

(vii) *There exists (general, – not depending on a, b, ε –) $n \in \mathbb{N}$ such that A is not isomorphic to $M_k(\mathbb{C})$ for $k = 1, \ldots, n$, and, for every non-zero $a, b \in A_+$ and $\varepsilon > 0$, there exists $d_1, \ldots, d_n \in A$ such that $\|b - \sum_{j=1}^{n} d_j^* a d_j\| < \varepsilon$.* [17]

(viii) *A is simple and is* weakly *purely infinite in the sense of Definition 2.0.4.* [18]

(ix) *A is non-elementary and every non-zero non-unital σ-unital hereditary C^*-subalgebra D of A is stable.*

(x) *A has real rank zero and every non-zero projection in A is properly infinite.*

(xi) *Every non-zero element $a \in A_+$ is infinite (and A is non-zero and simple).* [19]

(xii) *There exists $n \in \mathbb{N}$ such that A is not isomorphic to $M_k(\mathbb{C})$ for each $k < n$ and each n-homogenous non-zero element $a \in A_+$ is infinite.*

(xiii) *There exists $n \in \mathbb{N}$ such that $a \otimes 1_n$ is infinite in $A \otimes \mathbb{K}$ for each non-zero $a \in A_+$.*

(xiv) *A has property pi-n of Definition* **??** *for some $n \in \mathbb{N}$.*

(xv) *A is non-elementary and, for every $a, b \in A_+$ with $\|a\| = \|b\| = 1$ and every $\varepsilon > 0$, there exists $\nu := \nu(b, a, \varepsilon) \in \mathbb{N}$ (depending on each of a, b, ε) such that, for* every *$k = 1, 2, \ldots$, there exist* contractions *$c_1, c_2, \ldots, c_\nu \in A$*

---

[16] `check again, and give reference to` $W(A)$: Essentially, the assumptions of Part (iv) say that $[(b - \varepsilon)_+] \leq m(b, \varepsilon)[a]$ in the Cuntz semigroup $W(A)$, and are fulfilled with a fixed constant number $m(b, \varepsilon) := n$ if A is simple and has Property pi(n) of Definition 2.0.4 for some $n \in \mathbb{N}$.

[17] This property follows from Property pi(n) in Definition 2.0.4 in the special case that A is simple. It is *formally NOT* a special case of Part (iv).

[18] This Part is almost the same as in Part (vii). It is not a special case of Part (iv), because it implies no simplicity.

[19] Notice here our overall pre-assumption that A is simple and non-zero. It does not directly imply that A has Property pi(1) of Definition 2.0.4 or Property *pi*-1 of Definition **??**.

Property pi(1) says in case of simple A, that $A \neq \mathbb{C}$, and for every elements $a \in A_+$, $b \in A$ and $\varepsilon > 0$, that there exists $d_1, d_2 \in A$ with $\|d_1 a d_2 - b\| < \varepsilon$.

pi-1 says: Every non-zero element is properly infinite. But since A has no non-zero non-trivial quotients it is equivalent to require only that each $0 \neq a \in A$ is infinite.

But how to formulate the latter understandable?

(depending on k, a, b, ε, but with same number $\nu(b, a, \varepsilon) \in \mathbb{N}$) such that $\|b - \sum_{j=1}^{\nu} c_j^* a^k c_j\| < \varepsilon$. ([20]).

(xvi) *For each $n \in \mathbb{N}$ holds: If $V : A \to M_n$ and $W : M_n \to A$ are completely positive contractions, then for each finite subset $F \subset A$ and $\varepsilon > 0$ there exists contractions $d_1, d_2 \in A$ (depending on $W \circ V, F, \varepsilon$) with $d_1^* d_2 = 0$ and*

$$\|(W \circ V)(a) - d_k^* a d_k\| < \varepsilon \quad \textit{for all} \ \ a \in F, \ k \in \{1, 2\}.$$

(xvii) *For every non-zero $e \in A_+$ there exists in $C^*(\overline{eAe}, 1) \subseteq \mathcal{M}(A)$ an element that is left-invertible in $A + \mathbb{C}1$ but is not right-invertible.*

We shorten the proof of the equivalences of conditions in (ix, x) with the other conditions in Parts (i)–(viii), (xi)–(xiv) by using a stability criterium for σ-unital C^*-algebras of Hjelmborg and Rørdam [**373**] – cf. also our Corollary 5.5.1 with an alternative proof of this criterium –, and we use the characterizations of real rank zero C^*-algebras given by L.G. Brown and G.K. Pedersen in [**113**] as those C^*-algebras that have the property that every σ-unital hereditary C^*-subalgebra contains an approximate unit consisting of projections. See Remark 2.2.2 concerning applications of the (almost ridiculous) Part (xvii) and is applications.

PROOF. All in Part (o) has to be discussed and/or shifted to other places.
But remove or change references from (o) to more relevant!!
Needed/used? is reduction to separable case (Perhaps in Appendix A or B)

(o): We start with this preliminary observation (o) that is related to the conditions in Parts (iv) and (vii) but uses formally weaker assumptions. It has (implicit) applications in proofs of Parts (i)–(xvi) and in the proof of Corollary 2.4.6.

TO BE DONE !!!

Define the numbers $m(a, b, \varepsilon)$, $\mu(a, b, \varepsilon)$, $n(a, b, \varepsilon)$ $\nu(b, a, \varepsilon)$
and others carefully and relate them
to the reductions to separable cases ...
Do we really need for (xv)⇒(iv) the case
where the c_k are required to be contractions?

Those numbers should be also discussed in Appendices !!!! ????

Let A a *simple* and non-elementary C^*-algebra, $b \in A_+$ with $\|b\| = 1$, fixed from now on, and define maps $(0, 1] \ni \varepsilon \mapsto m(b, \varepsilon) \in \mathbb{N} \cup \{\infty\}$ with the following property:

Let $a, b \in A_+$ and $\varepsilon > 0$.

[20] In general, e.g. for non-simple A, the numbers $\nu(b, a, \varepsilon) \in \mathbb{N} \cup \{+\infty\}$, can be bigger than the $m(b, \varepsilon) \in \mathbb{N} \cup \{\infty\}$ in Part (iv): The c_j in (iv) are not necessarily contractions.

We say that b can be ε-accessed from a in $m := m(a,b,\varepsilon)$ steps if there exists $c_1,\ldots,c_m \in A$ with $\|b - \sum_{k=1}^m c_k^* a c_k\| < \varepsilon$. If A is not simple, then we allow here $m := +\infty$ if b is not in the closed ideal $\overline{\mathrm{span}(AaA)}$ generated by $a \in A_+$.

(It should be almost the smallest number m with $(b-\varepsilon)_+ \otimes p_{1,1} \precsim a \otimes 1_m$ in $M_n(A)$???????????)

Compare $(b-\varepsilon)_+ \precsim a \otimes 1_m$, i.e., $[(b-\varepsilon)_+] \leq m[a]$ in $\mathrm{Cu}(A)$, carefully with $m := m(a,b,\varepsilon)$. The point is that we allow that m variates with ε considerably. So it is not at point of start the same as $b \precsim a \otimes 1_m$ with fixed $m \in \mathbb{N}$

What is this/next ? Put it to right place!

For each $a, b \in A_+$ there exists a simple separable C^*-subalgebra $B \subseteq A$ with $a, b \in B$ and $n(c,d,\varepsilon;B) = n(c,d,\varepsilon;A)$ and $\nu(c,d,\varepsilon;B) = \nu(c,d,\varepsilon;A)$ for all $c, d \in B_+$.

In case of non-simple A we allow $m(a,b,\varepsilon) := \infty$ if b is not in the closed ideal of A generated by a, and can define $m(a,b,\varepsilon) := m \in \mathbb{N}$ if $(b-\varepsilon/2)_+$ is in the closed ideal of A generated by a.

?? with no restrictions on the values (except $m(b,\varepsilon) \neq \infty$ in case of simple A).

Let $X \subset A$ any subset.

We say that b is *approximately accessible in $m(b,\varepsilon)$-steps* from X, if for each $a \in X$ with $\|a\| = 1$ and each $\varepsilon > 0$ there exist $c_1,\ldots,c_m \in A$ – with $m := m(b,\varepsilon)$ – such that $\|b - \sum_{k=1}^m c_k^* a c_k\| < \varepsilon$. We require here no bound for the norms $\|c_k\|$ $(k = 1,\ldots,m)$.

Is it then not simply, -- in case $b \geq 0$ --, $[(b-\varepsilon)_+] \leq m(b,\varepsilon)[a]$ in $\mathrm{Cu}(A \otimes \mathbb{K})$????

Equivalent is that there exists $\gamma \in (0,\varepsilon)$ and $d_1,\ldots,d_m$ with $(b-\gamma)_+ = \sum_{k=1}^m d_k^* a d_k$.

Here $m := m(b,\varepsilon)$ depends on both of b and ε. But by our *assumption* this number m is independent from $a \in A_+ \setminus \{0\}$. Clearly, the $c_1,\ldots,c_m$ depend also on a. It implies, by Lemma 2.1.9, in the notation of Definition 2.4.2 that, for all $0 \neq a \in A$, $[(b-\varepsilon)_+] \leq m(b,\varepsilon)[a]$ in the large Cuntz semi-group $\mathrm{Cu}(A)$. Then the below given arguments can be roughly outlined by saying that for $0 \neq a \in A_+$ and $n \in \mathbb{N}$ there exists $0 \neq g \in A_+$ with $n[g] \leq [a]$ in case of non-elementary simple A. The latter is wrong for "elementary" $A \cong \mathbb{K}(\mathcal{H})$ for any Hilbert space $\mathcal{H}$. There $m(b,\varepsilon)$ behaves almost like the rank of $(b-\varepsilon)_+ \in \mathbb{K}(\ell_2(\mathbb{N}))$.

Suppose that A is a non-elementary simple C^*-algebra and that a given element $b \in A_+$ with $\|b\| = 1$ is *approximately accessible in $m(b,\varepsilon)$-steps* (from every $a \in A_+$ with $\|a\| = 1$).

Then we find for each $a \in A_+$ with $\|a\| = 1$ and each $\varepsilon \in (0,1)$, a contraction *$d := d(a,\varepsilon) \in A$ with $d^* a d = (b-\varepsilon)_+$.*

In particular, $\|b - d^*ad\| \leq \varepsilon$, and we can take $m = 1$ for the numbers $m(b, \varepsilon)$, i.e., $m(b, \varepsilon) := 1$ for all $\varepsilon > 0$.

`Compare next blue with proof of (iv).`
`What is shorter or more transparent?`

Indeed: Let $a \in A_+$ with $\|a\| = 1$ and $\varepsilon \in (0,1)$. Define $\delta := \varepsilon/2$, $f_0(t) := t$, $f_1(t) := \max(0, t - (1-\delta))$ and $f_2(t) := (1-\delta)^{-1}\min(t, 1-\delta)$, for $t \in [0,1]_+$. Notice $\|f_0 - f_2\| = \delta$ if $1 - \delta$ is in the spectrum of a. Thus if $\|a - f_2(a)\| \leq \delta$.

Then $g := (a - (1-\delta))_+ = f_1(a)$ has norm $\|g\| = \delta$. It implies $D := \overline{gAg} \neq 0$. The element $a_1 := (1-\delta)^{-1}\big(a - (a - (1-\delta))_+\big) = f_2(a)$ satisfies $ga_1 = g = a_1 g$ and $a \leq a_1 \leq (1-\delta)^{-1}a$.

Let $n := m(b, \delta) \in \mathbb{N}$ from now on in this part of proof. (Notice that we require for the given map $\varepsilon \mapsto m(b, \varepsilon)$ no kind of regularity or general bound and require only that $m(b, \varepsilon) < \infty$ for all $\varepsilon \in (0,1)$.)

The hereditary C^*-subalgebra $D = \overline{gAg}$ of A is simple and is non-elementary by assumption on A and because $g \neq 0$. Thus, D admits an irreducible representation $\rho\colon D \to \mathcal{L}(\mathcal{H})$ such that $\rho(D) \cap \mathbb{K}(\mathcal{H}) = \{0\}$. It implies that $\mathcal{H}$ is not finite-dimensional. In particular, there exists a projection $Q \in \mathbb{K}(\mathcal{H})$ of rank $= n$. Let $\lambda\colon M_n \to Q\mathbb{K}(\mathcal{H})Q$ an isomorphism from M_n onto $Q\mathbb{K}(\mathcal{H})Q$, and denote by $\mu\colon \varphi \mapsto \varphi(1)$ the evaluation map from $\mathrm{C}_0((0,1], M_n)$ onto M_n.

By Lemma 2.1.15(ii), there exists a C^*-morphism $\psi\colon \mathrm{C}_0((0,1], M_n) \to D$ with $(\rho \circ \psi)(\varphi) = \lambda(\varphi(1)) = (\lambda \circ \mu)(\varphi)$ for all $\varphi \in \mathrm{C}_0((0,1], M_n) \to D$. Let $h := \psi(f_0 \otimes p_{11}) \in D$. Then $\|h\| = 1$ and $n = m(b, \varepsilon/2)$ imply that there are elements $c_1, \ldots, c_n \in A$ with $\| b - \sum_k c_k^* h c_k \| < \delta$ – by the assumption that b is *approximately accessible in* $n := m(b, \delta)$*-steps*. The Lemma 2.1.9 shows the existence of a contraction $e_0 \in A$ such that $(b - \delta)_+ = \sum_k d_k^* h d_k$ for $d_k := c_k e_0$, $k \in \{1, \ldots, m\}$. Notice $\sum_k d_k^* h d_k = e^*e$ with $e := \sum_k \psi(f_0^{1/2} \otimes p_{k,1}) d_k$, and where $p_{k,\ell}$ denote the matrix units of M_n.

The element e is contained in the closed left-ideal $L := D \cdot A$ by Lemma 2.1.7(o) because $\psi(\mathrm{C}_0(0,1] \otimes M_n) \subseteq D$, and the equation $a_1 g = g$ implies that $a_1 x = x = x a_1$ for all $x \in D = \overline{gAg}$, and that $a_1 y = y$ for all $y \in L$. In particular, $(b - \delta)_+ = e^*e = e^* a_1 e$ and $\|e\|^2 = \|b\| - \delta = 1 - \delta$.

Thus, we obtain that $\|(b-\delta)_+ - e^* a e\| \leq (1-\delta)\|a_1 - a\| \leq (1-\delta)\delta$. By Lemma 2.1.9, there exists a contraction $f \in A$ such that $\big(b - (1 - \varepsilon/8)\varepsilon\big)_+ = d^*ad$ for $d := ef$. In particular, $\|b - d^*ad\| < \varepsilon$.

We consider in Proposition 2.2.1 also non-separable simple C^*-algebras A. Therefore we "relax" the definition of "approximately accessible" elements $b \in A_+$ with $\|b\| = 1$ by considering certain separable simple C^*-subalgebras B of A with $b \in B$ that we define in the following manner:

We define numbers $n(b, a, \varepsilon; B)$ for C^*-algebras B and non-zero $a, b \in B$ with b in the closed ideal $J(a)$ of B generated by a, by letting $n := n(b, a, \varepsilon; B)$ the minimal number $n \in \mathbb{N}$ such that there exist $c_1, \ldots, c_n, d_1, \ldots d_n \in B$ with

$$\| b - \sum_{j=1}^{n} d_j^* a c_j \| < \varepsilon .$$

Here we can take $d_j = c_j$ if $a, b \in B_+$ by Remark B.15.1. We can define $m(b, \varepsilon; B) \in \mathbb{N} \cup \{+\infty\}$ as the least upper bound of the numbers $n(b, a, \varepsilon; B)$ if B is simple.

`Give ref.s to def's of` $n(b, \ldots)$`!` The definitions of $n(b, a, \varepsilon; B) \in \mathbb{N}$ and $m(b, \varepsilon; B) \in \mathbb{N}$ for non-zero $a, b \in B_+$ says that $\sup_{a \in B_+ \setminus \{0\}} n(b, a, \varepsilon; B) = m(b, \varepsilon; B)$ if B is simple, the $m(b, \varepsilon; B)$ is defined as above `Where exactly?` and if the set of numbers $n(b, a, \varepsilon; B)$ is bounded.

Let A a simple C^*-algebra. We say that $b \in A_+$ with $\|b\| = 1$ is *local approximately accessible* if, – for every simple separable C^*-subalgebra $B \subseteq A$ with $b \in B$ and with the property that $n(x, y, \varepsilon; B) = n(x, y, \varepsilon; A)$ for all $x, y \in B_+$ – there exists a number $m := m(b, \varepsilon; B) \in \mathbb{N}$ such that, for each $a \in B_+$ with $\|a\| = 1$ there exist $f_1, \ldots, f_m \in A$ with $\|b - \sum_k f_k^* a f_k\| < \varepsilon$. This implies that $n(b, a, \varepsilon; A) \leq m(b, \varepsilon; B)$.

Now we use that $n(b, a, \varepsilon; B) = n(b, a, \varepsilon; A)$ for the selected B and obtain that b *is approximately accessible in* $m := m(b, \varepsilon; B)$*-steps* from each $a \in B_+$ with $\|a\| = 1$ (with the $c_1, \ldots, c_m$ inside B).

It says in particular that b is approximately accessible in B by $m(b, \varepsilon, B)$ steps. We have seen above that this implies that b is approximately accessible by one step from each $a \in B_+$ with $\|a\| = 1$. By Proposition B.15.2(iii,iv), there exists for each $a, b \in A_+$ a simple separable C^*-subalgebra $B \subseteq A$ with $a, b \in B$ and $n(b, a, \varepsilon; B) = n(b, a, \varepsilon; A)$. Thus, $n(b, a, \varepsilon; A) = 1$ for all non-zero $a \in A_+$. Where we use that $n(b, a, \varepsilon; B) \leq m(b, \varepsilon; B)$ for all non-zero $a \in B_+$.

(i)⇒(iii): Let $D \subseteq A$ be a non-zero hereditary C^*-subalgebra. The definition of J. Cuntz [**172**, p. 186] says that D contains an infinite projection $p \neq 0$. It means that pAp contains a C^*-subalgebra that is isomorphic to the Toeplitz algebra $\mathcal{T} := C^*(s\,;\; s^*s = 1)$. Thus, D contains an isomorphic copy of the compact operators $\mathbb{K} \subseteq \mathcal{T}$.

(iii)⇒(ii): Obviously $A \neq \mathbb{C}$.

Let $a, b \in A_+$ with $\|a\| = \|b\| = 1$ and $1 > \varepsilon > 0$ be given, and let $\eta := \varepsilon/3$.

Then $e := (a - (1 - \eta))_+ \in A_+$ and $D := \overline{eAe}$ are non-zero. By assumption, D contains a non-zero stable C^*-subalgebra $E \subseteq D$.

The multiplier algebra $\mathcal{M}(E)$ of the stable C^*-algebra E contains a copy $C^*(s_1, s_2, \ldots\,;\; s_i^* s_j = \delta_{ij} 1) \subseteq \mathcal{M}(E)$ of $\mathcal{O}_\infty$ unitally, because $\mathcal{L}(\ell_2(\mathbb{N}))$ is unitally contained in $\mathcal{M}(E)$, cf. Remark 5.1.1(8) or Lemma 2.1.7(iv).

If $d \in E_+ \subseteq D_+$ with norm $\|d\| = 1$, then the elements $f_j := s_j d^{1/2}$ ($j = 1, 2, \ldots$) are contractions in $E \subseteq D$ that satisfy $f_i^* f_j = \delta_{i,j} d$.

Since A is simple, we find $g_1, \ldots, g_n \in A$ with $\|b - \sum g_k^* d g_k\| < \eta$. Let $h := \sum_{1 \leq k \leq n} f_k g_k \in D \cdot A$, cf. Lemma 2.1.7(ii). Then $\|h^* h - b\| < \eta$ and, thus,

$0 < 1-\eta < \|h\|^2 < 1+\eta$. On the other hand, $(a-e)h = (1-\eta)h$ because $h = \lim e^{1/n}h$ and $(a-e)e^{1/n} = (1-\eta)e^{1/n}$. Let $c := \|h\|^{-1}\cdot h$, then $\|c\| = 1$, $h = \|h\|\cdot c$ and

$$c^*ac - b = c^*\big(a-(1-\eta)^{-1}(a-e)\big)c + (c^*c - h^*h) + (h^*h - b)\,.$$

This gives the estimate

$$\|c^*ac-b\| \le \|a-(1-\eta)^{-1}(a-e)\| + |1-\|h\|^2| + \|h^*h-b\| < 3\eta = \varepsilon\,.$$

(ii)⇒(i): The compact operators on a Hilbert space $\mathcal{H}$ of dimension >1 do not satisfy the criteria listed under (ii), because a rank-one projection is not equivalent to a rank-two projection.

We postpone for a moment the below given proof of the existence of a non-zero projection $p \in \overline{eAe} \subseteq E \subseteq A$ for any given non-zero hereditary C^*-subalgebra E of A and a suitable non-zero $e \in E_+$ with $\|e\| = 1$.

Let $p \in A$ any non-zero projection. The unital C^*-subalgebra $D := pAp$ (with unit p) contains $f \in D_+$ with $\|f\| = 1$ and $0 \in \operatorname{Spec}_D(f)$, because otherwise $pAp \cong \mathbb{C}\cdot p$ by the Gelfand-Mazur theorem, and A must be isomorphic to the algebra $\mathbb{K}(\mathcal{H})$ of the compact operators on some Hilbert space $\mathcal{H}$. But this has been excluded above.

By assumption, we find $c \in A$ with $\|c^*fc - p\| < 1/2$. Then $f^{1/2}cp \in pAp$ is left-invertible in pAp, but is not right-invertible in pAp, because $\|c\|^2 b \ge (b^{1/2}cp)(pcb^{1/2})$. It shows that every non-zero projection $p \in A$ is infinite. (And is then properly infinite inside pAp by Lemma 2.1.6 because A is simple.)

It remains to show that every non-zero hereditary C^*-subalgebra E of A contains a non-zero projection. We find a "scaling element" in E and modify the method of J. Cuntz and B. Blackadar in [**78**] to produce from this element a non-zero projection in E:

Take $e \in E_+$ with $\|e\| = 1$ and define the commuting positive contractions $a := (4e-3)_+$, $b := 4e-(4e-1)_+$ and $g := 2e-(2e-1)_+$ in $C^*(e)_+ \subset E_+$. Notice that $\|a\| = \|b\| = \|g\| = 1$, $ga = a$, $bg = g$ and, therefore, $(b-t)_+g = (1-t)g$ and $(b-t)_+a = (g-t)_+a = a$ for all $t \in [0,1)$.

If g is a projection then this is a non-zero projection in E, and nothing has to be shown anymore. Otherwise, $0 \ge g - g^2 = g(1-g) \ne 0$, and we can proceed further in the following way:

By Part (ii) there exists $c \in A$ with $\|c^*a^2c - b\| < (3/5)^2$. Then Lemma 2.1.9 gives a contraction $d \in A$ that satisfies

$$d^*c^*a^2cd = (b-(3/5)^2)_+\,.$$

It follows, by using $5^2 - 3^2 = 4^2$, that the element $z := (5/4)acd$ satisfies

$$z^*z = (1-(3/5)^2)^{-1}(b-(3/5)^2)_+\,.$$

The element z is in the hereditary C^*-subalgebra E because $a, b \in E$. Moreover $\|z\| = 1$, $gz = z$ (by $ga = a$), and $z^*zg = g = gz^*z$ (by $(b-t)_+g = (1-t)g$ for

$t := 9/25$). It implies $(g-g^2)z = 0$ and $(g-g^2)(1-z^*z)^{1/2} = 0$. Notice that $(z^*z)z = z$ (by $z = gz$ and $z^*zg = g$). Therefore, $(1-z^*z)^{1/2}z = 0$. Let

$$u := z + (1-z^*z)^{1/2} \in \widehat{E} := E + \mathbb{C}\cdot 1 \subseteq \mathcal{M}(E).$$

Then $(g-g^2)uu^* = 0$ and

$$u^*u = 1 + z^*(1-z^*z)^{1/2} + (1-z^*z)^{1/2}z + 1 - z^*z = 1.$$

This shows that u is a non-unitary isometry in $\widehat{E}$, and that $p := 1 - uu^* \in E$ is a projection in E with $(g-g^2) \leq p$. Thus, $p^*p = p \neq 0$.

(iv)⇒(ii): The conditions in Part(iv) on A require that A is non-elementary and they obviously imply that A is simple. Simple non-elementary C^*-algebras are *antiliminary* in the sense that each non-zero hereditary C^*-subalgebra contains a non-zero 2-homogenous element, cf. Remark 2.1.16(ii,iii).

Let $a, b \in A_+$ with $\|a\| = \|b\| = 1$ and $1 > \varepsilon > 0$, define $\eta := \varepsilon/3$. Then $e := \big(a - (1-\eta)\big)_+ \in A_+$ is non-zero. Let $m := m(b,\eta)$. By Remark 2.1.16(iii), we find in the non-zero hereditary C^*-subalgebra $D := \overline{eAe}$ an element $d \in D_+$ and $f_1, f_2, \ldots f_m \in D$ with $\|d\| = 1$ and $f_i^*f_j = \delta_{i,j}d$ for $i,j = 1,\ldots,m$, because A is antiliminary.

By assumption, we find $c_1,\ldots,c_m \in A$ with $\|b - \sum c_k^*dc_k\| < \eta$. Let $h := \sum_{1\leq k\leq m} f_kc_k$.

Then $hh^* \in D$, $\|h^*h - b\| < \eta$, $0 < 1-\eta < \|h\|^2 < 1+\eta$ and $(a-e)h = (1-\eta)h$. We get $\|c^*ac - b\| < 3\eta = \varepsilon$ for $c := \|h\|^{-1}\cdot h$, by the same calculation as in the proof of the implication (iii)⇒(ii).

If A is simple and has Property pi(n) of Definition 2.0.4 for some $n \in \mathbb{N}$ then we can take $m(b,\varepsilon) := n$ for each $b \in A_+$ and the Property pi(n) excludes the cases $A \cong M_k$ for $k \leq n$ in its definition. It follows that A with Property pi(n) can not be an elementary C^*-algebra, because if $A \cong \mathbb{K}(\mathcal{H})$ with $\mathrm{Dim}(\mathcal{H}) > n$ and $a, b \in A$ are contractions with ranks $(Rk)(a) = 1$ and $(Rk)(b) > n$ then there can not exist $c_1,\ldots,c_n \in A$ with $\|b - \sum c_k^*ac_k\| < 1/2$.

(ii)⇒(iv): The simple algebra A can not be elementary, because if $p, q \in A$ are non-zero projections with rank $\mathrm{Rk}(q) = 1$ then there exists $c \in A$ with $\|p - c^*qc\| < 1/2$, and this shows that all projections in $A \setminus \{0\}$ have rank one, i.e., $A \cong \mathbb{C}$. The case $A = \mathbb{C}$ has been excluded in Definition 1.2.1.

Thus A satisfies the assumptions of Part (iv) with $m(b,\varepsilon) = 1$.

(i)⇒(v): We show moreover that for each $a, b \in A_+$ and $\varepsilon > 0$ there exist $d_1, d_2 \in A$ with $d_1^*abd_2 = 0$, $\|a^2 - d_1^*a^2d_1\| \leq \varepsilon$, and $\|b^2 - d_2^*b^2d_2\| \leq \varepsilon$.

We may suppose that $\max(\|a\|,\|b\|) \leq 1$ and that $\varepsilon \in (0,1)$, because we can start here with smaller $\varepsilon > 0$ if necessary.

If $ab = 0$, then let $\beta := \varepsilon/2$, $d_1 := a^\beta$ and $d_2 := b^\beta$. We get $\|d_1^*abd_2\| = 0$, $\|a^2 - d_1^*a^2d_1\| \leq \varepsilon$, and $\|b^2 - d_2^*b^2d_2\| \leq \varepsilon$ by functional calculus, because $0 \leq t^2 - t^{2+\varepsilon} \leq \varepsilon$ for $t \in [0,1]$.

If $ab \neq 0$, then there is $\delta \in (0, \|ab\|^2)$ with $c := (ab^2a - \delta)_+ \neq 0$. The non-zero hereditary C^*-subalgebra $D := \overline{cAc}$ contains a non-zero infinite projection p by assumption (i).

The elements pcp and pab^2ap are strictly positive in pAp, because $p \in \overline{cAc}$ and $c \leq ab^2a$. Thus, pab^2ap and $pa^2p \geq pab^2ap$ are invertible inside the C^*-algebra pAp with unit p.

Let $f := (pab^2ap)^{-1/2} \in (pAp)_+$. It satisfies $fpab^2apf = p$. Since $f = pfp$, and $p \in \overline{cAc}$ we get $fab^2af = p \leq \delta^{-1}ab^2a \leq \delta^{-1}a^2$.

The element $v := baf$ is a partial isometry in A and $q := vv^* = baf^2ab$ is a projection in bAb. The element b^2 is strictly positive in $\overline{bAb}$, thus qb^2q must be invertible in qAq, i.e., there is $\eta > 0$ with $\eta q \leq qb^2q$. It follows that $\eta p = \eta v^*qv \leq v^*qb^2qv = v^*b^2v$, and that v^*b^2v is invertible in pAp.

All infinite projections in the simple algebra pAp are properly infinite by Lemma 2.1.6. Thus, partial isometries $s, t \in A$ with $s^*s = p = t^*t$ and $ss^* + tt^* \leq p$ exist.

Let $g_1 := fs$ and $g_2 := baft = vt$. Then $g_2^*bag_1 = t^*fab^2afs = t^*ps = 0$. Since f, pa^2p and v^*b^2v are invertible positive elements of pAp, we get that $g_1^*a^2g_2 = s^*fpa^2pfs$ and $g_2^*b^2g_2 = t^*v^*b^2vt$ are positive elements in pAp that are invertible inside pAp. It implies the existence of $h_1, h_2 \in (pAp)_+$ with $h_1(g_1^*a^2g_1)h_1 = p$ and $h_2(g_2^*b^2g_2)h_2 = p$. The elements $e_k := g_kh_k$ satisfy $e_1^*a^2e_1 = p = e_2^*b^2e_2$ and $e_2^*bae_1 = 0$.

Lemma 2.1.7(i) applies to pAp with properly infinite p. Thus, there are $x_1, x_2 \in A$ with $x_1^*x_1 = a^2$, $x_2^*x_2 = b^2$, and $x_1x_1^*$, $x_2x_2^* \in pAp$. The elements $d_1 := e_1x_1$ and $d_2 := e_2x_2$ in A satisfy $d_2^*bad_1 = x_2^*e_2bae_1x_1 = 0$, $d_1^*a^2d_1 = a^2$ and $d_2^*b^2d_2 = b^2$.

(v)⇒(xi): Let $a \in A_+$. If we take $a_1 := a_2 := a^{1/2}$ and $\varepsilon > 0$ in (v), then we get $d_1, d_2 \in A$ with $\|d_i^*ad_j - \delta_{ij}a\| < \varepsilon$. Thus, a is properly infinite.

(xi)⇒(vii): The algebra A is simple and non-zero – by our overall pre-assumption. If every non-zero element $a \in A_+$ is infinite and if A is simple then each non-zero a is also properly infinite by Lemma 2.1.6. In particular, A must be non-elementary, because rank-one projections are not infinite in the algebra of compact operators on a Hilbert space.

We show that A satisfies the assumptions of Part (vii) with $n := 1$:

A is non-zero and is not one-dimensional because A is non-elementary. Let $a, b \in A_+$ non-zero and $\varepsilon > 0$. Since A is simple there exist a *minimal* $m \in \mathbb{N}$ such that there exist elements $d_1, \ldots, d_m \in A$ with $\|b - \sum_{k=1}^m d_k^*ad_k\| < \varepsilon$. We show that necessarily $m = 1$ if a is properly infinite:
Suppose that $m > 1$. Then there is $\delta > 0$ with $\delta \cdot 2(\|d_{m-1}\| + \|d_m\|)^2 < \varepsilon - \|b - \sum_k d_k^*ad_k\|$. Since $a \in A_+$ is properly infinite, there are $e_1, e_2 \in A$ with $\|a - e_k^*ae_k\| < \delta$ and $\|e_1^*ae_2\| < \delta$. Let $f_{m-1} := e_1d_{m-1} + e_2d_m$ and $f_k := d_k$ for $j \leq m-2$. Then $\|b - \sum_{k=1}^{m-1} f_k^*af_k\| < \varepsilon$, which contradicts the minimality of $m > 1$ with this property.

(vii)⇒(iv): Let $n \in \mathbb{N}$ such that A is not isomorphic to $M_k(\mathbb{C})$ for each $k \leq n$ and that, for every non-zero $a, b \in A_+$ and $\varepsilon > 0$, there exists $d_1, \ldots, d_n \in A$ such that $\|b - \sum_{k=1}^n d_k^* a d_k\| < \varepsilon$.

We show that A satisfies the conditions of Part (iv) with $m(b, \varepsilon) := n$ for all $b \in A_+$ and $\varepsilon > 0$ with $\|b\| = 1$:

Suppose that $A \cong \mathbb{K}(\mathcal{H})$ for some Hilbert space $\mathcal{H}$, then each projection $p \in \mathbb{K}(\mathcal{H})$ has rank $\leq n$. Thus, $\mathcal{H}$ has dimension $\leq n$, and A is isomorphic to M_k for some $k \leq n$. Since the latter is excluded by the assumptions, A must be non-elementary.

Let $a, b \in A_+$ with $\|a\| = 1 = \|b\|$ and $\varepsilon > 0$. We let $\delta := \varepsilon/4$.

Consider $f := \big(a - (1 - \delta)\big)_+ \in A_+$. Then $f \neq 0$ and $(1 - a)f \leq \delta f$. By conditions in (vii), there are $d_1, \ldots, d_n \in A$ with $\|b - \sum_{k=1}^n d_k^* f d_k\| \leq \delta$. The elements $e_k := f^{1/2} d_k$ satisfy $\| \sum_k e_k^* e_k\| \leq 1 + \delta$ and $e_k^*(1 - a)e_k \leq \delta e_k^* e_k$. Thus, $\| \sum_k e_k^*(1 - a)e_k\| \leq (1 + \delta)\delta$. We let $c_k := (1 + \delta)^{-1/2} e_k$. Then $\|c_k\| \leq 1$, $\| \sum_k c_k^*(1 - a)c_k\| \leq \delta$, and $\|b - \sum_k c_k^* c_k\| \leq 2\delta$.

It follows $\|b - \sum_{k=1}^n c_k^* a c_k\| \leq 3\delta < \varepsilon$.

(viii)⇒(vii): Our overall assumption is that A is simple. For simple A the Definition 2.0.4 of weak pure infiniteness reformulates obviously as follows:
There exists (general) $n \in \mathbb{N}$ such that for each $a, b \in A_+$ with $a \neq 0$ and every $\varepsilon > 0$, there exists $d_1, \ldots, d_n \in A$ – depending on (a, b, ε) – such that

$$\|b - \sum_{j=1}^{n} d_j^* a d_j\| < \varepsilon$$

and the algebra $\ell_\infty(A)$ has no irreducible representation of dimension $\leq n$.

The latter implies for simple A that the algebra A can not be isomorphic to $M_k(\mathbb{C})$ for some $k \leq n$, because otherwise then $\ell_\infty(A) \cong M_k(\ell_\infty)$ would have irreducible representations of dimension $\leq n$, which is forbidden by (viii).

(i)⇒(vi): We may suppose that $\|a\| = 1$. Then the hereditary C^*-algebra E generated by $(a^*a - 1/2)_+$ contains an infinite projection $p \in E$. It follows that pa^*ap is invertible in pAp, and the positive element $v := (pa^*ap)^{-1/2} \in pAp$ satisfies $(va^*)av = p$. Since p is infinite, there exists a (non-zero) stable hereditary C^*-subalgebra $D \subseteq pAp$.

For every (full) stable hereditary C^*-subalgebra $D \subseteq A$ and every $b \in A$ there exists $d \in A$ with $dd^* \in D$ and $d^*d = (b^*b)^{1/4}$ by Lemma 2.1.7. Let $b = w(b^*b)^{1/2}$ the polar decomposition of b in A^{**}. The element $z := w(b^*b)^{1/4} \in A^{**}$ is in A, because

$$z = \lim_n b(1/n + (b^*b)^{1/4})^{-1}$$

in norm and $(1/n + (b^*b)^{1/4})^{-1}$ is a multiplier of A in A^{**}. Clearly $zd^*d = z(b^*b)^{1/4} = b$.

Let $x := zd^*va^*$ and $y := vd$. Then $xay = zd^*va^*avd = zd^*pd = b$.

(Alternatively one could combine Lemma 2.1.7 and [**616**, prop. 1.4.5] and gets almost the same decomposition.)

(vi)⇒(ii): Let $a, b \in A_+$ with $\|a\| = \|b\| = 1$ and $\varepsilon \in (0,1)$, and let $\delta := \varepsilon/3$. There are $x, y \in A$ with $x(a-(1-\delta))_+ y = b^{1/2}$. It follows that $x \neq 0$ and $e^*e \geq b$ for $e := \|x\|(a-1+\delta)_+^{1/2} y$. By Lemma 2.1.9 there exists a contraction $f \in A$ with $(ef)^*(ef) = (b-\delta)_+$. The element $d := ef$ is a contraction in A, and dd^* is contained in the hereditary C^*-subalgebra of A that is generated by $(a-(1-\delta))_+$, because

$$dd^* \leq ee^* \leq \|x\|^2\|y\|^2(a-(1-\delta))_+ .$$

Thus, $d^*h(a)d = d^*d$ and $\|d^*d - d^*ad\| \leq \|h(a) - a\| \leq \delta$ for the function $h(t) := \min((1-\delta)^{-1}t, 1)$ with property $(t-(1-\delta))_+ h(t) = (t-(1-\delta))_+$ for $t \in [0,1]$. Since $\|d^*d - b\| \leq \delta$, we get $\|d^*ad - b\| < \varepsilon$.

(ii)⇒(viii): Clearly, if A satisfies (ii) then A satisfies Condition (i) of Definition 2.0.4 of 1-purely infinite algebras.

Let $a \in A_+$ with $\|a\| = 1$, $b := (b_1, b_2, \ldots)$ a positive contraction in $\ell_\infty(A)$, and $\varepsilon \in (0,1)$. Define $g := \eta^{-1}(a-(1-\eta))_+$ for $\eta := \varepsilon/8$ and let $\Delta(a) := (a, a, \ldots) \in \ell_\infty(A)$ for $a \in A$. Then $\|g\| = 1$ and, by Part (ii), there exists elements h_k with $\|b_k - h_k^* g^2 h_k\| < \eta$ for $k \in \mathbb{N}$. It implies $\|gh_k\| < (1+\eta)^{1/2}$ and with $d_k := (1+\eta)^{-1/2} g h_k$, that $\|d_k\| < 1$ and $\|b_k - d_k^* a d_k\| \leq \varepsilon/2$ for $k \in \mathbb{N}$, because

$$b - d_k^* a d_k = (b - h_k^* g^2 h_k) + (1+\eta) d_k^*(1-a) d_k + \eta d_k^* a d_k .$$

This implies $\|b - d^*\Delta(a)d\| < \varepsilon$ in $\ell_\infty(A)$ for the contraction $d := (d_1, d_2, \ldots) \in \ell_\infty(A)$.

Since A has no non-zero character by assumption in (ii) and since $\Delta(A)$ generates $\ell_\infty(A)$ as a closed ideal of $\ell_\infty(A)$, it follows that $\ell_\infty(A)$ does not have a non-zero character. Thus, condition (ii) of the Definition 2.0.4 of 1-purely infinite algebras is also satisfied.

(ix)⇒(iii): Let D a non-zero hereditary C^*-subalgebra of A and $a \in D_+$ with $\|a\| = 1$. Then the non-zero σ-unital hereditary C^*-subalgebra $E := \overline{aDa} \subseteq D$ is non-unital – or – zero is isolated in the spectrum of a. In the first case E is stable by assumption of (ix). In the second case $E = pDp$ is simple and unital with unit given by the projection $p := \varphi(a)$ using the function

$$\varphi(t) := \min(1, \max(0, \alpha t - \gamma/2)),$$

where γ denotes the minimum of $\mathrm{Spec}(a) \setminus \{0\}$ and $\alpha := (\gamma+2)/2\gamma$. In the second case we can consider a maximal commutative C^*-subalgebra C of the unital C^*-algebra pDp. It is not difficult to check that a unital commutative C^*-algebra C with the property that every $c \in C_+$ with $\|c\| = 1$ has all spectral values $t \in (0,1) \cap \mathrm{Spec}(c)$ isolated from 0 and 1 must be of finite (linear) dimension. But this would cause that E must be isomorphic to M_n for some $n \in \mathbb{N}$. And this would imply that also D and A are elementary, but is excluded by the assumptions on A in Part (ix).

Thus, $C \subseteq E$ contains at least one $a \in C_+$ with $\|a\| = 1$, 0 not isolated from the spectrum of $a \in C$ and $F := \overline{aAa} \subseteq D$. Then F is a non-zero stable hereditary C^*-subalgebra of D by assumption of Part (ix). Hence, the algebra D contains in both cases a non-zero stable C^*-subalgebra.

(x)⇒(i): Our overall pre-condition on A requires that A is simple and is non-zero.

Suppose that A has real rank zero and every non-zero projection $p \in A$ is infinite. Then the simplicity of A implies that each projection p is properly infinite in A by Lemma 2.1.6.

Since every non-zero projection $p \in A$ is properly infinite, it suffices to show that a given non-zero σ-unital hereditary C^*-subalgebra D of A contains a non-zero projection.

By a result of L.G. Brown and G.K. Pedersen [**113**], A has real rank zero ($RR(A) = 0$), if and only if, every non-zero σ-unital hereditary C^*-subalgebra D of A contains an approximate unit consisting of projections. In particular, each nonzero hereditary D contains a projection $p \neq 0$. That is properly infinite by our assumptions.

(Notice here that the definition of the "real rank" in [**113**] – specialized to the case $RR(A) = 0$ – says that A has real rank zero, if and only if, the self-adjoint invertible elements of $A + \mathbb{C} \cdot 1 \subseteq \mathcal{M}(A)$ are dense in $A_{sa} + \mathbb{R} \cdot 1$. It is shown in [**113**] that this implies the property (FS), i.e., that the self-adjoint elements with finite spectrum are dense in A_{sa}. It is proven there that this is equivalent to the property that every nonzero hereditary C^*-subalgebra $D \subseteq A$ has an approximate unit of D consisting of projections.)

(i)⇒(x): Let $p \in A$ a non-zero projection. Then $E := pAp$ is a non-zero hereditary C^*-subalgebra of A. Since A is purely infinite in the sense of J. Cuntz, E contains a non-zero infinite projection $q \leq p$. Thus p is also infinite. Moreover p is properly infinite because A is simple, cf. Lemma 2.1.6.

By [**113**], A has real rank zero, if and only if, each non-zero σ-unital hereditary C^*-subalgebra D of A contains an approximate unit consisting of projections.

Recall that D is σ-unital, if and only if, $D = \overline{eAe}$ for some (inside D) strictly positive contraction $e \in D_+$. D is then unital, if and only if, 0 is isolated in the spectrum of e.

Thus, to conclude, it suffices to show that every non-unital σ-unital D is stable, because then $D \cong D \otimes \mathbb{K} \cong pAp \otimes \mathbb{K}$ for each non-zero projection $p \in D$ by L.G. Brown's stable isomorphism theorem [**107**], and D has an approximate unit consisting of projections $P_n \in D$ given by $P_n := p \otimes (e_{11} + \ldots + e_{nn})$, using the natural isomorphism $D \cong pAp \otimes \mathbb{K}$.

The stability of $D = \overline{eAe}$ follows from the fact that for each $\varepsilon > 0$ there exists $d \in D$ with $\|d^*ed\| \leq \varepsilon$ and $d^*d = (e - \varepsilon)_+$, because the (two-sided) annihilator $F := \mathrm{Ann}((e - \varepsilon)_+, D)$ of $(e - \varepsilon)_+$ in D is a non-zero hereditary C^*-subalgebra of

D, and contains a non-zero infinite projection $q \in F$ by assumptions in Part (i). Thus, there exists $d \in D$ with $d^*(e-\varepsilon)_+ d = 0$ and $d^*d = e$, by Lemma 2.1.7. The stability of D follows now from [**373**] – or alternatively from our Corollary 5.5.1 of our generalized version of the WvN-theorem.

(i)⇒(ix): The proof of the implication (i)⇒(x) applies almost verbatim. It shows

`Can delete next ''red/blue'' to get ''new version of (ix)''`

that every non-zero projection in A is infinite (even properly infinite by Lemma 2.1.6), and

that every non-zero non-unital σ-unital hereditary C^*-subalgebra D of A is stable.

Alternatively, the stability of non-zero non-unital σ-unital hereditary C^*-subalgebras D of purely infinite C^*-algebra follows also directly from [**462**, thm. 4.24]: If D is σ-unital, purely infinite, and has no unital quotient, then D stable. It uses [**373**]. Here we can use instead also Corollary 5.5.1 that does not use [**373**] for its proof and is not circular intertwined with proofs given here in Chapter 2 or on other places.

[Check/decide Alternative:]

A is non-elementary and every non-zero non-unital σ-unital hereditary C^*-subalgebra D of A is stable.

Still applicable for new Part (ix)?

Proof of alternative formulation of (ix) out of given (old?) formulation of Part (ix):

By assumption A is non-elementary, i.e., $A \ncong \mathbb{K}(\mathcal{H})$ for any Hilbert space $\mathcal{H}$.

In particular pAp is not of finite (linear) dimension for each non-zero projection $p^*p = p \in A$. It follows that every maximal commutative C^*-subalgebra C of pAp contains a positive element $b \in C \subseteq pAp$ with the property that 0 is not isolated in the spectrum of b. This implies that the non-zero σ-unital hereditary C^*-subalgebra $D := \overline{bAb}$ of A is not unital. Hence, D is stable by the assumptions in Part (ix). By our "overall assumption": A is simple. Thus D generates A as ideal of A. Then Part (ii) of Lemma 2.1.7 shows that there exists $c, d \in A$ with $d^*d = p = c^*c$, $cc^* = dd^* \in D \subseteq pAp$ and $c^*d = 0$. Thus, p is properly infinite in A, by assumptions.

(xii)⇒(xi): Suppose that A is simple and that there exists $n \in \mathbb{N}$ such that each n-homogenous non-zero element $a \in A_+$ is infinite, and that A is not isomorphic to $M_k(\mathbb{C})$ for $k = 1, \ldots, n-1$.

Since A is simple, it follows that each n-homogenous $a \in A_+ \setminus \{0\}$ is properly infinite in A. The algebra A is non-elementary, because the projections of rank equal to n in the algebra of compact operators on Hilbert spaces H of dimension $\geq n$ are n-homogenous, but – obviously – are not properly infinite.

It follows that the non-zero closed hereditary C^*-subalgebras D of A are also non-elementary. Hence, each non-zero D contains non-zero n-homogenous elements. It implies that every non-zero element $a \in A_+$ majorizes a non-zero properly infinite element. Thus, each non-zero $a \in A_+$ is itself properly infinite by Lemma 2.1.6.

(xi)⇒(xiii): It is obvious with $n := 1$.

(xiii)⇒(xii): Suppose that A is simple and there exists $n \in \mathbb{N}$ with the property that $a \otimes 1_n$ is infinite in $A \otimes \mathbb{K}$ for each non-zero $a \in A_+$. Then A is non-elementary because this can not happen for $a \in A_+$ with non-zero $a = a^2$ and $aAa = \mathbb{C} \cdot a$.

Apply Lemma 2.1.6 to the infinite elements $a \otimes 1_n$ and get that $a \otimes 1_n$ is *properly* infinite in the simple C^*-algebra $A \otimes \mathbb{K}$ for each $a \in A_+$.

Let $a \in A_+$ an n-homogenous contraction and $\varphi \colon \mathrm{C}_0((0,1], M_n) \to A$ a C^*-morphism with $a = \varphi(f_0 \otimes 1_n)$ for $f_0(t) := t$ $(t \in [0,1])$. If p_{jk} denote the matrix units, then $1_n := p_{11} + \ldots + p_{nn}$ is the unit element of M_n. Let $c := \varphi(f_0 \otimes p_{11}) \in A_+$.

The elements $a \otimes p_{11} = \varphi(f_0 \otimes 1_n) \otimes p_{11}$ and $c \otimes 1_n = \varphi(f_0 \otimes p_{11}) \otimes 1_n$ are Murray–von-Neumann equivalent in $A \otimes M_n \cong M_n(A)$, because $f_0 \otimes 1_n \otimes p_{11}$ is unitarily equivalent to $f_0 \otimes p_{11} \otimes 1_n$ in $\mathrm{C}_0(0,1] \otimes M_n \otimes M_n$ by a unitary in $1 \otimes M_n \otimes M_n$.

It is easy to check that proper infiniteness of positive elements is invariant under Murray–von-Neumann equivalence, because the proper infiniteness of an element a means $(a \oplus a) \approx a$ with Cuntz equivalence $\approx$. Therefore proper infiniteness passes to all elements $b \approx a$. Use that $\sim_{MvN}$ implies the (weaker) equivalence $\approx$ to obtain that $a \otimes p_{11}$ is properly infinite in $A \otimes \mathbb{K}$. Thus, each positive n-homogenous element a in $A \cong A \otimes p_{11}$ is properly infinite in $A \otimes \mathbb{K}$. The definition of proper infiniteness shows that the positive element a is also properly infinite in A itself, because the definition of properly infinite elements at the beginning of Section 1 shows that an inside A properly infinite element a is always in the hereditary C^*-subalgebra $D := \overline{aAa} \cong D \otimes p_{11}$ properly infinite if $a \otimes p_{11}$ is properly infinite in $A \otimes \mathbb{K}$, cf. the argument in proof of Proposition 2.2.5(i).

(xiii)⇔(xiv): Suppose that there exists $n \in \mathbb{N}$ such that $a \otimes 1_n$ is infinite in $M_n(A)$ for each non-zero $a \in A_+$. Since $M_n(A)$ is simple, $a \otimes 1_n$ is properly infinite by Lemma 2.1.6, i.e., A has property pi-n of Definition **??**.

The implication (xiv)⇒(xiii) is obvious by the Definition of property pi-n.

(ii)⇒(xv): If A satisfies (ii), then A is non-elementary and the additional condition $\|c\| \leq 1$ can be derived like in the proof of the implication (vi)⇒(ii).

It says that A satisfies the conditions in Part (xv) with $\nu(a, b, \varepsilon) := 1$ for all $a, b \in A_+$ and $\varepsilon > 0$.

(xv)⇒(iv): The conditions on the algebra A in Part (xv) imply that A is simple, because the existence of the numbers $\nu(a, b, \varepsilon) < \infty$ implies that the element b is contained in the ideal generated by a for each $a, b \in A_+$ with $\|a\| = 1$.

Only non-elementary A are allowed in Part (xv) by assumptions. Thus, to verify that the assumptions of Part (xv) imply the assumptions in Part (iv), we are going to show that there exists, for each $b \in A_+$ with $\|b\| = 1$ and each $\varepsilon > 0$, a number $m := m(b, \varepsilon) \in \mathbb{N}$ that satisfies the conditions in Part (iv), i.e., has the property that for any $a \in A_+$ with $\|a\| = 1$ there exists an "m-step inner" c.p. map $V := f_1^*(\cdot)f_1 + \cdots + f_m^*(\cdot)f_m$ with $\|b - V(a)\| < \varepsilon$. (If this is the case, then the above proven equivalence of Parts (iv) and (ii) shows that, moreover, $m(b, \varepsilon) = 1$ for all $b \in A_+$ with $\|b\| = 1$ and $\varepsilon > 0$.)

Notice that the definition of the numbers $m := m(b, \varepsilon) \in \mathbb{N}$ in Part (iv) is given by the upper bound (over all $a \in A_+$) of the numbers $m := m(b, a, \varepsilon) \in \mathbb{N}$ that are defined as follows:
Given non-zero $a \in A_+$ and $\varepsilon > 0$, then there exists a minimal $m \in \mathbb{N}$ such that there exist elements $f_1, \ldots, f_m \in A$ that satisfy the inequality $\|b - \sum_{\ell=1}^{m} f_\ell^* a f_\ell\| < \varepsilon$. Here without any proposed bound for the norms $\|f_\ell\|$.

The reader should observe here that the number $\nu := \nu(b, a, \varepsilon) \in \mathbb{N}$ is differently defined. It is the minimal number ν that satisfies the following condition:
For each power $\ell \in \mathbb{N}$ there exist $\nu(b, a, \varepsilon)$ *contractions* $c_1, \ldots, c_\nu \in A$ – depending on $\varepsilon > 0$, $b, a \in A_+$ and $\ell \in \mathbb{N}$ – such that $\| b - \sum_{k=1}^{\nu} c_k^* a^\ell c_k \| < \varepsilon$. The crucial point is here that we *require* here that this number ν is independent from the $\ell \in \mathbb{N}$.

We consider first the case of separable A, and discuss later the reduction to the study of suitable simple separable C^*-subalgebras B of A that have the same values $\nu(b, a, \varepsilon; B) = \nu(b, a, \varepsilon; A)$ for all $a, b \in B$.

We show for separable simple A that if $\nu(a, b, \varepsilon) < \infty$ for all $a \in A$ and $\varepsilon > 0$ then $m(b, \varepsilon) < \infty$ for all $\varepsilon > 0$. The latter causes that Part (iv) applies to A and shows that $m(b, \varepsilon) = 1$, i.e., that A is purely infinite by the implication (iv)⇒(ii).

We use in the separable case Part (iii) of Lemma 2.1.15, Lemma 2.1.17 and the classical "excision" Proposition A.21.4 for the proof.

Move the Excision Lemma back to Chp.2. !!?

Let $b \in A_+$ with $\|b\| = 1$ and let ρ denote a pure state on A with $\rho(b) = 1$.

Any pure state on A would do the job!
Only the below defined c plays a role.

By the above cited Lemmata

(???? Cite more precise !!!)

there exists a positive contraction $c \in A_+$ with $\|c\| = 1$ such that $\rho(c) = 1$, and for all $a \in A$,

$$\lim_n \|c^{2n}\rho(a) - c^n a c^n\| = 0\,.$$

By assumptions of Part (xv), there are numbers $\nu(b, c^2; \varepsilon) < \infty$, for every $\varepsilon > 0$ with the in Part (xv) quoted properties. But for fixed b and $\varepsilon > 0$ they could depend possibly on the contraction $c \in B_+$.

Let $\varepsilon > 0$ given and let $\delta := \varepsilon/(2\nu(b, c^2; \varepsilon/2))$.

Let $a \in A_+$ non-zero, w.l.o.g., $\|a\| = 1$. By Inequality (1.7) in Lemma 2.1.17 there exists a contraction $g \in A$ with $1 = \|a\| \leq \delta + \rho(g^*ag) \leq \delta + 1$. Thus, there exists $n_0 \in \mathbb{N}$ with $\|\rho(g^*ag)c^{2n} - c^n g^*agc^n\| < \delta$ for all $n \geq n_0$. Hence,

$$\|c^{2n} - c^n g^*agc^n\| < 2\delta \quad \text{for all } n \in \mathbb{N}, n \geq n_0 .$$

By assumptions of Part (xv), we find contractions $d_1, \ldots, d_\nu \in A$ with $\nu := \nu(b, c^2; \varepsilon/2)$ a fixed number, but with the d_k also depending from the power $n \in \mathbb{N}$ of $(c^2)^n$, such that

$$\|b - \sum_{k=1}^{\nu} d_k^* c^{2n} d_k\| < \varepsilon/2 .$$

Then $\|f_k^* a f_k - d_k^* c^{2n} d_k\| < \delta$ for the contractions $f_k := gc^n d_k$ $(k = 1, \ldots, \nu)$, and therefore

$$\|b - \sum_{k=1}^{\nu} f_k^* a f_k\| < \varepsilon/2 + 2\nu \cdot \delta \leq \varepsilon .$$

It shows that for $a, b \in A_+$ and $\varepsilon > 0$ and $\|a\| = \|b\| = 1$ holds $n(a, b, \varepsilon) \leq \nu(b, c^2, \varepsilon/2) < \infty$, with suitable fixed $c \in A_+$ and $\|c\| = 1$. Thus $m(b, \varepsilon) < \infty$ for each $b \in A_+$ with $\|b\| = 1$ and $\varepsilon > 0$.

This means that – in case that A is separable – the conditions in Part (xv) imply the conditions in Part (iv).

Case with separable A is ready here.

Now we discuss how to reduce to the separable case.

By Proposition B.15.2(iii,iv), there exists for each $a, b \in A_+$ a separable C^*-subalgebra $B \subseteq A$ with $a, b \in B$ and the property that $n(e, d, \varepsilon; B) = n(e, d, \varepsilon; A)$ and $m(e, d, \varepsilon; B) = m(e, d, \varepsilon; A)$ for all $\varepsilon > 0$ and $d, e \in B_+$, where for given C^*-subalgebras $B \subseteq A$ the numbers $n := n(e, d, \varepsilon; B)$ are defined for each $d, e \in B_+$ and $\varepsilon > 0$ as the minimal number $n \in \mathbb{N}$ with the property that there exists n contractions $c_1, \ldots, c_n \in B$ with $\|e - \sum_{k=1}^n c_k^* d c_k\| < \varepsilon$. The above defined (possibly infinite) numbers $\nu(b, a, \varepsilon; B) \in \mathbb{N} \cup \{+\infty\}$ is then equal to $\sup_{\ell \in \mathbb{N}} n(b, a^\ell, \varepsilon; B)$.

In particular this causes that B is simple if A is simple, and that $\nu(a, b, \varepsilon; B) = \nu(a, b, \varepsilon; A)$ for $a, b \in B_+$.

Since we can find for each $a, b \in A_+$ a separable C^*-subalgebra B with this property, we get finally that A satisfies the assumptions of Part (iv), i.e., $n(b, a, \varepsilon; A) = 1$ for all non-zero $a \in A_+$. Where we use $n(b, a, \varepsilon; B) \leq m(b, \varepsilon; B)$ for all non-zero $a \in B_+$.

We start now the study of the above proposed separable case:

We reduce the general case to the separable case by Proposition B.15.2(iii,iv).

It says that, for each $a, b \in A_+$, there exists a simple separable C^*-subalgebra $B \subseteq A$ with $a, b \in B$ and $n(c, d, \varepsilon; B) = n(c, d, \varepsilon; A)$ and $\nu(c, d, \varepsilon; B) = \nu(c, d, \varepsilon; A)$ for all $c, d \in B_+$.

In particular, $n(b,a,\varepsilon;A) = n(b,a,\varepsilon,B) = 1$. Thus, $n(b,a,\varepsilon) = 1$ for all $a,b \in A_+$ with $\|a\| = \|b\| = 1$. It implies finally that Part (xv) implies Part (iv) with $n(a,b;\varepsilon) = 1$.

(xvi)⇒(ii): Let $a,b \in A_+$ with $\|a\| = \|b\| = 1$ and $\varepsilon > 0$. There is a character χ on $C^*(a)$ with $\chi(a) = 1$. The character χ extends to a linear functional ρ on A with $\rho(a) = 1 = \|\rho\| = \|\chi\|$ by Hahn-Banach extension. Consider the maps $V\colon A \to \mathbb{C}$ and $W\colon \mathbb{C} \to A$ defined by $V(x) := \rho(x)$ for $x \in A$ and $W(\xi) := \xi \cdot b$. The maps V and W are completely positive, have norms $= 1$ and satisfy $W(V(a)) = b$. By assumptions of Part (xvi), there exist $d_1, d_2 \in A$ with $d_1^* d_2 = 0$ and $\|b - d_k^* a d_k\| = \|W(V(a)) - d_k^* a d_k\| < \varepsilon$ for $k \in \{1,2\}$. Thus, A satisfies the condition in Part (ii).

TEXT-Info (xvi):

For each finite subset $F \subset A$, each $n \in \mathbb{N}$, $\varepsilon > 0$, each completely positive contractions $V\colon A \to M_n$, $W\colon M_n \to A$ there exists contractions $d_1, d_2 \in A$ (depending from F, V, W and ε) with $d_1^* d_2 = 0$ and

$$\|(W \circ V)(x) - d_k^* x d_k\| < \varepsilon \quad \text{for all} \quad x \in F,\ k \in \{1,2\}\,.$$

From Proposition 3.1.9(ii):

Suppose that A has the property, that for every positive contraction $e \in A_+$ and $\varepsilon > 0$ there exist contractions $e_1, e_2 \in A$ with $\|e_j^* e_k - \delta_{jk} e\| < \varepsilon$ for $j,k \in \{1,2\}$.

This property of $e \in A_+$ has been studied also further above in Chp.2...??? Why refer to Chapter 3? Find it and compare the ref.s !!!

Then W can be "orthogonal approximated in norm" – in the sense that for each $\gamma > 0$ there exist c.p. maps $U_0, U_1\colon M_n \to A$ such that $U_k(1_n) \leq V(1_n)$, $\|U_k - W\| < \gamma$ and that U_0 and U_1 are "elementary" and "orthogonal" in the sense that there are column-matrices $d_k \in M_{n,1}(A)$ with $U_k(\beta) = d_k^* \beta d_k$ and $d_0^* \beta d_1 = 0$ for all $\beta \in M_n \cong M_n(\mathbb{C} \cdot 1) \subseteq M_n(\mathcal{M}(A))$ and $k \in \{0,1\}$.

(xi)⇒(xvi): Let $F \subset A$ a finite subset, $\varepsilon > 0$, $V\colon A \to M_n$, and $W\colon M_n \to A$ completely positive contractions. Let $b := W(1_n)$.

Let $0 < \delta := \varepsilon/?????$, ρ a pure states on A and $d_\rho\colon A \to \mathcal{L}(\mathcal{H})$ with $\mathcal{H} := L_2(A,\rho) := A/L_\rho$ the corresponding irreducible representation with cyclic vector x_0 satisfying $\rho(a) = \langle d_\rho(a) x_0, x_0 \rangle$. Here $L_\rho := \{a \in A\,;\ \rho(a^*a) = 0\}$.

By Lemma 2.1.22 there exist an isometry I from $\ell_2(n)$ into $\mathcal{L}(\mathcal{H})$ with $\|I^* d_\rho(a) I - V(a)\| < \delta$ for $a \in F$. By simplicity of A we can take any irreducible representation $\rho\colon A \to \mathcal{L}(\ell_2)$ and find a suitable isometry T from $\mathbb{C}^n$ into ℓ_2 such that $\|V(a) - T^* \rho(a) T\| < \delta$ for all $a \in F$.

By assumption of Part (xi), for each $a \in A_+$ there exists $d, e \in A$ with $d^* e = 0$ and $d^* d = (a - \gamma)_+ = e^* e$. This allows to apply Proposition 3.1.9(ii).

`Is it better to use an elementary tool? Not from Chp.3??`

It says that each c.p. contraction $W\colon M_n \to A$ can be approximated in norm by c.p. maps $U\colon M_n \to A$ with $U(1_n) \leq W(1_n)$, that are "elementary" in the sense that there are column-matrices $d \in M_{n,1}(A)$ with $U(\alpha) = d^*\alpha d$ for $\alpha \in M_n$.

This means that we can find $d \in M_{n,1}(A)$ with $\|W(Y) - d^*Yd\| < \delta\|Y\|$ for all $Y \in M_n$ and $d^*d = \sum_k d_k^* d_k \leq W(1_n)$. In particular $\|d^*d\| \leq 1$, because W is a c.p. contraction.

`Give reference for next ''blue''`

`Seems to be better to factorize over a fixed copy of` M_n `sitting in` A `itself ?`

By Part (i) and Lemma 2.1.6 there exists a properly infinite projection $0 \neq p^*p = p \in A$. Let $s, t \in pAp$ partial isometries with $s^*t = 0$ and $s^*s = t^*t = p$. Consider the partial isometry $v_k := t^k s$

(i)⇒(xvii): Let D a non-zero hereditary C^*-subalgebra of A and $p \in D$ an infinite projection. This means that $pDp = pAp$ contains a non-unitary isometry, i.e., there exists partial isometry $v \in D$ with $v^*v = p$, $vv^* \leq p$ and $vv^* \neq p$. Let 1 denote the unit of $\mathcal{M}(A)$. Then $T := (1-p) + v \in D + 1_{\mathcal{M}(A)}$ is a non-unitary isometry in the C^*-algebra $D + \mathbb{C} \cdot 1 \subseteq \mathcal{M}(A)$.

(xvii)⇒(iii): Let $D \subseteq A$ a non-zero hereditary C^*-subalgebra of A and $0 \neq e \in D_+$. The hereditary C^*-subalgebra $E := \overline{eAe}$ is non-zero. Let 1 denote the unit-element of A if A is unital, otherwise let it denote the unit $1_{\mathcal{M}(A)}$ of the multiplier algebra of A.

By assumptions of Part (xvii), there exists an element $T \in E + \mathbb{C} \cdot 1 \subseteq \mathcal{M}(A)$ that is left-invertible in $A + \mathbb{C} \cdot 1$ but is not right-invertible in $A + \mathbb{C} \cdot 1$.

Let $L \in A + \mathbb{C} \cdot 1$ a left inverse for T, i.e., $LT = 1$. Then $\|L\|^2 T^*T \geq T^*L^*LT = 1$. It implies that $(T^*T)^{-1/2} \in E + \mathbb{C} \cdot 1$ exists and that $S := T(T^*T)^{-1/2} \in E + \mathbb{C} \cdot 1$ is a non-unitary isometry in $E + \mathbb{C} \cdot 1$. The S is non-unitary, because otherwise T would be also right-invertible.

It follows that $p := 1 - SS^*$ is a non-zero projection in E and the hereditary C^*-subalgebra F of E generated by p and $S^n p (S^*)^n$ for $n \in \mathbb{N}$ is a non-zero stable C^*-subalgebra of $E \subseteq D$. □

Remark 2.2.2. The Part (xvii) of Proposition 2.2.1 is a "poor-man variant" of a criterium of L.G. Brown, P. Friis and M. Rørdam. See [**109**] and [**305**]:

If A is simple and satisfies the Friis-Rørdam "Property IR*", then there is a strict alternative that excludes each other:*
A is purely infinite or A has "stable rank one".

More precisely, the alternative for simple A with Property *IR* is: A is purely infinite or each element of $A + \mathbb{C} \cdot 1_{\mathcal{M}(A)} \subseteq \mathcal{M}(A)$ is contained in the norm closures of the *invertible* (!) elements of $A + \mathbb{C} \cdot 1_{\mathcal{M}(A)}$.

See Section 9 in Appendix B for the definitions of Friies-Rørdam "Property *IR*" and "stable rank one" and some explanations, in particular why Part (xvii) of

Proposition 2.2.1 is one of the observations for the proof of the Brown-Friis-Rørdam alternative for simple C^*-algebras with Property *IR* between pure infiniteness and "stable rank one".

Next lemma will be used later to prove in some cases pure infiniteness of tensor products of C^*-algebras.

LEMMA 2.2.3 ([**93**], lem. 2.15). *Let D be a non-zero hereditary C^*-subalgebra of the minimal C^*-algebra tensor product $A \otimes B$ of C^*-algebras A and B.*

Then there exists $0 \neq z \in A \otimes B$ with $zz^* \in D$ and $z^*z = e \otimes f$ for some non-zero $e \in A_+$ and $f \in B_+$.

If $d \in D_+$ and pure states $\varphi \in A^*$, $\psi \in B^*$ are given with $(\varphi \otimes \psi)(d) > 0$, then such element $z \in A \otimes B$ can be found such that, moreover, $\varphi(e)\psi(f) > 0$.

PROOF. Let $d \in D_+$ with $\|d\| = 1$, and let $C := A \otimes B$. The minimal C^*-algebra tensor product is the same as spatial tensor product with respect to the direct sum of irreducible representations of A and B (cf. [**704**, prop. 1.22.9], [**766**]). Thus, there are pure states φ on A and ψ on B such that $(\varphi \otimes \psi)(d) > 0$.

We can assume from now on, that fixed *pure* states φ and ψ and a fixed contraction $d \in D_+$ with $(\varphi \otimes \psi)(d) > 0$ are given, i.e., we prove also the second part of this Lemma (2.2.3) at the same time.

Then $a := (\varphi \otimes \mathrm{id}_B)(d) \in B_+$ is a non-zero contraction and $0 < \psi(a) \leq \|a\|$.

Let $\delta := \psi(a)/2$ and $f := (a - \delta)_+^2$. Thus $0 < \delta \leq 1/2$, $f \in B_+$ and $\psi(f) > 0$, because $\psi(f)^{1/2} \geq \psi(f^{1/2}) \geq \psi(a) - \delta > 0$.

There exists a separable C^*-subalgebra G of A such that d is in the closure of the *algebraic* tensor product $G \odot B$, because d is the limit of a sequence in $A \odot B$. By Proposition A.21.4 and Lemma A.21.3 there exists $b \in A_+$ with $\|b\| = 1 = \varphi(b)$ (for all $m \in \mathbb{N}$) such that

$$\lim_n \|b^n g b^n - \varphi(g) b^{2n}\| = 0 \quad \text{for all } g \in G\,.$$

The state φ extends to a state φ_e on the unitization $A + \mathbb{C}1 \subset \mathcal{M}(A)$ of A with $\varphi_e(1 - b) = 0$. It gives $\varphi_e(a(1 - b)) = 0$ by Cauchy inequality. In particular, $\varphi(a) = \varphi(ab)$ for all $a \in A$ and $\varphi(b^n) = 1$ for all $n \in \mathbb{N}$. Thus, the restriction of φ to $C^*(b) \subseteq A$ is a character on $C^*(b)$.

The maps

$$T_n \colon \ y \in A \otimes B \mapsto (b^n \otimes 1)y(b^n \otimes 1) - (b^{2n} \otimes (\varphi \otimes \mathrm{id})(y))$$

converge on $G \otimes B$ point-wise to zero, because T_n is a difference of two completely positive contractions on C and tends on $G \odot B$ point-wise to zero.

Thus, there exists n with $\|T_n(d)\| < \delta^2$, i.e.,

$$(b^{2n} \otimes a) - \delta^2 \ \leq \ (b^n \otimes 1)d(b^n \otimes 1)$$

in the unitization of C. Let $g := b^{2n}$ and $t := d^{1/2}(b^n \otimes 1)((g \otimes a) - \delta^2)_+^{1/2}$. Then we get $((g \otimes a) - \delta^2)_+^2 \leq t^*t$ and $t\, C\, t^* \subseteq d^{1/2}\, C\, d^{1/2} \subseteq D$.

Now let $e := (g - \delta)_+{}^2 \in A_+$. Using that $\varphi(g) = \|g\| = 1$ and $g \geq 0$, i.e., that φ is a character on $C^*(g)$, and that $0 < \delta \leq 1/2$, we get $\varphi(e) = (1 - \delta)^2 > 0$.

Recall that $f := (a - \delta)_+^2$. Functional calculus in $C^*(g) \otimes C^*(a)$ shows that $e \otimes f \leq ((g \otimes a) - \delta^2)_+)^2$.

If $t = (tt^*)^{1/2}v$ is the polar decomposition of t in the second conjugate of C, then $vxv^* \in \overline{t\, C\, t^*} \subseteq D$ and $vx^{1/2} \in C$ for every $x \in C$ with $0 \leq x \leq t^*t$, because $x^{1/2}$ is in the norm closure of $t^*\, C\, t$ and $vt^* = (tt^*)^{1/2}$.

Since $e \otimes f \leq t^*t$ we get that $z := v((g - \delta)_+ \otimes (a - \delta)_+)$ is in $A \otimes B$, and e, f, z satisfy $z^*z = e \otimes f$, $zz^* \in D$ and $\varphi(e)\psi(f) > 0$. □

Next Lemma 2.2.4 allows later applications by using suitable central sequences.

LEMMA 2.2.4. *Let $F \subseteq A \setminus \{0\}$ a finite subset of non-zero elements in a C^*-algebra A.*

Suppose that $f^* \in F$ for each $f \in F$ and that, for every $\mu \in (0, 1)$, there exist contractions $s_1, s_2 \in \mathcal{M}(A)$ *(depending on μ) with the properties that for all $f \in F$ and $j \in \{1, 2\}$ holds:*

$$\|s_j f - f s_j\| \; + \; \|(1 - s_j^* s_j)f\| \; + \; \|(s_1 s_1^* s_2 s_2^*)f\| \; < \; \mu \, \|f\| \,. \tag{2.1}$$

Then, for each finite sequence $d_1, d_2, \ldots, d_n \in \mathcal{M}(A)$ and $\varepsilon > 0$, there exists elements $g_1, g_2 \in A$ with $g_1^* g_2 = 0$, $g_k^* g_k \leq \sum_{\ell=1}^n d_\ell^* d_\ell$ for $k \in \{1, 2\}$ and

$$\|g_j^* f g_k \; - \; \delta_{j,k} \cdot \sum_{\ell=1}^n d_\ell^* f d_\ell\| \; < \; \varepsilon \cdot \| \, f \, \| \,, \quad \forall \; 0 \neq f \in F, \; j, k \in \{1, 2\} \,. \tag{2.2}$$

PROOF. We show below that the existence of contractions $s_1, s_2 \in \mathcal{M}(A)$ satisfying the inequalities (2.1) for each $\mu > 0$ and fixed given F implies that we can find for the given $f \in F$ the following, – formally stronger –, existence property (*):

(*) *For each $\gamma \in (0, 1)$ there exist contractions $t_1, \ldots, t_{2n} \in A$ with the property that $t_j^* t_k = 0$ for $j \neq k$ and $\|t_j^* f t_k - \delta_{j,k} f\| < \gamma$ for all $j, k \in \{1, \ldots, 2n\}$ and $f \in F$.*

If we have shown the existence (*) – for each given $\gamma > 0$ – then we can use the contractions $t_1, \ldots, t_{2n}$ to define $g_1 := \sum_{\ell=1}^n t_\ell d_\ell$ and $g_2 := \sum_{\ell=1}^n t_{\ell+n} d_\ell$. Clearly, $g_1^* g_2 = 0$ and $g_k^* g_k \leq \sum_{\ell=1}^n d_\ell^* d_\ell$ for $k \in \{1, 2\}$. This elements $g_1, g_2 \in A$ satisfy then the Inequalities (2.2):

Indeed, consider the matrices $S[f] := [\delta_{j,k} f] \in M_{2n}(A)$ and $T[f] := [t_j^* f t_k] \in M_{2n}(A)$, and the columns $Z_1 := [d_1, \ldots, d_n, 0, \ldots, 0]^\top \in M_{2n,1}(\mathcal{M}(A))$ and $Z_2 := [0, \ldots, 0, d_1, \ldots, d_n]^\top \in M_{2n,1}(\mathcal{M}(A))$. Then, for $f \in F$, $g_j^* f g_k = Z_j^* T[f] Z_k$ and

$\delta_{j,k}\sum d_\ell^* f d_\ell = Z_j^* S[f] Z_k$. Thus,

$$\|g_j^* f g_k - \delta_{j,k}\sum_\ell d_\ell^* f d_\ell\| \,\le\, \|S[f]-T[f]\|\cdot \|\sum_{\ell=1}^{n} d_\ell^* d_\ell\|\,.$$

The entries of the self-adjoint matrix $S[f]-T[f] \in M_{2n}(A)$ have norms $\le \gamma$ by Property (*). A simple matrix-norm estimate says that an operator $m\times m$ matrix $[x_{jk}] \in M_m(A)$ has operator norm $\le m\max\{\|x_{j,k}\|\,;\ 1\le j,k\le m\}$ in $M_m(A)$, cf. Section 19 of Appendix B and Remark 2.1.10, thus: $\|S[f]-T[f]\| \le 2n\cdot\gamma$.

Hence, we get elements $g_1, g_2 \in A$ that satisfy all desired properties if we can show – for given $\varepsilon \in (0,1)$ – the existence of the contractions t_k with above properties (*) for suitable $\gamma \in (0,1)$ – that satisfies e.g.

$$2n\gamma \cdot \big(1+\sum_\ell \|d_\ell\|^2\big) \,\le\, \varepsilon\,.$$

Now we are going to derive the existence of contractions $t_1,\ldots,t_\ell,t_{2n} \in A$ for given $\gamma \in (0,1)$ with the above listed property (*) for given $\gamma \in (0,1)$ fixed given finite subset $F \subset A$, with $f^* \in F$ for $f \in F$.

We avoid complicate iterated estimates for commutators of polynomials and use instead its translation into precise algebraic relations in corona spaces – together with a sort of approximate semi-projectivity for relations like $x_j^* x_k f = \delta_{j,k} f$ and $\|x_k\| \le 1$ for $j,k \in \{1,\ldots,2n\}$ and f in a finite set.

Indeed, we derive from the existence of s_1, s_2 that satisfy the inequalities (2.1) for $\mu = 2^{-m}$ $(m = 1,2,\ldots)$ the following observation ([21]):

`Above are used other/same letters, give new notation!`

For each $n \in \mathbb{N}$ there exists of $2n$ contractions $T_\ell = (t_{\ell,1}, t_{\ell,2},\ldots) \in \ell_\infty(A)$ $(\ell \in \{1,2,\ldots,2n\})$ that have the following properties:

$T_\ell^* T_k = 0$ for $k \ne \ell$, $T_\ell f - f T_\ell \in c_0(A)$ and $f - T_\ell^* T_\ell f \in c_0(A)$ for all $f \in F$, – where we identify here $f \in F$ with $(f,f,\ldots) \in \ell_\infty(A)$.

We can find finally the desired contractions $t_1,\ldots,t_\ell,\ldots t_{2n} \in A$ – with the above discussed desired properties – by picking up entries $t_\ell := t_{\ell,n_0}$ for suitable (fixed) $n_0 \in \mathbb{N}$ from the elements $T_\ell = (t_{\ell,1},\ldots,t_{\ell,n_0-1},t_{\ell,n_0},\ldots)$.

Thus, the proof is complete if we have shown the *existence* of the contractions $T_\ell \in \ell_\infty(A)$ $(\ell = 1,\ldots,2n)$ with the above proposed property,

To get such $T_\ell \in \ell_\infty(A)$, we modify the elements $s_1, s_2 \in \mathcal{M}(A)$ that satisfy the inequalities (2.2) with help of a quasi-central approximate unit of A in the sense of [**616**, thm. 3.12.14], cf. also Part (3) of Remarks 5.1.1:

If $\tau \in (0,1)$ is given, then we use that $F \subseteq A$ is a finite set and find – in a quasi-central approximate unit of A – a positive contraction $e \in A_+$ such that, for

[21] Here $n \in \mathbb{N}$ can not be replaced by "∞" because the used projectivity property does not work for *infinitely many* generators! Says that the estimates are delicate and need some care.

$j \in \{1,2\}$ and $f \in F$,

$$\|s_j e - e s_j\| < \tau \quad \text{and} \quad \|ef - f\| + \|fe - f\| < \tau \|f\| .$$

It follows for $0 \neq f \in F$ that $\|ef - fe\| < \tau\|f\|$, $\|efe - f\| < \tau\|f\|$, $\|e^2 f - f\| \leq 2\tau\|f\|$ and that $\|s_1 e^2 s_1^* s_2 e^2 s_2^* - e^2 s_1 s_1^* s_2 s_2^* e^2\| \leq 4\tau$. It allows to calculate that the contractions $s_1 e, s_2 e \in A$ satisfy, for $f \in F$ and $j \in \{1,2\}$, that the sum of norms

$$\|(s_j e)f - f(s_j e)\| + \|f - (s_j e)^*(s_j e)f\| + \|(s_1 e)(s_1 e)^*(s_2 e)(s_2 e)^* f\|$$

is less or equal to the sum

$$\|s_j f - f s_j\| + \|f - s_j^* s_j f\| + \|s_1 s_1^* s_2 s_2^* f\| + 7\tau \cdot \|f\| .$$

Thus, if the contraction $e \in A_+$ is chosen as above for sufficiently small $\tau > 0$, then we obtain that the contractions $s_1 e$ and $s_2 e$ satisfy again the Inequality (2.1) in place of s_1 and s_2. It follows that our assumptions imply that for each $\mu \in (0,1)$ there are contractions $s_1, s_2 \in A$ that satisfy the inequalities (2.1). Thus, we can find the s_1, s_2 with this properties in A itself.

Now let $A_\infty := \ell_\infty(A)/c_0(A)$, consider A as C^*-subalgebra of A_∞ via the natural C^*-monomorphism $A \ni a \mapsto (a, a, \ldots) + c_0(A)$, and let $C := C^*(F) \subseteq A \subseteq A_\infty$ the separable C^*-subalgebra of A generated by the finite set F.

Let $s_{1,n}, s_{2,n} \in A$ contractions that satisfy the inequalities (2.1) for $s_{j,n}$ ($j \in \{1,2\}$) in place of s_j and with $\mu := 2^{-n}$ ($n = 1, 2, \ldots$). Define contractions $S_j \in A_\infty$ ($j \in \{1,2\}$) by $S_j := (s_{j,1}, s_{j,2}, \ldots, s_{j,n}, \ldots)$.

Here is ... ???

`Compare above with below def.s and notations !!! ???`

We use now that the universal C^*-algebra

$$C^*(x_1, \ldots, x_n \,;\; \|x_k\| \leq 1\,,\; x_j^* x_k = 0\;,\; j \neq k\,,\, j,k = 1, \ldots, n\,)$$

is projective, cf. Corollary A.8.5. It shows the existence of the above predicted contractions $T_1, \ldots, T_{2n} \in \ell_\infty(A)$ with orthogonal ranges ([22]).

This method allows to translate the question, if contractions $t_1, \ldots, t_{2n}$ with the above quoted properties exist, into the question, if we can find isometries

$$D_1, \ldots, D_{2n} \in (C' \cap A_\infty)/\operatorname{Ann}(C, A_\infty)$$

with mutually orthogonal ranges, i.e., with $D_j^* D_k = \delta_{jk} 1$ for $j,k \in \{1, \ldots, 2n\}$.

It works well because we can lift the isometries D_j by Corollary A.8.5 to contractions

`HERE are the` E_j `defined. Somewhere below called` T_j `???`

[22] Instead using the projectivity of this universal C^*-algebra we could use – only for this part of the proof – that the below considered subalgebras and sub-quotients of A_∞ are all "locally" sub-Stonean to get the desired lifts with pairwise *orthogonal* ranges. But it isn't much simpler all together.

$E_j := (e_{j,1}, e_{j,2}, \ldots) + c_0(A) \in C' \cap A_\infty$ with $E_j^* E_k = 0$ for $j \neq k$ and $E_j f - f E_j = 0$ and $f - E_j^* E_j f = 0$, where we identify here the $f \in F$ with $(f, f, \ldots) + c_0(A)$.

Then we can use the Corollary A.8.5 a second time to lift the contractions $E_j \in A_\infty = \ell_\infty(A)/c_0(A)$ to contractions $T_j \in \ell_\infty(A)$ with mutually orthogonal ranges, i.e., $\|T_j\| = 1$, $T_k^* T_j = 0$, $T_j f - f T_j, f - T_j^* T_j f \in c_0(A)$, where we identify $f \in F$ with $(f, f, \ldots) \in \ell_\infty(A)$.

Recall that $C \subseteq A \subset A_\infty$ denotes the separable C^*-subalgebra of A generated by $F \subseteq A_\infty$. The two-sided annihilator of C in A_∞ is defined by

$$\mathrm{Ann}(C, A_\infty) := \left\{ X \in A_\infty\, ;\ X \cdot C = \{0\} = C \cdot X \right\}.$$

It is easy to see that $\mathrm{Ann}(C, A_\infty)$ is a closed ideal of the relative commutant $C' \cap A_\infty$ of $C \subseteq A_\infty$, cf. [**448**] for similar definitions and considerations in the – perhaps for some readers more delicate – case of ultra-powers $A_\omega := \ell_\infty(A)/c_\omega(A)$, in place of $A_\infty := \ell_\infty(A)/c_0(A)$.

The contractions $t_1, \ldots, t_{2n} \in A$, with the property that

$$t_j^* t_k = 0 \quad \text{and} \quad \|t_j^* f t_k - \delta_{j,k} f\| < \gamma \quad \text{for all } j, k \in \{1, \ldots, 2n\} \text{ and } f \in F,$$

can be obtained by lifting the

`Where` E_k `!!!,` T_k `was defined?`

to contractions T_k with pairwise orthogonal ranges in $\ell_\infty(A)$, where we use that F is a finite subset of A, because then we can select suitable “coordinates” $t_k := T_{k,n_0}$ (n_0 sufficiently large and then fixed) of $T_k = (T_{k,1}, T_{k,2}, \ldots) + c_0(A)$ in an obvious manner such that the considered inequalities are fulfilled.

`Here !!! and a bit above` $\Uparrow$ `starts notation disorder.`
`New attempts below?` E `and` T `and` S `same?:`

The assumptions allow to find for $\mu_n = 2^{-n}$, $n = 2, 3, \ldots$ sequences $(s_{j,1}, s_{j,2}, \ldots)$ of contractions in A such that $s_{j,n}$, $j \in \{1, 2\}$, define an element $S_j := (s_{j,1}, s_{j,2}, \ldots) \in \ell_\infty(A)$ ($j \in \{1, 2\}$) such that, for $f \in F$ and $k \in \{1, 2\}$,

$$S_j f - f S_j\,, \quad f - (S_j^* S_j) f\,, \quad (S_1 S_1^* S_2 S_2^*) f \in c_0(A)\,.$$

Let $A_\infty := \ell_\infty(A)/c_0(A) \supset A$, and consider the bounded sequences in A modulo $c_0(A)$ as elements of A_∞, i.e., $S_k := (s_k^{(1)}, s_k^{(2)}, \ldots) + c_0(A)$ where we embed here A into A_∞ by $a \mapsto (a, a, \ldots) + c_0(A)$.

Then it happens in the algebra A_∞ that $\|S_k\| \leq 1$, $S_1^* S_2 = 0$, $S_k f = f S_k$ and $(1 - S_k^* S_k) f = 0$ for all $f \in F$ and $k \in \{1, 2\}$.

It implies $(1 - S_k^* S_k)(f^* f + f f^*) = 0$ for all $f \in F = F^*$. Since $1 - S_k^* S_k \geq 0$ it follows that $F \cup F \cdot F$ is contained in the two-sided annihilator of the positive element $2 - S_1^* S_1 - S_2^* S_2$ of A_∞. Thus, the C^*-algebra $C := C^*(F) \subseteq A \subseteq A_\infty$ is contained in the two-sided annihilator of $2 - S_1^* S_1 - S_2^* S_2$.

Using that $f^* \in F$ for all $f \in F$ we get that $F \subseteq \{S_1, S_1^*, S_2, S_2^*\}'$.

It follows that the elements of the C^*-subalgebra C of $B := A_\infty$???? generated by F commute with S_1 and S_2. Thus $S_1, S_2 \in C' \cap B$, i.e., the elements S_k commute with all elements in the C^*-subalgebra $C \subseteq B$ generated by F.

Since $F^* = F$, we get that C is the closure of the linear span of products of elements $f^* + f$, f^*f and ff^* with $f \in F$.

This implies that $(1 - S_k^* S_k)C = \{0\}$, $S_k c - cS_k = 0$ for all $c \in C$, ... $(k \in \{1, 2\})$.

???? CHECK !!! ???

$Y := \operatorname{Ann}(1 - S_k^* S_k, B) \subseteq B := \ell_\infty(\mathcal{M}(A))/c_0(A) \supseteq A_\infty$ is a hereditary C^*-subalgebra of B with $F \subseteq Y$. It follows $C := C^*(F) \subseteq Y$. Thus $(1 - S_k^* S_k) \in C' \cap B$.

Thus we can consider first the two-sided annihilator $\operatorname{Ann}(C, B)$ of C in B and the commutator $C' \cap B$ of C in B.

Then $\operatorname{Ann}(C, B)$ is a closed ideal of $C' \cap B$. If we find isometries $T_1, \ldots, T_n \in (C' \cap B)/\operatorname{Ann}(C, B)$ with pairwise orthogonal ranges. Then we can lift them to contractions $t_1, \ldots t_n$ in $C' \cap B$ with pairwise orthogonal ranges such that $t_j^* c t_k = \delta_{j,k} c$ for all $1 \le j, k \le n$ and $t_j^* t_k = 0$ for $j \ne k$.

If $d_1, \ldots, d_n \in \mathcal{M}(A) \subseteq B$ are given, then $g := \sum_k t_k d_k$ satisfies $g^* g \le \sum_k d_k^* d_k$ and $g^* f g = \sum d_k^* f d_k$.

Now one can take take ??or?? find mutually orthogonal representing sequences for the element $g \in B$ and of the $d_1, \ldots, d_n$.

By Corollary A.8.5, we get that the universal C^*-algebra generated by n contractions with orthogonal ranges is projective.

We consider first the case of isometries $s_1, s_2 \in \mathcal{M}(A)$ with the quoted properties, to make the idea of the proof transparent. The additional study for the approximate version will be added at the end of the proof.

Notice that the isometries s_1, s_2 with $s_k^* s_\ell = \delta_{k,\ell}$ $(k, \ell \in \{1, 2\})$ define isometries by $t_1 := s_1$ and $t_{n+1} := s_2^n s_1$ for $n = 1, 2, \ldots$ that satisfy $t_m^* t_n = \delta_{m,n} 1$ for $n, m \in \mathbb{N}$.

If $a \in F$ satisfies $\|s_k a - a s_k\| < \gamma$ $(k = 1, 2)$ for some $\gamma \in (0, \infty)$ and $k \in \{1, 2\}$ then, using that $t_m^*(a t_n - t_n a) = t_m^* a t_n - \delta_{m,n} a$, we get

$$\|t_m^* a t_n - \delta_{m,n} a\| \le \|a t_n - t_n a\| < n\gamma .$$

Follows from

$$\|a(b_1 \cdot b_2) - (b_1 \cdot b_2)a\| \le \|b_2\| \|[a, b_1]\| + \|b_1\| \|[a, b_2]\| .$$

`What about working in` $\mathcal{M}(A)_\infty$
`and replacing then` γ `by zero,` e.g.
$s_1, s_2 \in \mathcal{M}(A)_\infty$ `with` $s_1^* s_2 = 0$, $(1 - s_k^* s_k)a = 0$ `and` $[a, s_k] = 0$
`for` $a \in F$, $k \in \{1, 2\}$ `...`
`It implies` $(s_2^k s_1)^* a (s_2^\ell s_1) = \delta_{k,\ell} a$ `for` $a \in F$, $k, \ell \in \{0, 1, \ldots, n\}$, `with` $s_2^0 := 1$.

`The problem is:`
`Does there exist a ''local unit''` $e \in \mathcal{M}(A)_\infty$ `with` $0 \leq e \leq 1$ `for` F `such that` $ea = a = ae$ `for` $a \in F$ `and` $(s_2^k s_1)^* e (s_2^\ell s_1) = \delta_{k,\ell} e$ `??`

Let $s_1, s_2 \in A$ contractions with $s_1^* s_2 = 0$, $\|s_k a - a s_k\| < \gamma \cdot \|a\|$ and $\|(1 - s_k^* s_k)a\| < \gamma \cdot \|a\|$ $(k \in \{1,2\})$ for all $a \in F$ and some $\gamma \in (0,1)$. We can define contractions $t_n \in \mathcal{M}(A)$ by $t_1 := s_1$ and $t_{n+1} := s_2^n s_1$ for $n = 1, 2, \ldots$, and show that, for each $a \in F$,

$$\|t_n a - a t_n\| \leq n \cdot \gamma \|a\| \quad \text{and} \quad \|t_m^* a t_n - \delta_{m,n} a\| \leq 2 \min(m,n) \cdot \gamma \|a\| \,.$$

It implies that $\|(1 - t_n^* t_n)a\| \leq 3n \cdot \gamma \|a\|$.

We use the convention $s_2^0 := 1 \in \mathcal{M}(A)$. By assumptions, $\|t_1 a - a t_1\| \leq \gamma \|a\|$ for $t_1 := s_1$ and $a \in F$. Then $[a, xy] = x[a,y] + [a,x]y$ shows that $t_{n+1} a - a t_{n+1} = s_2^n (s_1 a - a s_1) + (s_2^n a - a s_2^n) s_1$ and

$$\|s_2^n a - a s_2^n\| \leq n \|s_2\|^{n-1} \|s_2 a - a s_2\| \leq n \cdot \gamma \|a\| \,.$$

Since s_1 and s_2 are contractions we get $\|t_n a - a t_n\| \leq n \cdot \gamma \|a\|$ for all $n = 1, 2, \ldots$.

An estimate for $\|t_m^* a t_n - \delta_{m,n} a\|$:
Let $s_k^0 := 1$ for $k \in \{1,2\}$. It suffices to consider the case where $1 \leq m \leq n$ because $(t_m^* a t_n)^* = t_n^* a^* t_m$ and $a^* \in F$ for $a \in F$. If $1 \leq m \leq n$ then $t_m = s_2^{m-1} s_1$, $t_n = s_2^{m-1} s_2^{n-m} s_1$ and $\delta_{n,m} = 1$ if and only if $n = m$.

$X := (s_2^*)^{m-1} a s_2^{m-1} - a$, $Y := s_1^* X s_2^{n-m} s_1$ and $Z := s_1^* a s_2^{n-m} s_1 - \delta_{m,n} a$, satisfy $Y + Z = t_m^* a t_n - \delta_{m,n} a$. Thus $\|t_m^* a t_n - \delta_{m,n} a\| \leq \|X\| + \|Z\|$.

If $\delta_{m,n} = 1$ then $m = n$ and $Z = s_1^* a s_1 - a$. If $\delta_{m,n} = 0$ then $m < n$, $Z = s_1^* (s_2 a - a s_2)(s_2^{n-m-1} s_1)$. The latter implies $\|Z\| \leq \gamma \|a\|$.

The equations $s_k^* a s_k - a = s_k^* (a s_k - s_k a) - (1 - s_k^* s_k) a$ imply $\|s_k^* a s_k - a\| \leq 2 \cdot \gamma \|a\|$ for $k \in \{1,2\}$. In particular, $\|Z\| \leq 2 \cdot \gamma \|a\|$ if $\delta_{n,m} = 1$. We show that $\|X\| \leq 2(m-1) \cdot \gamma \|a\|$:

Let $p > 1$. Then $(s_2^*)^p a (s_2)^p - a = \sum_{\ell=1}^{p} (s_2^*)^{p-\ell} (s_2^* a s_2 - a)(s_2)^{p-\ell}$.

Hence, $\|(s_2^*)^p a (s_2)^p - a\| \leq 2p \cdot \gamma \|a\|$.

Summing up, our calculations show that

$$\|t_m^* a t_n - \delta_{m,n} a\| \leq \|X\| + \|Z\| \leq 2 \min(m,n) \cdot \gamma \|a\| \,.$$

`Consider here the easy case of isometries` s_1, s_2 `.`

Let $a \in F$, $\varepsilon > 0$ and $d_1, \ldots, d_n \in A$ given, take $\mu := \| \sum_k d_k^* d_k \|$.

We find for each $\gamma > 0$ isometries $s_1, s_2 \in \mathcal{M}(A)$ with $\|s_k a - a s_k\| < \gamma$???? for $k = 1, 2$ and $a \in F$.

Let ?????

$$\gamma := \varepsilon / \big(1 + 2n \, (\|d_1\| + \ldots + \|d_n\|)^2\big) \,.$$

By assumptions, we find isometries $s_1, s_2 \in \mathcal{M}(A)$ with $s_1^* s_2 = 0$ and $\|s_k a - a s_k\| < \gamma$ for $k \in \{1,2\}$. The above from the s_1, s_2 defined isometries $t_1, \ldots t_n$ satisfy

$$\|d_i^*(t_i^* a t_j - \delta_{ij} a) d_j\| < n\gamma \|d_i\| \|d_j\| \,.$$

Let $c := \sum t_i d_i$. Then $c^*c = \sum_i d_i^* d_i$, $c^*ac - \sum_i d_i^* a d_i \; = \; \sum_{i,j=1}^n d_i^*(t_i^* a t_j - \delta_{ij} a) d_j$ and

$$\|c^*ac - \sum_{i=1}^n d_i^* a d_i\| \;\le\; \sum_{i,j=1}^n \|d_i^*(t_i^* a t_j - \delta_{ij} a) d_j\| \;<\; \varepsilon\,.$$

Detailed calculations:

$c^*ac = \sum_{i,j} x_i^* t_i^* a t_j x_j$.

$\|c^*ac - b\| \le \|c^*ac - \sum x_i^* a x_i\| + \|b - \sum x_i^* a x_i\|$.

$\|b - \sum x_i^* a x_i\| < \varepsilon/2$ by property of the chosen x_i .

$\sum_i x_i^* a x_i = \sum_{i,j} x_i^* \delta_{ij} a x_j$.

$$\sum_{i,j=1}^n \|x_i^*(t_i^* a t_j - \delta_{ij} a) x_j\| \le \sum_{i,j=1}^n \|x_i\| \cdot \|x_j\| \cdot \|t_i^* a t_j - \delta_{ij} a\| \,.$$

Using that $\|[a, s_k]\| \le \gamma := \varepsilon/2n(1 + (\sum_i \|x_i\|)^2)$, and $n \max_{k=1,2} \|[a, s_k]\| \ge \|a t_j - t_j a\| \ge \|t_i^* a t_j - \delta_{ij} a)\|$ for $i, j \le n$, we get for $\sum_{i,j=1}^n \|x_i\| \cdot \|x_j\| \cdot \|t_i^* a t_j - \delta_{ij} a)\|$ the estimate $n(\|x_1\| + \ldots + \|x_n\|)^2 \cdot \gamma \le \varepsilon/2$.

Recall here that $\gamma := \varepsilon / \big(2n(1 + (\sum_i \|x_i\|)^2)\big)$. END OF THE EASY CASE is here !!!???

Let $a \in F$, $\varepsilon > 0$ and $d_1, \ldots, d_n \in A$ given, take $\mu := \|\sum_k d_k^* d_k\|$.

By assumptions, we find for each $\delta > 0$ contractions $s_1, s_2 \in \mathcal{M}(A)$ with $s_2^* s_1 = 0$ and $\|s_k a - a s_k\| < \delta$ and $\|(1 - s_k^* s_k) a\| < \delta$ for $k = 1, 2$ and $a \in F$.

Attempt (?? !!!): $g := \sum_{k=1}^n t_k d_k$ for sufficiently small γ.

Calculate $\|g^* a g - \sum_k d_k^* a d_k\|$ for $a \in F$. Uses matrix-norm of $[t_j^* a t_k - \delta_{jk} a]$ for contractions $a \in F$ and $\|\sum d_k^* d_k\|$ with suitable bound. □

We list some *sufficient criteria* for a C^*-algebra A to be simple and purely infinite:

Proposition 2.2.5. *Let A be a non-zero C^*-algebra. Each one of the following permanences or properties* (i)–(v) *implies that A is simple and purely infinite.*

(i) *A is a hereditary C^*-subalgebra of a simple purely infinite C^*-algebra.*
(ii) *$A \otimes \mathbb{K} \cong B \otimes \mathbb{K}$ for a simple purely infinite C^*-algebra B and the compact operators $\mathbb{K}$ on some Hilbert space $\mathcal{H}$.*
(iii) *A is isomorphic to the inductive limit* $\operatorname{indlim}_n(h_n \colon A_n \to A_{n+1})$ *of non-zero C^*-algebras $A_n \neq \mathbb{C} \cdot 1$ with non-zero C^*-morphisms h_n that satisfy:*
   (*) *For every positive integer n, every $\varepsilon > 0$ and every $a, b \in (A_n)_+$ with $\|b\| \le \|a\| = 1$, there exists a contraction $c \in A_{n+1}$ such that $\|c^* h_n(a) c - h_n(b)\| < \varepsilon$.*

(In particular, the property (*) is satisfied if all A_n are simple and purely infinite.)

(iv) *The C^*-algebra A is simple and has the following property (Δ):*

(Δ) *For every $a \in A_+$ and $\varepsilon > 0$, the multiplier algebra $\mathcal{M}(A)$ contains isometries s_1, s_2, depending on (a, ε), with*

$$s_1^* s_2 = 0 \quad \text{and} \quad \|s_j a - a s_j\| < \varepsilon \quad \text{for } j \in \{1, 2\}\,.$$

(v) *The C^*-algebra A is isomorphic to the relative commutant $D' \cap B$ of D in B, where D is a separable C^*-subalgebra of a unital C^*-algebra B that satisfies following properties (α) and (β):*

(α) $D' \cap B \neq \mathbb{C}1$.

(β) *For every $a \in (D' \cap B)_+$ with $\|a\| = 1$, there exists a contraction $s \in B$ with $d = s^* a d s$ for every $d \in D$.*

REMARK 2.2.6. It is evident that Proposition 2.2.5(iii) and Proposition 2.2.1(ii) together imply that *inductive limits of simple purely infinite C^*-algebras are again simple purely infinite C^*-algebras* ([23]).

Parts (i) and (ii) of Proposition 2.2.5 together show invariance of the class of simple p.i. C^*-algebras under Morita equivalence.

Notice also that every simple purely infinite C^*-algebra A is isomorphic to each of the types of algebras considered in Parts (i)–(iii):

Indeed, take $B := A \otimes \mathbb{K}$ to fulfill the conditions in Parts (i) and (ii), and take $A_n := A$ and $h_n := \mathrm{id}_A$ for the conditions in Part (iii). The Condition (*) in Part (iii) is satisfied for $h_n = \mathrm{id}_A$, because if $a, b \in A_+$ are contractions with $\|a\| = 1$ and $\|b\| = 1$ then there exists $c \in A$ with $\|c^* a c - b\| < \varepsilon$ by Part (ii) of Proposition 2.2.1. The arguments in the proof of the implication (iv)⇒(ii) or of the implication (iii)⇒(ii) for Proposition 2.2.1(ii,iii,iv) show that we can take here $c \in A$ with $\|c\| \leq 1$.

That the above examples satisfy the assumptions (i–iii) can be seen from

Parts (??? to be listed !!!) of Proposition 2.2.1. (Must show for (i,ii) that $A \otimes \mathbb{K}$ is p.i. if A p.i. and that pi passes to non-zero hereditary C^*-subalgebras. The latter is done in the proof.)

For the general general property pi(1) (which is equal to "purely infinite" in sense of Definition 1.2.1) the passage to $M_2(A)$ is equivalent to the (not obvious) proof that Property pi(1) is equal to Property pi-1.

But for simple A the equivalence of pi(1) and pi-1 is given by of Parts (???) and (???) of Proposition 2.2.1 ??? Condition (*) in Part (iii) implies injectivity

of the h_n:
If the h_n are non-zero (as required !) then Condition (*) causes that each h_n is injective.

[23] If they are "non-zero" in the sense that the all C^*-morphisms $\psi_{m,n} \colon A_m \to A_n$ are non-zero!

Indeed, since h_n is non-zero there exists $b \in (A_n)_+$ with $\|b\| = 1$ and $\|h_n(b)\| = 1$. Let $a \in (A_n)_+$ with $\|a\| = 1$. Then condition (*) on h_n provides $c \in A_{n+1}$ with $\|c^* h_n(a)c - h_n(b)\| < 1/2$. It implies $h_n(a) \neq 0$, and that each h_n is faithful.

The Property (Δ) of Part (iv) holds for all σ-unital purely infinite simple C^*-algebras A.

Indeed, by Proposition 2.2.1(v) all simple purely infinite C^*-algebras are strongly purely infinite, Theorem **??** (A.spi.implies.M(A).spi???.is where?) says that the multiplier algebra $\mathcal{M}(A)$ of every σ-unital strongly purely infinite C^*-algebra A is again strongly purely infinite and Theorem **??** (nuclear.embed.of.exact) says that each nuclear C^*-morphism $h\colon C \to E$ of a separable exact C^*-algebra into a strongly purely infinite "corona" C^*-algebra E – e.g. as it is the case for $E = \mathcal{M}(A)_\infty := \ell_\infty(\mathcal{M}(A))/c_0(\mathcal{M}(A))$ – extends to a C^*-morphism $h_{\text{ext}}\colon C \otimes \mathcal{O}_\infty \to E$ with $h_{\text{ext}}(c \otimes 1) = h(c)$. Then apply this to

$$\iota\colon C^*(a, 1) \to \mathcal{M}(A) \subseteq \mathcal{M}(A)_\infty .$$

It gives that all (not necessary simple) σ-unital strongly purely infinite C^*-algebras A satisfy Property (Δ) of Part (iv) of Proposition 2.2.5.

The approximate decomposition condition (Δ) in Part (iv) of Proposition 2.2.5 is satisfied for every not necessarily simple but *strongly* purely infinite σ-unital C^*-algebra A, because for them $C' \cap \mathcal{M}(A)_\omega$ is purely infinite for every nuclear embedded separable exact C^*-subalgebra C of A_ω. This applies to $C := C^*(\pi_\omega(a, a, \ldots)) \in A_\omega$ and yields the existence of the $s_1, s_2 \in \mathcal{M}(A)$ with the property in Part (iv).

Simple purely infinite C^*-algebras are strongly purely infinite by Proposition 2.2.1(v). Thus, the condition in Proposition 2.2.5(iv) is moreover *equivalent* to pure infiniteness of σ-unital *simple* C^*-algebras A.

Proof of Proposition 2.2.5. The assumptions in Parts (i), (ii) or (iv) assume or imply the simplicity of A. But we prove also the similar statement for non-simple C^*-algebras if possible, i.e., if the condition itself implies the simplicity.

???

It is not difficult to see that each of the properties (i)–(iv) of A in Proposition 2.2.5 implies that A is simple and that A is *not* isomorphic to the compact operators on some Hilbert space. `Why it is easy to see from (iv)?` i.e., where A is simple and has Property (Δ): The $\mathbb{K}(\mathcal{H})$ do not satisfy (Δ).

(i): Part (i) follows straight from the definition of J. Cuntz, cf. [**172**, p. 186] or Part (i) of Proposition 2.2.1, in case of simple C^*-algebras.

But we use here the general Definition 1.2.1, because it is also suitable for non-simple C^*-algebras B. The proof that non-zero hereditary C^*-subalgebras $D \subseteq B$ satisfy Part (ii) of Definition 1.2.1 is easy:
If $a, b \in D_+$ and $\varepsilon > 0$ are given with $a \neq 0$ and b in the closed ideal of B generated by a, then, by Definition 1.2.1, there exists $g \in B$ with $\|g^* a g - b\| < \varepsilon/3$, because

$b \in D_+$ is in the closed ideal of D generated by a, then it is also in the closed ideal of B generated by a.

Let $\gamma := \|g\|$, $\delta := \varepsilon/(3\gamma^2+3)$ and $\psi(t) := \min\big(1, \delta^{-1}\cdot \max(0, t-\delta)\big)$.

Define $g_1 \in D$ by $g_1 := \psi(a)^{1/2} g \psi(b)^{1/2}$. Then $\|g_1^* a g_1 - b\| < \varepsilon$.

But we must prove that quotients B/J of B can not contain non-zero projections $p \in B/J$ with $p(B/J)p = \mathbb{C}\cdot p$. This requires to show first that quotients B/J are also purely infinite in sense of Definition 1.2.1.

It is obvious from the Definition 1.2.1 that non-zero ideals J of B (respectively non-zero quotients B/J of B) can not have a non-zero character, because otherwise such a character *extends* to, respectively *defines*, a non-zero character of B.

If $a, b \in B_+$ and $\pi_J(b)$ is in the closed ideal of B/J that is generated by $\pi_J(a)$ the for $\varepsilon > 0$ there exists $\delta > 0$ and $c_1, \ldots, c_n \in B$ with $(b-\varepsilon/3)_+ - \sum_{k=1}^n c_k^*(a-\delta)_+ c_k \in J$. By Part (ii) of Definition 1.2.1 there exists $d \in B$ with

$$\|d^* a d - \sum_{k=1}^n c_k^*(a-\delta)_+ c_k\| < \varepsilon/3\,.$$

This implies together that

$$\|\pi_J(b) - \pi_J(d)^*\pi_J(a)\pi_J(d)\| < \varepsilon\,.$$

The map $\pi_J\colon B \to B/J$ is surjective. Hence B/J is again purely infinite in the sense of Definition 1.2.1 for each closed ideal $J \neq B$ of B.

Let $D \subseteq B$ is a non-zero hereditary C^*-subalgebra of purely infinite C^*-algebra B. We show that D can not have a non-zero character (and is therefore also purely infinite in sense of Definition 1.2.1):

Suppose that D has a non-zero character $\xi\colon D \to \mathbb{C}$. The kernel $K \subset D$ of ξ is a closed ideal of D. The closed ideal J of B generated by K has the property that $J \cap D = K$, cf. ?????

Cite here the intersection Lemma ????

The argument (for the in Definition 1.2.1 required non-existence of characters on D) is the following – that works also in the non-simple case:

THE NEXT HERE is an application of the study of residually anti-liminariy C^*-algebras. Refere to there!!!

By assumption (i) of Definition 1.2.1, the algebra B has no characters. But the Property (ii) of Definition 1.2.1 implies then moreover that no irreducible representation λ of B contains a non-zero compact operator in its image, because otherwise λ must be necessarily one-dimensional representation, by Property 1.2.1(ii) and the combination of the Kadison transitivity theorem and the semi-projectivity of $C_0((0,1], M_n)$ applied in Lemma 2.1.15, i.e., λ would be a character on B. (Notice here that the Properties 1.2.1(i,ii) pass to quotients B/J of B and hereditary C^*-subalgebras of B also in case where B is non-simple.)

The property of a C^*-algebra B having only irreducible representations that do not contain non-zero compact operators passes as a property to all non-zero quotients of B.

It passes also to all non-zero hereditary C^*-subalgebras of B, because for hereditary $D \subseteq B$ each irreducible representation $\rho\colon D \to \mathcal{L}(\mathcal{H}_1)$ extends, up to unitary equivalence, uniquely to an irreducible representation $\lambda\colon B \to \mathcal{L}(\mathcal{H}_1 \oplus_2 \mathcal{H}_2)$ such that $\lambda(d) = \rho(d) \oplus 0$ for $d \in D$.

(ii): By Part (i), the Definition 1.2.1 of pure infiniteness passes to non-zero hereditary C^*-subalgebras. In case of simple C^*-algebras it is equivalent to all other definitions of pure infiniteness (except being only *stably properly infinite* !).

It remains to observe that the simple C^*-algebra $B \otimes \mathbb{K}$ is purely infinite in the sense of J. Cuntz if B is purely infinite:
Let $D \subseteq B \otimes \mathbb{K}$ be any non-zero hereditary C^*-subalgebra.

By Lemma 2.2.3 there exists non-zero $z \in B \otimes \mathbb{K}$ with $zz^* \in D$ and $z^*z = b \otimes a$ for some (non-zero) $b \in B_+$ and $a \in \mathbb{K}_+$. Then $w = z(1 \otimes v)$ satisfies $w^*w = b \otimes p_{11}$ and $ww^* \in D$ for a suitable element $v \in \mathbb{K}$. Thus, D contains the closure of $w(B \otimes \mathbb{K})w^*$ which is isomorphic to the (non-zero) closure of bBb (cf. Remark 2.3.1). Now use that $b \neq 0$ and B is purely infinite in the sense of J. Cuntz. It says that $\overline{bBb}$ and D contain both (non-zero) infinite projections $p \in \overline{bBb}$ and $q \in D$, that are Murray–von-Neumann equivalent in $B \otimes \mathbb{K}$. Thus, $B \otimes \mathbb{K}$ is purely infinite in the sense of Cuntz.

(iii): We establish here a more general *necessary and sufficient* condition for inductive limits of C^*-algebras to be simple and purely infinite. It is easy to see that the assumptions of Part (iii) satisfy this condition:

Let $h_n\colon A_n \to A_{n+1}$ be a sequence of C^*-morphisms. Then for $m < n$

$$h_{m,n} := h_{n-1} \cdot \ldots \cdot h_{m+1} h_m \colon A_m \to A_n$$

is a C^*-morphism. We embed the inductive limit $B := \operatorname{indlim}(h_n\colon A_n \to A_{n+1})$ naturally in $(\prod_{n=1}^\infty A_n)/(\bigoplus_{n=1}^\infty A_n)$ in the below described way.

We explain sometimes our viewpoint by use of the different notations

$$(\prod_{n=1}^\infty A_n)/(\bigoplus_{n=1}^\infty A_n) = \ell_\infty(A_1, A_2, \ldots)/c_0(A_1, A_2, \ldots) \subseteq \mathcal{L}(\mathcal{H})_\infty$$

if the A_n are considered as C^*-subalgebras of $\mathcal{L}(\mathcal{H})$.

The canonical morphisms $h_n^\infty\colon A_n \to B$ are then given by

$$h_n^\infty(a) := (0, \ldots, 0, a, h_{n,n+1}(a), h_{n,n+2}(a), \ldots) + \oplus_k^\infty A_k \qquad \forall\, a \in A_n.$$

Thus $\ker(h_{n,k}) \subseteq \ker(h_{n,k+1}) \subseteq \ker(h_n^\infty)$ and the kernel of h_n^∞ is the closure of the union of the kernels of $h_{n,k}$ for $k = n+1, n+2, \ldots$. If the h_n are injective, then the $h_{m,n}\colon A_m \to A_n$ and the $h_n^\infty\colon A_n \to B$ are injective. In this case it follows $\dim(B) > 1$ if $\dim(A_{n_0}) > 1$ for some n_0.

In the inductive limit B holds $h_m^\infty(A_m) \subseteq h_n^\infty(A_n)$ for $m < n$, and B is the closure of $\bigcup h_n^\infty(A_n)$. We show that
B is simple and purely infinite, if and only if,

(1) $\mathrm{Dim}(B) > 1$, *and*
(2) *for every $m \in \mathbb{N}$, $\varepsilon > 0$, and $e, f \in (A_m)_+$ with $\|f\| \leq 1 = \|e\| = \|h_{m,m+k}(e)\|$ for $k = 1, 2, \ldots$, there exist $p > n > m$ and a contraction $g \in A_n$ such that the distance of $h_{m,n}(f) - g^* h_{m,n}(e) g$ from* $\ker(h_{n,p})$ *is less than ε.*

Note that the distance from $c := h_{m,n}(f) - g^* h_{m,n}(e) g$ in A_n to $\ker(h_n^\infty)$ is less than ε, if and only if, $\|h_n^\infty(c)\| < \varepsilon$, if and only if, there exists $p > n$ such that c has distance from $\ker(h_{n,p})$ less than ε.

For the proof of Proposition 2.2.1(ii) it suffices to consider the only elements a and b in $\bigcup_n h_n^\infty(A_n)$ with $0 \leq a$, $0 \leq b$ and $\|a\| = \|b\| = 1$. Let such a and b given and let $m \in \mathbb{N}$ such that $a, b \in h_m^\infty(A_m)$. Then there exist contractions $e, f \in (A_m)_+$ with $h_m^\infty(e) = a$ and $h_m^\infty(f) = b$. It implies $1 \leq \|h_{m,m+k}(e)\| \leq \|e\| \leq 1$ and $\|f\| = 1$.

By (2) there exits, for given $\varepsilon > 0$. indices $n > m$ and a contraction $g \in A_m$ such that $\|b - d^* a d\| < \varepsilon$ for the contraction $d := h_m^\infty(g)$. Thus, (1) and (2) imply together that B is simple and purely infinite.

Conversely, suppose that B is simple and purely infinite. Then $\mathrm{Dim}(B) > 1$ by Proposition 2.2.1. Let $\varepsilon > 0$ and $e, f \in (A_m)_+$ with $\|f\| \leq 1 = \|h_{m,m+k}(a)\| = \|a\|$.

Then $a := h_m^\infty(e)$ and $b := h_m^\infty(f)$ are in B_+ and $\gamma := \|b\| \leq 1 = \|a\|$. By Proposition 2.2.1(ii), there exist a contraction $d \in B$ such that $\|b - \gamma d^* a d\| < \varepsilon$. If we replace d by a small perturbation of d it satisfies the same inequality. Therefore we can assume that $d \in h_n^\infty(A_n)$ for some $n > m$. If $g \in A_n$ is a contraction with $h_n^\infty(g) = \gamma^{1/2} d$, then there exists $p > n$ such that (2) is satisfied for $m, e, f, \varepsilon, g, n, p$. Thus (1) and (2) is satisfied if B is simple and purely infinite.

(iv): The algebra A is supposed to be simple by assumption in Part (iv). But we show that all – not necessarily simple – non-zero C^*-algebras A with Property (Δ) are purely infinite in sense of Definition 1.2.1:

If the algebra $A \neq \{0\}$ satisfies Property (Δ), then A can not have a character because $\mathcal{M}(A)$ contains two isometries s_1, s_2 with orthogonal ranges. (In particular A is not commutative, especially $A \neq \mathbb{C}$.)

Let $a, b \in A$ with $\|a\| = 1$ and let $\varepsilon > 0$.

We can consider here also non-simple A with property (Δ). But then we must require in addition that b is in the closed ideal generated by a, i.e., that $\|\pi_J(b)\| = 0$ if $\|\pi_J(a)\| = 0$ for all ideals J of A. It is enough to know this for all primitive ideals J of A.

Since b is in the ideal generated by a (that is automatic if A is simple and a is non-zero), there are $x_1, x_2, \ldots, x_n$ in A such that $\|b - \sum_k x_k^* a x_k\| < \varepsilon/2$.

The set $X := \{a\} \subset A$ satisfies the assumptions of Lemma 2.2.4. Thus, there exists for $x_1, \ldots, x_n$ an element $d \in A$ with

$$\|d\|^2 = \|\sum_k x_k^* x_k\| \quad \text{and} \quad \|d^* a d - \sum_k x_k^* a x_k\| < \varepsilon/2 .$$

In particular, $\|b - d^* a d\| < \varepsilon$.

Thus, Property (Δ) implies that A satisfies all conditions of the Definition 1.2.1 of purely infinite C^*-algebras. If A is simple, then A satisfies the criterium in Proposition 2.2.1(ii) for A being purely infinite. It causes that A is strongly p.i. in sense of Definition 1.2.2 if A is simple, cf. Proposition 2.2.1(v).

(v): We use criterion (ii) of Proposition 2.2.1. Notice first that $A := D' \cap B \neq \mathbb{C}$ by our assumptions. For $a \in (D' \cap B)_+$ and $\|a\| = 1$ there are unital *-epimorphisms $h_1\colon \mathrm{C}(\mathrm{Spec}(a)) \otimes D \to C^*(a, D)$ and $h_2\colon \mathrm{C}(\mathrm{Spec}(a)) \otimes D \to D$ given by $h_1(f \otimes d) = f(a)d$ and $h_2(f \otimes d) = f(1)d$ for $f \in \mathrm{C}(\mathrm{Spec}(a))$ and $d \in D$. If $f \otimes d$ is in the kernel of h_1, and $d \neq 0$, then $f(a) = 0$, because D is simple. Thus $f = 0$ on $\mathrm{Spec}(a)$. Therefore, by Lemma 2.2.3, the kernel of h_1 is zero. By assumption, there exists an isometry s in B with $s^* f(a) d s = h(f(a)d) = h_2((h_1^{-1})(f(a)d)) = f(1)d$ for $f \in C(\mathrm{Spec}(a))$ and $b \in D$. This yields $s \in D' \cap B$ and $s^* a s = 1$. □

Corollary 2.2.7. *The algebra $\mathcal{O}_\infty$ is simple and purely infinite.*

If C is a unital C^*-algebra with properly infinite unit element and B is any C^*-algebra, then $B \otimes^{\max} C \otimes^{\max} C \otimes^{\max} \cdots$ and its quotient $B \otimes^{\min} C \otimes^{\min} C \otimes^{\min} \cdots$ are purely infinite.

In particular, $B \otimes \mathcal{O}_\infty$ (and thus $B \otimes \mathcal{O}_\infty \otimes \mathcal{O}_\infty \otimes \cdots$) are simple and purely infinite if B is simple.

We remind our convention that $\otimes$ always denotes the minimal (= spatial) C^*-algebra tensor product $\otimes^{\min}$.

`Check consistency of notations:`
$\otimes^{\min}$, $\otimes_{\min}$, $\otimes$, $\otimes^{\max}$, $\otimes_{\max}$, $\widehat{\otimes}$
`Where used? For what?`

Other tensor products will be denoted by $\odot$ (= algebraic tensor product) and $\otimes^{\max}$ (= maximal tensor product = universal in both variables short exact tensor product functor). Notice that there exist (at least) continuously may tensor product functors on the category of separable C^*-algebra with very different partial injectivity or (short-) exactness properties, see Ozawa and Pisier [**602**] if combined with considerations in [**431**].

Proof. Check and sort proof again or move it or parts of it to the appendices.

`Give here exact ref's to` $\mathcal{E}_n$ `in Appendices !!! ??`

In proof of property (sq) for $\mathcal{E}_n$ in Chp. 4
is already said something about the ''algebraic'' version of $\mathcal{E}_n$.
Give ref's to all places with $\mathcal{E}_n$ and $\mathcal{O}_n$ discussion.

The C^*-algebra $\mathcal{E}_n$ is the universal C^*-algebra generated by n isometries with orthogonal ranges, i.e.,

$$\mathcal{E}_n := C^*(s_1, \ldots, s_n\,;\; s_k^* s_\ell \,=\, \delta_{k\ell} 1)\,,$$

and the C^*-algebra $\mathcal{O}_\infty$ is the universal unital C^*-algebra generated by a (countable) sequence of isometries with mutually orthogonal ranges:

$$\mathcal{O}_\infty := C^*(s_1, s_2, \ldots\,;\; s_k^* s_\ell = \delta_{k\ell} 1\,,\; k, \ell = 1, 2, \ldots)\,.$$

It implies immediately that the C^*-algebra $\mathcal{O}_\infty$ is isomorphic to the inductive limit of the sequence of the natural unital C^*-morphisms $h_n \colon \mathcal{E}_n \to \mathcal{E}_{n+1}$ defined by $h_n(s_k) := s_k$ for $k = 1, \ldots, n$.

We are going to show that the C^*-morphisms h_n are injective and satisfy the condition (*) of Proposition 2.2.5(iii). It implies that $\mathcal{O}_\infty$ is simple and purely infinite.

Let $T_q(w) := s_{k_1} s_{k_2} \cdot \ldots \cdot s_{k_q}$ for the "word" $w = k_1 k_2 \ldots k_q$ of length $q \in \mathbb{N}$ with $k_1, k_2, \ldots, k_q \in \{1, 2, \ldots, n\}$.

Denote by A_n the (algebraic) linear span of elements 1, $T_q(w)$, $T_q(w)^*$ and $T_p(v) T_q(w)^*$ with $p, q \in \mathbb{N}$, v a word of length $= p$ and w a word of length $= q$. Calculation shows that A_n is a *-subalgebra of $\mathcal{E}_n$. Since A_n contains the canonical generators of $\mathcal{E}_n$ the vector space A_n is a *dense* *-subalgebra of $\mathcal{E}_n$.

Let $p_n := 1 - (s_1 s_1^* + \ldots + s_n s_n^*)$. Then p_n is a projection in $\mathcal{E}_n$ that satisfies $p_n T_q(w) = 0$ for "words" w in the "alphabet" $\{1, \ldots, n\}$ if w is not the "empty" word (i.e., if the "lengths" q of w is not zero).

It implies that $p_n A_n p_n = \mathbb{C} \cdot p_n$ and – therefore – that $p_n \cdot \mathcal{E}_n \cdot p_n = \mathbb{C} \cdot p_n$, i.e., p_n is a minimal projection in $\mathcal{E}_n$ that generates a closed ideal $J(p_n)$ of $\mathcal{E}_n$ that is isomorphic to an elementary simple C^*-algebra, i.e., $J(p_n) \cong \mathbb{K}(\ell_2(\mathbb{N}))$.

Clearly, $T_q(w) p_n \neq 0$ because $T_q(w)^* T_q(w) = 1$. But $p_n T_r(v)^* T_q(w) p_n = 0$ for $w \in \{1, \ldots, n\}^q$ and $v \in \{1, \ldots, n\}^r$ if $r \neq q$, or if $r = q$ and $v \neq w$.

This shows that $J(p_n) \cong \mathbb{K}(\ell_2(\mathbb{N}))$, i.e., the closed ideal $J(p_n)$ of the C^*-algebra $\mathcal{E}_n$ generated by $p_n := 1 - (s_1 s_1^* + \ldots + s_n s_n^*)$ is isomorphic to $\mathbb{K}(\ell_2(\mathbb{N}))$, and p_n is a minimal projection of $J(p_n) \cong \mathbb{K}$.

The results of J. Cuntz in [**169, 172**] show that the ideal $J(p_n)$ is an *essential* ideal of $\mathcal{E}_n$ and that $\mathcal{O}_n \cong \mathcal{E}_n / J(p_n)$ is simple.

We explore her a different method to show that $J(p_n)$ is an essential ideal of $\mathcal{E}_n$ by using the "gauge action" action of S^1 on $\mathcal{E}_n$ defined by $\gamma(z)(s_n) := z s_n$ on $\mathcal{E}_n$ (calculated modulo $J(p_n)$ in $\mathcal{O}_n$) for all $z \in S^1 \subseteq \mathbb{C}$

But it shows not that $\mathcal{O}_n := \mathcal{E}_n / J(p_n)$ is simple, instead only the – here sufficient – result that $\mathcal{O}_n$ contains no nontrivial closed ideal that is invariant under the "gauge action" of S^1 defined by $\gamma(z)(s_n) := zs_n$ on $\mathcal{E}_n$ (calculated modulo $J(p_n)$ in $\mathcal{O}_\mathrm{n}$) for all $z \in S^1 \subseteq \mathbb{C}$ and, of course, ([24]).

([25]).

It satisfies $\gamma(z)(e_n) = e_n$ for all $z \in S^1$. Therefore, the closed ideal $J(e_n)$ of $\mathcal{E}_n$ generated by p_n is invariant under the action of the gauge group. To distinguish between the gauge action on $\mathcal{E}_n$ and $\mathcal{O}_\mathrm{n}$ we denote by $[\gamma](z)$ the action on $\mathcal{O}_\mathrm{n}$.

The projection $p_n \in \mathcal{E}_n$ is fixed by the natural/canonical circle action given by $\gamma(z)(s_k) := z \cdot s_k$ on $\mathcal{E}_n$ for $z \in \mathbb{C}$ with $|z| = 1$. This action is called "gauge action" and is well-defined by the universality of the defining relations for $\mathcal{E}_n$. Clearly, the ideal $J(p_n)$ generated by p_n is invariant under the circle action $\gamma(z)$,because $\gamma(z)(p_n) = p_n$ for $z \in S^1 \subseteq \mathbb{C}$. It follows immediately that also the set K of all elements $b \in \mathcal{E}_n$ with $b \cdot J(p_n) = \{0\}$ is a closed ideal of $\mathcal{E}_n$ that is invariant under the gauge action, i.e., that $\gamma(S^1)(K) \subseteq K$. This annihilator K of the ideal $J(p_n)$ is a closed ideal K of $\mathcal{E}_n$ and must be $\gamma(S^1)$-invariant – by $\gamma(S^1)$-invariance of $J(p_n)$. Therefore $\pi_{J(p_n)}(K)$ must be a closed ideal of $\mathcal{O}_\mathrm{n}$ that is invariant under the gauge action $[\gamma]$ (modulo $J(p_n)$) on $\mathcal{O}_\mathrm{n}$. Moreover, $\pi_{J(p_n)}|K$ is faithful on K and is equivariant with respect to the gauge actions γ on $\mathcal{E}_n$ and $[\gamma]$ on $\mathcal{O}_\mathrm{n}$.

The fix-point algebra of $[\gamma]$ on $\mathcal{O}_\mathrm{n}$ is isomorphic to the UHF-algebra M_{n^∞} as a study of the algebraic dense subalgebra $\pi_{J(p_n)}(A_n)$ of $\mathcal{O}_\mathrm{n}$ shows. In particular it contains no non-trivial ideals. It allows to apply the following general elementary observation: Each continuous action of a compact group G on a C^*-algebra B has a fix-point algebra that contains an approximate unit of B, this happens also for every G-invariant closed ideal I of B, and the G-fix-point algebra of I is a closed ideal of the fix-point subalgebra of G in B.

If we apply this to $I := \pi_{J(p_n)}(K)$ and the circle action $[\gamma]\colon S^1 \to \mathrm{Aut}(\mathcal{O}_\mathrm{n})$ then we get that the intersection of I with the fixed point-algebra of $[\gamma]$ is an ideal of the fix-point algebra of $[\gamma]$ that contains a strictly positive element of $\pi_{J(p_n)}(K)$. Straight forward calculation shows that the fix-point algebra of the gauge action on $\mathcal{O}_\mathrm{n}$ is isomorphic to the simple UHF algebra M_{n^∞}. It proves that the ideal $\pi J(p_n)(K) \cong K$ of $\mathcal{O}_\mathrm{n}$ can only be zero or all of $\mathcal{O}_\mathrm{n}$, i.e., $K = \{0\}$ or $1 \in \pi J(p_n)(K)$.

Suppose that $1 \in \pi_{J(p_n)}(K)$. The orthogonality $K \cdot J(p_n) = 0$ implies that the quotient map $\pi_{J(p_n)}$ is faithful on K. Hence, K contains a projection $Q \in K$ with $\pi_{J(p_n)}(Q) = 1$, and it follows that $Q \cdot J(p_n) \subseteq K \cdot J(p_n) = \{0\}$ and that

[24] This arguments are elementary but do not prove the simplicity of $\mathcal{O}_\mathrm{n}$.

[25] It proves the simplicity of $\mathcal{O}_\mathrm{n}$ not completely. A complete proof of the simplicity and nuclearity of $\mathcal{O}_\mathrm{n}$ can be obtained by showing that the canonical conditional expectation onto the fix-point algebra $\cong M_{n^\infty}$ of the gauge action is an approximately inner c.p. map on $\mathcal{O}_\mathrm{n}$. Equivalently, by nuclearity and simplicity of M_{n^∞}, that the natural conditional expectation P_n is "faithful" as c.p. map and must preserve all closed ideals, i.e., for each positive $a \in \mathcal{O}_\mathrm{n}$ the element $P_n(a) \in M_{n^\infty} \subset \mathcal{O}_\mathrm{n}$ is contained in the ideal generated by by a. This can be seen by approximating a by elementary elements b and then show that $P_n(b)$ can be approximated up to $\varepsilon > 0$ by X^*bX for a suitable elementary element X. It shows that also that all positive elements of $\mathcal{O}_\mathrm{n}$ are purely infinite.

$\pi_{J(p_n)}(1-Q)=0$, i.e., $1-Q\in J(p_n)$. Since Q is a projection with $Qx=0=xQ$ for all $x\in J(p_n)$. It follow that $P:=1-Q$ is a unit element for $J(p_n)$. But we have seen above that $J(p_n)\cong \mathbb{K}(\ell_2(\mathbb{N}))$ is not unital. This shows that only the case $K=\{0\}$ remains, and this implies that $J(p_n)$ is an essential ideal of $\mathcal{E}_n$ (as discussed above).

It gives us the here needed injectivity of the natural map from $\mathcal{E}_n$ into $\mathcal{E}_{n+1}$????

The $[\gamma]$-simplicity and nuclearity of $\mathcal{O}_{\rm n}$ follows from the fact that M_{n^∞} is the fixed point algebra of the circle action (and that S^1 is a compact group), and that the by this action define conditional expectation P_n from $\mathcal{O}_{\rm n}$ onto M_{n^∞} defined by the integral over this action is an *approximately inner* u.c.p. map. There exists an explicit approximation by inner c.p. maps. It is a 1-step innerness that proves also the pure infiniteness if the elements of $\mathcal{O}_{\rm n}$. It can be seen by considering "algebraic" elements.

But we do not us it this here. See ... ... give Citation ???? to Appendix

Since, as above shown, $a\in\mathcal{E}_n\mapsto L(a)\in\mathcal{M}(J(p_n))$ with $L(a)b=ab$ for all $b\in J(p_n)$ is a faithful unital C^*-morphism, we obtain for $a\in(\mathcal{E}_n)_+$ with $\|a\|=1$ that there exists a partial isometry $z\in J(p_n)\cong\mathbb{K}$ with $z^*z=p_n$ and $\|p_n-z^*az\|<\varepsilon$.

We define $c:=h_n(z)s_{n+1}h_n(b^{1/2})\in\mathcal{E}_{n+1}$. Notice that $h_n(p_n)=p_{n+1}+s_{n+1}s_{n+1}^*\in\mathcal{E}_{n+1}$ and $p_{n+1}s_{n+1}=0$. This shows that

$$\|c^*h_n(a)c-h_n(b)\|<\varepsilon\,.$$

It means that the canonical morphisms $h_n\colon\mathcal{E}_n\to\mathcal{E}_{n+1}$ satisfies the criterium (*) of Proposition 2.2.5(iii). Thus $\mathcal{O}_\infty=\operatorname{indlim}_{n\to\infty}(h_n\colon\mathcal{E}_n\to\mathcal{E}_{n+1})$ is simple and purely infinite.

Part (iv) of Proposition 2.2.5 implies that $B\otimes C\otimes C\otimes\cdots$ is simple and purely infinite if B is simple and C is a simple C^*-algebra with properly infinite unit element 1_C, because then $1_C\in\mathcal{O}_\infty\subseteq\mathcal{E}_2\subseteq C$ (with *-monomorphism defined by $\mathcal{O}_\infty\ni s_n\mapsto t_2^{n-1}t_1\in\mathcal{E}_2$ for $\mathcal{O}_\infty=C^*(s_1,s_2,\ldots)$ and $\mathcal{E}_2=C^*(t_1,t_2)\subseteq C$.

For each $a\in B\otimes C\otimes C\otimes\cdots$ and $\varepsilon>$ there exists $a'\in B\otimes C\otimes\cdots\otimes C\otimes 1_C\otimes 1_C\otimes\cdots$ with $\|a'-a\|<\varepsilon/2$ and a' commutes with a copy of $\mathcal{O}_\infty\cong 1_B\otimes 1_C\otimes\cdots\otimes 1_c\otimes\mathcal{O}_\infty\otimes 1_C\otimes\cdots$.

The proof shows also for every (not necessarily simple) C^*-algebra B that $B\otimes C\otimes C\otimes\cdots$ (with $\otimes:=\otimes^{\min}$) is strongly purely infinite if C is a unital properly infinite C^*-algebra and the argument works also for finitely many $a_1,\ldots,a_n\in B\otimes C\otimes C\otimes\cdots$.

Can also use dichotomy for tensor prod.s of simple $C*$-alg.s
if B and C are *simple* !!!
Then it is only needed that both are non-elementary and that one of
B or C is stably infinite. ∎

LEMMA 2.2.8. *Let* $\varepsilon \in (0, 1/4)$ *and* $a, b \in A_+$ *contractions that satisfy*

$$\|ab^{1/2} - b^{1/2}a\| < \varepsilon \qquad \text{and} \qquad \|aba\| > 1 - \varepsilon .$$

Then $\|b^{1/2}a^2b^{1/2} - aba\| < 2\varepsilon$ *and the non-zero hereditary* C^**-subalgebra* $E := \overline{abaAaba}$ *of* $\overline{aAa}$ *has the property that*

$$\|(1 - b)^{1/2}d\| \le \sqrt{3\varepsilon} \cdot \|d\| \quad \text{for all } d \in E . \tag{2.3}$$

Notice here for later applications that $(1 - b)^{1/2}$ is a (positive) contraction.

PROOF. Suppose that $e \in A_+$ is a contraction with $3/4 < 1 - \varepsilon < \|e\| \le 1$, and let $f := (e - (1 - \varepsilon))_+$. Then $0 \le f \ne 0$, $\|f\| \le \varepsilon$ and $E := \overline{fAf}$ is a non-zero hereditary C^*-subalgebra of A. We use that

$$(1 + 2\varepsilon - t)(t - 1 + \varepsilon)^{1/n} \le 3 \cdot \varepsilon \quad \text{for all } t \in [1 - \varepsilon, 1] \text{ and } n \in \mathbb{N} ,$$

to obtain that $\|(1+2\varepsilon-e)f^{1/n}\| \le 3\varepsilon$ for all $n \in N$. Since the $f^{1/n}$ commute with the positive element $(1 + 2\varepsilon - e)$ and f is a strictly positive element in E, we get that $\|d^*(1 + 2\varepsilon - e)d\| \le 3\varepsilon \cdot \|d\|^2$ for all $d \in E$. It shows that

$$\|(1 + 2\varepsilon - e)^{1/2}d\| \le \sqrt{3\varepsilon}\|d\| \quad \text{for all } d \in E . \tag{2.4}$$

We apply this observation to our special case:

Let $a, b \in A_+$ elements that satisfy the in Lemma 2.2.8 listed pre-assumptions with $0 < \varepsilon < 1/4$, and let $x := b^{1/2}a$. Then $\|x\| \le 1$ and $\|x^* - x\| = \|ab^{1/2} - b^{1/2}a\| < \varepsilon$. It gives

$$\|b^{1/2}a^2b^{1/2} - aba\| = \|xx^* - x^*x\| < 2\varepsilon .$$

Thus, $b^{1/2}a^2b^{1/2} - aba \le 2\varepsilon \cdot 1$. Together with $0 \le a^2 \le 1$ it implies

$$0 \ge 1 - b \le 1 - b^{1/2}a^2b^{1/2} \le 1 + 2\varepsilon - aba .$$

Now let $e := aba$ and $f := (e - (1 - \varepsilon))_+$ build from a and b with the listed properties. This $e, f \in A_+$ have the previously considered properties $3/4 < 1 - \varepsilon < \|e\| \le 1$, because $a, b \in A_+$ are contractions that satisfy $\|aba\| > 1 - \varepsilon$ by assumptions on a, b and ε .

The monotony of the C^*-norm on positive parts of C^*-algebras implies that for all elements $d \in E := \overline{fAf}$ holds

$$\|d^*(1 - b)d\| \le \|d^*(1 + 2\varepsilon - aba)d\| .$$

The above shown Inequality 2.4 says that $\|d^*(1 + 2\varepsilon - e)d\| \le 3\varepsilon \cdot \|d\|^2$ for all $d \in E := \overline{fAf}$, where we let here $e := aba$ and $f := (aba - (1 - \varepsilon))_+$.

Using again monotony of the C^*-norm on A_+ we get that

$$\|d^*(1 - b)d\| \le \|d^*(1 + 2\varepsilon - aba)d\| \le 3\varepsilon \cdot \|d\|^2 ,$$

for all $d \in E := \overline{fAf}$. This is equal to the Inequality (2.4). □

LEMMA 2.2.9. *Let A a non-zero σ-unital C^*-algebra, and $S \in \mathcal{M}(A)_+$ a positive contraction with norm $\|\pi_A(S)\| = 1$ for the image $\pi_A(S)$ of S in the corona $\mathrm{Q}(A) := \mathcal{M}(A)/A$ of A.*

(i) *There exists a positive contraction $T \in \mathcal{M}(A)_+$ with $\|\pi_A(T)\| = 1$ and $(1 - S)T \in A$.*
(ii) *If A is* antiliminary *in the sense of* [**616**, sec. 6.6.1]*, cf. our Definition 2.7.2, i.e., if a^*Aa is non-commutative for each non-zero $a \in A$, then there exists a contraction $T \in \mathcal{M}(A)$ with $T^2 = 0$, $\|\pi_A(T)\| = 1$ and $(1 - S)T$, $T(1 - S) \in A$.*
(iii) *If A is simple and non-elementary then for each $a \in A_+$ with $\|a\| = 2$ there exists a sequence of contractions $d_1, d_2, \ldots \in A$ such that $(a-(a-1)_+)d_n = d_n$, $\|d_n\| = 1$, $d_m^* d_n = 0$ and $d_n(d_m)^* = 0$ for $m, n \in \mathbb{N}$, and such that the sum $\sum_n d_n^* d_n$ is strictly convergent in $\mathcal{M}(A)$ to a contraction $T := \sum_n d_n^* d_n \in \mathcal{M}(A)_+$ that satisfies $\|\pi_A(T)\| = 1$ and $(1 - S)T \in A$.* ([26]).

PROOF. The corona algebra $\mathrm{Q}(A) := \mathcal{M}(A)/A$ is non-zero (and therefore is unital) by existence of a contraction $S \in \mathcal{M}(A)_+$ with $\|\pi_A(S)\| = 1$.

(i) and preparations for (ii): Let $e \in A_+$ with $\|e\| = 1$ strictly positive in A, i.e., $\overline{eAe} = A$. For every separable C^*-subalgebra $B \subseteq \mathcal{M}(A)$, e.g. for $B := C^*(e, S)$ with the considered contraction $S \in \mathcal{M}(A)_+$, we find a linear filtration $X_n \subseteq B$ with $S, e \in X_1$, $\dim(X_n) < \infty$ and $X_n^* = X_n \subseteq X_{n+1}$ – as considered in Remark 5.1.1(3) of Chapter 5 – and an approximate quasi-central unit $(e_n)_{n\in\mathbb{N}}$ of form $e_n := f_n(e)$ with continuous functions $f_n \in \mathrm{C}_0(0, 1]$ with $f_0(t) := t$, $f_n f_{n+1} = f_n$ for $n \geq 1$, $\|f_0 - f_n f_0\| \to 0$, and, for $b \in X_n$,

$$\| [f_n(e), b] \| \; + \; \|[(f_m(e) - f_n(e))^{1/2}, b] \| \; < \; 4^{-n}\|b\| \, .$$

Then, for every sub-selection $g_k := f_{n_k}(e)$, $n_{k+1} > n_k \geq k > 0$ (and $g_0 := 0$), we can build the completely positive unital map $V \colon \ell_\infty(\mathcal{M}(A)) \to \mathcal{M}(A)$ with help of the strictly convergence of sums

$$V(a_1, a_2, \ldots) := \sum_{k=1}^{\infty} (g_k - g_{k-1})^{1/2} a_k (g_k - g_{k-1})^{1/2}$$

for bounded sequences $a_1, a_2, \ldots$ in $\mathcal{M}(A)$. Notice that $b - V(b, b, \ldots) \in A$ for all $b \in B$ and that $V(ba_1, ba_2, \ldots) - bV(a_1, a_2, \ldots) \in A$ for each sequence $(a_1, a_2, \ldots) \in \ell_\infty(\mathcal{M}(A))$ and every $b \in B$. This is the case because V is a unital completely positive map from $\ell_\infty(\mathcal{M}(A))$ into $\mathcal{M}(A)$ with $V(b, b, \ldots) = b$ for all $b \in B \subseteq \mathcal{M}(A)$, i.e., the images $(b, b, \ldots)$ by the diagonal embedding of $b \in B$ in $\ell_\infty(\mathcal{M}(A))$ are contained in the multiplicative domain of V.

(See Remarks 5.1.1(2,...,5) for more details on this standard constructions.)

If $c_1, c_2, \ldots \in A$ is a bounded sequence that satisfies the condition $c_k = c_k(g_k - g_{k-1}) = (g_k - g_{k-1})c_k$ (e.g. if $c_k g_k = c_k$ and $c_k g_{k-1} = 0$) for $k \in \mathbb{N}$ then

[26] But the sum $d_1 + d_2 + \cdots$ is in general not strictly convergent in $\mathcal{M}(A)$.

$\|\pi_A(V(c_1, c_2, \ldots))\| = \limsup_n \|c_n\|$, $c_k c_{k+1} = 0 = c_k^* c_{k+1}$ and the series $\sum_k c_k$ is strictly convergent in $\mathcal{M}(A)$ and $\sum_k c_k = V(c_1, c_2, \ldots)$.

If moreover $\lim_k \|c_k S - c_k\| = 0$, then $V(c_1, c_2, \ldots)S - V(c_1, c_2, \ldots) \in A$, because of $V(a_1, a_2, \ldots) \in A$ if $\lim \|a_n\| = 0$.

It follows $T - TS \in A$ and $\|\pi_A(T)\| = 1$ for the contraction $T := V(c_1, c_2, \ldots)$ with $c_1, c_2, \ldots \in A$ contractions that satisfy $\limsup_n \|c_n\| = 1$ and $\lim_n \|c_n S - c_n\| = 0$ and $c_n(g_n - g_{n-1}) = c_n = (g_n - g_{n-1})c_n$. Similarly also $T - ST \in A$ if here in addition the contractions c_n satisfy $\lim \|c_n - Sc_n\| = 0$.

If, moreover, those c_n can be fund such that $c_n^2 = 0$ in addition, then $T^2 = 0$, i.e., in the hereditary C^*-subalgebra $\mathrm{Ann}(1 - \pi_A(S))$ of elements $X \in \mathrm{Q}(A)$ with $X(1 - \pi_A(S)) = 0$ and $X^*(1 - \pi_A(S)) = 0$ is not Abelian.

Notice that $\mathrm{Ann}(1 - \pi_A(S))$ is automatically contained in $\pi_A(S)\,\mathrm{Q}(A)\pi_A(S) \subseteq D$ if $S \in \mathcal{M}(A)_+$ is a positive contraction with $\pi_A(S) \in D$.

The above outlined method requires a careful inductive choice of the $g_k := e_{n_k} := f_{n_k}(e)$ for suitable $n_1, \ldots, n_k, \ldots$ and then of non-zero hereditary C^*-subalgebras E_k with the property that for all $d \in E_k$ holds $d(g_{k+1} - g_k) = d$ and $\|dS - d\| < 1/2^k$.

(Those n_k and E_k can be selected suitably with help of Lemma 2.2.8.)

Then all elements $X = \pi_A(V(d_1, d_2, \ldots))$ are in $\mathrm{Ann}(1 - \pi_A(S))$ if $d_k \in E_k$ for $k = 1, 2, \ldots$ and $\limsup_n \|d_k\| = \|X\|$. If $d_k^2 = 0$ for all $k \in \mathbb{N}$ it follows that $X^2 = 0$.

`Compare below text with above. Give precise selection rule.`

Let $S \in \mathcal{M}(A)_+$ with $\|S\| = \|\pi_A(S)\| = 1$ and $B := C^*(S, e)$. Choose $e_n := f_n(e)$ for B as above described for $n = 1, 2, \ldots$.

We select $g_k := e_{n_k} := f_{n_k}(e)$ such that there exists a non-zero hereditary C^*-subalgebra E_k of A with $\|d - Sd\| < 2^{-n}$ and $d(g_k - g_{k-1}) = d$ for all $d \in E_k$.

Then $V(d_1, d_2, \ldots)$ defines a C^*-morphism from $\prod_k E_k := \ell_\infty(E_1, E_2, \ldots)$ into $\mathcal{M}(A)$ with $V(c_0(E_1, E_2, \ldots)) \subseteq A$, and $(1-S)V(d_1, d_2, \ldots), V(d_1, d_2, \ldots)(1-S) \in A$ for all $(d_1, d_2, \ldots) \in \ell_\infty(E_1, E_2, \ldots)$.

We find $m_1 \in \mathbb{N}$ with $\|e_{m_1} S e_{m_1}\| \geq 1 - 2^{-2}$ and $\|[S, e_{m_1}]\| < 2^{-2}$.

by Lemma 2.2.8 ??

Let E_1 the hereditary C^*-algebra generated by $((e_{m_1} S e_{m_1}) - 1/2)_+$. Then $e_{m_1+1} d = d$ for all $d \in E_1$, and $\|d - Sd\| \leq$?????.

Take ????

???? with the above listed properties such that $\|c_k\| = 1$ in addition. Then $T := V(c_1, c_2, \ldots) \in \mathcal{M}(A)$ has the desired property $T - ST \in A$.

Define contractions $c_1, c_2, \ldots \in A_+$ and $n_k \in \mathbb{N}$ step-wise:

Recall that $\|(e_n - e_m)S\| \geq$????. Take $g_1 := e_2$, i.e., $k_1 := 2$, and find in the hereditary C^*-algebra generated by e_1Se_1 let $c_1 := e_1 = e_1e_2$ for Part (i).

Find for Part (ii) in the hereditary C^*-subalgebra E_1 generated by e_1Se_1 an element with $d_1^2 = 0$ and $\|d_1\| = 1$ if $E_1 \neq \{0\}$

and ????.

Then $\|c_1\| = 1$ and $c_1(e_3 - e_0) = c_1$.

Then $\|(1-e_4)S(1-e_4)\| = 1$ in $B \subset \mathcal{M}(A)$ and we find $n_k \in \mathbb{N}$, $n_{k+1} \geq 2+n_k$ with $\|(e_{n_{k+1}-1} - e_{n_k+1})^{1/2}S^{1/2}\| > 1-2^{-n_k}$. It follows that in the closed right ideal L_k generated by $(e_{n_{k+1}-1} - e_{1+n_k})^{1/2}S^{1/2}A$ contains a positive contraction c_k with $\|c_kS\| \geq 1 - 2^{-k_1}$.

The $c_1, c_2, \ldots$ and $g_1, g_2, \ldots$ have the desired properties.

(ii): The pairwise orthogonal non-zero hereditary C^*-subalgebras E_k considered in the proof Part (i) contain elements $c_k \in E_k$ with $c_k^2 = 0$, $\|c_k\| = 1$. Then $T = \sum_k c_k = V(c_1, c_2, \ldots)$ satisfies $T^2 = 0$, $\|T\| = \|\pi_A(T)\| = 1$ and $TS - S, ST - S \in A$.

(iii): With the hereditary C^*-subalgebras E_k considered in Parts (i,ii) we need only to find in the hereditary C^*-subalgebra $F := \overline{(a-1)_+A(a-1)_+}$ a sequence of elements $a_1, a_2, \ldots \in F_+$ with $\|a_n\| = 1$, $a_ma_n = 0$ for $m \neq n$. Then the simplicity of A allows to find $d_1, d_2, \ldots \in A$ with $d_n^*d_n \in E_n$, $d_n(d_n)^* \in \overline{a_nAa_n}$ and $\|d_n\| = 1$. This is possible for simple non-elementary A. □

Lemma 2.2.10. *Let A a σ-unital C^*-algebra and let $D \subseteq \mathrm{Q}(A)$ a non-zero* simple *hereditary C^*-subalgebra of $\mathrm{Q}(A)$. Then D has the following properties:*

(i) *D is purely infinite or is "elementary"* ([27]).

(ii) *If A is antiliminary, in the sense of Definition 2.7.2, then D is non-elementary, i.e., D can not contain a non-zero minimal projection.*

(iii) *The corona $\mathrm{Q}(A)$ of A is purely infinite if $\mathrm{Q}(A)$ is simple (and non-zero).*

If $\mathrm{Q}(A)$ is simple then, for each $S \in \mathcal{M}(A)_+$ with $\|\pi_A(S)\| = 1$, there exists a contraction $d \in \mathcal{M}(A)$ with $1 - d^*Sd \in A$.

Proof. (i): The non-zero simple C^*-subalgebra $D \subseteq \mathrm{Q}(A)$ satisfies the condition (xv) of Proposition 2.2.1 if D is non-elementary:

Let $a, b \in D_+$ with $\|a\| = \|b\| = 1$ and $\varepsilon > 0$. There exist $R, S \in \mathcal{M}(A)_+$ with $\pi_A(R) = b$, $\pi_A(S) = a$, $\|R\| = 1$ and $\|S\| = 1$.

By Lemma 2.2.9(i) there exists $T \in \mathcal{M}(A)_+$ with $\|T\| = \|\pi_A(T)\| = 1$ and $TS - T \in A$.

Let $g := \pi_A(T)$. We get $g = aga \in D$, because $g = ga = ag$ and D is hereditary in $\mathcal{M}(A)$. Since D is simple and $g \in D_+$ has norm $\|g\| = 1$ we find for every $\varepsilon > 0$ a number $\nu \in \mathbb{N}$ such that there exists *contractions* $d_1, \ldots, d_\nu \in D$ with

[27] The simple D is "elementary", if and only if, D contains a non-zero projection $p \in D$ with $p\,\mathrm{Q}(A)p = \mathbb{C} \cdot p$. Then $D \cong \mathbb{K}(\mathcal{H})$ for some Hilbert space $\mathcal{H}$.

$\|b - \sum d_j^* g^2 d_j\| < \varepsilon$. Define $\nu(b, a, \varepsilon)$ as this $\nu \in \mathbb{N}$. Then $\|b - \sum_{j=1}^{\nu} c_j a^k c_j\| < \varepsilon$ with contractions $c_j := g d_j$ for each $k \in \mathbb{N}$.

Thus, D is purely infinite by Proposition 2.2.1(xv).

(ii): Let $p \in D \subseteq \mathrm{Q}(A)$ a non-zero projection. There exists a positive contraction $S \in \mathcal{M}(A)_+$ with $\pi_A(S) = p$.

By Lemma 2.2.9(ii) there exists $T \in \mathcal{M}(A)$ such that $b := \pi_A(T) \in \mathrm{Q}(A)$ satisfies $\|b\| = 1$, $b^2 = 0$ and $pb = b = bp$. Thus $b \in p\,\mathrm{Q}(A)p \subseteq D$ and $b \notin \mathbb{C} \cdot p$.

(iii): Suppose that $0 \neq p$ is a projection in $\mathrm{Q}(A)$ with $p\,\mathrm{Q}(A)p = \mathbb{C} \cdot p$ and that $\mathrm{Q}(A)$ is simple. Then there exists $d_1, \ldots, d_n \in \mathrm{Q}(A)$ with $\sum_k d_k^* p d_k = 1$. It follows that $\mathrm{Q}(A) \cong M_m(\mathbb{C})$ for some $m \leq n$.

The following argument shows that σ-unital A is unital (i.e., $\mathrm{Q}(A) = \{0\}$) if every Abelian C^*-subalgebra of $\mathrm{Q}(A)$ is finite dimensional.

If $a \in A_+$ is a strictly positive contraction then $\mathcal{M}(C^*(a))/C^*(a) \subseteq \mathrm{Q}(A)$ by a natural unital *-monomorphism.

Let $X \subseteq (0, 1]$ denote the non-zero values in the spectrum of a in $C^*(a) \cong \mathrm{C}_0(X)$. If 0 is in the closure of X, then $\mathrm{C_b}(X)/\,\mathrm{C}_0(X)$ infinite dimensional (as vector space) because then $\ell_\infty(\mathbb{N})/c_0(\mathbb{N})$ is a quotient of it.

Thus, A is unital if $\mathrm{Q}(A)$ has only finite dimensional abelian C^*-subalgebras (which is equal to $\mathrm{Q}(A)$ finite-dimensional). □

Corollary 2.2.11. *Let A a non-zero C^*-algebra, and $\mathbb{K} := \mathbb{K}(\ell_2(\mathbb{N}))$.*

(i) *The stable corona $\mathrm{Q}^s(A) := \mathcal{M}(A \otimes \mathbb{K})/(A \otimes \mathbb{K})$ is simple, if and only if,*
 (a) *A is σ-unital and simple,* and
 (b) *A is either purely infinite or is "elementary" (i.e., $A \otimes \mathbb{K} \cong \mathbb{K}$).*
 If $\mathrm{Q}^s(A)$ is simple then $\mathrm{Q}^s(A)$ is purely infinite.

(ii) *The ultrapower A_ω is simple, if and only if, either A is simple and purely infinite, or $A \cong M_n$ for some $n \in \mathbb{N}$.*

(iii) *The hereditary C^*-subalgebra of A_ω generated by $A \subseteq A_\omega$ is simple, if and only if, either A is simple and purely infinite or A is isomorphic to the compact operators $\mathbb{K}(\mathcal{H})$ on some Hilbert space $\mathcal{H}$.*

Remarks 2.2.12. `To be re-read again and sorted !!!`

(1) There is an interesting observation of the author that is related to Part (iii) of Corollary 2.2.11, but with a technically much more involved proof (cf. [**448**, thm. 2.12]).

`HERE check "cite" (of article and of thm.)  of new version !!!`

It says:

If A is separable, then the algebra $F(A) := (A' \cap A_\omega)/\operatorname{Ann}(A, A_\omega)$ is simple, if and only if, A is nuclear (sic !) and simple *and, either A is purely infinite, or $A \otimes \mathbb{K} \cong \mathbb{K}$. The isomorphism $A \otimes \mathbb{K} \cong \mathbb{K}$ is equivalent to $F(A) \cong \mathbb{C}$, because only $A = M_n$ or $A = \mathbb{K}$ are isomorphic to hereditary C^*-subalgebras of $\mathbb{K}$.*

Here $\omega \in \beta(\mathbb{N}) \setminus \mathbb{N}$, is a "free" ultrafilter on $\mathbb{N}$, $A_\omega := \ell_\infty(A)/J_\omega$ is the (ω-) ultrapower of A with

$$J_\omega := \{(a_1, a_2, \ldots) \in \ell_\infty(A) \,;\, \lim_{n\to\omega} \|a_n\| = 0\,\}\,,$$

and $\mathrm{Ann}(A, A_\omega)$ is the two-sided annihilator of A in A_ω, that is obviously an ideal in $A' \cap A_\omega$.

(Hint: The main reason for this result is that the elements $d := \pi_\omega(d_1, d_2, \ldots) \in A_\omega$ with the property that there exists a bounded sequence of nuclear maps $V_n \colon A \to A$ such that $\omega - \lim \|d_n^* a d_n - V_n(a)\| = 0$ for all $a \in A$, build a non-zero closed right ideal of A_ω. It is a left module for $A' \cap A_\omega$, is not contained in $\mathrm{Ann}(A, A_\omega)$ and it contains an element in $A' \cap A_\omega$ that is not in the two-sided annihilator $\mathrm{Ann}(A, A_\omega)$. Now the reader can start here/his exercise by combining this with (ii).)

No other single property of separable non-elementary C^*-algebras characterizes the pi-sun C^*-algebras by only one condition!

(2) ????

Compare next ''blue'' with further below

Part(i) of Corollary 2.2.11 was proved by M. Rørdam [**674**, thm. 3.2] for the special case of non-elementary unital A.

(2??) The Parts (i,ii) of Corollary 2.2.11 has been proved for *unital* A by M. Rørdam ([**674**, thm. 3.2], [**681**]).

Then H. Lin [**517**, thm. 3.8] studied the case of non-elementary σ-unital A and observed that A must be algebraically simple. It implies that $A \otimes \mathbb{K}$ contains a scaling element.

The latter is equivalent by [**78**, thm. 1.2] to the existence of a projection in $A \otimes \mathbb{K}$. This proves the general result by reduction to the unital case considered in [**674**, thm. 3.2] by M. Rørdam.

Notice that we use a different and more elementary idea in the proof of Part (i).

Part (i) of Corollary 2.2.11 has also been obtained by S. Zhang [**842**] under the additional pre-assumptions that A is σ-unital and has real rank zero. Then H. Lin [**517**, thm. 3.8] extended the result [**674**, thm. 3.2] of M. Rørdam by replacing the requirement that A is unital by the requirement that A σ-unital.

The new argument of

S. Zhang ... or was it Lin? ...

is that stable σ-unital simple A with simple $\mathcal{M}(A)/A$ contains a "scaling" element in the sense of B. Blackadar and J. Cuntz [**78**].

They show in [**78**] that it allows to define a non-zero projection in A, cf. proof of the implication (iii)⇒(ii) for Proposition 2.2.1 for a similar argument. This allows to apply [**674**, thm. 3.2] also for the σ-unital case without the extra assumption that A is unital.

Later H. Lin proved in [**526**] that, if A is simple, σ-unital and non-unital then simplicity of $\mathcal{M}(A)/A$ is equivalent to $\mathcal{M}(A)/A$ being purely infinite and simple.

But he contributed also examples of

separable ??? `or non-separable??` `non-stable`

simple non-unital C^*-algebras A with $\mathcal{M}(A)/A$ simple but where A is not purely infinite (but is then at least "algebraically simple").

It follows that *a non-stable version of Part (i) of Corollary 2.2.11(i) can not exist*!

Our proofs of Propositions 2.2.1 and 2.2.5 and Corollary 2.2.11 are more general and elementary in a sense, because Remark 2.2.6, Lemma 2.2.3 and the used technical Lemmata A.21.3 and 2.1.22 and the passage to the non-separable case in Proposition A.21.4 are elementary basic observations in C^*-algebra theory (that we here often apply).

Our Corollary 5.7.3 characterizes the *nuclear* simple unital p.i. C^*-algebras $A \neq \mathbb{C}$ by the property that for each separable unital C^*-subalgebra $C \subseteq \mathcal{M}(A \otimes \mathbb{K})$ and *each* unital C^*-morphism

$$h\colon C \to \mathcal{M}(A \otimes \mathbb{K}) \qquad \text{with} \quad h(C \cap (A \otimes \mathbb{K})) = \{0\}$$

there exists a unitary $U \in \mathcal{M}(A \otimes \mathbb{K})$ such that

$$c \oplus h(c) - U^* c U \in A \otimes \mathbb{K} \quad \text{for all } c \in C\,.$$

The proof uses Proposition 2.2.5(vi) and a Weyl–von-Neumann type theorem, that is related to an absorption result of G. Elliott and D. Kucerovsky, cf. [**264**] and a correction (of what?) observed by J. Gabe [**309**].

Recall that the Calkin algebra $\mathrm{C}(\ell_2) = \mathrm{Q}(\mathbb{K}) = \mathcal{L}(\ell_2)/\mathbb{K}$ is simple and purely infinite.

Proposition 2.2.5(iii) shows that *any unital simple C^*-algebra A that contains an approximately central sequence of copies of $\mathcal{O}_\infty$ is purely infinite.*

We can replace $\mathcal{O}_\infty$ in the statement of Proposition 2.2.5(iii) by $\mathcal{E}_2 := C^*(s, t\colon s^*s = t^*t = 1, s^*t = 0)$ or any C^*-algebra with properly infinite unit because

$$\mathcal{E}_2 \subseteq \mathcal{O}_\infty \subseteq \mathcal{E}_2 \subseteq \mathcal{O}_\mathrm{n}$$

(via suitable unital monomorphisms) for every $n > 1$. See Chapter 10 on related topics.

(3??) $F(\mathcal{L}(\ell_2)/\mathbb{K}(\ell_2)) \cong \mathbb{C}$. `Mention here also the result of Farah and Phillips` on $F\big(\mathcal{L}(\ell_2(\mathbb{N}))\big)$. It is simple if and only if one uses Axiom of Choice?

Proof of Corollary 2.2.11. (i): Let $\mathrm{Q}^\mathrm{s}(A) := \mathcal{M}(A \otimes \mathbb{K})/(A \otimes \mathbb{K})$, and $a \in A_+$ with $\|a\| = 1$.

If the unital C^*-algebra $\mathrm{Q}^\mathrm{s}(A)$ is simple then there exist $c_1, \ldots, c_n \in \mathcal{M}(A \otimes \mathbb{K})$ with $c_1^*(a \otimes 1)c_1 + \ldots + c_n^*(a \otimes 1)c_n = 1 + d$ for some $d \in A \otimes \mathbb{K}$, – here $1 \in \mathcal{M}(\mathbb{K}) \cong$

$\mathcal{L}(\ell_2(\mathbb{N}))$, by using that $\mathcal{M}(A) \otimes \mathcal{M}(\mathbb{K})$ is naturally contained in $\mathcal{M}(A \otimes \mathbb{K})$ and identifying $\mathcal{M}(\mathbb{K})$ with $1_{\mathcal{M}}(A) \otimes \mathcal{M}(\mathbb{K})$ naturally. We find a projection $p_n \in \mathbb{K}$ with $\|(1 \otimes p_n)d(1 \otimes p_n) - d\| < 1/2$. Thus, there is an isometry $s \in \mathcal{M}(\mathbb{K})$ with $\|(1 \otimes s)^* d(1 \otimes s)\| < 1/2$. If we let $g_k := c_k(1 \otimes s)$, then the positive element $T := g_1^*(a \otimes 1)g_1 + \ldots + g_n^*(a \otimes 1)g_n$ satisfies $\|1 - T\| < 1/2$ in $\mathcal{M}(A \otimes \mathbb{K})$, and the elements $e_1, \ldots, e_n \in \mathcal{M}(A \otimes \mathbb{K})$ given by $e_k := g_k T^{-1/2}$ satisfy with $\sum_k e_k^*(a \otimes 1)e_k = 1$.

It implies that $f_n := \sum_k e_k^*(a \otimes p_n)e_k \in A \otimes \mathbb{K}$ is a countable approximate unit of $A \otimes \mathbb{K}$ if p_n is an approximate unit of $\mathbb{K}$ (consisting of projections). In particular, each non-zero element $a \in A_+$ is not contained in a non-trivial ideal of A. It proves that A *is σ-unital and simple* if $\mathrm{Q^s}(A)$ is simple.

In case where A is the algebra of compact operators on a Hilbert space $\mathcal{H}$, it implies that $\mathcal{H}$ must be separable. Hence $A \otimes \mathbb{K} \cong \mathbb{K}$, if A is isomorphic to the compact operators on a Hilbert space, i.e., $A \cong M_n$ or $A \cong \mathbb{K}(\ell_2(\mathbb{N}))$.

It remains to consider the case where A is not isomorphic to the compact operators on a Hilbert space.

We show that the non-elementary simple stable σ-unital C^*-algebra $B := A \otimes \mathbb{K}$ satisfies in this case the criteria in Part (vx) of Proposition 2.2.1 for the pure infiniteness of B (thus also of A) if A is non-elementary:

Let $a, b \in B_+$ with $\|a\| = \|b\| = 1$ and $\varepsilon \in (0, 1/2)$, and define $e := (a - (1-\varepsilon))_+$ and $c := a - e$.

Since B is again non-elementary, the non-zero hereditary C^*-subalgebra $D := \overline{eBe}$ of B contains a sequence of mutually orthogonal positive contractions $f_1, f_2, \ldots \in D_+$ with $\|f_n\| = 1$. Notice that $dc = cd = (1-\varepsilon)d$ for all $d \in D$. Let $s_1, s_2, \ldots \in \mathcal{M}(\mathbb{K}) \subset \mathcal{M}(B)$ a sequence of isometries with the property that $\sum_n s_n s_n^*$ converges strictly to $1_{\mathcal{M}(\mathbb{K})} = 1_{\mathcal{M}(B)}$. Then $\sum_k s_n f_n^2 s_n^*$ converges strictly to an element $S \in \mathcal{M}(B)$ with norms $\|S\| = \|\pi_B(S)\| = 1$.

By Lemma 2.2.10(i) the simplicity of $\mathcal{M}(B)/B$ implies that $\mathcal{M}(B)/B$ is purely infinite. Thus, there exists a contraction $Z \in \mathcal{M}(B)$ with $1 - Z^*SZ \in B$ by using Parts (ii) or(vi) of Proposition 2.2.1.

It follows that there exist $m \in \mathbb{N}$ with $\|1 - s_m^* Z^* S Z s_m\| < 1/2$ and $1 - s_m^* Z^* S Z s_m \in B$. It implies there exists $G \in \mathcal{M}(B)$ with $G^*SG = 1$. Then $b = y^*Sy$ with $y := Gb^{1/2} \in B$. The strict convergence of $\sum_k s_n f_n^2 s_n^*$ to S implies that

$$b = \lim_p \sum_{n=1}^{p} y^* s_n f_n^2 s_n^* y$$

in the norm of B. It means that b is the limit of the increasing sequence $x_1^* x_1, x_2^* x_2, \ldots$ in B, where $x_p := \sum_{n=1}^{p} f_n s_n^* y \in B$, and where we use that $f_n f_m = 0$ for $m \neq n$. (The sequence $x_1, x_2, \ldots$ itself is not necessarily convergent in B.)

Now we use that $f_n \in D$ and get that $cx_p = (1-\varepsilon)x_p$, $x_p^* c x_p = (1-\varepsilon)x_p^* x_p$ and $c \leq a \leq 1$. Thus, $(1-\varepsilon)x_p^* x_p \leq x_p^* a x_p \leq x_p^* x_p$, and $\|b - x_p^* a x_p\| \leq \|b - x_p^* x_p\| + \varepsilon$. Since $b = \lim_p x_p^* x_p$, we get that $\lim_p \|x_p\| = \|b\|^{1/2}$. Thus, B is simple and is purely infinite if B is not elementary.

(ii,iii): If J is a non-zero closed ideal of A, then J_ω is a non-zero closed ideal of A_ω that has non-trivial intersection with the hereditary C^*-subalgebra $D := D(A) := \overline{A \cdot A_\omega \cdot A}$ of A_ω generated by A. Thus $J = A$ and A is simple if D is simple.

If $A = M_n$, then $A_\omega = M_n$.

If $A \cong \mathbb{K}(\mathcal{H})$ and if the Hilbert space $\mathcal{H}$ has infinite dimension, then $D(A)$ is a hereditary C^*-subalgebra of the closed ideal of A_ω that is generated by a rank-one projection in $A \cong \mathbb{K}(\mathcal{H})$ (in fact the closed ideal of A_ω generated by $A = \mathbb{K}(\mathcal{H})$ is naturally isomorphic to the compact operators $\mathbb{K}(\mathcal{H}_\omega)$ on $\mathcal{H}_\omega$). But the whole ultrapower $\mathbb{K}(\mathcal{H})_\omega$ of the compact operators $\mathbb{K}(\mathcal{H})$ on $\mathcal{H}$ (with $\mathrm{Dim}(\mathcal{H}) = \infty$) is *not* simple, because $\mathbb{K}(\mathcal{H}_\omega) \neq \mathbb{K}(\mathcal{H})_\omega$. The latter can be seen directly or by the fact that $\mathbb{K}(\mathcal{H})_\omega$ contains the CAR-algebra as a subalgebra (and, therefore, is not of type I).

If A is not isomorphic to the compact operators on a Hilbert space, and if $D(A) = A(A_\omega)A$ is simple, then A must satisfy the criteria in Proposition 2.2.5(iv): The element that is represented by the constant sequence $(b, b, \ldots) \in A$ is in the closed ideal generated by the element with representing sequence $(a^3, a^4, a^5, \ldots) \in A(A_\omega)A \subseteq A_\omega$ if $a \in A_+$, $\|a\| = 1$ and there is $c \in A_+$ with $c\,a = a$, $\|c\| \leq 1$, compare Remark 2.2.6.

Conversely, if A is simple and purely infinite, then Proposition 2.2.1(ii) implies that for positive contractions $a, b \in A_\omega$ with $\|a\| = \|b\| = 1$ there is a contraction $d \in A_\omega$ with $d^* a d = b$. This can be seen with help of representing sequences $a = \pi_\omega(a_1, a_2, \ldots)$, $b = \pi_\omega(b_1, b_2, \ldots)$ and $d = \pi_\omega(d_1, d_2, \ldots)$, because one can find the representing sequences such that $\|a_n\| = \|b_n\| = 1$ for $n = 1, 2, \ldots$. □

3. Proof of the Dichotomy Theorem E for simple C^*-algebras

The proof of the in the Introduction 1 stated Theorem E uses some elementary observations, and from our general study of p.i. algebras only that for simple C^*-algebras pure infiniteness and local pure infiniteness are the same.

Among the needed observations is that, *for every $n \in \mathbb{N}$, every non-elementary simple C^*-algebra A and every non-zero hereditary C^*-subalgebra D of A, there exists a non-zero n-homogenous element $a \in D_+$*, cf. Remark 2.1.16.

We call a simple C^*-algebra A **non-elementary** if A is simple (and non-zero) and is not isomorphic to the algebra of compact operators on some Hilbert space (of finite or infinite dimension). An element $a \in D_+ \subseteq A$ is n-**homogenous** if there exists an isomorphism $\lambda\colon C^*(a) \otimes M_n \to D$ with $\lambda(a \otimes 1_n) = a$.

Notice that then $\overline{aDa} \cong D_0 \otimes M_n$ for the closure D_0 of $\lambda(a \otimes e_{11}) D \lambda(a \otimes e_{11})$.

The following remark will be used in the proof of Theorem E. It is stated here more general than needed in the proof of Theorem E, because the more general statement will be used in Chapters 4, 5 and 7.

REMARK 2.3.1. Let $A \subseteq E$ C^*-algebras, $x \in A$ and $v \in E$ with $\|v\| \leq 1$, $xv^* = (xx^*)^{1/2}$ and $v^*x = (x^*x)^{1/2}$.

If $D_1, D_2 \subseteq A$ denote the hereditary C^*-subalgebras of A that are generated by x^*x respectively by xx^*, then $\varphi(a) := vav^*$ defines an isomorphism φ from D_1 onto D_2.

For example, if we let $E := A^{**}$ then such an element $v \in A^{**}$ is given by the partial isometry v arising in the polar decomposition $x = v(x^*x)^{1/2}$ of x in A^{**}.

DETAILS FOR REMARK 2.3.1. The mappings $v(\cdot)v^*$ and $v^*(\cdot)v$ are completely positive contractions on E, and map D_1 into D_2 respectively D_2 into D_1. Indeed:

$$\begin{aligned} vD_1v^* = v(\overline{x^*Ax})v^* &\subseteq \overline{vx^*Axv^*} = \overline{(xx^*)^{1/2}A(xx^*)^{1/2}} = D_2, \\ v^*D_2v = v^*(\overline{xAx^*})v &\subseteq \overline{v^*xAx^*v} = \overline{(x^*x)^{1/2}A(x^*x)^{1/2}} = D_1. \end{aligned}$$

The equations $xv^*vx^* = xx^*$ and $x^*vv^*x = x^*x$ imply, that $\varphi(ab) = \varphi(a)\varphi(b)$, for $a, b \in x^*Ax$, and that $xv^*v = x$, $vv^*x = x$, i.e., that φ and $v^*(.)v|\, D_2$ are inverse to each other. □

PROOF OF THEOREM E.. (i): By a result of M. Takesaki [**767**, cor. IV.4.21], $A \otimes B$ is simple if A and B are simple, because the C^*-tensor product $\otimes := \otimes^{\min}$ is the completion of the algebraic tensor product $A \odot B$ with respect to the *minimal* C^*-seminorm $N(\cdot)$ on $A \odot B$ with the property that $N(a \otimes b) \neq 0$ for all non-zero $a \in A_+$ and $b \in B_+$, [**767**, thm. IV.4.19]. It turns out that this norm is the same as the "spatial" tensor product norm on $A \odot B \subseteq \mathcal{L}(\mathcal{H}_1 \otimes_2 \mathcal{H}_2)$ given by any faithful representations $A \subseteq \mathcal{L}(\mathcal{H}_1)$ and $B \subseteq \mathcal{L}(\mathcal{H}_2)$, cf. [**767**, lem. IV.4.11].

It suffices to consider the case where A is not stably finite, because for all C^*-algebras A and B holds $A \otimes B \cong B \otimes A$.

If A is not stably finite then for every non-zero hereditary C^*-subalgebra F of A there is a positive integer $n = n(F)$ such that $M_n(F)$ contains an infinite projection $p \in M_n(F)$. It follows that $p(M_n(F))p$ contains an isomorphic copy of the Toeplitz algebra $C^*(s\,;\ s^*s = 1)$ and, therefore, $M_n(F)$ contains a copy of algebra of compact operators $\mathbb{K} \subset C^*(s\,;\ s^*s = 1)$, cf. [**172**].

Now let $D \subseteq A \otimes B$ be a non-zero hereditary C^*-subalgebra of $A \otimes B$. By Lemma 2.2.3 and Remark 2.3.1, there exist non-zero hereditary C^*-subalgebras $E \subseteq D$, $F \subseteq A$ and $G \subseteq B$ such that $E \cong (F \otimes G)$. Here F, G and E denote the hereditary C^*-subalgebras that are generated by the elements e, f and zz^* of Lemma 2.2.3, and the natural isomorphism is given by the partial isometry v in the second conjugate of $A \otimes B$ which appears in the polar decomposition of z, cf. Remark 2.3.1.

We show that $F \otimes G$ contains a non-zero *stable* C^*-subalgebra:

The algebra $F \otimes M_n \cong M_n(F)$, for the number $n := n(F)$ as above defined, contains a hereditary C^*-subalgebra D_1 that is stable and non-zero.

By assumption, the algebra B is non-elementary, i.e., B is simple and is not isomorphic to the compact operators on some Hilbert space. Hence, B is necessarily antiliminary, i.e., every non-zero hereditary C^*-subalgebra G of B has no finite-dimensional irreducible representations. This applies to our above defined G:

By Remark 2.1.16, the non-zero hereditary C^*-subalgebra G of B contains a non-zero hereditary C^*-subalgebra G_1 which is isomorphic to $M_n \otimes G_2$ for a suitable non-zero hereditary C^*-subalgebra G_2 of G_1.

We get that

$$D_1 \otimes G_2 \subseteq F \otimes M_n \otimes G_2 \cong F \otimes G_1 \subseteq F \otimes G \cong E \subseteq D\,,$$

and the C^*-algebra $D_1 \otimes G_2$ is non-zero and stable. Thus, the given non-zero hereditary C^*-subalgebra $D \supseteq E$ contains a non-zero stable C^*-subalgebra.

In conclusion, every non-zero hereditary C^*-subalgebra $D \subseteq A \otimes B$ contains a non-zero stable C^*-subalgebra. By Proposition 2.2.1(iii), this is equivalent to the pure infiniteness of the simple C^*-algebra $A \otimes B$.

(ii): The algebras A and B are simple and nuclear, because $A \otimes B$ is simple and nuclear by assumption in Part (i): E.g. A is nuclear, because $\theta \circ \mathrm{id}_{A\otimes B} \circ \eta = \mathrm{id}_A$, for the completely positive maps

$$\eta \colon A \ni a \mapsto a \otimes b \in A \otimes B \text{ and } \theta := (\mathrm{id}_A \otimes \psi) \colon\ A \otimes B\ \to A$$

for some $b \in B_+$ with $\|b\| = 1$ and a state ψ with $\psi(b) = 1$, and $\mathrm{id}_{A\otimes B}$ is nuclear. The simplicity of $A \otimes^{\min} B$ implies that A and B must be simple, because the minimal tensor product is a bi-functor with respect to A and B.

Suppose that $A \otimes B$ is *not* purely infinite. Then A and B are both stably finite by Part (i). By [**342**] (see [**441**] for the non-unital case) there are non-zero lower semi-continuous semi-finite traces on A_+ and B_+. Thus, there is a non-zero lower semi-continuous trace on $(A \otimes B)_+$, which contradicts $T^+(A \otimes B) = 0$ (for the simple stably infinite $A \otimes B$). □

4. On absence of infinitesimal sequences

The – not so deep – results of this section are mostly known to experts (since about 1970?) and have been considered as “folklore”, but we could not find always elementary and precise references for them.

Check here, and sort, definitions and blue discussions on Cuntz semi-groups! e.g. ‘‘$\precsim$’’ and ‘‘$\approx$’’ given in Def. 2.5.1.
Go into opposite direction to restrict to minimal necessary pre-info ...
Move then all further details to an overview section,
e.g. to a Section 5 in Appendix A,

or to places where they will used first time.
Check again the def.'s for $\mathrm{CS}(A)$.

The here considered "small" Cuntz semigroup $\mathrm{CS}(A)$ has not been used ever before, despite it reflects the original version of the semigroups introduced and considered in [**170, 171**] by J. Cuntz, but here we generalize it to the cases of non-simple and non-unital C^*-algebras. The different generalization of the definition of J. Cuntz require some explanations at the beginning, because we use here the – not so common – "smallest possible" variant of the original definition of J. Cuntz. It is the "small Cuntz semi-group" $\mathrm{CS}(A)$ – near to the original definition of J. Cuntz,

??? even if in that time there was not the Pedersen ideal invented ???:

We explain it with help of the **Pedersen ideal** $\mathrm{Ped}(B)$ of a C^*-algebra B: It is the smallest *dense* ideal of a C^*-algebra B. It is algebraical generated by the set of all ε-cut-downs $(b-\varepsilon)_+$ of elements $b \in B_+$ with $\varepsilon \in (0, \|b\|)$.

Check next blue again!

It considers only classes of elements in the $\mathrm{Ped}(A \otimes \mathbb{K})$ of $A \otimes \mathbb{K}$, i.e., the minimal dense ideal of $A \otimes \mathbb{K}$. If we identify $M_n(A)$ in the natural way with $(1 \otimes p_n)(A \otimes \mathbb{K})(1 \otimes p_n)$ then $\mathrm{Ped}(A \otimes \mathbb{K})$ is in general not contained in $\bigcup_n M_n(A)$ and $M_n(A) \neq M_n(\mathrm{Ped}(A))$,

$$\bigcup_n M_n(A) \not\supset \mathrm{Ped}(A \otimes \mathbb{K}) \subset A \otimes \mathbb{K}\,.$$

On the other hand $\bigcup_n M_n(\mathrm{Ped}(A))$ is contained in $\mathrm{Ped}(A \otimes \mathbb{K})$ and contains all representatives, but is not identical to $\mathrm{Ped}(A \otimes \mathbb{K})$...

For each element $a \in \mathrm{Ped}(A \otimes \mathbb{K})$ there exists some element $b \in \bigcup_n M_n(\mathrm{Ped}(A))$ with the property that b^*b is MvN-equivalent to a^*a, i.e., $b^*b \sim_{MvN} a^*a$.

There are natural semigroup morphisms

$$\mathrm{V}(A) \to \mathrm{CS}(A) \to \mathrm{W}(A) \to \mathrm{Cu}(A)\,. \tag{4.1}$$

They are given by the map that respects the $\approx$-relation between elements, cf. Definition 2.4.1, for the below defined or "recalled" semigroups $\mathrm{V}(A)$, $\mathrm{CS}(A)$, $\mathrm{W}(A)$ and $\mathrm{Cu}(A)$.

Here $\mathrm{V}(A)$ denote the Murray–von-Neumann equivalence ($\sim_{MvN}$) classes of projections in $A \otimes \mathbb{K}$, cf. Definition 2.0.1, that is in general considerably stronger relation than the ($\approx$) relation.

Beginning with $\mathrm{CS}(A)$, the natural morphisms of pre-ordered semigroups in (4.1) are *injective*, but the natural semi-group morphism $\mathrm{V}(A) \to \mathrm{CS}(A)$ is in general not necessarily injective, e.g. . $\mathrm{CS}(\mathcal{O}_2) = \mathrm{CS}(\mathcal{O}_\infty) = \{[0], [1]\}$ but ??????

E.g. $\mathrm{V}(\mathcal{O}_2) = \{[0], [1]\}$ and $\mathrm{V}(\mathcal{O}_\infty)\backslash\{[0]\}$ is naturally isomorphic to $\mathbb{Z}$, $\mathrm{CS}(A) = \mathrm{W}(A) = \mathrm{Cu}(A) = \{[0], [1]\}$ for all purely infinite simple unital C^*-algebras A.

In particular their equivalence classes have nothing to do with with its K_*-theory!

More generally, for all simple purely infinite C^*-algebras A holds $\mathrm{CS}(A) = \{[0],[p]\} = \mathrm{Cu}(A)$, with any non-zero projection $p \in A \otimes \mathbb{K}$, i.e., for each $a, b \in (A \otimes \mathbb{K}) \setminus \{0\}$ there exist $c, d, e, f \in A$ with $cad = b$ and $ebf = a$.

If non-zero A is simple and stably projection-less then $\mathrm{V}(A) = \{0\}$, but $\mathrm{CS}(A) \neq \{0\}$.

But one can adjoin a unit to A and then consider the kernel of $a + z \cdot 1 \to z \cdot 1$ ...

Next ‘‘filtration’’ has to be explained -- if true

There are natural filtrations (indexed by sub-semigroups of $\mathbb{R}_+ \cup \{+\infty\}$) and certain order topologies that allow to see that the right ones are completions of the left ones (except $\mathrm{V}(A)$, where this happens only in the case where A has real rank zero).

This does not say that the *set of elements* $a \in X_b \subseteq A \otimes \mathbb{K}$ that represent the class of $b \in \bigcup_n M_n(A)$ in $A \otimes \mathbb{K}$ with respect to the below defined equivalence relation $a \approx b$ (given by $a \precsim b$ and $b \precsim a$ in $A \otimes \mathbb{K}$) is the same as the class of $c \in \bigcup_n M_n(A)$ with $c \approx a$

?????

This causes that it is in general not clear under what circumstances $c \in A \otimes \mathbb{K}$ and $c \precsim a \in M_n(A)$ implies that $c \approx b$ for some $b \in \bigcup_n M_n(A)$ ([28]).

The point is that $a \approx b$ in $A \otimes \mathbb{K}$ and $a, b \in M_n(A)_+$ (respectively $a, b \in \mathrm{Ped}(A \otimes \mathbb{K})_+$) implies that $a \approx b$ also inside $M_n(A)$ (respectively inside $\mathrm{Ped}(A \otimes \mathbb{K})$).

The "$\approx$" classes become in $A \otimes \mathbb{K}$ much bigger. For example, in case $A := \mathrm{C}_0(0,1]$, we can take the increasing pice-wise linear functions $h_n \in \mathrm{C}_0(0,1]_+$ given by $h_n(t) := \min(1, \max(2^n t - 1, 0))$ for $t \in [0,1]$, $(n = 0, 1, \ldots)$. (We use them for some constructions, see Section 22 in Appendix A.)

If we define $f_n(t) := \left(2^{-n}(h_{n+1}(t) - h_n(t))\right)^{1/2}$ and let $T := \sum_{n=1}^{\infty} f_n \otimes p_{1,n}$, then $T \in \mathrm{C}_0(0,1] \otimes \mathbb{K}$ and $TT^* = (\sum f_n^2) \otimes p_{11} = e_0 \otimes p_{11}$ for $e_0(t) := t$, but $T^*T \notin \bigcup_n M_n(A)$.

It is not clear if in general the natural *image* of $\mathrm{W}(A)$ in $\mathrm{Cu}(A)$, i.e., the image of the map that sends classes in $\mathrm{W}(A)$ into the corresponding – usually much bigger classes (of $\approx$-equivalent elements in $A \otimes \mathbb{K}$) which are elements of $\mathrm{Cu}(A)$ is a *hereditary* sub-semigroup in $\mathrm{Cu}(A)$ with respect the natural order in Abelian semi-groups. (It has to do with variants of the so-called "radius of comparison".)

I.e. it is unknown if $\mathrm{W}(A)$ "is" a "hereditary" sub-semigroup of $\mathrm{Cu}(A)$, i.e., it is not known if $c \in A \otimes \mathbb{K}$ and $c \precsim a$ for some $a \in M_m(A)$ and $m \in \mathbb{N}$ implies the existence of some $n \in \mathbb{N}$ and $b \in M_n(A)$ such that $c \approx b$. See [**85**] for an additional property on A (that is inspired by the "bounded radius of comparison" for vector bundles) which implies that $\mathrm{W}(A)$ is "hereditary" in $\mathrm{Cu}(A)$.

[28] It has to do with the classical idea of a "radius of comparison" for vector bundles on compact manifolds.

It is not difficult to see that for each element $a \in \mathrm{Ped}(A \otimes \mathbb{K})_+$ there exists $n \in \mathbb{N}$ and $b \in (\mathrm{Ped}(A) \otimes M_n)_+$ such that $a \sim_{MvN} b$. But there are elements in $a \in \mathrm{Ped}(A \otimes \mathbb{K})_+$ that are not itself contained in the algebraic tensor product $A \odot F$, where here $F \subset \mathbb{K}$ means here the *-algebra of finite rank operators on $\ell_2(\mathbb{N})$.

It shows that $\mathrm{CS}(A)$ is isomorphic to a $\precsim$-hereditary sub-semigroup both of $\mathrm{W}(A)$ and of $\mathrm{Cu}(A)$, that $\mathrm{W}(A)$ is in a natural manner a sub-semigroup of $\mathrm{Cu}(A)$ and that $\mathrm{CS}(A)$ and $\mathrm{Cu}(A)$ are stable invariants of C^*-algebras A, i.e., there are natural isomorphisms $\mathrm{CS}(A) \cong \mathrm{CS}(A \otimes \mathbb{K})$ and $\mathrm{Cu}(A) \cong \mathrm{Cu}(A \otimes \mathbb{K})$. Moreover, it is not difficult to check that $\mathrm{W}(A \otimes \mathbb{K}) = \mathrm{Cu}(A)$ in a natural way (using the flip on $\mathbb{K} \otimes \mathbb{K}$).

This natural isomorphisms are induced by the embedding $T \in \mathbb{K} \mapsto T \otimes p_{11} \in \mathbb{K} \otimes \mathbb{K}$ that extends to a *-monomorphism of $A \otimes \mathbb{K}$ onto the full stable corner $A \otimes \mathbb{K}) \otimes p_{11}$ of $A \otimes \mathbb{K} \otimes \mathbb{K}$. The *-endomorphism is unitarily homotopic to an isomorphism from $A \otimes \mathbb{K}$ onto $A \otimes \mathbb{K} \otimes \mathbb{K}$, because the *-monomorphism $T \in \mathbb{K} \mapsto T \otimes p_{11} \in \mathbb{K} \otimes \mathbb{K}$ is unitarily homotopic in sense of Definition 5.0.1 to an isomorphism from $\mathbb{K}$ onto $\mathbb{K} \otimes \mathbb{K}$ by a norm-continuous path $t \in [0, \infty) \to U(t)$ of unitary elements in $\mathcal{M}(\mathbb{K} \otimes \mathbb{K})$. (See the comments following Definition 5.0.1 for more details.)

?? Verification discussion?:

Take an isometry S from $\ell_2(\mathbb{N} \times \mathbb{N})$ onto $\ell_2(\mathbb{N})$, that is defined by a suitable bijection from $\mathbb{N} \times \mathbb{N}$ onto $\mathbb{N} \times \mathbb{N}$. It defines an isomorphism from $\mathbb{K}$ onto $\mathbb{K} \otimes \mathbb{K}$ by $a \mapsto S^* a S$. Let p_{11} the upper-left minimal projection in $\mathbb{K}$. There is an isometry R from ℓ_2 onto $\ell_2 \otimes e_1$ given by $R(x) = x \otimes e_1$. It defines the map $a \to RaR^* = a \otimes p_{11}$. Then $a \to SRaR^*S^* = TaT^*$ is a C^*-morphism from $\mathbb{K}$ into $\mathbb{K}$ given by an isometry $T \in \mathcal{M}(\mathbb{K}) = \mathcal{L}(\ell_2)$. If we find a norm-continuous path $t \mapsto U(t)$ in the unitaries of $\mathcal{M}(\mathbb{K})$ with $U(t)^* TaT^* U(t) \to a$ for all $a \in \mathbb{K}$ then

$$S^* a S = \lim_{t \to \infty} (S^* U(t) S)(a \otimes p_{11})(S^* U(t) S)^* .$$

Consider projections in $\mathbb{K}$ with $q_1 \leq q_2 \leq \cdots$ and $\lim_n \|q_n a q_n - a\| = 0$ for all $a \in \mathbb{K}$ and then find $t \mapsto U(t)$ norm-continuous with $U(t)^* T q_n T^* U(t) = q_n$ for $t \geq n = 1$.

Compare next with comments below Def. 5.0.1

The latter holds because $\mathcal{M}(\mathbb{K} \otimes \mathbb{K}) \cong \mathcal{L}(\ell_2)$, $\mathcal{U}(\mathcal{L}(\ell_2)) = \mathcal{U}_0(\mathcal{L}(\ell_2))$ and all isometries $s \in \mathcal{L}(\ell_2)$ with $\mathrm{Dim}((1 - ss^*)\ell_2) = \infty$

Are (???) unitary equivalent. Perhaps only in case that $\bigcup_n (1 - s^n (s^n)^*)\ell_2$ is dense in ℓ_2???

Needs to study the unitary part of s for the unitary equivalence? Does the standard part for Wold decomposition $U \oplus (T \otimes \mathrm{id}_{\mathcal{H}_3})$ – up to unitary equivalence of $\mathcal{H}$ with $\mathcal{H}_1 \oplus (\ell_2 \otimes \mathcal{H}_3)$, where $T \in \mathcal{L}(\ell_2)$ is the Toeplitz shift (unilateral shift) and U is a unitary on $\mathcal{H}_1$ – always "absorb" the unitary part?

Or try to show that there is a unitary V from $\ell_2(\mathbb{N}) \otimes \ell_2(\mathbb{N})$ onto $\ell_2(\mathbb{N})$ such that $V \circ (1 \otimes S) = s \circ V$?

Give Ref for precise unitary equivalence!!!

But there exists also something explicit ?????

Alternatively, one can take the isometry $R := 1 \otimes s \in \mathcal{M}(A \otimes \mathbb{K} \otimes \mathbb{K})$ with $RR^* = 1 \otimes p_{11}$. It gives $RbR^* \sim_{MvN} b$ (in $A \otimes \mathbb{K} \otimes \mathbb{K}$ itself) and $RbR^* = h(b) \otimes p_{11}$ for well-defined $h(b) \in A \otimes \mathbb{K}$ for all $b \in (A \otimes \mathbb{K} \otimes \mathbb{K})$. Then check that h is an isomorphism from $A \otimes \mathbb{K} \otimes \mathbb{K}$ onto $A \otimes \mathbb{K}$ and that $h(\cdot) \otimes p_{11}$ is unitary homotopic to id on $A \otimes \mathbb{K} \otimes \mathbb{K}$.

This monomorphism defines isomorphisms from $\mathrm{CS}(A)$ onto $\mathrm{CS}(A \otimes \mathbb{K})$ and from $\mathrm{Cu}(A)$ onto $\mathrm{Cu}(A \otimes \mathbb{K})$, because each positive element of $\mathrm{Ped}(A \otimes \mathbb{K})$ is Murray–von-Neumann equivalent ($\sim_{MvN}$ equivalent) to an element of $\bigcup_n M_n(\mathrm{Ped}(A))$ by Pedersen's characterization of sets of generators of the minimal dense ideal $\mathrm{Ped}(B)$ of a C^*-algebra B, as the ε-cut-down's $(a - \varepsilon)_+$ for $a \in G$ in any – fixed given – subset $G \subseteq B_+$ that generates a dense two-sided ideal of B.

The semigroup $\mathrm{V}(A)$ consists of the Murray–von-Neumann equivalence classes of projections in $A \otimes \mathbb{K}$ (It is zero if A is stably projection less). Projections are always in the Pedersen ideal $\mathrm{Ped}(A \otimes \mathbb{K})$ of $A \otimes \mathbb{K}$ and $p \precsim q$ implies that there exists a partial isometry $v \in A \otimes \mathbb{K}$ with $v^*v = p$ and $vv^* \leq q$. Thus, $v^*qv = p$.

The map from $\mathrm{V}(A)$ to $\mathrm{CS}(A \otimes \mathbb{K})$ is the natural one and is not necessarily injective, because properly infinite full projections in $A \otimes \mathbb{K}$ (if exist) are all $\approx$-equivalent but need not to be $\sim_{MvN}$ equivalent in $A \otimes \mathbb{K}$:

The existence of partial isometries $v, w \in A \otimes \mathbb{K}$ with $v^*v = p$, $vv^* \leq q$, $w^*w = q$ and $ww^* \leq p$ does not imply that p and q are MvN-equivalent. The existence of such v, w is equivalent to the existence of projections $p_1 \leq q_1 \leq p$ with $q_1 \sim_{MvN} q$ and $p_1 \sim_{MvN} p$. The latter does not imply $q \sim_{MvN} p$ because p might be an infinite projection (e.g. $p_1 \neq p$).

The equation $\mathrm{CS}(A) = \mathrm{CS}(A \otimes \mathbb{K})$ can be seen as follows:

Notice that $\mathrm{Ped}(A \otimes \mathbb{K})$ is the same as the algebraic ideal of $A \otimes \mathbb{K}$ generated by $\mathrm{Ped}(A) \otimes p_{11}$. Here $\mathrm{Ped}(A)$ denotes the *Pedersen ideal* of A. If $a, b \in \mathrm{Ped}(A) \otimes M_n$ with $a \precsim b$ in $A \otimes \mathbb{K}$ are given, then $a \precsim b$ in $\mathrm{Ped}(A) \otimes M_n$, i.e., if $a = \lim_n d_n^* b c_n$ for suitable sequences $c_n, d_n \in \mathcal{M}(A \otimes \mathbb{K})$. We can replace the c_n and d_n by $e_n := (b - 1/n)_+^{1/n} c_n (a - 1/n)_+^{1/n}$ and $f_n := (b - 1/n)_+^{1/n} d_n (a - 1/n)_+^{1/n}$. Then $e_n, f_n \in \mathrm{Ped}(A \otimes M_n) = \mathrm{Ped}(A) \otimes M_n$ and $a = \lim_n f_n^* b e_n$.

The ideal $\mathrm{Ped}(A)$ is algebraically generated by the ε-cut-downs $(a - \varepsilon)_+$ of positive contractions $a \in A_+$, and the ideal $\mathrm{Ped}(A) \otimes p_{11}$ of $A \otimes p_{11}$ generates (algebraically) a minimal dense ideal ideal of $A \otimes \mathbb{K}$ – as one can see from Lemma 2.1.9. This implies that for each element b in the Pedersen ideal $\mathrm{Ped}(A \otimes \mathbb{K})$ of $A \otimes \mathbb{K}$ there exists $n = n(b) \in \mathbb{N}$, contractions $e_1, f_1, \ldots, e_n, f_n \in A_+$ and $d_1, d_2 \in A \otimes \mathbb{K}$ with $f_k e_k = e_k$ for $k = 1, \ldots, n$, $b^*b = d_1^* \operatorname{diag}(e_1, \ldots, e_n) d_2$. It follows that $b \approx b^*b \sim_{WvN} cc^*$ with $2cc^* \operatorname{diag}((f_1 - 1/2)_+, \ldots, (f_n - 1/2)_+) = cc^*$ for suitable $c \in A \otimes \mathbb{K}$. Thus, $cc^* \in \mathrm{Ped}(A \otimes M_n) = M_n(\mathrm{Ped}(A))$, and each $b \in \mathrm{Ped}(A \otimes \mathbb{K})$ is $\approx$-equivalent to some element in $\bigcup_n M_n(\mathrm{Ped}(A)) \subseteq \mathrm{Ped}(A \otimes \mathbb{K})$.

(But notice here that $\mathrm{Ped}(A\otimes\mathbb{K})\neq\bigcup_n \mathrm{Ped}(A)\otimes M_n$ in general, if the M_n are considered here as $P_n\mathbb{K}P_n$ with P_n of rank $= n$, and $P_n\leq P_{n+1}$ and $\bigcup_n P_n\mathbb{K}P_n$ dense in $\mathbb{K}$, e.g. this happens even for $A:=\mathbb{C}$ or $A:=\mathrm{C}_0(0,1]$.)

We use here the (in literature not common) small "local" hereditary sub-semigroup $\mathrm{CS}(A)$ of the "larger" Cuntz-semigroups $\mathrm{W}(A)\subseteq\mathrm{Cu}(A)$. for an "infinitesimal" characterization of simple p.i. C^*-algebras. Therefore we discuss the differences and different applications before we return to the study of p.i. simple C^*-algebras. The definition of J. Cuntz in [**171**] itself did not care about the possibly different definitions of the related semi-group, and that they have different properties – even for simple ASH C^*-algebras or Cuntz-Pimsner algebras.

The below displayed elements and semigroups show that ????? what ???

$\mathbb{Z}_+\cong\mathrm{V}(\mathbb{C})=\mathrm{CS}(\mathbb{C})=\mathrm{W}(\mathbb{C})=\mathrm{CS}(A)\neq\mathrm{W}(A)$ if $A=\mathbb{K}$ because then $\mathrm{W}(\mathbb{K})=\mathrm{Cu}(\mathbb{K})\cong\mathbb{Z}_+\cup\{+\infty\}$. The isomorphism $\mathrm{Cu}(\mathbb{K})\to\mathbb{Z}_+\cup\{+\infty\}$ is given by $[a]\mapsto\mathrm{Rk}(a)$ the rank of a.

Moreover $\mathrm{W}(A)\neq\mathrm{Cu}(A)$ if A is unital and stably finite.

There exists a C^*-algebra A with $\mathrm{CS}(A)\neq\mathrm{W}(A)$

`Really?` $A=c_0$ `?, Cite ???`

`Above examples correct? Below considerations?`

The "small" Cuntz algebras $\mathrm{CS}(A)$ have in particular the following extra property:

The C^*-algebra A is simple if and only if for each non-zero $a,b\in\mathrm{Ped}(A)$ there exists $m,n\in\mathbb{N}$ with $[a]\leq m[b]$ and $[b]\leq n[a]$ in $\mathrm{CS}(A)$.

This is not the case for the semigroup $\mathrm{W}(A)$.

Example of simple A and elements $a\in M_m(A)$ and $b\in M_n(A)$ with the property that $[b]\not\leq k[a]$ for all $k\in\mathbb{N}$: $A=\mathbb{K}$, $b:=\mathrm{diag}(1,1/2,1/3,\ldots)$ $a:=\mathrm{diag}(1,0,0,\ldots)$.

`Compare Definition 2.5.1 !!`

Definition 2.4.1. Let B denote a non-zero (not necessarily simple) C^*-algebra and let $b,c\in B$. We write $b\precsim c$ if there exist sequences $d_n,e_n\in B$ such that $b=\lim_n d_n\,c\,e_n$.

We say that b and c are **Cuntz equivalent** if $b\precsim c$ and $c\precsim b$ and denote this by $b\approx c$.

It is easy to see that $a\precsim b$, and $b\precsim c$ implies $a\precsim c$, and that the relation $b\approx c$ is an equivalence relation on B. It will be also denoted sometimes by $b\sim c$. The corresponding equivalence classes, say of $b\in B$ will be denoted by $[b]$. Thus $b\approx c$ or $[b]=[c]$ are equivalent to $b\precsim c$ and $c\precsim b$.

In some special (notational) situation $b\approx c$ will be also denoted by $b\sim c$ or by $[b]=[c]$. We write later also $[b]\leq[c]$ for $b\precsim c$.

`Decide here for` $\approx$ `or` $\sim$ `!!! ?? ??`

Then $\approx$ becomes an equivalence relation on B. The $\approx$-class of $b \in B$ will be denoted by $[b]$ (and sometimes more precisely by $[b]_B$).

It is easy to see that $\precsim$ is a transitive relation on $B \times B$ with $b \precsim b$ and $0 \precsim b$ for all $b \in B$. And it is not difficult to see that $b \precsim b^*b \precsim b$, and $b \precsim c$ for $0 \leq b \leq c$.

There is an in some cases different equivalence relation $[a] = [b]$ that considers the isomorphism classes of the right Hilbert B-modules $\overline{aB}$ and $\overline{bB}$.

`Find reference for above and next red!?`
`The source is a bit semi-philosophic ... (Elliott and Co.)`

I.e., if there exists a linear isometry T from the closed right ideal $R_a := \overline{aB}$ generated by a onto $R_b := \overline{bB}$ that satisfies with $(Tx)c = T(xc)$ for all $c \in B$??

Gives that $T(aa^*)^{1/m} = \lim_n bx_{m,n}$????? Not really understood!!!

(??? What happens with "open" support projections P and Q in B^{**} of aa^* and bb^*. What gets lost in the exact or amenable case?

Seems to be that T is given by a partial isometry in B^{**} with $T = QTP$ and

We can here always suppose that the sequences (d_n) and (e_n) satisfy $d_n \in (bb^* - 1/n)_+^{1/n} \cdot B \cdot (cc^* - 1/n)_+^{1/n}$ and $e_n \in (c^*c - 1/n)_+^{1/n} \cdot B \cdot (b^*b - 1/n)_+^{1/n}$. It does not change the definition of " $\precsim$ " in Definition 2.4.1.

Sometimes we write more precisely $b \precsim_B c$ (or later $[b]_B \leq [c]_B$ for its equivalence classes) if $b, c \in A \subseteq B \subseteq D$, $a \precsim b$ in B but not $b \precsim c$ in A. Clearly $[b]_D \leq [c]_D$ if $[b]_B \leq [c]_B$ and $B \subseteq D$.

The definition of $\approx$ implies that $b \precsim c$, $d \approx b$ and $c \approx e$ imply $d \precsim e$. Therefore we can define on the classes $[b]$ and $[c]$ a pre-order $[b] \leq [c]$ if $b \precsim c$. ([29])

The MvN-equivalence $b \sim_{MvN} c$ of elements $b, c \in B_+$ – defined by the existence of $d \in B$ with $d^*d = b$ and $dd^* = c$ – implies that $b \approx c$, i.e., $[b] = [c]$. It is also easy to see that $a, b \in B_+$ and $a \leq b$ imply that $[0] \leq [a] \leq [b]$.

If $\mathcal{M}(B)$ is properly infinite – as it is e.g. the case for $B := A \otimes \mathbb{K}$ –, then we can define on the $\approx$-classes $[b]$ a commutative and associative addition by $[b] + [c] := [sbs^* + tct^*]$, where $s, t \in \mathcal{M}(B)$ are isometries with orthogonal ranges: $s^*s = 1$, $t^*t = 1$ and $s^*t = 0$. It is easy to see that it is well-defined on the family of $\approx$-classes $[b]$ and that it is independent from the chosen isometries s and t (with $s^*t = 0$). See Lemma 4.2.6 and its proof for the transformation of those generalized Cuntz-sums.

It studies the invariance for unitary equivalence classes if $ss^* + tt^* = 1$ or in case that $1 - ss^* + tt^*$ is full and infinite. But that can be carried over to $\approx$-classes in case where $1 - ss^* + tt^*$ is full and infinite e.g. by passage to st, t ...

Need Remark (!) to Lemma 4.2.6, that explains that in the sufficiently degenerated case this shows also the $\approx$-invariance, $a_1 \approx a_2$, $b_1 \approx b_2$ implies that $a_1 \oplus_{s,t} b_1 \approx a_1 \oplus_{q,r} b_1$ if $s, t, q, r \in \mathcal{M}(A)$ are isometries with $s^*t = 0$ and $q^*r = 0$.

---

[29] The classes will be sometimes also denoted by $[b]$, $\langle b \rangle$ or $[b]_\approx$, simply because for the later used several equivalence classes similar notations have to be used.

We define now a *large* (or *maximal*) version of the Cuntz semigroup that contains the usual used semigroup $W(A)$ and our very *small* version

DEFINITION 2.4.2. We define here a **large Cuntz-semigroup** $\mathrm{Cu}(A)$ by taking above $B := A \otimes \mathbb{K}$, i.e.,

$$\mathrm{Cu}(A) := \{[a]_{\approx}\,;\ a \in A \otimes \mathbb{K}\}$$

consisting of the $\approx$-classes $[a]$ with $a \in A \otimes \mathbb{K}$ and with addition defined by

$$[a] + [b] := [a \oplus b]$$

the direct sum of representatives of the classes: $[a] + [b] := [a \oplus_{s,t} b]$ with help of any unital copy of $\mathcal{E}_2 = C^*(s,t)$ in $\mathcal{M}(A \otimes \mathbb{K})$.

We define $\mathrm{W}(A)$ as the sub-semigroup of $\mathrm{Cu}(A)$ given by the classes $[a] \in \mathrm{Cu}(A)$ with $a \approx b$ for some $b \in \bigcup_n M_n(A) \subseteq A \otimes \mathbb{K}$.

The usual definition of $W(A)$, e.g. in ?????? is given on the disjoint union of the sets $M_n(A)$ and use of "canonical" unital C^*-morphisms from $M_m \oplus M_n$ into M_{m+n}. This definitions of $\mathrm{W}(A)$ are equivalent on $\approx$-classes, because the cartesian sum

$$M_m(A) \oplus M_n(A) \to M_{m+n}(A)$$

defined by

$$(b_1, b_2) \mapsto b_1 \oplus b_2 \in M_{m+n}(A) \subseteq A \otimes \mathbb{K} \quad \text{for} \quad b_1 \in M_m(A)\,,\ b_2 \in M_n(A)\,,$$

– using the natural C^*-morphisms $M_n(A) \cong A \otimes M_n$ and $M_m \oplus M_n \to M_{m+n}$ –, is unitary equivalent to the map

$$(b_1, b_2) \mapsto b_1 \oplus_{s,t} b_2 \in sM_m(A)s^* + tM_n(A)t^*\,,$$

by a suitable unitaries $U_{n,m} \in \mathcal{M}(A \otimes \mathbb{K})$.

But notice here that $b_1 \oplus_{s,t} b_2$ is not necessarily in $\bigcup_n M_n(A)$ – interpreted as $\bigcup_n A \otimes M_n \subset A \otimes \mathbb{K}$ anymore. But there exists for given $m.n \in \mathbb{N}$ isomorphisms of $A \otimes \mathbb{K}$ that are approximately inner inside $\mathcal{M}(A \otimes \mathbb{K})$ and define a "natural" isomorphism from $sM_m(A)s^* + tM_n(A)t^* \subset A \otimes \mathbb{K}$ onto $(A \otimes M_m) \oplus (A \otimes M_n) \subseteq A \otimes M_{m+n} \subset A \otimes \mathbb{K}$.

The "large" semi-group $\mathrm{Cu}(A)$ is often not useful for our application, because it contains in the case of σ-unital A always an additively absorbing "infinite" idempotent $[e]$, e.g. let $f \in A_+$ a strictly positive contraction and define a strictly positive contraction $e \in A \otimes \mathbb{K}$ by $e := \sum_n n^{-1/4} f^{1/n} \otimes p_{n,n}$. Then $[b] \leq [b] + [e] = [e]$ in $\mathrm{Cu}(A)$ for all $b \in A \otimes \mathbb{K}$. In particular, the Grothendieck group $\mathrm{Gr}(\mathrm{Cu}(A))$ is zero for each σ-unital C^*-algebra A. The reasons for $[b] + [e] = [e]$ are that for all C^*-algebras B with strictly positive element $e \in B$ holds $b \precsim e$ for all $b \in B$, $e \oplus_{s,t} e$ is again strictly positive in $A \otimes \mathbb{K}$, $e \approx 0 \oplus e \precsim b \oplus e$, $b \precsim e$ and $e \oplus e \approx e$.

DEFINITION 2.4.3. We define the **local Cuntz semigroup** as the sub-semigroup $\mathrm{CS}(A)$ of $\mathrm{Cu}(A)$ given by

$$\mathrm{CS}(A) := \{[a] \in \mathrm{Cu}(A)\,;\ a \in \bigcup_n M_n(\mathrm{Ped}(A))\,\}\,.$$

Notice here that for the Pedersen ideals always holds $\bigcup_n M_n(\mathrm{Ped}(A)) \subseteq \mathrm{Ped}(A \otimes \mathbb{K})$, but also that for each positive element b in the Pedersen ideal $\mathrm{Ped}(A \otimes \mathbb{K})$ of $A \otimes \mathbb{K}$ there exists $n \in \mathbb{N}$ and a positive element $c \in M_n(\mathrm{Ped}(A))_+$ that is Murray–von Neumann equivalent to b. Therefore $\mathrm{CS}(A)$ and $\mathrm{Cu}(A)$ are both invariants of the Morita equivalence classes of σ-unital C^*-algebras A.

The most common sub-semigroup of the "large" Cuntz semigroup $\mathrm{Cu}(A)$ is its sub-semigroup $\mathrm{W}(A)$ consisting of the $\approx$-classes of elements in $\bigcup_n M_n(A) \subseteq A \otimes \mathbb{K}$.

It does not matter if we consider in the definition $\bigcup_n M_n(A)$ as "disjoint" union of the sets $M_n(A)$, or if we consider $M_n(A)$ in a natural way as $M_n(A) \oplus 0_p \subset M_{n+p}(A) \subset \mathcal{M}(A \otimes \mathbb{K})$ and "identify" Cuntz-equivalent elements, because (it is easy to see that) inside $A \otimes \mathbb{K}$ holds

$$SaS^* + TbT^* \approx a \oplus b \approx \mathrm{diag}(a, b)$$

for $a \in M_n(A)$, $b \in M_p(A)$ and any isometries $S, T \in \mathcal{M}(A \otimes \mathbb{K})$ with $S^*T = 0$.

Further notice that $\mathrm{W}(A) = \mathrm{CS}(A) = \mathrm{CS}(A \otimes \mathbb{K})$ if A is *unital*, but that $\mathrm{W}(A \otimes \mathbb{K}) = \mathrm{Cu}(A)$ is not isomorphic to $\mathrm{W}(A)$ if A is stably finite.

An alternative way – inspired by [**171**] – to define $\mathrm{W}(A)$ and our version $\mathrm{CS}(A)$ is the following (that is near to the original definition of J. Cuntz in [**171**]):

Take a unital copy of $\mathcal{O}_2$ given by isometries $s, t \in \mathcal{M}(\mathbb{K})$ with $ss^* + tt^* = 1$. Define a copy of $\mathcal{O}_2$ in $\mathcal{M}(A \otimes \mathbb{K})$ by $S, T \in \mathcal{M}(A) \otimes \mathcal{M}(\mathbb{K}) \subseteq \mathcal{M}(A \otimes \mathbb{K})$ by $S := 1_{\mathcal{M}(A)} \otimes s$ and $T := 1_{\mathcal{M}(A)} \otimes t$ (recall that $\otimes$ denotes here the minimal C^*-algebra tensor product, that is also called *spatial* tensor product).

Let $F \subset \mathbb{K}(\ell_2)$ denote the the set of all operators of finite rank on $\ell_2(\mathbb{N})$. It is an ideal of $\mathbb{K}(\ell_2)$, because it is just the Pedersen ideal of $\mathbb{K}(\ell_2)$ because it is algebraically generated by all elements $(T - \varepsilon)_+$ for compact positive operators $T \in \mathbb{K}(\ell_2)_+$. Notice that the algebraic tensor product $F \odot F$ is a dense *-subalgebra of the C*-algebra tensor product of $\mathbb{K}(\ell_2) \otimes \mathbb{K}(\ell_2) \cong \mathbb{K}(\ell_2 \otimes_2 \ell_2)$. But is not an ideal of $\mathbb{K}(\ell_2) \otimes \mathbb{K}(\ell_2)$, because, e.g., the operator $X := \sum_n 2^{-n} P_n \otimes P_n$ (with $P_n(v) :=< v, e_n > \cdot e_n$ for $v \in \ell_2$ and $\{e_1, e_2, ..., e_n, ...\}$ an orthogonal basis of ℓ_2) is the orthogonal projection of vectors $w \in \ell_2 \otimes_2 \ell_2 \cong \ell_2$ on the vector $v_X := \sum_n 2^{-n} e_n \otimes e_n$. Thus X is a projection in $\mathbb{K}(\ell_2 \otimes_2 \ell_2)$ but is not in the algebraic tensor product $F \otimes F \subseteq \mathbb{K}(\ell_2 \otimes_2 \ell_2)$. But the algebraic ideal (!) of $\mathbb{K}(\ell_2 \otimes_2 \ell_2)$ generated by the algebra $F \otimes F$ is again the minimal dense ideal of $\mathbb{K}(\ell_2 \otimes_2 \ell_2)$.

The set F is identical with the norm-dense algebraic *ideal* of the closed ideal $\mathbb{K} := \mathbb{K}(\ell_2(\mathbb{N}))$ *generated* by its subset $\bigcup_n M_n$ – where we identify here M_n naturally with $p_n \mathbb{K} p_n$ and p_n is the orthogonal projection onto the linear span of $\{e_1, \ldots, e_n\}$ for the canonical basis of $\ell_2(\mathbb{N})$.

Obviously, F is a *-ideal of $\mathcal{M}(\mathbb{K}) \cong \mathcal{L}(\ell_2)$, that is dense in $\mathbb{K}$, and is *minimal* with this properties. Thus, F is exactly the Pedersen ideal $\mathrm{Ped}(\mathbb{K})$ of $\mathbb{K}$, i.e., is the minimal dense ideal of $\mathbb{K}$.

But the algebraic tensor product ???? ???

The algebraic tensor products $A \odot F$ and $\mathrm{Ped}(A) \odot F \subseteq A \odot F$ are dense in the algebra $A \otimes \mathbb{K}$ and are algebraic *-ideals of the *algebraic* (!) tensor product $\mathcal{M}(A) \otimes^{alg} \mathcal{M}(\mathbb{K})$ that is in general strictly contained in $\mathcal{M}(A \otimes \mathbb{K})$.

By the definition of the Pedersen ideal, the algebraic ideal of $A \otimes \mathbb{K}$ generated by $\mathrm{Ped}(A) \odot F$ contains the Pedersen ideal $\mathrm{Ped}(A \otimes \mathbb{K})$ (:= minimal dense ideal of $A \otimes \mathbb{K}$).

This follows from the general observation (that is easy to see) that $\mathrm{Ped}(A) \otimes \mathrm{Ped}(B) \subseteq \mathrm{Ped}(A \otimes B)$, because for positive contractions $a \in A_+$ and $b \in B_+$ the products $(a - \varepsilon)_+ \otimes (b - \delta)_+ \leq ((a \otimes b) - \gamma)_+$ for $a \in A_+$, $b \in B_+$, $\varepsilon > 0$, $\delta > 0$, and $0 < \gamma < (\varepsilon \cdot \delta)/2$

$A \otimes \mathbb{K}$???? and generates ????. Above we have seen that sometimes $\mathrm{Ped}(A) \odot F$ is not an (algebraic) ideal of $A \otimes \mathbb{K}$.

Thus are in general not algebraic *-ideals of the C^*-algebra $\mathcal{M}(A) \otimes \mathcal{M}(\mathbb{K})$. The "sum" $X \oplus Y := SXS^* + TYT^*$ for given isometries, e.g. $S := 1 \otimes s$ and $T := 1 \otimes t$ is well defined and preserve $\approx$ (and $\sim_{MvN}$) classes of the elements in $A \odot F$, respectively in $\mathrm{Ped}(A) \odot F$.

The classes of elements in $A \odot F$ build $\mathrm{W}(A)$ and the classes of elements in $\mathrm{Ped}(A) \otimes F$ build $\mathrm{CS}(A)$.

The definition of the Pedersen ideal of a C^*-algebra shows that $\mathrm{Ped}(A \otimes \mathbb{K})$ is identical with the algebraic ideal of $A \otimes \mathbb{K}$ generated by $\mathrm{Ped}(A) \otimes F$, in particular $F = \mathrm{Ped}(\mathbb{K})$.

????

The *set* $F \cdot F$ of products $f_1 \cdot f_2$ is in in general not identical with F, i.e., $F \odot F$ (perhaps) generates F of $A \otimes B$ even in case $A = \mathbb{K}$ $B = \mathbb{K}$.

Here is something wrong!!!

$F = \mathrm{Ped}(\mathbb{K})$ seems to be OK! This are all elements in $\mathbb{K}$ with finite ranks.

But $F \odot F$ is not the Pedersen ideal of $\mathbb{K} \otimes \mathbb{K}$ but is contained in the Pedersen ideal and generates the Pedersen ideal of $\mathbb{K} \otimes \mathbb{K} \cong \mathbb{K}$.

Consider it in $\ell_2 \otimes \ell_2$????

Thus, $\mathrm{CS}(A \otimes \mathbb{K}) \cong \mathrm{CS}(A)$ in a natural way. ???? Checked ???

??? Moreover $(A \otimes \mathbb{K}) \odot F$ is "locally" isomorphic to $A \otimes \mathbb{K} \otimes \mathbb{K}$????

The only stably invariant versions of the original Cuntz semigroups are $\mathrm{CS}(A) \cong \mathrm{CS}(A \otimes \mathbb{K})$ and $\mathrm{Cu}(A) \cong \mathrm{Cu}(A \otimes \mathbb{K}) \cong \mathrm{W}(A \otimes \mathbb{K})$, where we take for $\mathrm{Cu}(A)$ "our" – above given – Definitions.

That $\mathrm{W}(A \otimes \mathbb{K}) \cong \mathrm{Cu}(A \otimes \mathbb{K})$ follows from $A \otimes \mathbb{K} \otimes M_n \cong A \otimes \mathbb{K} \otimes e_{11}$ by *-conjugating with an isometry in $1_{\mathcal{M}(A)} \otimes \mathcal{M}(\mathbb{K} \otimes M_n)$.

The "large" Cuntz semigroup can give some sort of informations about the countably generated Hilbert-modules over A.

But notice that there are examples of C^*-algebras A where $\mathrm{CS}(A)$, $\mathrm{W}(A)$ and $\mathrm{Cu}(A)$ are all different, e.g. for $A := c_0(\mathbb{N}) \otimes \mathrm{C}([0,1]^\infty)$, the zero sequences in $\mathrm{C}([0,1]^\infty)$.

`last example A OK ??  Check it??`

But, since they are all contained in $\mathrm{Cu}(A)$, one can carry out all calculations inside $\mathrm{Cu}(A)$, – except some relations in their corresponding (pre-ordered) Grothendieck groups, i.e. given by additional absorbing elements.

`Check Def. Cuntz semi-group. Compare with that in Sec. ??? in App. A`

The difference between $\mathrm{Cu}(A)$ and its hereditary sub-semigroup $\mathrm{CS}(A)$ becomes visible in case of simple C^*-algebras A, because then $\mathrm{CS}(A)$ is a simple semi-group, i.e., for any two non-zero elements $[a], [b] \in \mathrm{CS}(A)$ there exist $m, n \in \mathbb{N}$ such that $[b] \leq m[a]$ (i.e., $b \precsim a \otimes 1_m$) and $[a] \leq n[b]$. But in general, for

$$a \in \mathrm{Ped}(A)_+ \cong \mathrm{Ped}(A)_+ \otimes p_{11} \subseteq \mathrm{Ped}(A \otimes \mathbb{K})$$

in the Pedersen ideal of A there does not exist a positive integer m such that $[e] \leq m[a]$, i.e., $e \precsim a \otimes 1_m$, for the above defined "infinite" element $[e] \in \mathrm{Cu}(A)$. It would imply that $3m[a] \leq m[a]$ and causes the existence of a scaling element $b \in A \otimes \mathbb{K}$. But the existence of non-zero scaling elements causes the existence of a non-zero projection $p \in A \otimes \mathbb{K}$ and $k \geq 1$ with $2k[p] \leq k[p]$.

`Exactly as ''absorbing'' is defined? Check this:`

Thus, the "large" semi-groups $\mathrm{Cu}(A)$ of σ-unital A contain always a kind of "absorbing" infinite elements by this trivial reason (and is therefore not suitable for our purpose).

If A is simple and σ-unital then $\mathrm{Cu}(A) = \mathrm{CS}(A)$ if and only if A is stably infinite, i.e., if and only if $A \otimes \mathbb{K}$ contains an infinite projection $p \neq 0$ (which is then a properly infinite projection by Lemma 2.1.6) ([30]).

`A better ''defining'' name could be:`
`''compatibly pre-ordered additive semi-group''`

DEFINITION 2.4.4. Let $\mathcal{S} = (S, +, 0, \leq)$ a **compatibly pre-ordered additive semigroup** (shortly named as **c.p.a.** semigroup) with order-minimal zero-element 0, i.e., $(S, +)$ is a commutative semigroup, and for $x, y \in S$ holds: $x + 0 = x$, $y \leq x + y$, and that $x \leq 0$ implies $x = 0$.

We say that $\mathcal{S}$ is **simple** if for every for every $x, y \in S \setminus \{0\}$ there exist $n \in \mathbb{N}$ with $y \leq nx$.

A sequence $(x_1, x_2, \ldots)$ with $x_n \in S$ is **infinitesimal** (with respect to given $y \in S \setminus \{0\}$) if $k_n \to \infty$ (by $n \to \infty$) for each sequence of natural numbers $k_1, k_2, \ldots \in \mathbb{N}$ with the property that $y \leq k_n x_n$ for all $n \in \mathbb{N}$.

[30] We have introduced here the "small" variant $\mathrm{CS}(A)$ of a Cuntz semi-group for a transparent formulation of the proof and statement of Corollary 2.4.6.

Clearly *every infinitesimal sequence* $(x_1, x_2, \ldots)$ *satisfies that the set* $X := \{x_1, x_2, \ldots\} \subseteq S$ *is an infinite subset of* S.
Indeed, consider – more general – any finite subset X of S and let $y \in S \setminus \{0\}$. Then – alternatively – there exists $x_{n_0} \in X$ such that there is no $k \in \mathbb{N}$ with $y \leq kx_{n_0}$ or there exists $k(y) \in \mathbb{N}$ with $y \leq k(y)x_n$ for all $x_n \in X$. Hence, the sequence $x_1, x_2, \ldots \in X$ is not infinitesimal (with respect to y).

Thus, *finite* pre-ordered additive semigroups $\mathcal{S} = (S, +, 0, \leq)$ with order-minimal zero-element can not contain an infinitesimal sequence.

In particular, the semi-group $S = \{0, y\}$ with relations $0 \leq y$ and $2y = y$ has no infinitesimal sequence.

The pre-ordered semi-group $(\mathbb{Z}_+, +)$ is simple and does not contain any infinitesimal sequence $(x_1, x_2, \ldots) \in \mathbb{Z}_+^\infty$, because for $0 < y \in \mathbb{Z}$ holds that the relation $y \leq m \cdot x$ implies that $m, x \in \mathbb{N} = \mathbb{Z}_+ \setminus \{0\}$, i.e., $1 \leq x$ and $y \leq y \cdot x$. Thus, with $k(y) := y$ we can see that $(\mathbb{Z}_+, +)$ *contains no infinitesimal sequence.*

LEMMA 2.4.5. *Let* $\mathcal{S} = (S, +, 0, \leq)$ *a simple pre-ordered additive semi-group.*

Then $S \setminus \{0\}$ *contains no infinitesimal sequence, if and only if, for each* $y \in S \setminus \{0\}$ *there exists* $k(y) \in \mathbb{N}$ *such that* $y \leq k(y)x$ *for all* $x \in S \setminus \{0\}$.

PROOF. Suppose that for each $y \in S \setminus \{0\}$ there exists $k(y) \in \mathbb{N}$ – depending only on y – such that $y \leq k(y)x$ for all those $x \in S \setminus \{0\}$ that have the property that there exists $\ell(x, y) \in \mathbb{N}$ with $y \leq \ell(x, y)x$.

Let $(x_1, x_2, \ldots)$ is a sequence in S and $k_1, k_2, \ldots$ a sequence in $\mathbb{N}$. If $y \in S \setminus \{0\}$ satisfies $y \leq k_n x_n$ then $x_n \neq 0$ and $y \leq k(y)x_n$ for all $n \in \mathbb{N}$, i.e., $(x_1, x_2, \ldots)$ is not an infinitesimal sequence. Thus, S contains no infinitesimal sequences (with respect to any y).

Now suppose that S contains no infinitesimal sequence (with respect to $y \in S \setminus \{0\}$) and that S is simple. We show that this implies the existence of $k(y) \in \mathbb{N}$ with $y \leq k(y)x$ for all $x \in S \setminus \{0\}$.

Notice that if $z \in S \setminus \{0\}$, then there are $m, n \in \mathbb{N}$ with $y \leq mz$, $z \leq ny$ for suitable $m, n \in \mathbb{N}$, and that if $(x_1, x_2, \ldots)$ is a sequence in $S \setminus \{0\}$, then this sequence is infinitesimal with respect to z, if and only if, $(x_1, x_2, \ldots)$ is infinitesimal with respect to y. This is because, e.g. $z \leq nk_n x_n$ if $y \leq k_n x_n$.

The simplicity of S implies that, for each $x \in S \setminus \{0\}$, there exists $n \in \mathbb{N}$ with $y \leq nx$. Let $\ell(y, x) \in \mathbb{N}$ denote the minimal number $n \in \mathbb{N}$ with this property. We show that the subset $M_y := \{\ell(y, x)\,;\ 0 \neq x \in S\}$ is bounded:

Otherwise there exists a sequence $(x_1, x_2, \ldots)$ in $S \setminus \{0\}$ with $\ell(y, x_n) \to \infty$ for $n \to \infty$.

Let $k_1, k_2, \ldots \in \mathbb{N}$ with $y \leq k_n x_n$. Then $k_n \geq \ell(y, x_n)$ by definition of $\ell(y, x_n)$. Thus, $k_n \to \infty$. It means that $(x_1, x_2, \ldots)$ is an infinitesimal sequence in $S \setminus \{0\}$. Its existence contradicts our assumption on infinitesimal sequences.

It implies that the number $k(y) := \max M_y \in \mathbb{N}$ exists and satisfies $y \leq k(y)x$ for all $x \in S \setminus \{0\}$. □

... Where is the definition of "non-elementary" ?

COROLLARY 2.4.6. *A non-elementary simple C^*-algebras A is purely infinite, if and only if, the "small" Cuntz semigroup* $\mathrm{CS}(A)$ *of A does not contain an infinitesimal sequence, in the sense of Definition 2.4.4.*

If a non-elementary simple C^*-algebra A has real rank zero and the natural image of $\mathrm{V}(A)$ *in* $\mathrm{CS}(A)$ *does not contain an infinitesimal sequence for* $\mathrm{CS}(A)$ *then A is purely infinite.*

If A is an elementary simple C^*-algebra then $\mathrm{CS}(A) \cong (\mathbb{Z}_+, 0, +)$, *and* $(\mathbb{Z}_+, 0, +)$ *does not contain an infinitesimal sequence.*

PROOF. If A is elementary, then the pre-ordered semi-group $\mathrm{CS}(A)$ is isomorphic to the ordered additive semi-group of non-negative integers $\mathbb{Z}_+ = \{0, 1, \ldots\}$, given by semi-group isomorphism $[a] \mapsto \mathrm{Rk}(a)$ for $a \in \mathrm{Ped}(\mathbb{K})$ (where $\mathrm{Rk}(a)$ denotes the rank of $a \in \mathbb{K}$, it is on other places also denoted by: $\mathrm{rank}(a)$).

Above we have seen that the semigroup $(\mathbb{Z}_+, 0, +)$ contains no infinitesimal sequence – in sense of our Definition 2.4.4.

Recall that $[a] = [a^*] = [a^*a]$ in $\mathrm{CS}(A)$ for $a \in \mathrm{Ped}(A \otimes \mathbb{K})$, cf. [**175**], – or use our Lemma 2.5.3(xi) and Lemma A.6.1.

If A is purely infinite and simple, then Definition 2.4.1 of Cuntz equivalence classes $[a]$ and Proposition 2.2.1(ii) implies that $[a] = [a^*a] = [b^*b] = [b]$ for any non-zero $a, b \in A \otimes \mathbb{K}$, cf. Lemma 2.5.3(xi), and that A is *non-elementary* (i.e., A is not isomorphic to the compact operators on a Hilbert space). Thus, $\mathrm{CS}(A) = \{[0], [a]\}$ for any non-zero element $a \in A$, $[0]$ is the zero of $\mathrm{CS}(A)$, and $2[a] = [a] > [0]$. By the considerations on finite additive semi-groups (above here and in Lemma 2.4.5) this finite pre-ordered semi-group with zero element does not contain any infinitesimal sequence in the sense of Definition 2.4.4.

To show the opposite direction we suppose that *A is simple and non-elementary, and that* $\mathrm{CS}(A)$ *does not contain an infinitesimal sequence.*

It is easy to see that for all simple $A \neq \{0\}$ the "small" Cuntz semigroup $\mathrm{CS}(A)$ is simple (and vice versa).

By Lemma 2.4.5, the non-existence of infinitesimal sequences in simple semigroups is equivalent to the existence of – "universal" = only from y depending – numbers $\nu(y) \in \mathbb{N}$ with the property that $y \leq \nu(y)x$ for all non-zero elements x.

Thus, for every non-zero $b \in \mathrm{Ped}(A)$ there exist $\nu(b) \in \mathbb{N}$ such that $[b] \leq \nu(b) \cdot [a]$ for every non-zero $a \in \mathrm{Ped}(A)$. But this implies the following:

Let $a, b \in A_+$ with $\|a\| = 1 = \|b\|$ and $\varepsilon \in (0, 1)$. If we let $\delta := \varepsilon/3$ then $(a-\delta)_+$ and $(b-\delta)_+$ are in $\mathrm{Ped}(A)$. Thus, there exists numbers $n := n(b, \varepsilon) := \nu((b-\delta)_+) \in \mathbb{N}$, – depending only from b and $\varepsilon > 0$ – with the property $(b - \delta)_+ \otimes e_{11} \precsim$

$(a-\delta)_+ \otimes 1_n$ in $A \otimes M_n$. In particular, there exists $c_1, \ldots, c_n \in A$ with

$$\|b - (c_1^* a c_1 + \ldots + c_n^* a c_n)\| < \varepsilon\,.$$

It says that A satisfies the criteria in Part (iv) of Proposition 2.2.1. Therefore A is purely infinite.

Now we consider the more special case where A satisfies the additional pre-assumptions that A is a simple, non-elementary C^*-algebra, that has real rank zero, again with the additional non-degeneracy property that there exists $0 \neq y \in \mathrm{Ped}(A \otimes \mathbb{K})_+$

with what ????

Then there exists a non-zero projection $q \in A \otimes \mathbb{K}$ and $m, n \in \mathbb{N}$ with $[q] \leq m[y]$ and $[y] \leq n[q]$.

Suppose that there are $a_1, a_2, \ldots \in \mathrm{Ped}(A \otimes \mathbb{K})_+$ with $\|a_k\| = 1$ that represent an infinitesimal sequence $[a_1], [a_2], \ldots \in \mathrm{CS}(A)$, then nonzero projections

$$p_k \in \overline{(a_k - 1/2)_+ (A \otimes \mathbb{K})_+ (a_k - 1/2)_+}$$

build an infinitesimal sequence in $[p_1], [p_2], \ldots \in \mathrm{CS}(A)$ with respect to $[q]$.

By assumptions, we have excluded the existence of infinitesimal sequences defined by projections in the Cuntz semigroup $\mathrm{CS}(A)$. Thus, $\mathrm{CS}(A)$ does not contain any infinitesimal sequence, and the above considered cases apply here also to A and prove purely infiniteness of A. □

5. Properly infinite elements in non-simple C^*-algebras

The study of non-simple purely infinite algebras requires basics on majorization in the sense of J. Cuntz and properly infinite elements as defined by M. Rørdam. Some needed properties of the majorization relation $b \precsim c$ are considered here. Others are listed and studied in Appendix A, see e.g. the Lemma A.6.1.

Our Definition 1.2.1 becomes more transparent and applicable by [**462**, thm. 4.16]. It says that non-zero C^*-algebras A are purely infinite in the sense of Definition 1.2.1, if and only if, each element $a \in A_+$ is *properly infinite* in the sense of following Definition 2.5.1. We outline a proof of this result, because the behavior of properly infinite elements play a fundamental role in proofs of our main results.

Versions of $\mathrm{Cu}(A)$ have been defined also before!!? Refer to this Defs.!!
Compare also Definition 2.4.1 for the relation $\precsim$, ...
There exist other Defs of infinite or properly infinite elements of $C*$-algebras.
Even on the level elements are sometimes diferent.
Only in case of elements in $s$imple $C*$-algebras all the definitions are equivalent ...

DEFINITION 2.5.1. Let a, b, c elements of a C^*-algebra A.

We say that c **majorizes** b (denoted by $b \precsim c$) if there exist sequences of elements $d_n, e_n \in A$ with $b = \lim_n e_n c\, d_n$ ([31]). It is easy to check that for $b \in A_+$ and $c \in A$ holds $b \precsim c$ if and only if $(b - \varepsilon_n)_+ \precsim c$ for a zero-sequence (ε_n) in $(0, \|b\|)$.

Refer here to Appendix Section for $\precsim$ (continuity) properties.

The relation $\precsim$ is transitive and becomes "reflexive" with respect to the as follows defined equivalence relation " $\approx$ " :

We write $a \approx b$ if $a \precsim b$ *and* $b \precsim a$. The $\approx$-class of $a \in \bigcup_n M_n(A) \subset M_\infty(A)$ will be denoted also by $[a]_\approx$, or simply by $[a]$ if it can not mixed up in some places with the considerably smaller class $[a]_{MvN}$ of elements in $\bigcup_n M_n(A)$ that are Murray–von-Neumann equivalent to a. The definition shows that the $\approx$-classes of elements in $M_\infty(A)$ are (relatively) closed subsets, and that the set of $b \in M_\infty(A)$ with $b \approx a$ are closed sets (relatively to $M_\infty(A)$).

Then a partial order $[b] \leq [a]$ can be defined by $b \precsim a$.

There are natural embeddings $a \in A \mapsto a \oplus 0 \in M_2(A)$ and – more generally – $M_m(A) \oplus 0_n \subset M_{m+n}(A)$, consider them as a common $*$-subalgebra $\bigcup_n M_n(A)$ of $M_\infty(A) \supseteq A \otimes \mathbb{K}(\ell_2)$. In this way the $\approx$-classes become an pre-ordered abelian semi-group with addition $[a] + [b] := [a \oplus b]$ and the relation $[a] \leq [b]$ is compatible with this addition.

We denote the corresponding pre-ordered semi-group by $\mathrm{W}(A)$, and call it the **Cuntz semigroup** of A. In case of non-unital A the semigroup $\mathrm{W}(A)$ can be bigger than the "small" local Cuntz semigroup $\mathrm{CS}(A)$ of Definition 2.4.3 and is for all stably finite σ-unital C^*-algebras A smaller than the in Definition 2.4.2 defined (large) general Cuntz semi-group $\mathrm{Cu}(A)$, because $\mathrm{Cu}(A)$ contains always an "infinite" absorbing idempotent, cf. the remarks below Definition 2.4.3. If A is unital, then obviously $\mathrm{W}(A) = \mathrm{CS}(A)$.

The element $a \in A$ **absorbs** the element $b \in A$, if a majorizes $a \oplus b$, i.e., if $a \oplus b \precsim a \oplus 0$ in $M_2(A)$ (The matrix $a \oplus b := \mathrm{diag}(a, b) \in M_2(A)_+$ denotes the diagonal 2×2-matrix with diagonal entries a and b).

Let $I(a) \subseteq A$ denote the set of $b \in A$ that are absorbed by a, i.e.,

$$I(a) := I_A(a) := \{ b \in A\, ;\ [b] + [a] \leq [a] \} .$$

We write $I(a)$ if it should be clear which C^*-algebra A is considered in that moment. Notice that the natural semigroup morphism $I_B(a) \to I_A(a)$ for $a \in B \subset A$ is not necessarily injective. It was denoted by $J(a)$ in [**462**, def. 3.11].

Check if notation is consistent to other use of $I(a)$, $J(a)$, $I_A(a)$, ... etc.

Give an example where $I_B(a) \to I_A(a)$ for some $a \in B \subset A$ is not injective.

[31] The sequences (d_n) and (e_n) are here not necessarily required to be bounded.

Then $a \in A$ is called **finite** if $I(a) = \{0\}$, and **infinite** if $I(a) \neq \{0\}$.

We say that $a \in A$ is **properly infinite**, if $a \in I(a)$, i.e., if $a \oplus a \precsim a \oplus 0$ in $M_2(A)$, here we allow only $a \neq 0$ ([32]), i.e., $a \in A$ is properly infinite if and only if $2[a] \leq [a]$ in the pre-ordered Abelian semi-group $\mathrm{Cu}(A)$ of Cuntz equivalence classes in $A \otimes \mathbb{K}$ with $[a]$ corresponding naturally to the class of $a \otimes p_{11}$ in $\mathrm{Cu}(A)$, cf. Definition 2.4.2.

There exist several other formulations of infiniteness of elements or of Next Remark 2.5.2 is used in the proofs of Part(viii) of Lemma 2.5.3 and of Lemma 2.5.4.

Remark 2.5.2. If $d \in A_+$ and $b \in D := \overline{dAd}$ then $b \precsim d$ in D and A. But from $b \precsim d$ in A one gets only that $b \in J(d)$, where $J(d)$ denotes the closed ideal of A generated by d.

Indeed, the existence of elements $e_n, f_n \in D$ with $b = \lim_n e_n\, d\, f_n$ follows from the equation $D = \overline{D \cdot d \cdot D}$, that is implied by the equations $D = \overline{d \cdot D}$ and $D = D \cdot D$ ([33]).

Moreover, this shows that $b \precsim c$ if $c \in A$ is properly infinite in A and b is contained in the closed ideal of A generated by $c \in A$.

Obviously, the Murray–von-Neumann equivalence $a \sim_{MvN} b$ of Definition 2.0.1 implies $a \approx b$.

Recall that a positive element $a \in B_+$ is **stable** by Definition 2.1.1 if the hereditary C^*-subalgebra $\overline{aBa}$ is stable (or zero). By Part (viii) of the following Lemma 2.5.3, every non-zero *stable* element is properly infinite. But properly infinite elements, e.g. projections, that are not stable.

In particular, the elements a*,* a^*a*,* aa^* *and* $(a^*a)^{1/2}$ *are all properly infinite if one of them is properly infinite.*

PROOF. We use in the proof of Part (i) the precise notation $X \oplus 0_m \in M_{n+m}(A)$ if $X \in M_n(A)$, but in the proofs of other parts we write simply X for $X \oplus 0_m$.

(i): More generally we define $I_n := I_n(a)$ for $a \in A$ as the *set* of $x \in M_n(A)$ with $a \oplus x \precsim a \oplus 0_n$ in $M_{n+1}(A)$. In particular $I_1(a) = I_A(a)$. Below given arguments show that the I_n are closed ideals of $M_n(A)$ and $I_n = M_n(I_A(a))$ for $n \in \mathbb{N}$. Clearly

[34] Identify here a with $a \otimes p_{11}$ in $A \otimes M_2$, or with the matrix $[a_{j,k}]$ given by $a_{1,1} := a$ and $a_{j,k} = 0$ if $j \neq 1$ or $k \neq 1$.

[35] Case $I_A(a) = \{0\}$ and $I_{A/J}(\pi_J(a)) = A/J$ can appear, cf. Examples 2.5.12 and 2.5.13.

we get the same subset of $M_n(A)$ if we consider the elements $x \in M_n(A)$ with the property $x \oplus a \precsim 0_n \oplus a$ in $M_{n+1}(A)$.

In the case where $x \in M_n(A)_+$ and $a \in A_+$ this is equivalent to $(x-\gamma-\varepsilon)_+ \oplus (a-\varepsilon)_+ \precsim a$ for all $\varepsilon \in (0,\gamma)$ and $\gamma \in (0,\|x\|)$, because it implies $(x-\gamma)_+ \oplus a \precsim a$ for every $\gamma \in (0,\|x\|)$ and then the relation $x \oplus a \precsim a$. Both implications follow from the continuity properties of the relation $\precsim$ on $M_2(A)$, respective from the fact that $I_n(a)$ is closed in $M_n(A)$, as shown now in more detail:

Temporarily and only here, we denote by $\xi(a \oplus 0_n)$ the set of elements $z \in M_{n+1}(A)$ with $z \precsim (a \oplus 0_n)$. We write this as $z \precsim a$ via identifying A with $A \otimes e_{11} \cong A \oplus 0_n$. Likewise, we can use here instead the identification of A with $A \otimes e_{n+1,n+1} \cong 0_n \oplus A$ in $M_{n+1}(A)$.

By Lemma A.6.1(iv,viii), the set $\xi(a \oplus 0_n)$ is a *closed* subset of $M_{n+1}(A)$ that satisfies $X\xi(a \oplus 0_n)Y \subset \xi(a \oplus 0_n)$ for all $X, Y \in \mathcal{M}(M_{n+1}(A)) \cong M_{n+1}(\mathcal{M}(A))$. More precisely, $\xi(a \oplus 0_n)$ is the closure in $M_{n+1}(A)$ of the set of elements $X(a \oplus 0_n)Y$ with $X, Y \in \mathcal{M}(M_{n+1}(A)) \cong M_{n+1}(\mathcal{M}(A))$.

The sets $I_n(a)$ are closed subsets of $M_n(A)$ because

$$a \oplus I_n(a) \;=\; (a \oplus M_n(A)) \cap \xi(a \oplus 0_n)\,.$$

This equation shows also that $I_n(a)$ invariant under right and left multiplications by operators in $\mathcal{M}(M_n(A))$.

In particular, $I_A(a) = I_1(a) \subseteq A$ and the sets $I_n(a) \subseteq M_n(A)$ are *closed* in $M_n(A)$ and satisfy $cI_n(a)d \subseteq I_n(a)$ for all $c, d \in \mathcal{M}(M_n(A))$.

We derive that if $x \in I_m(a)$ and $y \in I_n(a)$, then $x \oplus y \in I_{m+n}(a)$:

Notice that in $M_{m+n+1}(A)$ for all $v \in M_m(A)$ and $z \in M_n(A)$ holds

$$(a \oplus v) \oplus z \approx a \oplus (v \oplus z) \approx a \oplus (z \oplus v) \approx (a \oplus z) \oplus v\,,$$

where the middle equivalence is given by $1_{\mathcal{M}}(A) \oplus S$ for some suitable inner automorphism S of M_{n+n}. The elements $x \in I_m(a) \subseteq M_m(A)$ and $y \in I_n(a) \subseteq M_n(A)$ satisfy $a \oplus x \precsim a \oplus 0_m$ in $M_{m+1}(A)$ and $a \oplus y \precsim a \oplus 0_n$ in $M_{n+1}(A)$.

It follows that

$$a \oplus (x \oplus y) \approx (a \oplus x) \oplus y \precsim (a \oplus 0_m) \oplus y$$

in $M_{m+n+1}(A)$. Then

$$(a \oplus 0_m) \oplus y \approx (a \oplus y) \oplus 0_m \precsim (a \oplus 0_n) \oplus 0_m \approx a \oplus 0_{m+n}\,.$$

Together it gives that

$$a \oplus (x \oplus y) \precsim a \oplus 0_{m+n}$$

in $M_{m+n+1}(A)$, i.e., $x \oplus y \in I_{m+n}(A)$. We can also use the relations

$$a \oplus x \precsim a \oplus 0_m\,,\;\; a \oplus (0_m \oplus y) \precsim a \oplus 0_{m+n}$$

and Lemma A.6.1(ii) to get the relation:

$$a \oplus (x \oplus y) \approx (a \oplus x) \oplus y \precsim (a \oplus 0_m) \oplus y \precsim a \oplus 0_{m+n}\,.$$

Since $M_{m+1}(A)$ is naturally isomorphic to the hereditary C^*-subalgebra D of $b \in M_{m+n+1}(A)$ with $b = c \oplus 0_n$ for some $c \in M_{m+1}(A)$, and since $a \oplus 0_m \oplus 0_n$ and $a \oplus x \oplus 0_n$ are both in D, we get that $x \in M_m(A)$ is in $I_m(a)$, if and only if, $x \oplus 0_n \in I_{m+n}(a)$, cf. Lemma A.6.1(viii).

If $x, y \in I_n$, then $a \oplus (x+y) \oplus 0_n \precsim a \oplus (x \oplus y) \precsim a \oplus 0_{2n}$ in $M_{2n+1}(A)$, because $(x+y) \oplus 0_n \precsim x \oplus y$ in $M_{2n}(A)$, cf. Lemma A.6.1(x).

Thus, $I_n(a)$ is also additively closed, i.e., is a closed *ideal* of $M_n(A)$. In particular there is a unique ideal J of A such that $I_n(a) = J \otimes M_n \cong M_n(J)$ and this ideal is determined by the equation $J \otimes e_{11} = (A \otimes e_{11}) \cap I_n(a)$.

Then $I(a) \oplus 0_{n-1} = I_n(a) \cap (A \oplus 0_{n-1})$ by the above gives definitions of $I_n(a) \subseteq M_n(A)$ and $I(a) \subseteq A$. Combined with the natural isomorphism $A \oplus 0_{n-1} \cong A \otimes e_{11}$ it gives that $I_n(a) = M_n(I(a))$.

Alternatively one could use here that $I(a) \oplus 0_{n-1}$ is a full hereditary C^*-subalgebra of the ideal $I_n(a) \subseteq M_n(A)$, to obtain that $I_n(a) = M_n(I(a))$.

For all elements $X \in I_n(a) = M_n(I(a))$ holds $X \oplus a \approx a \oplus X \precsim a \oplus 0_n$ inside $M_{n+1}(A)$.

If $a \approx c$ and $x \in I(a)$, then $x \in I(c)$, because

$$c \oplus x \precsim a \oplus x \precsim a \oplus 0 \precsim c \oplus 0 \,.$$

It implies then $I_n(a) = I_n(c)$ for all $n \in \mathbb{N}$.

It holds $X + Y \precsim X \oplus Y$ for all $X, Y \in M_n(A)$ by Lemma A.6.1(x), and $|Z|^2 = Z^2 \approx Z$ for all selfadjoint $Z \in I_n(a)$. It implies that $|Z| \oplus a \precsim a$ if $Z \oplus a \precsim a$. Thus, $|b| \oplus [d,e]^* a [d,e] \precsim |b| \oplus a \precsim a$ for each $a \in A_+$ and $b^* = b \in M_2(I(a))$.

(ii): Clearly, $I_D(a) \subseteq I_A(a) \cap D$ by definitions of $I_A(a)$ and $I_D(a)$ in case of $a \in D$. If $x \in I_A(a) \cap D$, then $a \oplus x \precsim a \oplus 0$ in $M_2(A)$. Since $M_2(D)$ is hereditary in $M_2(A)$ and $a \oplus x, a \oplus 0 \in M_2(D)$, it follows $x \in I_D(a)$ by Lemma A.6.1(viii).

(iii): The observation in Part (iii) is equivalent to [**462**, lem. 3.13]. We give an alternative proof:

Let $a \in A_+$ and denote by $\pi := \pi_{I(a)} \colon A \to A/I(a)$ the quotient map, where here $I(a) := I_A(a)$.

Let $x \in A_+$ with $\pi(x) \oplus \pi(a) \precsim \pi(a)$, i.e., with $\pi(x) \in I(\pi(a))_+$. Here the short notation $I(\pi(a))$ means – more precisely – the ideal $I_{A/I(a)}(\pi(a))$ of $A/I(a)$, and $\pi(x)$ denotes the element $\pi_{I(a)}(x)$ of $A/I(a)$.

We show below that this implies $\pi(x) = 0$, i.e., show that $x \in I_A(a)$. It follows then that $I(\pi(a)) = 0$, which means that the element $\pi(a)$ is finite in $A/I(a)$.

Since $I(a)$ is a closed ideal of A, it suffices to show that $(x - \gamma)_+ \in I(a)$ for each $\gamma \in (0, \|x\|)$, i.e., that $(x - \gamma)_+ \oplus a \precsim a$.

By definition of $\precsim$ in $A/I(a)$, for each $\varepsilon \in (0,\gamma)$ there exist $\delta := \delta(\varepsilon) > 0$ and $d, e \in A$ with

$$[\pi(d),\pi(e)]^*\pi((a-\delta)_+)[\pi(d),\pi(e)] = (\pi(x)-\gamma-\varepsilon)_+ \oplus (\pi(a)-\varepsilon)_+ \,.$$

We can rewrite this equivalently as "$Y \in M_2(I(a))$" for the selfadjoint element $Y \in M_2(A)$ defined by

$$Y := \big((x-\gamma-\varepsilon)_+ \oplus (a-\varepsilon)_+\big) - [d,e]^*(a-\delta)_+[d,e] \;\in M_2(I(a))\,.$$

It follows that

$$(x-\gamma-\varepsilon)_+ \oplus (a-\varepsilon)_+ = Y + [d,e]^*(a-\delta)_+[d,e] \le |Y| + [d,e]^*(a-\delta)_+[d,e] \in M_2(A)\,.$$

Since $Y \in M_2(I(a))$ we get $|Y| \in M_2(I(a))$ and by Part (i), this implies that $|Y| + [d,e]^*(a-\delta)_+[d,e] \precsim a\,$.

Thus $(x-\gamma-\varepsilon)_+ \oplus (a-\varepsilon)_+ \precsim a$ in $M_2(A)$. This happens for every $\varepsilon \in (0,\gamma)$, and implies $(x-\gamma)_+ \oplus a \precsim a$, i.e., $(x-\gamma)_+ \in I(a)$ for each $\gamma \in (0,\|x\|)$. Thus $x \in I(a)$, because $I_A(a)$ is closed.

(iv): By Lemma A.6.1(iii), if $a \oplus x \precsim a \oplus 0$ and

$$\psi := \mathrm{id} \otimes \varphi \colon M_2 \otimes A \,\to\, M_2 \otimes B\,,$$

then $\psi(a \oplus x) \precsim \psi(a \oplus 0)$ in $M_2(B)$. Thus, $\varphi(I_A(a)) \subseteq I_B(\varphi(a)) \subseteq B$.

(v): It is – up to suitable notation – an almost trivial consequence of parts (iii) and (iv). Let $J \subseteq I(a)$ a closed ideal. Define $K := \pi_J(I_A(a)) = I_A(a)/J \lhd A/J$, $L := I_{A/J}(a+J) \lhd A/J$, $B := A/I_A(a)$ and $b := \pi_{I_A(a)}(a) \in B$ (To inflate not iterated indices).

Notice that $I_B(b) = 0$ by Part (iii), i.e., $b := \pi_{I_A(a)}(a)$ is finite in B. By Part (iv) we get $K \subseteq L$ in A/J.

Now, under natural identification of $(A/J)/K$ with $B := A/I_A(a)$, we get $\pi_K(\pi_J(x)) = \pi_{I_A(a)}(x)$ for all $x \in A$. Thus, Part (iv) says also that

$$\pi_K \colon A/J \to (A/J)/K \cong B$$

maps $L := I_{A/J}(\pi_J(a))$ into

$$I_B\big(\pi_K(\pi_J(a))\big) \;=\; I_B\big(\pi_{I_A(a)}(a)\big) \;=\; I_B(b) = \{0\}\,.$$

It implies that also $L \subseteq K$. Now $L = K$ rewrites as $\pi_J(I_A(a)) = I_{A/J}(\pi_J(a))$.

(vi): If $a, b \in A_+$ are orthogonal, and $x \in I(a)$, $y \in I(b)$, then $(a+b) \oplus 0 \sim a \oplus b$, and $a \oplus b \oplus x \oplus y \precsim a \oplus b$, i.e., $x \oplus y \in I(a \oplus b) = I_2(a+b)$ – with notations in proof of Part(i). Then $x + y \in I(a+b)$ follows finally from $(x+y) \precsim x \oplus y$.

(vii): $a \oplus a \precsim a$ implies $I_A(a) \supseteq \overline{\mathrm{span}\, AaA}$. Thus, $(a+x) \oplus 0 \precsim a \oplus x \precsim a \oplus 0$ for positive $x \in \overline{\mathrm{span}\, AaA}$. This and $a \le a + x$ imply $a \sim a + x$.

(viii): Let $0 \ne d \in A_+$ a *stable element* in A. Then $D \cong D \otimes \mathbb{K}$ for $D := \overline{dAd}$ by Definition 2.1.1. Then $\mathcal{M}(D)$ contains isometries $s_1, s_2 \in \mathcal{M}(\mathbb{K}) \subseteq \mathcal{M}(D)$ with orthogonal ranges, i.e., $s_1^* s_2 = 0$.

Let $d \in A_+$ a non-zero positive element, $D := \overline{dAd}$ and suppose that $s_1, s_2 \in \mathcal{M}(D)$ are isometries with $s_1^* s_2 = 0$. Thus, $d \sim_{MvN} d_k := s_k d s_k^* = g_k^* g_k$ for $g_k := d^{1/2} s_k$ and $k \in \{1,2\}$, because $g_k g_k^* = d$.

The element $d_1 + d_2 = d \oplus_{s_1,s_2} d \in D$ is Cuntz-equivalent in $M_2(A)$ to $\operatorname{diag}(d,d) = d \oplus d$. Hence $\operatorname{diag}(d,d) \precsim d_1 + d_2 \in D$ in $M_2(D)$. Since d is a strictly positive element of D we get that $d \oplus_{s_1,s_2} d \precsim d$ by Remark 2.5.2.

Thus, $d \oplus d \precsim d \oplus 0$ in $M_2(D)$. Hence d is properly infinite in D and in A in the sense of Definition 2.5.1.

(ix): If $a \in A_+$, then $a \oplus a \precsim a$, if and only if, for every $\varepsilon > 0$, there exists $x \in M_{1,2}(A)$ such that $x^* a x = ((a \oplus a) - \varepsilon)_+$, cf. Lemma A.6.1(vi).

(x): $((a \oplus a) - \nu)_+ = (a - \nu)_+ \oplus (a - \nu)_+ \precsim (a - \nu)_+ \leq a$ for all $\nu \in (0, \delta)$ implies $a \oplus a \precsim a$ by Lemma A.6.1(vii).

(xi): $b \oplus b \precsim a \oplus a \precsim a \precsim b$ if $a \approx b$ and a is properly infinite. Thus $b \in I(b)$ by Lemma A.6.1(ii,i). It applies to $|a| = (a^* a)^{1/2} \approx a \approx a^* a \sim a a^*$ by Lemma A.6.1(v). □

MORE of ABOVE? OR LESS?

A rather practical elementary *sufficient* criteria of – not necessarily proper – infiniteness is contained in the following lemma:

LEMMA 2.5.4. *An element $0 \neq a \in A_+$ is infinite in A*

Where is "infinite" defined? Give Reference !!

if there exists non-zero positive $c \in D := \overline{aAa}$ with the property that, for each $\varepsilon > 0$, there exists $b \in D_+$ and $d \in A$ with

More BETTER And Clear DETAILS !!!

$c \oplus a \precsim a$ (depending on ε) with $bc = 0$ and $d^* b d = (a - \varepsilon)_+$.

In particular, $a \geq 0$ is infinite in A if there exists a non-zero projection $p \in \overline{aAa}$ that is infinite in A .

Notice that the element $c \geq 0$ is untouched here – in the sense that the d can be chosen that $cd = 0$ –, because we can replace b by $b^{1/3}$ and d by $b^{1/3} d$. Recall that the notation $x \oplus y$ denotes the the 2×2 matrix a_{ij} with entries $a_{1,2} = 0 = a_{2,1}$, $a_{1,1} = x$ and $a_{2,2} = y$.

MORE details !!!!! ???

PROOF. Let $D := \overline{aAa}$ and non-zero $c \in D_+$ with proposed property: For each $\varepsilon \in (0, \|a\|)$ there exist $b \in D_+$ with $bc = 0$ and $d \in A$ with $d^* b d = (a - \varepsilon)_+$.

Then $c + b \in D_+$ implies that $c + b \precsim a$, cf. Remark 2.5.2, and $c \oplus b = g^* g \sim_{MvN} g g^* = c + b \oplus 0$ in $M_2(D) \subseteq M_2(A)$, by the row matrix $g \in M_2(D)$ with entries $g_{11} := c^{1/2}$, $g_{12} := b^{1/2}$ and $g_{2,1} = 0 = g_{22}$.

The equation $d^*bd = (a-\varepsilon)_+$ implies then, that $c \oplus (a-\varepsilon)_+ \precsim c \oplus b$. Using that $\sim_{MvN}$ implies $\approx$, we get that $c \oplus (a-\varepsilon)_+ \precsim a \oplus 0$ in $M_2(A)$ for each $\varepsilon > 0$. But this says that $c \oplus a \precsim a \oplus 0$ in $M_2(A)$ by lower semi-continuity of $\precsim$. Thus, $c \in I_A(a)_+$ and a is infinite in A by Definition 2.5.1 and Lemma 2.5.3(i).

Now we consider the case of $a \in A_+$ with the property that there exists an inside A infinite projection $0 \neq p \in D := \overline{aAa}$. We show below that this implies the existence a non-unitary isometry $T \in \mathcal{M}(D)$, with $1 - TT^* \in D$. It follows that $c := (1-TT^*)a(1-TT^*) \neq 0$ and $b := Ta^{1/3}T^*$, $d := Ta^{1/3}$ satisfy $bc = 0$, $d^*c = 0 = cd$ and $d^*bd = a$ ([36]).

By Definition 2.5.1 and Lemma 2.5.3 the projection $p \in D$ is infinite if $I_D(p) \neq 0$, i.e., there exists nonzero $b \in I_D(p)_+$ with $b \oplus p \precsim p$. We can suppose here that $\|b\| = 1$ and $b \in pAp \subseteq D$. Then $b \oplus p \precsim p$ implies that there exists $G \in M_2(D)$ with

$$\|G^* \operatorname{diag}(p,0)G - \operatorname{diag}(p,b)\| < 1/2\,.$$

We apply Lemma 2.1.9 to this inequality and get a contraction $d \in M_2(D)$ with $(Gd)^* \operatorname{diag}(p,0)(Gd) = \operatorname{diag}((p-1/2)_+, (c-1/2)_+)$. This rewrites as a row $f := [f_1, f_2] := \operatorname{diag}(p,0)Gd \in M_{1,2}(D)$, and the equations $f_1^*pf_1 = (1/2)p$, $f_1^*pf_2 = 0$ and $f_2^*pf_2 = (b-1/2)_+$. In particular, $v := \sqrt{2}pf_1 \in D$ is a partial isometry with $v^*v = p$ and $g := pf_2f_2^*p \neq 0$. Then $gv = 0 = v*g$, $vv^* \leq p$ and $c \leq q := p - vv^* \leq p$.

It gives that $q \neq 0$ and that $p - q = vv^*$, $v^*v = p$. The operator $T := (1_{\mathcal{M}(D)} - p) + v \in 1 + D$ is an isometry with $T^*T = 1$ and $0 \neq 1 - TT^* = q \in D$. □

`Next: General criteria of infiniteness. Not urgent!`

Question 2.5.5. What about the necessary direction of Lemma 2.5.4 for infiniteness?

Let $a \in A_+$ with $\|a\| = 1$ and $D := \overline{aAa}$. Consider D as a C^*-subalgebra of $D_\infty := \ell_\infty(D)/c_0(D)$ by the map $b \in D \mapsto (b, b, \ldots) + c_0(D)$.

Is a infinite in A if a is infinite in D_∞?

Is a infinite in A if a is infinite in the ultrapower A_ω?

Suppose that $a \in A_+$ is infinite in A. Does there exist in $D_\infty := \ell_\infty(D)/c_0(D)$ a (fixed) positive $c \in D_\infty$ with $\|c\| = 1$ such that for each $\varepsilon > 0$ there exists $d \in D_\infty$ with $d^*c = 0$ and $d^*d = (a-\varepsilon)_+$?

Can we find in $(D_\infty)_+$ positive contractions $b, c \in A_\infty := \ell_\infty(A)/c_0(A)$ with $bc = 0$, and for every $\varepsilon > 0$ some (bounded) $d_\varepsilon \in A_\infty$ with $d^*bd = \psi((a-\varepsilon)_+)$ for $\psi \colon A \to A_\infty$ defined by $\psi(a) := (a, a, \ldots) + c_0(A)$?

An attempt is the following: Suppose that non-zero $a \in A_+$ is infinite in A, i.e., $I_A(a) \neq 0$ by Definition 2.5.1 and Lemma 2.5.3(i). Take $g \in I_A(a)_+$ with $\|g\| = 1$.

[36] It shows also that there exists $q = (1-TT^*) \in pDp$ with $a \precsim (1-q)a(1-q)$ in A. So q can play the role of c – instead the inside qAq invertible qaq –, but needs an approximation argument ... an exercise for the reader.

Then $g \oplus a \precsim a$ by definition of $\precsim$ in Definition 2.5.1, i.e., for every sufficiently small $\varepsilon > 0$ there exist $\delta \in (0, \varepsilon)$ and $d_1, d_2 \in A$ with $d_1^*(a-\delta)_+ d_1 = (a-\varepsilon)_+$, $d_2^*(a-\delta)_+ d_2 = (g-1/2)_+$ and $d_2^*(a-\delta)_+ d_1 = 0$. We could consider $c_\varepsilon := (a-\delta)_+^{1/2} d_2 d_2^* (a-\delta)_+^{1/2}$, and $b_\varepsilon := ((a-\delta)_+ d_1 d_1^* (a-\delta)_+)^{1/4}$

?? Perhaps power $^{1/3}$ better?? Check it!

The polar decomposition of $(a-\delta)_+^{1/2} d_1$ is equal to BZ with a partial isometry $Z \in A^{**}$ and $B := b_\varepsilon^2$. We can take $d_\varepsilon := b_\varepsilon \cdot Z$. Get $b_\varepsilon \cdot c_\varepsilon = 0$, $d_\varepsilon^* b_\varepsilon d_\varepsilon = (a-\varepsilon)_+$, $c_\varepsilon \leq \|d_2\|^2 \cdot (a-\delta)_+$ and

$\|b_\varepsilon\|^2 = \|a\| - \varepsilon$???,

$\|c_\varepsilon\| = \|(g-1/2)_+\|$.

We only know that $\delta \in (0, \varepsilon)$ ... no reasonable functional dependence. ?????

The cases of pi(n) are similar to pi(1)?

Notice that for all positive elements X, Y in a C^*-algebra A with $\|X\| = \|Y\| = 1$ and $X \in \overline{(Y-1/2)_+ A (Y-1/2)_+}$ holds that $X(Y-(Y-1/2)_+) = (1/2)X$ and for $Z := 2(Y-(Y-1/2)_+) - 2(X-(X-1/2)_+)$ that $\|Z\| = 1$ and $Z(X-1/2)_+ = 0$. If $(X-1/2)_+$ is in the ideal generated by Z, and if each element of this ideal is in the closure of the *set* of products $A \cdot Z \cdot A$ (not its linear span), then Z is infinite.

COROLLARY 2.5.6. *For (non-zero) C^*-algebras A following properties* (1)-(4) *are equivalent:*

(1) *A is purely infinite in sense of Definition 1.2.1.*
(2) *A satisfies property pi*(1) *of Definition 2.0.4.*
(3) *A satisfies property pi*-1 *of Definition* **??**.
(4) *Every non-zero element of A_+ is properly infinite in A in sense of Definition 2.1.1.*

PROOF. (3)⇔(4): The definitions of property pi-n in Definition **??** imply in case $n = 1$ that A satisfies pi-1, if and only if, each element of A is properly infinite in the sense of Definition 2.1.1.

(4)⇒(2): (Compare Lemma 2.1.2 for more details.) Suppose that every non-zero element $a \in A_+$ is properly infinite in A in sense of Definition 2.1.1.

Then it is easy to see that each non-zero element of $\ell_\infty(A)_+$ is properly infinite, and that this property pass to all non-zero quotients of $\ell_\infty(A)$. In particular, $\ell_\infty(A)$ can not have a non-zero character, because $1 \in \mathbb{C}$ is not infinite in $\mathbb{C}$.

If a is properly infinite and b is in the closed ideal generated by a then there exist for $\varepsilon > 0$ elements $c_1, d_1, \ldots, c_m, d_m \in A$ with $\|b - \sum_{\ell=1}^m c_k a d_k\| < \varepsilon/2$. The proper infiniteness of a causes that there exists $g, h \in M_{1,m}(A)$ with

$$\|1_m \otimes a - g^*(a \oplus 0_{m-1})h\| < \varepsilon/(2m^2(\max_k(\|c_k\| + \|d_k\|)))\,.$$

Thus, there exist $e, f \in A$ with $\|b - eaf\| < \varepsilon$. It shows that A satisfies property pi(1) of Definition 2.0.4.

(2)⇒(1): The property pi(1) in Definition 2.0.4 requires from A that $\ell_\infty(A)$ has no non-zero character, and that, for each element $a \in A_+$ and $c \in A_+$ in the closed ideal generated by a and for each $\varepsilon > 0$, there exists $d \in A$ with $d^*ad = (c-\varepsilon)_+$.

It implies immediately that A is purely infinite in sense of Definition 1.2.1, because this requires only that A has no non-zero character and that for every $a \in A_+$ and every positive c in the closed ideal generated by a, and every $\varepsilon > 0$, there exists an element $d \in A$ such that $\|c - d^*ad\| < \varepsilon$.

(1)⇒(4): Suppose that A has no character and that for every non-zero $a \in A$, every $b \in A$ in the closed ideal $J(a) \subseteq A$ generated by a, and every $\varepsilon > 0$ there exists $d, e \in A$ (depending from a, b, ε) with $\|dae - b\| < \varepsilon$. It it easy to reformulate this property with help of polar decomposition and Lemma 2.1.9 as follows:
The C^*-algebra A has no character and, for every positive contractions in $a, b \in A_+$, with b in the closed ideal $J(a) \subseteq A$ generated by a and $\varepsilon > 0$, there exists $\delta > 0$ and $d \in A$ with $d^*(a-\delta)_+d = (b-\varepsilon)_+$.

The properties of A carry over to each non-zero quotient A/K of A by a closed ideal K of A, because if A has no non-zero character then A/K can not have a non-zero character, and if $e, f \in (A/K)_+$, $f \in J(e)$ in A/K and $\varepsilon \in (0, \|f\|)$ given, then there exist $a \in A_+$ with $e = \pi_K(a)$ and elements $g_1, \ldots, g_n \in A$ such that $\pi_K(b) = (f - \varepsilon/2)_+$ for $b := g_1^*ag_1 + \ldots + g_n^*ag_n \in J(a)$. There exists $d \in A$ and $\delta > 0$ with $d^*(a-\delta)_+d = (b-\varepsilon/2)_+$. It says that $(f-\varepsilon)_+ = \pi_K(d)^*(e-\delta)_+\pi_K(d)$ for given $\varepsilon \in (0, \|f\|)$ and suitable $\delta \in (0, \|e\|)$.

By Part (v) of Lemma 2.5.3, non-zero elements $a \in A$ are *properly* infinite, if and only if, $\pi_J(a)$ is infinite for each closed ideal J of A with $a \notin J$.

Above we have seen that non-zero quotients A/K satisfy the same properties as A. Therefore it suffices to show in general that each non-zero element of A_+ is infinite if A is purely infinite in sense of Definition 1.2.1.

If $D \subseteq A$ is a non-zero hereditary C^*-subalgebra of A then D can not have a character $\chi\colon D \to \mathbb{C}$:

Indeed: Suppose that a non-zero character χ on D exists and let $I \subseteq D$ the kernel ideal of χ.

Let $J \subseteq A$ the closed ideal J of A generated by the kernel I of χ. Then the ideal J has the property that $\mathbb{C} \cong D/I \subseteq A/J$ is a 1-dimensional hereditary C^*-subalgebra of A/J, because $J \cap D = I$ by Lemma ??.

Let $p \in D/I \subseteq A/J$ the unique projection with $\mathbb{C}\cdot p = D/I$, then every element in the closed ideal K of A/J generated by p is itself in $\mathbb{C} \cdot p$. Thus, J must be the kernel of a character on A. But this is forbidden for A in Definition 1.2.1.

It follows that each non-zero hereditary C^*-subalgebra D of A has no character. It implies by Lemma 2.1.15(ii) that the D contains a 2-homogenous element $g := \psi(f_0 \otimes 1_2)$ for some non-zero *-morphism $\psi\colon \mathrm{C}_0((0,1], M_2) \to D$ with $\|g\| = 1$.

Now let $a \in A_+$ non-zero and $\|a\| = 1$. The hereditary C^*-subalgebra $D := \overline{(a-1/2)_+A(a-1/2)_+}$ contains a 2-homogenous element $g := \psi(f_0 \otimes 1_2)$ with $\|g\| = 1$.

Let $c := \psi((f_0 - 1/2)_+ \otimes p_{22}) \in D$, $d := 2\psi((f_0 - (f_0 - 1/2)_+) \otimes p_{22}$, and $e := 2(a - (a-1/2)_+) - d$. Then $dc = c = cd$, $da = d = ad$, a is in the ideal of $\overline{aAa}$ generated by e, and $ec = 0$.

There exists a pure state $\rho\colon A \to \mathbb{C}$ with $\rho(a) = 1$. Let $d_\rho\colon A \to \mathcal{L}(\mathcal{H})$ the corresponding irreducible representation and $x \in \mathcal{L}(\mathcal{H})$ with $\|x\| = 1$ and

$\rho(a) = \langle d_\rho x, x\rangle$

Perhaps it is easier to show first that $(a-1/2)_+A(a-1/2)_+$ can not have a character

By Lemma **??**

NO-NO! need here a new criteria for infiniteness! Which one? ???

Part (v) of Lemma 2.5.3

to show that a (respectively $\pi_J(a)$) is infinite.

Something like:

?????????????? PROOF? □

There are places, e.g. Lemma 2.6.8(i) - or ?? -, with results partly similar to the in Lemma 2.5.7 considered!

LEMMA 2.5.7. *Let $p, q \in B$ projections and $b \in B_+$. If $(b \oplus q) \precsim (p \oplus 0)$ in $M_2(B)$, then for each $0 < \varepsilon < \min(\|b\|, 1)$ there exists an element $d = d(\varepsilon) \in B$ and a partial isometry $z = z(\varepsilon) \in B$ – depending both on ε –, such that for $r := z(z^*)$ holds $r \leq p$, $z^*z = q$, $(p-r)d = d$ and $d^*d = (b-\varepsilon)_+$.*

Special cases are:

(i) *If, moreover, b is a projection then this implies that $b \oplus q$ is in $M_2(B)$ MvN-equivalent to a sub-projection of $p \oplus 0$, i.e., there are projections $p_1, p_2 \in B$ such that $p_1p_2 = 0$, $p_1 + p_2 \leq p$, $p_1 \sim_{MvN} b$ and $p_2 \sim_{MvN} q$.*

(ii) *If $p, q \in B$ are projections that satisfy $p \precsim q$ then there exists a projection $r \leq q$ that is Murray–von-Neumann equivalent to p, i.e., there exists a partial isometry $v \in B$ with $v^*v = p$ and $vv^* =: r \leq q$.*

In particular, $p \approx q$, if and only if, there exist partial isometries $v, w \in B$ such that $v^*v = q$, $vv^* \leq p$, $w^*w = p$ and $ww^* \leq q$ ([37]).

(iii) *If B is unital and $1 := 1_B$, then there exists $0 \neq c \in B$ with $c \oplus 1 \precsim 1$, if and only if, B contains a non-unitary isometry.*

And this is equivalent to $I(1) \neq \{0\}$ by the definition of the ideal $I(1)$ given in Lemma 2.5.3.

[37] Compare Remark 2.5.8.

(iv) *The unit* $1 := 1_B$ *is properly infinite in* B, *– in the sense that there exists isometries* $S, T \in B$ *with* $S^*T = 0$ *–, if and only if,* $1 \oplus 1 \precsim 1 \oplus 0$ *in* $M_2(B)$*, if and only if,* $1 \in I(1)$*, if and only if,* $I(1) = B$ *.*

PROOF. Recall that $b \approx b^*b \approx (b^*b)^{1/2}$. It implies that the relation $b \oplus q \precsim p$ is equivalent to $(b^*b)^{1/2} \oplus q \precsim p$. Thus, we can suppose that b is positive in all later considered cases.

The relation $b \oplus q \precsim p \oplus 0$ implies by Lemma A.6.1(iv) that for each $\varepsilon > 0$ there exists $\delta = \delta(\varepsilon) > 0$ and a matrix $T \in M_2(B)$ such that

$$(b - \varepsilon)_+ \oplus (q - \varepsilon)_+ \;=\; ((b \oplus q) - \varepsilon)_+ \;=\; T^*((p \oplus 0) - \delta)_+ T\,.$$

Since $\varepsilon < \min(\|b\|, 1)$, it follows that the left side is non-zero, and therefore $\delta < 1$. Thus,

$$(b - \varepsilon)_+ \oplus (1 - \varepsilon)p \;=\; (1 - \delta)S^*(p \oplus 0)S\,,$$

where $S := [x, y]$ is the first row of T (and we can suppose that $px = x$ and $py = y$). We get that $x^*py = 0$ and $S^*(p \oplus 0)S = \mathrm{diag}(x^*px, y^*py)$. It implies that $(b - \varepsilon)_+ = (1 - \delta)x^*px$ and $(1 - \varepsilon)p = (1 - \delta)y^*py$ We define a partial isometry by

$$z := z(\varepsilon) \;:=\; (1 - \varepsilon)^{-1/2}(1 - \delta)^{1/2}py$$

and an element $d := d(\varepsilon) \in B$ by

$$d \;:=\; (1 - \delta)^{1/2}px\,.$$

Straight calculation shows that z and d have the proposed properties.

Proof of the special cases:

(i): If b is a projection and $\varepsilon < 1/2$ then let $p_1 := r = z(\varepsilon) \cdot z(\varepsilon)^*$ and $p_2 := (1 - \varepsilon)^{-1} d(\varepsilon) \cdot d(\varepsilon)^*$. This works because $b = (1 - \varepsilon)^{-1} d(\varepsilon)^* d(\varepsilon)$.

(ii): It if moreover $b = 0$, then (i) says $p_1 = 0$ and that $r := p_2 \subseteq p$ and $v := (1 - \varepsilon)^{-1/2} d(\varepsilon)$ satisfy $v^*v = q \leq p$ and $vv^* = r$.

(iii): The definition of the ideal $I(1) \subseteq B$ with $1 := 1_B$, given in Lemma 2.5.3, says that $c \in I(1)$ if and only if $c \oplus 1 \precsim 1$. Thus, $I(1) \neq \{0\}$, if and only if, there exists non-zero $c \in B$ with $c \oplus 1 \precsim 1$.

If there exists $0 \neq c \in B$ with $c \oplus 1 \precsim 1$, then $b \oplus 1 \precsim 1$ for $b := c^*c$, because $b \approx c$.

Let $q := 1$, $p := 1$, $b := c^*c$ and $\varepsilon := \|b\|/2$ in the general case. Then there exists elements $d \in B$ and $z \in B$ with $z^*z = 1$, $d^*d = (b - \|b\|/2)_+$ and $(1 - zz^*)d = d$. It follows that z is a non-unitary isometry in B.

If B contains a non-unitary isometry $z \in B$, then $c \oplus 1 \precsim 1$ for $c := 1 - zz^* \neq 0$, because $c \oplus 1 \approx c \oplus zz^*$ and $1 - zz^* \oplus zz^* = R^*(1 \oplus 0)R$ for the row $R := [1 - zz^*, zz^*]$,. Thus, $(1 - zz^*) \oplus 1 \precsim 1$.

(iv): The subset $I(1) \subseteq B$ is a closed ideal of B by Lemma 2.5.3(i). Thus, $1 \in I(1)$, if and only if, $B = I(1)$. By Definition of the ideal $I(1)$ of B, $1 \in I(1)$, if and only if, $1 \oplus 1 \precsim 1 \oplus 0$ in $M_2(B)$.

The latter $1 \oplus 1 \precsim 1$ is the case of Part (i) with $b := 1$, $q := 1$ and $p := 1$. By Part (i), there are projections $p_1, p_2 \in B$ such that $p_1 p_2 = 0$, $p_1 + p_2 \leq 1$, $p_1 \sim_{MvN} 1$ and $p_2 \sim_{MvN} 1$. It says that there exists elements $S, T \in B$ with $S^*S = 1 = T^*T$ with $S(S^*) = p_1$ and $T(T^*) = p_2$. This are isometries with $S^*T = S^*(SS^*)(TT^*)T = S^*p_1p_2T = 0$. □

Remark 2.5.8. The relations $v^*v = q$, $vv^* \leq p$, $w^*w = p$ and $ww^* \leq q$ in Part(ii) of Lemma 2.5.7 do not imply W-vN equivalence: This can be seen in stable simple purely infinite C^*-algebras: The W-vN equivalence classes of projections in $B \otimes \mathbb{K}$ correspond bijective to the elements of $\mathrm{K}_0(B)$ but all non-zero projections in $p, q \in B \otimes \mathbb{K}$ satisfy $p \approx q$.

Corollary 2.5.9. *Let A a unital C^*-algebra. Then 1_A is properly infinite in A, if and only if, A/J contains a non-unitary isometry for each closed ideal $J \neq A$ of A.*

Proof. Part (v) of Lemma 2.5.3 says that 1 is properly infinite in A, if and only if, $\pi_J(1) = 1_{A/J} \in A/J$ is infinite in A/J for each closed ideal $J \neq \{0\}$ of A. By Part (iii) of Lemma 2.5.7, $1_{A/J}$ is infinite in A/J, if and only if, there exists a non-unitary isometry in A/J. □

Remark 2.5.10. The closed ideal $I_A(a)$ is always contained in the closed ideal $J(a)$ of A generated by a, and $J(a) = I_A(a)$ if and only if a is properly infinite. Then $J(a)$ is equal to the closure of $\bigcup_n A \cdot (a^*a - 1/n)_+ \cdot A$, i.e., of the *set* of products $b \cdot (a^*a - 1/n) \cdot c$, with $b, c \in A$ ([38]).

The Definition 2.0.4 of property pi(n) immediately allows to see that it implies that each non-zero $(n+1)$-homogenous element is properly infinite in A if A has property pi(n). But the Corollary 2.7.18 of Proposition 2.7.16 gives the better result that all non-zero n-homogenous elements are properly infinite in A with property pi(n). It implies that $\ell_\infty(A)$ has no irreducible representation on a Hilbert space of dimension $\geq n$, and that property pi(n) passes to $\ell_\infty(A)$ if A has property pi(n).

Property pi-n in Definition **??** implies property pi(m) for some $m \leq n$, but no explicit *lower* bound for m is known. The non-trivial direction is, that each C^*-algebra with property pi(m) has property pi-n for some $n \geq m$, but it seems that some property of the ideal system of the multiplier algebra plays a certain role.

For real-rank zero C^*-algebras they are all the same and say that each non-zero projection is infinite.

Some sensible property of the definitions of infiniteness of elements can be seen in the C^*-subalgebra $A \subseteq \mathrm{C}([0,1], \mathcal{O}_2)$ of operator-valued functions

$$f\colon [0,1] \to \mathcal{O}_2 := C^*(s_k\,;\; s_k^*s_k = 1 = s_1s_1^* + s_2s_2^*)$$

with $f(1) \in M_{2^\infty} \subseteq \mathcal{O}_2$. There $f \in A_+$ is infinite if and only if $f(1) = 0$. The – inside A – properly infinite element f given by the function $f(t) := (1-t)s_1s_1^* \in$

[38] But it seems that the latter property does not imply always that a is properly infinite. Examples for that?

$C_0([0,1),\mathcal{O}_2)$ has the property that no element $g\in A_+$ with $\|g\|\leq 1$ and $gf=f$ can be infinite in A.

LEMMA 2.5.11. *Let* $b:=\sum_{k=1}^m a_k$ *with* $a_1,\ldots,a_m\in A_+$.

If the elements $a_k\otimes 1_n$ *are all properly infinite in* $M_n(A)$, *i.e., if* $a_k\otimes 1_{n+1}\precsim a_k\otimes 1_n$ *for* $k=1,\ldots,n$, *then* $b\otimes 1_{m\cdot n}$ *is properly infinite in* $M_{m\cdot n}(A)$.

PROOF. Notice that $b\precsim (a_1\oplus\ldots\oplus a_m)\leq b\otimes 1_m$ in $M_m(A)$, and that $(a_1\oplus\ldots\oplus a_m)\otimes 1_{n+1}\precsim (a_1\oplus\ldots\oplus a_m)\otimes 1_n$ in $M_{m\cdot n}(A)$, because the $a_k\otimes 1_n$ are properly infinite in $M_n(A)$.

Induction over $k\in\mathbb{N}$ gives that $(a_1\oplus\ldots\oplus a_m)\otimes 1_{k+n}\precsim (a_1\oplus\ldots\oplus a_m)\otimes 1_n$.

Gives $b\otimes 1_{k+n}\precsim b\otimes 1_{mn}$. for all $k\in\mathbb{N}$. In particular, $b\otimes 1_{1+(mn)}\precsim b\otimes 1_{mn}$, i.e., $b\otimes 1_{mn}$ is properly infinite. □

EXAMPLE 2.5.12. There exist a closed ideal $J\lhd A$ and $a\in A_+$ with $J\subseteq D:=\overline{aAa}$, such that D is stably finite and $I(d)=\{0\}$ for all $d\in D$ (hence A is stably finite), but $\pi_J(a)=a+J$ is properly infinite in A/J.

Indeed: By an "opposite version" of a theorem of Glimm in [**438**, cor.1.4(v)] there exists a hereditary C^*-subalgebra D of the CAR-algebra $B:=M_{2^\infty}$ such that the unital two-sided normalizer algebra $A:=\mathcal{N}(D,B)\subseteq B$ of D in B satisfies $A/D=\mathcal{O}_2$. Then $a:=1\in A$ satisfies that the C^*-subalgebra $\overline{aAa}=A\subseteq B$ is stably finite, i.e., $I(a\otimes 1_n)=\{0\}$ for all $n\in\mathbb{N}$. But $\pi_J(a)$ is the properly infinite unit of $\mathcal{O}_2$ for $J:=D\lhd A$.

EXAMPLE 2.5.13. The unit element 1 of the unitization $\widetilde{A}$ of $C_0((0,1],\mathcal{O}_2)$ is a *stably finite* element of $\widetilde{A}$.

More generally, the unit element 1_A of the "join" algebras

$$A:=\mathcal{E}_{\max}(B,C)\subseteq C([0,1],B\otimes^{\max}C)$$

of unital algebras B and C, or its quotient

$$A:=\mathcal{E}(B,C)\subseteq C([0,1],B\otimes^{\min}C)$$

is stably finite if $1_n\otimes 1_B$ finite in $M_n\otimes B$ for all $n\in\mathbb{N}$.

Even more generally, 1_A is infinite in A if and only if $1_A=T^*T$ for some non-unitary isometry $T\in A$, cf. Lemma 2.6.8(i).

In the next lemma we can replace the pair $(\varepsilon,2\varepsilon)$ with $0<\varepsilon<\|a\|/2$ obviously by any pair of positive reals $0<\delta<\gamma<\|a\|$, simply by passing from a to $f(a)$ with a suitable strictly increasing continuous real function $f\in C_0(0,\|a\|]_+$ on $[0,\|a\|]$ with $f(0)=0$.

LEMMA 2.5.14. *Let* B *a* C^**-algebra,* $a\in B_+$ *non-zero,* $\varepsilon\in(0,\|a\|/2)$ *and denote by* J *the closed ideal that is generated by the two-sided annihilator*

$$\operatorname{Ann}((a-2\varepsilon)_+,B)\;:=\;\{\,b\in B\,;\;b\,(a-2\varepsilon)_+\;=\;0\;=\;(a-2\varepsilon)_+\,b\,\}$$

of $(a-2\varepsilon)_+$ *in* B.

(i) *If* $(a-\varepsilon)_+$ *is in* J *then* $J = B$*, i.e., then* $\mathrm{Ann}((a-2\varepsilon)_+, B)$ *is a* full *hereditary C^*-subalgebra of* B*.*

(ii) *The hereditary C^*-subalgebra* $\mathrm{Ann}((a-2\varepsilon)_+, B)$ *is full in* B *if there exists* $b \in B$ *that satisfies the equations:*

$$b^*(a-2\varepsilon)_+ = 0 \quad and \quad b^*b = (a-\varepsilon)_+ \,. \tag{5.1}$$

If, moreover, the elements of $\mathrm{Ann}((a-2\varepsilon)_+, B)$ *are properly infinite, then conversely the fullness of* $\mathrm{Ann}((a-2\varepsilon)_+, B)$ *implies the existence of* $b \in B$ *that satisfies Equations* (5.1)*.*

More generally, $\mathrm{Ann}((a-2\varepsilon)_+, B)$ *is full in* B *if there exist elements* $u, v \in B$ *and* $\delta > 0$ *such that* $(vv^* - \delta)_+ = (a-2\varepsilon)_+$*,* $u^*(vv^*-\delta)_+ = 0$*, and* $[u] \geq [v]$ *in* $\mathrm{Cu}(B)$*.*

(iii) *If* $J \neq B$ *then* B/J *is unital, and* $\pi_J((a-\varepsilon)_+)$ *is invertible in* B/J *with spectrum in* $[\,\varepsilon,\, \|a\| - \varepsilon\,]$*.*

In particular, $\pi_J(a)$ *is invertible in* B/J*, if and only if,* $\pi_J(a) \neq 0$*.*

Proof. Let $\varepsilon, \mu > 0$. Define $f_\mu(t) := \min\{\,1,\, (t/\mu - 1)_+\,\}$ for $t \in [0, \infty)$, i.e., $f_\mu(t) := 0$ for $t \leq \mu$, $f_\mu(t) := t/\mu - 1$ for $t \in [\mu, 2\mu]$ and $f_\mu(t) := 1$ for $t \in [2\mu, \infty)$. Notice that $\mu f_\mu(t) \leq \max(t-\mu, 0)$ and $(1 - f_\mu(t))\max(t - 2\mu, 0) = 0$.

(i,iii): Let $a \neq 0$, $0 < \varepsilon < \|a\|/2$ and let J denote the closed ideal J of B, generated by $\mathrm{Ann}((a-2\varepsilon)_+, B)$.

The ideal $C^*(a) \cap J$ of the C^*-subalgebra $C^*(a) \subseteq B$ contains the closed ideal K of $C^*(a)$ that is generated by $(1 - f_\varepsilon(a)) \cdot C^*(a)$ because $f_\varepsilon(t) = 1$ for $t \geq 2\varepsilon$.

It follows that the non-zero values of the spectrum of $\pi_J((a-\varepsilon)_+)$ are contained in the spectrum of $\pi_K((a-\varepsilon)_+)$ in $C^*(a)/K$. The latter is contained in $[\varepsilon, \|a\| - \varepsilon]$ if $2\varepsilon < \|a\|$.

The elements $(1 - f_\varepsilon(a))a$ and $f_\varepsilon(a) - f_\varepsilon(a)^2$ are contained in $K \subseteq J$. It follows that $P := \pi_J(f_\varepsilon(a))$ is a projection in B/J.

The equation $(1 - f_\varepsilon(a))(a - 2\varepsilon)_+ = 0$ implies that $b - f_\varepsilon(a))b \in J$ for all $b \in B$, because

$$(1 - f_\varepsilon(a))B(1 - f_\varepsilon(a)) \subseteq \mathrm{Ann}((a-2\varepsilon)_+, B) \subseteq J\,.$$

Thus, P is the unit element of B/J if $J \neq B$, and then $\varepsilon P \leq \pi_J((a-\varepsilon)_+) \leq (\|a\| - \varepsilon)P$. We get that $\pi_J((a-\varepsilon)_+)$ and $\pi_J(a)$ are invertible in B/J with inverses of norms $\leq \varepsilon^{-1}$, respectively $\leq (2\varepsilon)^{-1}$.

The equation $J = B$ is equivalent to $(a-\varepsilon)_+ \in J$ because that latter causes $P = 0$.

(ii): If $a \in J = B$ then there exist $b_1, \ldots, b_n \in B$ with $b_k b_k^*(a - 2\varepsilon)_+ = 0$ and $\sum_{k=1}^n b_k^* b_k = (a - \varepsilon/2)_+\,$.

If the elements of $\mathrm{Ann}((a-2\varepsilon)_+, B)$ are properly infinite, then it follows that there exists $\gamma > 0$ and $d_1, d_2 \in B$ such that

$$\sum_{k=1}^{n} (d_1 b_k d_2)^* (f-\gamma)_+ (d_1 b_k d_2) \;=\; (a-\varepsilon)_+$$

for the element $f := \sum_{k=1}^{n} b_k b_k^*$ of $\mathrm{Ann}((a-2\varepsilon)_+, B)$.

By assumption on $\mathrm{Ann}((a-2\varepsilon)_+, B)$, the element f is properly infinite. It implies that there exist $g_1, \ldots, g_n \in B$ such that $g_j^* f g_k = \delta_{jk}(f-\gamma)_+$. The element $b := \sum_{k=1}^{n} f^{1/2} g_k d_1 b_k d_2$ satisfies $bb^*(a-2\varepsilon)_+ = 0$ and $b^*b = (a-\varepsilon)_+$.

If there exists $b \in B$ with $bb^*(a-2\varepsilon)_+ = 0$ and $b^*b = (a-\varepsilon)_+$, then $(a-\varepsilon)_+ \in J$. It implies $J = B$ by Part (i). (This particular observation do not use an assumption on infiniteness of elements in $\mathrm{Ann}((a-2\varepsilon)_+, B)$.)

Suppose, more generally, that there exist elements $u, v \in B$ and $\delta > 0$ such that $(vv^* - \delta)_+ = (a-2\varepsilon)_+$, $u^*(vv^*-\delta)_+ = 0$, and $[u] \geq [v]$ in $\mathrm{Cu}(B)$.

Then $vv^* \precsim u^*u$, and there exist $d \in B$ with $d^*u^*ud = (vv^*-\delta/2)_+ \sim_{MvN} (v^*v - \delta/2)$. The element $b := ud$ satisfies $b^*(vv^*-\delta)_+ = 0$ and $b^*b = (vv^*-\delta/2)_+$.

Thus $\mathrm{Ann}((vv^*-\delta)_+, B) = \mathrm{Ann}((a-2\varepsilon)_+, B)$ is full in B, because we can take $(vv^*, \delta/2)$ in place of (a, ε) in our former considerations.

In case where $\mathrm{Ann}((a-2\varepsilon)_+, B)$ is full and purely infinite, we can find the above considered element b and can define $u := b$, $v := b^*$, $\delta := \varepsilon$. They satisfy the requirements on v, w and δ, because $b^*(b^*b-\varepsilon)_+ = b^*(a-2\varepsilon) = 0$ and $[b] \geq [b]$. □

`Does there exists a ''relative'' variant for some spectral p.i. elements in` $e \in J$??

LEMMA 2.5.15 ([**462**]). *Let $a \in A_+$ with $A = \overline{aAa}$, and let $J \lhd A$ a closed ideal, such that $\pi_J(a) = a + J$ is properly infinite in A/J. Then:*

(i) *For $b, c_1, c_2, c_3 \in A_+$ holds $c_1 \oplus c_2 \oplus c_3 \precsim b \oplus 0 \oplus 0$ in $M_3(A)$, if and only if, for every $\varepsilon > 0$, there are $f_1, f_2, f_3 \in bA$ and $\gamma > 0$ such that*

$$f_j^*(b-\gamma)_+ f_k \;=\; \delta_{j,k}(c_k-\varepsilon)_+ \quad \text{for } j,k = 1,2,3\,.$$

(ii) *For every $\varepsilon > 0$,there exist elements $a_1, a_2 \in A_+$, $e \in J_+$ and $n \in \mathbb{N}$, such that $a_1 a_2 = 0$, $(a_1 + a_2)e = 0$, and $(a-\varepsilon)_+ \precsim a_k \oplus (e \otimes 1_n)$ for $k = 1, 2$.*

(iii) *If each $0 \neq e \in J_+$ is properly infinite, then a is properly infinite.*

PROOF. We give here a proof that contains more details than in [**462**].

(i): Let $c := c_1 \oplus c_2 \oplus c_3$ and $\varepsilon > 0$. By Lemma A.6.1(vi), there are $F \in M_3(A)$ and $\delta > 0$ with $(c-\varepsilon)_+ \;=\; F^*((b-\delta)_+ \oplus 0 \oplus 0)F$.

We define $f_k := \xi(b)F_{1,k}$ for $k \in \{1,2,3\}$, where $\xi \in \mathrm{C}_0(0, 1+\|b\|]$ is given by $\xi(t) := \min(1, (2/\delta)\max(0, t-\delta/2))$.
Then $f_k \in bA$ and the row $G := [f_1, f_2, f_3] \in M_{1,3}(A) \subset M_3(A)$ satisfies

$$(c-\varepsilon)_+ = F^*((b-\delta)_+ \oplus 0_2)F \;=\; G^*((b-\delta)_+ \oplus 0_2)G\,.$$

(ii): Let $\varepsilon \in (0, \|\pi_J(a)\|)$ and $\mu := \varepsilon/3$. Since $\pi_J(a) \otimes 1_3 \precsim \pi_J(a)$ by proper infiniteness of $\pi_J(a)$, and since always $a \approx a^2$, there exist $g_1, g_2, g_3 \in A/J$ and $\delta > 0$ with $g_i^* \pi_J((a-\delta)_+) g_j = \delta_{i,j} \pi_J((a-\mu)_+)$. If we let $x_k := \pi_J((a-\delta)_+)^{1/2} g_k$, then

$$(x_k x_k^* - \mu)_+ \sim (x_k^* x_k - \mu)_+ = \pi_J((a-2\mu)_+)\,,$$

in A/J, and there is a (unique) C^*-morphism $\varphi\colon \mathrm{C}_0(0,1] \otimes M_3 \to A/J$ with $\varphi(f_0 \otimes p_{ij}) = x_i(x_j^*)$. The C^*-algebras $\mathrm{C}_0(0,1] \otimes M_n$ are projective by Proposition A.8.4 in the sense of Definition A.8.1 in Appendix A . It implies that there exists a C^*-morphism $\psi\colon \mathrm{C}_0(0,1] \otimes M_3 \to A$ with $\pi_J \circ \psi = \varphi$, cf. also Lemma 2.1.15 and Remark 2.1.16 concerning the projectivity of $\mathrm{C}_0((0,1], M)$, for C^*-algebras M of finite dimension.

Let $b_k := \psi(f_0 \otimes p_{kk})$, for $k = 1, 2, 3$ and take $y_k \in A$ with $\pi_J(y_k) = x_k$. Then $b_1 \sim b_2 \sim b_3$, $b_j b_k = 0$ for $j \neq k$, and define

$$z_k := \big(y_k^*(b_k - \mu)_+ y_k\big) - \big((a-2\mu)_+ \cdot (a-\mu)_+\big) \in J\,.$$

Thus, $(a-2\mu)_+ \precsim (b_k - \mu)_+ \oplus v$ for $k = 1, 2$ and $v := |z_1| + |z_2|$. It follows, that there exists $\gamma > 0$ such that, for $k = 1$ and $k = 2$, holds

$$(a-\varepsilon)_+ \precsim (b_k - \mu)_+ \oplus (v-\gamma)_+\,.$$

The annihilator $D := \mathrm{Ann}((b_1 + b_2 - \mu)_+, A)$ is a hereditary C^*-subalgebra of A that contains b_3 . It implies that $b_1 + b_2$ is in the closed ideal generated by D, and that D is full by Lemma 2.5.14. Since D is full, also $J \cap D$ is full in J , i.e., $\mathrm{span}(J(D \cap J)_+ J)$ is dense in J .

It follows that there exist $d_1, \ldots, d_n \in J$ and $e \in (D \cap J)_+$ with $\sum_j d_j^* e d_j = (v-\gamma)_+$. In particular, $(v-\gamma)_+ \precsim e \otimes 1_n$.

(iii): Let $\varepsilon > 0$, $a_1, a_2, e \in A_+$ and $n \in \mathbb{N}$ as in Part (ii). Then

$$(a-\varepsilon)_+ \oplus (a-\varepsilon)_+ \precsim a_1 \oplus a_2 \oplus (e \otimes 1_{2n})\,.$$

Since e is properly infinite, and since a_1, a_2, e are pairwise orthogonal, we get:

$$((a \otimes 1_2) - \varepsilon)_+ \precsim a_1 \oplus a_2 \oplus e \sim a_1 + a_2 + e \precsim a\,,$$

because a is a strictly positive element of A. Since $\varepsilon > 0$ is arbitrary, we obtain $a \otimes 1_2 \precsim a$. □

DEFINITION 2.5.16. We say that $0 \neq b \in A_+$ is **spectral properly infinite** if $(b-t)_+$ is properly infinite in A for each $t \in (0, \|b\|)$. (See Section 1 or Definition 2.5.1 of properly infinite elements.)

LEMMA 2.5.17. *Let A a C^*-algebra and $\varepsilon > 0$.*

(o) *Each $b \in A_+ \setminus \{0\}$ is spectral properly infinite, if and only if, A is a purely infinite C^*-algebra.*

(i) *If $b \in A_+$ is spectral properly infinite in sense of Definition 2.5.16, then elements $d_1, d_2 \in A$ with $d_j^* b d_k = \delta_{j,k}(b-\varepsilon)_+$ can be found with norm-bound $\|d_j\|^2 \leq 2\|b\|/\varepsilon$.*

(ii) *If the positive part A_+ of a C^*-algebra A contains a dense subset $X \subseteq A_+$ such that each $b \in X$ is spectral properly infinite, then A is purely infinite, i.e., each non-zero $a \in A_+$ is properly infinite.*

PROOF. (o): By definition, A is purely infinite if each non-zero element $a \in A_+$ is properly infinite. In particular $(b-t)_+$ is properly infinite in A for each $b \in A_+$ and $t \in (0, \|b\|)$.

(i): Let $b \in A_+$ spectral properly infinite, and $\varepsilon = 2\delta \in (0, \|b\|)$. There exist $g_1, g_2 \in A$ with $g_j^*(b-\delta)_+ g_k = \delta_{jk} \cdot (b-2\delta)_+$ because $(b-\delta)_+$ is properly infinite. Then $d_k := b^{-1/2}(b-\delta)_+^{1/2} g_k$ is in A and $\|d_k\|^2 \leq \delta^{-1}\|(b-2\delta)_+\|$, because $\delta(t-\delta)_+ \leq t(t-\delta)_+$ for $t \in (0, \infty)$, and $A_+ \ni a \mapsto \|g_k^* a\, g_k\| \in \mathbb{R}_+$ is order monotone.

(ii): Let $a \in A_+$ with $\|a\| = 1$ and $\varepsilon > 0$. There exists $b \in X$ with $\|b - a\| < \gamma := \varepsilon/3$. It implies $\|(b-2\gamma)_+ - a\| < 3\gamma$, because $\|(b-2\gamma)_+ - b\| \leq 2\gamma$.

By Lemma 2.1.9 there exists *contractions* $d_1, d_2 \in A$ with $d_1^* a d_1 = (b-\gamma)_+$ and $d_2^*(b-2\gamma)d_2 = (a-3\gamma)_+$.

By assumption, each $b \in X$ is spectral properly infinite, thus $(b-\gamma)_+$ is properly infinite for each $\gamma \in (0, \|b\|)$, i.e., $(b-\gamma)_+ \oplus (b-\gamma)_+ \precsim (b-\gamma)_+$, and we find $e_1, e_2 \in A$ with $e_j^*(b-\gamma)_+ e_k = \delta_{jk}(b-2\gamma)_+$. It follows that $c_k := d_1 e_k d_2$ satisfies $c_j^* a c_k = \delta_{jk}(a-3\gamma)_+$. Thus, each $a \in A_+$ is properly infinite and A is purely infinite. □

EXAMPLE 2.5.18. Let $a_1, a_2, \ldots \in \mathbb{K} := \mathbb{K}(\ell_2(\mathbb{N}))_+$ defined by $a_n := \mathrm{diag}(1, (n+1)^{-1}, (n+1)^{-2}, \ldots)$ then each a_n is properly infinite, and the sequence $(a_1, a_2, \ldots)$ is decreasing with norm-limit $(1, 0, 0, \ldots)$ in $\mathbb{K}$. Thus, convergent sequence of of properly infinite contractions have in general no properly infinite limit.

Are they really properly infinite?

Does there exist $d_k \in \mathbb{K}$ with

$$\mathrm{diag}(1, 1, 1/n, 1, n, 1/n^2, 1/n^2, \ldots) = \lim_k d_k^* \,\mathrm{diag}(1, 1/n, 1/n^2, \ldots) d_k$$

in norm?

$(1, 1/n, 1/n^2, \ldots) \precsim (1, 1/n^2, 1/n^4, 1/n^6, \ldots) \oplus (1/n, 1/n^3, 1/n^5, 1/n^7 \ldots) \approx (1, 1/n, 1/n^2, 1/n^3, \ldots) \oplus (1, 1/n, 1/n^2, 1/n^3, \ldots)$ via $d_k := a_k \oplus b_k$ $a_k := (1, n^{1/2}, n, 1/n^6, \ldots)$

The above technical lemmata on the properties of the Cuntz-relation $\precsim$ and $\approx$ yield almost immediately the following permanence properties of the class of purely infinite C^*-algebras.

Notice that $A \otimes \mathrm{C}_0(0,1]$ is not in this list.

PROPOSITION 2.5.19 (Permanence of pure infiniteness). *The class of (not necessarily simple) purely infinite C^*-algebras A is invariant under following operations:*

(i) *passage to quotients* A/J,
(ii) *inductive limits,*
(iii) *infinite direct products* $\ell_\infty(A_1, A_2, \ldots)$ *and ultrapowers* A_ω,
(iv) *passage to hereditary* C^**-subalgebras* $D = DAD$,
(v) *Morita equivalence, and*
(vi) *extensions.*

PROOF. Recall that A is purely infinite, if and only if, for each $a \in A$,

$$a \in I(a) := \{b \in A;\ b \oplus a \precsim a\},$$

and recall that $I(a)$ is a closed ideal of A by Lemma 2.5.3(i).

(i): If $a \in A \setminus J$ is properly infinite in A, i.e., $a \in I(a)$, then $\pi_J(a) = a + J$ is properly infinite in A/J, i.e., $\pi_J(a) \in I(\pi_J(a))$ because $\pi_J(I(a)) \subseteq I(\pi_J(a))$ by Lemma 2.5.3(v). Thus, each quotient A/J by a closed ideal $J \neq A$ of A is purely infinite if the C^*-algebra A is purely infinite.

(ii): If $\{ h_{\sigma,\tau} \colon A_\sigma \to A_\tau\}_{\tau,\sigma \in T}$ is a directed net of C^*-morphisms,

$$A := \operatorname{indlim}_{\tau \to T}(h_{\sigma,\tau} \colon A_\sigma \to A_\tau)$$

is the (canonical) inductive limit of C^*-algebras, then A is generated by the upward directed net of the images of $h_{\sigma,\infty} \colon A_\sigma \to A$. Thus, A contains an upward directed net of C^*-subalgebras $h_{\sigma,\infty}(A_\sigma)$ that are quotients of purely infinite C^*-algebras. By Part (i), this C^*-subalgebras are purely infinite. The elements of the images build together a dense *-subalgebra of A. The elements $(a^*a - t)_+$ in the positive part of this *-subalgebra are properly infinite. By Lemma 2.5.17(ii) this implies that A is purely infinite.

(iii): Let $A_1, A_2, \ldots$ a sequence of purely infinite C^*-algebras, $a_n \in A_n$ positive contractions (possibly $a_n = 0$), and $\varepsilon > 0$.

For $n \in \mathbb{N}$ with $a_n \neq 0$ there exist by Lemma 2.5.17(i) elements $d_1^{(n)}, d_2^{(n)} \in A_n$ with

$$\|d_k^{(n)}\|^2 \leq 2\|a_n\|/\varepsilon$$

and

$$(d_j^{(n)})^* a_n d_k^{(n)} = \delta_{j,k}(a_n - \varepsilon)_+ .$$

Let $a := (a_1, a_2, \ldots)$ and $d_k := (d_k^{(1)}, d_k^{(2)}, \ldots)$ $(k = 1, 2)$, where we put $d_k^{(n)} = 0$ if $a_n = 0$. Then $d_k \in \ell_\infty(A_1, A_2, \ldots)$ and $d_j^* a d_k = \delta_{j,k}(a - \varepsilon)_+$. Hence, each positive contraction in $\ell_\infty(A_1, A_2, \ldots)$ is properly infinite.

The ultrapower A_ω is purely infinite by Part (i), because it is a quotient of $\ell_\infty(A)$.

(iv): If D is a hereditary C^*-subalgebra of A, $a \in D$ and a is properly infinite in A, i.e., $a \in I_A(a)$, then a is properly infinite in D, i.e., $a \in I_D(a)$, because $I_D(a) = I_A(a) \cap D$ by Lemma 2.5.3(ii). Hence, D is purely infinite if A is purely infinite.

(v): Clearly, a C^*-algebra B is purely infinite if there exists a purely infinite C^*-algebra D and a *-isomorphism from D onto B,

Two C^*-algebras B_1 and B_2 are Morita equivalent (in the category of C^*-algebras), if there exists a C^*-algebra A and *-monomorphisms $\varphi_k \colon B_k \to A$ with $k \in \{1, 2\}$ such that $D_k := \varphi_k(B_k)$ are *full* hereditary C^*-subalgebras of A. Here "*full*" means that A is the closure of the ideal in A generated by D_k.

We know from Part (iv) that a hereditary C^*-subalgebra D of A is purely infinite if A is purely infinite.

It follows that the invariance of pure infiniteness under Morita equivalence is equivalent to the following statement:
C^*-algebras A are purely infinite if they contain a full hereditary C^*-subalgebra D that is purely infinite.

We show more generally that a purely infinite hereditary C^*-subalgebra D of A generates a purely infinite closed ideal J of A.

Let D a purely infinite hereditary C^*-subalgebra of A and let $J := \overline{\mathrm{span}(ADA)}$ the ideal J of A generated by D.

Let $a \in J_+ \subseteq A_+$ and $\varepsilon > 0$. There exist $b_1, \ldots, b_n \in D_+$ and $f_1, \ldots, f_n \in A$ with

$$\| \sum_{k=1}^{n} f_k^* b_k f_k - a \| < \varepsilon/2\,.$$

It follows for $b := b_1 + \cdots + b_n \in D_+$ that $a \leq \varepsilon/2 + \sum_{k=1}^n f_k^* b f_k$, calculated in $A + \mathbb{C}1 \subseteq \mathcal{M}(A)$. Let $\gamma := \| \sum_{k=1}^n f_k^* f_k \|$ and $\nu := \varepsilon/(2 + 3\gamma)$.

By assumption on D, $b \in D_+$ is properly infinite in D. Thus, $b \otimes 1_n \precsim b$ inside D, and there exist $e_1, \ldots, e_n \in A$ with $e_j^* b e_k = \delta_{jk}(b - \nu)_+$. The element $g := \sum_k e_k d_k$ satisfies $g^* b g = \sum_{k=1}^n d_k^* (b - \nu)_+ d_k$ and $a \leq \varepsilon/2 + g^* b g$.

By Lemma 2.1.9, there exists a contraction $h \in A$ such that $(a - \varepsilon)_+ = z^* z$ for $z := (\sum_k (b - \nu)_+^{1/2} d_k) h$.

Since $zz^* \in D$ and $z^* z = (a - \varepsilon)_+$ we get $[zz^*] = [z^* z] = [(a - \varepsilon)_+] \leq [a]$ and $[zz^*] + [zz^*] \leq [zz^*] \leq [a]$. It follows that $[(a - \varepsilon)_+] + [(a - \varepsilon)_+] \leq [a]$ for all $\varepsilon > 0$. But this is equivalent to $[a] + [a] \leq [a]$, i.e., to $a \oplus a \precsim a$ in J, and a is properly infinite in J. This shows that for each $a \in J_+ \setminus \{0\}$, and shows that J is purely infinite.

Alternatively expressed: Take $a \in J_+$ and verify that for each $\varepsilon \in (0, \|a\|)$ the element $(a - \varepsilon)_+$ is M-vN-equivalent to some element in D_+. The use that proper infiniteness is invariant under M-vN equivalence.

(vi): Let $J \triangleleft A$ a purely infinite closed ideal with purely infinite quotient A/J, and let $a \in A_+$.

We can replace A by its hereditary C^*-subalgebra $D := \overline{aAa}$. Then still $D \cap J$ and $D/(D \cap J) \cong \overline{\pi_J(a)(B/J)\pi_J(a)}$ are purely infinite by Parts (i) and (iv). Then

aDa is dense in D and $\pi_J(a)$ is properly infinite in $D/(D\cap J)$. Thus, Lemma 2.5.15(iii) applies and a is properly infinite in A.

This applies to each $a \in A_+$ and shows that A is purely infinite. □

We underline that some proofs of similar permanence properties for the classes of weakly purely infinite and of strongly purely infinite C^*-algebras are much more involved. The latter class of C^*-algebras is relevant for our classification. Up to now (2019) it is unknown if this three infiniteness properties (locally, weakly, pi(1)) are different or not, even in the case of separable nuclear C^*-algebras. It is also unknown if $\mathrm{C}([0,1], A)$ p.i. if A is p.i.

QUESTION 2.5.20. Suppose that A is a C^*-algebra with properly infinite unit element and let $a \in A$ a contraction.

Does there exist isometries $s, t \in A$ with $3\|s^*at\| < 2$?

(The latter is the "squeezing property" of Definition 4.2.14.)

`Compare next with Proof of Prop. 4.2.15(b) and with Prop. ??!!`
`New references give different results??`

The property that for each contraction $a \in A$ there exist isometries $s, t \in A$ with $3\|s^*at\| < 2$ is equivalent to the "*squeezing*" Property (sq) for A, cf. Definition 4.2.14.

It is easy to see that it holds for all unital *strongly* purely infinite C^*-algebras, because it is true for all contractions $a \in A$, if and only if, the positive 2×2-matrix $M := [b_{jk}]$ with entries $b_{11} := b_{22} := 1$ and $b_{21}^* = b_{12} := a$ can be approximately diagonalized with help of a diagonal matrix $D := \mathrm{diag}(d_1, d_2)$ up to $\varepsilon \in (0, 1/2)$, i.e.,

$$\| 1_2 - D^*MD \| < \varepsilon .$$

The Lemma 4.2.13 allows to show that all unital purely infinite (not necessarily simple) C^*-algebras A have the squeezing property, cf. Part (b) of Proposition 4.2.15.

The Property (sq) alone does not imply that a properly infinite unital C^*-algebra A is purely infinite, e.g. take $A := \mathcal{M}(B)$ for $B := \mathrm{C}([0,1], \mathbb{K})$ or $B := M_{2^\infty} \otimes \mathbb{K}$. In the case $B := M_{2^\infty} \otimes \mathbb{K}$ the corona $\mathrm{Q}(B)$ has Property (sq) and is residually antiliminary, but is *not weakly p.i.*.

Question concerning Property (sq):
What happens in case of "properly" infinite non- p.i. *simple* unital A ? Examples? Relations to (Q.1) in real rank zero case?

`Optional one could attempt to use`
`--e.g. in case of linearly ordered ideal lattice --`
`following Definition 2.5.21.`
`But it could be that it is equivalent to ''residually antiliminary''`

Definition 2.5.21. We call a C^*-algebra B "**locally infinite**" if for every pure state ρ on B and each hereditary C^*-subalgebra D of B with $\|\rho|D\| = 1$ there exists a contraction $d := d(D, \rho) \in D$ with $\rho(d^*d) = 1$, $\rho(dd^*) = 0$ and $(dd^* - 1/3)_+ \leq d^*d$.

Where is here really "infiniteness" ??? What is it in case of simple C*-algebras with RR=0?

Definition 2.5.21 implies:

A "locally infinite" C^*-algebra B is **residual antiliminary** in the sense of Definition 2.7.2, because the property of "local infiniteness"

(i) passes to each non-zero quotient and every non-zero hereditary C^*-subalgebra, and
(ii) implies that a pure state ρ on a non-zero hereditary C^*-algebra D of B can not be a non-zero character on D.

It is not difficult to see that for pure states ρ on $D \subseteq B$ ...

Does "l.p.i." or "pi(n)" imply this? (Both pass to hereditary C^*-subalgebras and quotients!)

If $E \subseteq D$ is hereditary, stable and σ-unital with $\rho(E) \neq \{0\}$ then there exists an element $d := d(\rho, D) \in E$ with the properties in Definition 2.5.21...

6. Cases: many projections, linear ordered ideal-lattice ...

`Still to be worked out in detail!!!`

Desired Main Result:

If A has the property that for each closed ideal $J \neq A$ and any non-zero hereditary C^*-subalgebra D of A/J contains a (non-zero) projection $p \in D$, then A is strongly purely infinite, if and only if, A is locally purely infinite, ...

Definition 2.6.1. We say that a C^*-algebra A is *rich of projections* if, for each closed ideal $J \neq A$ of A and non-zero hereditary C^*-subalgebra D of A/J, there exists a non-zero projection $p \in D$.

In particular, A has then the "small projections" property (SP) that requires that every non-zero hereditary C^*-subalgebra D of A contains a non-zero projection.

Among the C^*-algebras that are "rich of projections" are the C^*-algebras A with *real rank zero*, a property that is equivalent to the property that each hereditary C^*-subalgebra D of A contains an approximate unit of D consisting of projections in D, cf. [**73**, thm. 6.5.6].

(We do not know if C^*-algebras that are "rich of projections" have real rank zero, because projections usually do not lift to projections.

It is also not clear if every non-zero hereditary C^*-subalgebra $D \subseteq A$ contains an approximate unit for D consisting of convex combinations of projections ...)

LEMMA 2.6.2. *Let A a unital C^*-algebra. If for each pure state ρ of A there exits a stable C^*-subalgebra $D \subseteq A$ with $\rho(D) \neq \{0\}$ then there exists $n \in \mathbb{N}$ such that $1_A \otimes 1_n \in A \otimes M_n$ is properly infinite in $A \otimes M_n$.*

If there exists a stable C^*-subalgebra $D \subseteq A$ that generates A (in the sense that the linear span of $A \cdot D \cdot A$ is dense in A), then 1_A itself is properly infinite.

PROOF. The algebraic union V of the upward directed family of finite sums of stably generated ideals of A is an ideal of A that is dense in A by its definition, because V can not be in the kernel of any pure state. It implies that $1 \in V$. Thus, 1 is contained in an ideal that is a finite sum of stably generated ideals, i.e., there exists – by assumptions and Part (ii) of Lemma 2.1.7 – stable hereditary C^*-subalgebras $D_1, \ldots, D_n \subset A$ and elements $d_j \in A$ $(j = 1, \ldots, n)$ with $d_1^* d_1 + \ldots + d_n^* d_n = 1$ and $d_j d_j^* \in D_j$.

The $n \in \mathbb{N}$ with this property can be chosen minimal with the property that the sum of ideals generated by the D_j contains 1, because if $d_j d_j^*$ and $d_k d_k^*$ both are in a closed ideal J that is generated by some stable C^*-subalgebra D, then one can find $d \in A$ with $dd^* \in D$ and $d^* d = d_j^* d_j + d_k^* d_k$, because $\mathcal{M}(D)$ contains isometries $S_1, S_2 \in \mathcal{M}(D)$ with $S_1^* S_2 = 0$.

The stability of the D_j causes that its two-sided multiplier algebra $\mathcal{M}(D_j)$ contains a copy B_j of $\mathcal{E}_{2n}$ generated by $2n$ isometries $S_{jk} \in B_j$, $k \in \{1, \ldots, 2n\}$, with mutually orthogonal ranges:
$S_{jk}^* S_{j,\ell} = \delta_{k,\ell} 1_j$, where 1_j denoted the unit element of $\mathcal{M}(D_j)$.

Consider the two $n \times n$ matrices $T_0 := [T_{j,k,0}]$ and $T_1 := [T_{j,k,1}]$ in $M_n(A)$ with entries $T_{j,k,0} := S_{j,k} d_k$ and $T_{j,k,1} := S_{j,(k+n)} d_k$ for $j, k \in \{1, \ldots, n\}$ then $T_x^* T_y = \delta_{x,y} \cdot 1_n$ for $x, y \in \{0, 1\}$.

Thus, $1_n \in M_n(A)$ is properly infinite.

In case that a single hereditary C^*-subalgebra D generates A then there exist $d_1, d_2 \in A$ with $d_1 d_1^* + d_2 d_2^* \in D$, $d_1^* d_2 = 0$ and $d_1^* d_1 = d_2^* d_2 = 1$. □

LEMMA 2.6.3. *The class of C^*-algebras $A, B, \ldots$ that are rich of projections is invariant under following operations:*

(i) *passage to non-zero hereditary C^*-subalgebras $D \subseteq A$,*
(ii) *passage to non-zero quotients A/J,*
(iii) *extensions $0 \to A \to E \to B \to 0$,*
(v) *building inductive limits,*
(iv) *passage to a Morita equivalent algebras. In particular A is rich of projections, if and only if, $A \otimes \mathbb{K}$ is rich of projections.*

Each C^*-algebra A that is rich of projections is the inductive limit of the net of separable C^*-subalgebras that are rich of projections and are relatively weakly injective in A.

PROOF. `to be filled in` ?? □

PROPOSITION 2.6.4. *Suppose that a C^*-algebra A is rich of projections in the sense of Definition 2.6.1. Then the following properties (i)–(iii) are equivalent:*

(i) *For each closed ideal $J \neq A$ and nonzero hereditary C^*-subalgebra $D \subseteq A/J$ the algebra D contains a (non-zero) infinite projection $q \in D$.*
(ii) *A is locally purely infinite in sense of Definition 2.0.3.*
(iii) *A is purely infinite, cf. Definition 1.2.1.*

The C^*-algebra A is strongly purely infinite in sense of Definition 1.2.2, if A is purely infinite and has the stronger property that, for each closed ideal J of A and each hereditary C^*-subalgebra $D \subseteq A/J$ there exists a projection $p \in A \setminus J$ with $\pi_J(p) \in D$.

We do not know if for separable C^*-algebras that are "rich of projection" in the fairly weak sense of ?????

Compare with Proposition 2.6.5!

Notice that Part (i) of Proposition 2.6.4 is just the the definition of J. Cuntz for pure infiniteness.

PROOF. Obviously (iv) implies (iii). Part (iii) is equivalent to properties pi(1) and pi-1 on A by Corollary 2.5.6, and property pi(n) implies that A is locally purely infinite, i.e., Part (ii).

⇐ References?

(ii)⇒(i):

(i)⇒(iii):

(iii)⇒(ii):

Still not understood... (iii)⇒(iv): Perhaps wrong ?? **??** □

From (ii) to (i):

First step:

Suppose that A is is locally purely infinite, i.e., for each non-zero $b \in A_+$ and pure state λ on $E := \overline{bAb}$ there exists a C^*-morphism $\psi \colon \mathrm{C}_0(0,1] \otimes \mathbb{K} \to E$ with $\lambda \circ \psi \neq 0$.

We show that it implies that, for each closed ideal $J \neq A$ of A, every nonzero hereditary C^*-subalgebra $D \subseteq A/J$ and every non-zero projection $p \in D$, there exists $n \in \mathbb{N}$ such that $p \otimes 1_n$ is properly infinite in $D \otimes M_n$. (The multiplicity n could depend here from p, D and J.)

Let J, $D \subseteq A/J$ given and $p \in D \subseteq A/J$ a non-zero projection. We are going to show that for each pure state ρ on the unital C^*-algebra $pDp = p(A/J)p$, – i.e., with $\rho(p) = 1$ –, there exist a stable C^*-subalgebra $G \subseteq pDp$ with $\rho(G) \neq \{0\}$.

By Lemma 2.6.2 it follows that the upward directed net of finite sums of stably generated ideals of pDp must contain p and this implies that $p \otimes 1_n$ is properly infinite in $pDp \otimes M_n$ for suitable $n \in \mathbb{N}$.

There is a nonzero contraction $b \in A_+$ with $\pi_J(b) = p$ and a pure state and $\rho\colon A/J \to \mathbb{C}$ with $\rho(p) = 1$. The state $\xi := \rho \circ \pi_J$ satisfies $\xi(b) = 1$ and is a pure state on $F := \overline{bAb}$. Since A is w.p.i., there exists a C^*-morphism $\psi\colon \mathrm{C}_0(0,1] \otimes \mathbb{K} \to F$ with $\xi \circ \psi \neq 0$. Thus $\rho \circ (\pi_J \circ \psi) \neq 0$. Now the Lemma 2.6.2 applies, and shows that there exists $n \in \mathbb{N}$ such that $p \otimes 1_n$ is properly infinite in $pDp \otimes M_n$.

We combine this with the assumption that A is "rich of projections" in sense of Definition 2.6.1, ...

Let $0 \neq a \in A_+$ and $J \subseteq A$ a closed ideal of A with $a \notin J$, $\delta \in (0, \|\pi_J(a)\|)$, then let $E := \overline{(a-\delta)_+ A (a-\delta)_+}$ and $D := \pi_J(E) \cong E/(E \cap J)$. Then D is a non-zero hereditary C^*-subalgebra of A/J. By the general pre-assumption that A is "rich of projections", there exists a non-zero projection $q \in D \subseteq A/J$.

The above given arguments show that, for a pure state ρ on A/J with $\rho(q) = 1$ there exists a nonzero stable C^*-subalgebra of qDq given by the image of a non-zero morphism $\psi\colon \mathrm{C}_0(0,1] \otimes \mathbb{K} \to qDq = q(A/J)q$ with $\rho \circ \psi \neq 0$. Now we can consider the non-zero hereditary C^*-subalgebra $F := \overline{cAc}$ for some positive contraction $c \in A_+$ with $\pi_J(c) = \psi(f_0 \otimes p_{11})$. Then $G := \pi_J(F)$ is a hereditary C^*-subalgebra of A/J.

By assumption that ... 12.11.2018, not clear which one...

Let $b \in E_+$ a contraction with $\pi_J(b) = p$ and ρ a pure state on A/J with $\rho(p) = 1$ and $\rho(b) = \|b\| = 1$, i.e., there is a pure state ρ_1 on A/J with $\rho := \rho_1 \circ \pi_J$ and $\rho_1(p) = 1$.

`sort best from below:`

By Part (ii), ... there exists C^*-morphism $\psi\colon \mathrm{C}_0(0,1] \otimes \mathbb{K} \to F := \overline{bAb} \subseteq E$ with $\rho \circ \psi \neq 0$.

Let $F := \overline{bAb} \subseteq A$, then $\pi_J(F) = pDp$. By the assumption that A is locally purely infinite there exist a non-zero C^*-morphism $\psi\colon \mathrm{C}_0((0,1], \mathbb{K}) \to F$ with $\rho \circ \psi \neq 0$.

Thus, $\pi_J \circ \psi$ is non-zero, and its image is a non-zero stable hereditary C^*-subalgebra of $\pi_J(F) \subseteq pDp$.

Define $f_0 \in \mathrm{C}_0(0,1]$ by $f_0(t) := t$, and let $H := \psi(f_0 \otimes p_{11})$. Then $G := \overline{H \cdot A \cdot H)} \subset F$ is a hereditary C^*-subalgebra of A with $\pi_J(G) = \overline{HAH}$ ...

`check again`

Then the hereditary C^*-subalgebras of $pDp = \pi_J(F)$ defined by $\overline{\pi_J(G) D \pi_J(G)}$ is a stable hereditary C^*-subalgebra of pDp.

It contains the nonzero hereditary C^*-subalgebra generates a non-zero stable C^*-subalgebra of pDp.

Has then A then the additional property that for each closed ideal J of A and hereditary C^*-subalgebra D of A with $\pi_J(D) \neq \{0\}$ there exists a projection $p \in D$ with $\pi_J(p)$ infinite or zero?

Answer unknown! The assumptions say only that that there is a non-zero projection $q \in \pi_J(D)$. But it is not clear under which circumstances it can be lifted to a projection in $p \in D$ ...

Then A has the property that for each pure state ρ on $\pi_J(D) \subset A/J$ there exists a properly infinite projection $p \in D$ with $\rho(p) \neq 0$?

For separable C^*-algebras A the prime and primitive ideals are the same, cf. [**616**, Prop. 4.3.6]. Thus, if one can reduce a property to (suitably selected) separable C^*-subalgebras and pure states, then separating pure states (from zero) is the same as separating factorial states ...

It seems that one must require also that $\rho(p) \neq 0$ for a given nonzero pure state ρ on D ??

Or that $p = \pi_J(q)$ comes from a projection q

No! It is inclusive in case of pure state!:

One get this, if ρ is any nonzero state on A with $\rho(J) = \{0\}$ and with kernel $I \geq J$ of the cyclic representation defined by ρ. If $\rho|D \neq 0$, then $\pi_I(D) \neq 0$, and $\pi_I(D)$ is a non-zero hereditary C^*-subalgebra of A/I. If $q \in A$ is a nonzero projection with

with by passing to $E := \pi_I(D)$

PROPOSITION 2.6.5. *If a C^*-algebra A has real rank zero, then following properties of A are equivalent:*

(i) *A is p.i.*
(ii) *For every non-zero projection $p \in A$ there exist partial isometries $u, v \in A$ with $u^*u = v^*v = p$ and $uu^* + vv^* \leq p$.*
(iii) *Every quotient of A is purely infinite in the sense of Cuntz, i.e., for every hereditary C^*-subalgebra D and every closed ideal J of A which does not contain D, there is a (non-zero) infinite projection in $D/(D \cap J)$.*
(iv) *A is locally purely infinite.*
(v) *A_∞ has no non-trivial l.s.c. quasi-trace.*

`Compare with Proposition 2.6.4!`

See [**93**, thm. 4.17] for the equivalence of (iii) and (iv). The equivalence of (i), (ii) and (iii) follows from Corollaries 2.15.7(ii) and 2.15.8. Recall here that an infinite projection p is not necessarily properly infinite. It can be shown to be properly infinite only if all $\pi_J(p)$ are infinite or zero for all closed ideals J of A.

PROPOSITION 2.6.6. *If A is a C^*-algebra with linear ordered lattice $\mathcal{I}(A)$ of closed ideals and A is locally purely infinite, then A strongly purely infinite.*

There exist at most one non-zero simple quotient A/J and at most one non-zero simple closed ideal $I \subseteq A$.

If, in addition, A is separable (or σ-unital = A has a strictly positive element) and has no unital quotient, then A is stable.

There are/can exist non-simple unital or stable simple quotients, and there can be non-simple unital quotients:

Consider $\mathcal{L}(\ell_2(N))$ or any extension of a simple separable C^*-algebra by the compact operators.

DEFINITION 2.6.7. A C^*-algebra B has the **small projection property** if every non-zero hereditary C^*-subalgebra D of B contains a non-zero projection.

(If this happens also for all quotients, i.e., for non-zero hereditary $D \subseteq B/J$, then we say that B is *rich of projections*, cf. Definition 2.6.1.)

Suppose that a C^*-algebra B has the small projection property. Then we say that B "*has sufficiently many* **locally bounded dimension functions**" if for each non-zero contraction $a \in B_+$ and each non-zero projection $p \in \overline{aBa}$ there exists a *dimension function* $D\colon B \to [0, \infty]$ with

$$0 < D(p) < \infty \quad \text{and} \quad \sup_{n\in\mathbb{N}} D((a - 1/n)_+) < \infty .$$

We do not require that the dimension function D is lower semi-continuous on $\overline{a\,B_+\,a}$ or bounded. In particular it may happen that $D(a) = \infty$.

Are above Lemma and next two Lemmas 2.6.8 and 2.6.9 used? cited? Otherwise put it into Appendix A/B. Eg. with title "Pure infiniteness for algebras that are rich of projections"?.

There are in next? section some study of projections in locally p.i. algebras. Compare!!!

Recall that $I(a)$ is the closed ideal of A defined for $a \in A$ in Definition 2.5.1 and Lemma 2.5.3(i).

LEMMA 2.6.8. *Let A a C^*-algebra.*

(i) *If $p \in A$ is a projection, then $I(p) \neq 0$, if and only if, pAp contains a non-unitary isometry, i.e., if and only if p is Murray–von-Neumann equivalent to a proper sub-projection $q \leq p$, $q \neq p$ in A.*

   In particular, a projection p is infinite with respect to the family of projections of A, i.e., there exists a non-zero projection $r \in A$ such that $p \oplus r$ is MvN-equivalent in $M_2(A)$ to $p \oplus 0$, if and only if, p is infinite as an element of A_+, i.e., if there exists non-zero $a \in A$ with $[p] + [a] \leq [p]$ in $\mathrm{Cu}(A)$.

(ii) `Exists also in other lemmas:` *If $q \in \overline{cAc}$ is a properly infinite projection, then $c \oplus q \precsim c$, i.e., $q \in I(c)$.*

(iii) `Exists also in other lemmas:` *If p is a properly infinite projection in A and $p \precsim c \in A_+$, then $p \in I(c)$, i.e., $c \oplus p \precsim c$. In particular c is infinite in A.*

(iv) `Where is it used?:` *If A has the "small projection property" of Definition 2.6.7 and has "sufficiently many locally bounded dimension functions" in the sense of Definition 2.6.7, then each non-zero element $a \in A_+$ is finite, i.e., $I(a) = \{0\}$, which says for $b \in A_+$ that $b \oplus a \precsim a$ implies $b = 0$.*

Proof. (i): Let $p \oplus x \precsim p$ with $0 \neq x \in A_+$ and $0 < \varepsilon < \min(\|x\|, 1)$, $\delta \in (0, \varepsilon)$ and $f = [f_1, f_2] \in M_{1,2}(A) \subseteq M_2(A)$ with $f^*(p-\delta)_+ f = (p-\varepsilon)_+ \oplus (x-\varepsilon)_+$. Notice that $(p-t)_+ = (1-t)p$ for $t \in [0,1]$. Then $(1-\delta) f_1^* p f_1 = (1-\varepsilon)p$ and $f_1^* p f_2 = 0$, but $(1-\delta) f_2^* p f_2 = (x-\varepsilon)_+ \neq 0$. Thus, $V := (1-\varepsilon)^{-1/2}(1-\delta)^{1/2} p f_1 p$ is a non-unitary isometry in pAp.

Conversely, if $V \in pAp$ is a non-unitary isometry, then $p \oplus (p - VV^*) = f^* p f$ for $f := [V, (p - VV^*)]$.

(ii): Let $c \in A_+$ and $q \in \overline{cAc}$ a properly infinite projection. Then the projection $q \in A$ is also properly infinite in the hereditary C^*-subalgebra $qAq \subseteq \overline{cAc}$ by Part (ii) of Lemma 2.5.3. Thus, we may suppose that c is a strictly positive element of A. Let $d := (1-q)c(1-q)$. Then $d + q$ is also a strictly positive element of $A = \overline{cAc}$, and therefore, $(d+q) \approx c$.

Take $u, v \in qAq$ that satisfy $u^*v = 0$, $u^*u = v^*v = q$ and define

$$f := [(d^{1/2} + u), v] \in M_{1,2}(A)\,,$$

then in $M_2(A)$ holds

$$(d+q) \oplus q \approx (d+q) \oplus q = f^*f \approx ff^* = d + uu^* + vv^* \leq d + q\,.$$

Thus, $c \oplus q \approx (d+q) \oplus q \precsim d + q \approx c$.

(iii): If $p^* = p^2 = p \precsim c$ for $c \in A_+$, then there is $d \in A$ with $d^*cd = (1/2)p$, and $q = 2c^{1/2}dd^*c^{1/2}$ is a projection in $\overline{cAc}$ with $q \sim p$. If p is properly infinite (in pAp), then q is properly infinite in $\overline{cAc}$. Thus $p \oplus c \approx q \oplus c \precsim c$ by Part (ii), i.e., $p \in I(c)$.

(iv): Let $a \in A_+$ and *suppose* that $I(a) \neq \{0\}$, i.e., that there exists non-zero $b \in A_+$ with $b \oplus a \precsim a$.

Then $a \oplus b \precsim a$ implies $b \precsim a$. The latter says that there exists, for each $\varepsilon \in (0, \|b\|)$, some $\gamma \in (0, \varepsilon)$ and $d \in A$ with $d^*(a-\gamma)_+ d = (b-\varepsilon)_+$.

Since A has the "small projection" property by assumptions in (iv), there exists a projection $q \in A$ with

$$0 \neq q \in \overline{(b-\varepsilon)_+ A (b-\varepsilon)_+}\,.$$

In particular

$$q \precsim (a \oplus q) \precsim (a \oplus b) \precsim a\,.$$

Since $q \in A$ is a projection with $q \precsim a$, there are $\delta \in (0, \|a\|)$, a partial isometry $v \in A$ such that $vv^* = q$ and $p := v^*v \in \overline{(a-\delta)_+ A (a-\delta)_+}$. It follows that $a \oplus p \precsim a$ inside $\overline{aAa}$, because

$$(a \oplus p) \sim (a \oplus q) \precsim (a \oplus (b-\varepsilon)_+) \precsim a\,.$$

It implies that, for each $\varepsilon \in (0, \|a\|)$, there exists $\gamma \in (0, \|a\|)$ and $d = [d_1, d_2] \in \mathcal{M}_{1,2}(A)$ with

$$d^*((a-\gamma)_+ \oplus 0)d = (a-\varepsilon)_+ \oplus p\,.$$

Now we apply the assumption on the (local) existence of locally bounded dimension functions: There is a dimension function $D\colon \bigcup_n M_n(\overline{aAa}) \to [0,\infty)$ with $D(p) > 0$ and

$$\theta := \sup_{\gamma>0} D\big((a-\gamma)_+\big) = \sup_k D\big((a-1/k)_+\big) < \infty\,.$$

We get, for each $\varepsilon \in (0, \|a\|)$, that

$$\theta \geq D\big((a-\gamma)_+\big) \geq D(p) + D\big((a-\varepsilon)_+\big)\,.$$

Since $\theta = \sup\{D((a-\varepsilon)_+)\,;\ \varepsilon \in (0, \|a\|)\,\}$ this contradicts $D(p) > 0$, and – by assumptions on A – that $a \oplus b \precsim a$. $\square$

LEMMA 2.6.9. *Let A denote an AW*-algebra, a Rickart algebra , or let A the C^*-subalgebra of B^{**} generated by the elements in the σ-up-hull of a C^*-algebra B in B^{**}.*

We need "finiteness" of the projections and that each element $a \in B_+$ has a "support projection" $p_a := 1 - P$, where $PB = R_a$ for $R_a = \{b \in B\,;\ ab = 0\}$. Moreover we need that $p_a = \bigvee\{p_{(a-t)_+}\,;\ t \in (0, \|a\|]\}$.

(i) *There is no (non-zero) properly infinite element in a finite Rickart C^*-algebra.*

(ii) *If A is an AW*-algebra and if $b \in A_+$ is properly infinite, then the support projection p_b of b is a properly infinite projection.*

(iii) *If, for every $\varepsilon > 0$, there exists $\delta \in (0, \varepsilon)$ and $a \in A_+$ with properly infinite support projection p_a such that ??????? and $(b-\varepsilon)_+ \leq a \leq (b-\delta)_+$, then b itself is properly infinite (in the AW*-algebra A).*

PROOF. (i): We use only that the Rickart C^*-algebras and AW*-algebras A have the "small projection" property because they have real rank zero as C^*-algebras.

And we claim that A has sufficiently many "locally bounded" dimension functions if A is a finite Rickart algebra or finite AW*-algebras A. Then Part (iv) of Lemma 2.6.8 applies.

`Are the` *`finite`* `2-q-traces on` $M_2(A)_+$ `separating from` 0
`for the non-zero projections` p `in`
`finite Rickart` *`C*`*`-algebra or AW*-algebras` A`??`

If A is a finite AW*-algebra, then there is a unique center-valued 2-quasi-trace $T\colon A_+ \to \mathcal{Z}(A)$ on a A_+ (cf. [**79**, p. 320]).

It extends to $T_2\colon M_2(A)_+ \to \mathcal{Z}(M_2(A)) \cong \mathcal{Z}(A)$.

The restrictions to (the positive parts of maximal) commutative C^*-subalgebras C of $M_2(A)$ are faithful, because $T_2(p) \neq 0$ for non-zero projections $p \in C$, see [**64**, Chap. 6]. Thus, $0 \leq T_2(a) \neq 0$ for $0 \neq a \in A_+$.

Let $\mathrm{diag}(a,p) \precsim \mathrm{diag}(a,0)$?????

Let $\chi\colon \mathcal{Z}(A) \to \mathbb{C}$ a character with $\chi(T(a)) = \|T(a)\|$. The dimension function $D\colon M_\infty(A) \to [0,\infty)$ corresponding to the 2-quasi-trace $\chi \circ T\colon A_+ \to [0,\infty)$ must satisfy $D(a) \neq 0$. Hence, a can not be properly infinite.

Check above and below arguments for Rickart algebras again.
The $\mathcal{Z}$-bimodule A is not a $\mathcal{Z}$-bundle ??!!!
The fibers are not simple in general.
And $[\chi \circ T]$ need not to be faithful on the fibers.

(ii): The element b is properly infinite inside the Rickart C^*-algebra or AW*-algebra $B := p_b A p_b$.

Now let $q \in \mathcal{Z}(B)$ a central projection that is finite in B.

Then every element of qB is finite, because otherwise there exists

– by the consideration in proof of Part (i) ??? –

an infinite projection r in qB and $q = r + (q-r)$ is infinite in $rBr + \mathbb{C}\cdot(q-r)$.

The element qb is zero or properly infinite in qB if b is properly infinite, by Lemma A.6.1(iii), ?????

Since qB is finite, it follows that $qb = 0$. Only 0 is orthogonal to b in $p_b B p_b$. This implies that the support projection p_b is properly infinite in the AW*-algebra A.

Same argument applies for Rickart algebras etc.

(iii): Suppose that, for every $\varepsilon > 0$, there exists $\delta > 0$ and $a \in A_+$ with properly infinite support projection p_a such that

?????? and $(b-\varepsilon)_+ \leq a \leq (b-\delta)_+$. Then

$$(b-\varepsilon)_+ \otimes 1_2 \leq \|b\|(p_a \otimes 1_2) \precsim p_a \leq p_{(b-\delta)_+} \leq \delta^{-1} b\,.$$

Thus, b is properly infinite, by Part (ix) of Lemma 2.5.3. □

End of Rickart-algebra considerations!!!

HERE ENDS PART 1 of Chp. 2

7. Residually antiliminary C^*-algebras

We define here the class of "residual antiliminary" C^*-algebras A and obtain for this particular class of (not necessarily simple) C^*-algebras A some relations between the there formally different definitions (and classes) of pure infiniteness.

In a not obvious sense the class of residually antiliminary C^*-algebras is the "strict opposite" of the class of C^*-algebras of type I, – that are also called "post-liminal" C^*-algebras ([39]).

Lemma 2.7.1. *Let $\mathbb{K}(\mathcal{H})$ denote the algebra of compact operators on a Hilbert space $\mathcal{H}$, and let $A \subseteq \mathbb{K}(\mathcal{H})$ a C^*-subalgebra of of $\mathbb{K}(\mathcal{H})$.*

If A is irreducible on $\mathcal{H}$, – in the sense that Ax is dense in $\mathcal{H}$ for every non-zero $x \in \mathcal{H}$ –, then it follows that $A = \mathbb{K}(\mathcal{H})$.

Proof. The C^*-subalgebras A of $\mathbb{K}(\mathcal{H})$ are generated by projections $p \in A$ of finite rank, because each $T^* = T \in A \subseteq \mathbb{K}(\mathcal{H})$ has discrete spectrum that related to operators $P \in A$ of finite rank. The transitivity of A on $\mathcal{H}$ of PAP in $P\mathbb{K}(\mathcal{H})P$ shows that $PAP = P\mathbb{K}(\mathcal{H})P$. In particular, this shows that A contains projections of rank $= 1$. The transitivity of A in $\mathcal{H}$ implies that A contains all rank-one projections in $\mathbb{K}(\mathcal{H})$. Since $\mathbb{K}(\mathcal{H})$ is generated as C*-algebra from its rank-one projection, this shows that $A = \mathbb{K}(\mathcal{H})$. □

Definition 2.7.2. A (non-zero) C^*-algebra A is **residual antiliminary** if, for each closed ideal $I \neq A$ of A and each non-zero $b \in A/I$ the hereditary C^*-subalgebra $E := \overline{b^*(A/I)b}$ of A/I is *not* commutative.

Is it not identical to the property that each non-zero hereditary C^*-subalgebra $D \subseteq A$ of A has not a character?
(= D has not a 1-dimensional quotient-algebra)
What is perhaps different?

Here there is also a good place for my separate notes on the ultra-power property: If $c_0(A_1, A_2, ...)$ has no quotient of dimension $= n$, then $\ell_\infty(A_1, A_2, \ldots)$ has no quotient of dimension $= n$. (Same with ultra -powers.)

A C^*-algebra B (as e.g. $B := A/I$) is **antiliminary** if B contains no non-zero hereditary Abelian C^*-subalgebra, i.e., $\overline{b^*Bb}$ is not Abelian for every non-zero $b \in B$, compare [**616**, sec. 6.1.1].

Notice that Definition 2.7.2 equivalently says that a C^*-algebra B is (only) *antiliminary*, if and only if, the hereditary C^*-subalgebra $\overline{b^*Bb}$ of B is not Abelian for every non-zero $b \in B$, and the Definition says that a C^*-algebra A is *residual antiliminary*, if and only if, for every non-zero $a \in A$ the hereditary C^*-subalgebra $D := \overline{a^*Aa}$ of A has no non-zero character.

List of topics to be considered:

(0.1) Each irreducible representation of A comes fro a pure state of ρ of A. If A is residually anti-liminary then the image $d_\rho(A)$ of every irreducible representation $d_\rho \colon A \to \mathcal{L}(\mathcal{H}_\rho)$ does not contain a non-zero compact operator. Here d_ρ is defined by (some suitable) pure state ρ on A.

[39] Could be called also "residual liminal" by some intuition based on old history of math ...

(Proof: A non-zero intersection of $d_\rho(A)$ with the algebra $\mathbb{K}(\mathcal{H}_\rho)$ of compact operators on $\mathcal{H}_\rho$ must necessarily be the image $d_\rho(I)$ of a non-zero closed ideal I of A, e.g. $I := (d_\rho)^{-1}(d_\rho(A) \cap \mathbb{K}(\mathcal{H}_\rho)$.

If the C^*-subalgebra $J := \mathbb{K} \cap d_\rho(A)$ of $\mathbb{K}$ acts irreducible on $\mathcal{H}_\rho$ then necessarily $J = \mathbb{K}$. Every

again an irreducible C*-subalgebra of the compact operators, because otherwise ?????????

This can only happen if $d_\rho(A)$ contains all compact operators.)

(0.2) If A has the property that $d_\rho(A)$ for every irreducible representation d_ρ of A does not contain a non-zero compact operator, then this property passes to all non-zero hereditary C^*-subalgebras $D \subseteq A$ of A.

In particular, then all non-zero hereditary C^*-subalgebras D of A have no characters.

And this implies that no non-zero hereditary C^*-subalgebra D of A has a non-zero quotient C^*-algebra D/J with finite dimension.

(????? Fist attempt of proof ... : ????)

Suppose that $d_0 \colon D \mapsto \mathcal{L}(H)$ is an irreducible *-representation such that $d_0(D)$ contains a non-zero compact operator.

Let $x_0 \in H$ with $\|x_0\| = 1$, and let ρ_0 denote the pure state of D given by $\rho_0(a) :=< ax_0, x_0 >$, and *suppose* that the corresponding irreducible representation $d_0 \colon D \mapsto \mathcal{L}(H)$ contains nonzero compact operators in its image.

The inverse image $I := (d_0)^{-1}(d_0(D) \cap \mathbb{K}(H))$ of the ideal of compact operators defines a closed ideal I of D.

The closed ideal J of A generated by I and I itself have the following properties:

(0.2. i) The set $I \subseteq A$ is also a hereditary closed C^*-subalgebra of A, because I is hereditary in D as every closed ideal of D. (And the hereditary C*-subalgebras have a lattice order given by its open support projections in A^{**}.)

(0.2. ii) We show that $I = J \cap D$, that the support projections of the hereditary C^*-subalgebras J, D and I of A are *open* projections in A^{**}, and that the support projection of J is in the centre of A^{**} and the support projections of I in the centre of D^{**} – here considered as hereditary W*-subalgebra of A^{**}.

(We obtain implicit that $p_J \cdot p_D = p_I$ for the corresponding open questions in A^{**}.)

Proof of $I = J \cap D$:

The ideal J is the closed *linear span* of AIA. The intersection $J \cap D$ is an ideal of D, obviously with $I \subseteq J \cap D$. The latter because $I = I \cdot I \cdot I$ (as for every C^*-algebra) and $I^3 \subseteq AIA \subseteq J$.

The closed linear span L of $A \cdot I$ is a left ideal of A with bi-polar (here = second conjugate) $L^{**} = A^{**}p_L$, where p_L is an open projection in A^{**} (with respect to $\sigma(A^{**}, A^*)$ - topology on A^{**}).

and more ???????? what is needed below ????

The element $d \in D$ is in $J \cap D$ if there exists for each $\varepsilon > 0$ elements $a_1, \ldots, a_n \in A$, $b_1, \ldots, b_n \in A$ and $c_1, \ldots, c_n \in I$ with the property

$$\|d - \sum_k a_k c_k b_k\| < \varepsilon .$$

If we use an approximate quasi-central unit (e_τ) of D and an approximate quasi-central unit (f_τ) of I, then the sum $\sum_k a_k c_k b_k$ can be replaced by suitable summands

$$\sum_k (e_\tau a_k f_\tau c_k f_\tau b_k e_\tau)$$

with suitable index τ such that also $e_\tau d e_\tau - d$ is sufficiently small. The elements $e_\tau a_k f_\tau$ and $c_k f_\tau b_k e_\tau$ are then in DAI respectively in IAD.

(0.3) Question:
Does for every separable C^*-subalgebra $B \subseteq A$ of A exists a separable C^*-subalgebra $C \subseteq A$, such that C has the property in (0.1) – for irreducible $d(C)$ –, if A has the property in (0.1)?

(0.4) Suppose that A is separable and satisfies the conditions (0.1). Can then $\mathcal{M}(A)$ have an irreducible representation of finite dimension? e.g. a character?

(0.5a) ?????????

(0.5b) If $\mathcal{M}(A)$ has no irreducible representation of dimension $\leq n$ then, A, $\ell_\infty(A)$ and $\ell_\infty(\mathcal{M}(A))$ (and all non-zero quotient C*-algebras and ideals of them) have no irreducible representation of dimension $\leq n$.

Suppose that one of A, $\ell_\infty(A)$ or $\ell_\infty(\mathcal{M}(A))$ have an irreducible representation ρ of dimension $k \leq n$ (here k = dimension of the corresponding Hilbert space).

Thus, suppose that one of the cases $\rho(A) = M_k$, $\rho(\ell_\infty(\mathcal{M}(A))) = M_k$, or $\rho(\ell_\infty(A)) = M_k$ with some $k \leq n$ appears.

In the first case ρ extend a normal unital morphism from A^{**} onto M_k with $k \leq n$. Since $A \subseteq \mathcal{M}(A) \subseteq A^{**}$, this shows that, in the case $\rho(A) = M_k$ with $k \leq n$, there must exists an irreducible representation of $\mathcal{M}(A)$ of some dimension $k \leq n$.

In the case of an irreducible representation $\rho\colon \ell_\infty(\mathcal{M}(A)) \to M_k$ it is always $\rho(1, 1, \ldots) = 1_k$ in M_k. The natural diagonal embedding Δ given by $y \in \mathcal{M}(A) \mapsto (y, y, \ldots) \in \ell_\infty(\mathcal{M}(A))$ is unital and $\rho \circ \Delta\colon \mathcal{M}(A) \to M_k$ is a unital C*-algebra morphism from $\mathcal{M}(A)$ into M_k.

(0.6) Question:
Suppose that A is separable and $\mathcal{M}(A)$ has an irreducible representation of finite dimension. Has then A_∞ (or A_ω) an irreducible representation of finite dimension?

Hope? Question: Are elements of $\mathcal{M}(A)/A$ expressible as sum of two commuting elements of A_∞? (perhaps then with a shift of one those 2 elements?)

Are separable parts of $\mathcal{M}(A)/A$ contained in sums of suitable separable ?????

Using a quasi-diagonal approximate unit of A, we can find 2 hereditary C^*-subalgebras of $\ell_\infty(A)$ that have irreducible ????

If $\mathcal{M}(A)$ has no irreducible representation of finite dimension, then $\mathcal{M}(A)/A$ (??? and ???? $\ell_\infty(A)$????) have no irreducible representation of finite dimension.

Suppose that $\ell_\infty(A)$ has no irreducible representation of finite dimension. Does it imply that $\mathcal{M}(A)$ has no irreducible representation of finite dimension (at least in case that A is σ-unital, or separable)?

(0.7) If any irreducible representation of A does not contain non-zero compact operators in its image, then each hereditary C^*-subalgebra of A has this property.

(1) l.p.i, weakly p.i., p.i., and strongly p.i. C^*-algebras are all residually antiliminary.

(1.0) It suffices to show that locally p.i. C^*-algebras are residual antiliminary. This can be seen as follows:

Foe each non-zero quotients $D/(D \cap J)$, where J is a closed ideal of A and $D \subseteq A$ is a hereditary C^*-subalgebra of A, there exist a pure state ρ on D with $\rho(D \cap J) = \{0\}$ and a positive contraction $d \in D_+$ with $\rho(d) = 1$ (by using Kadison transitivity theorem, or Lemma **??**). By Definition 2.0.3 of locally purely infinite C^*-algebras, there exists a C^*-morphism $h \colon \mathrm{C}_0((0,1], \mathbb{K}) \to \overline{dAd} \subseteq D$ with $\rho \cdot h \neq 0$. It shows that $D/(D \cap J)$ can not be one-dimensional (i.e., is $\ncong \mathbb{C}$). This shows that A must be residual antiliminary.)

The implications "strongly p.i. $\Rightarrow$ p.i. $\Rightarrow$ weakly p.i. $\Rightarrow$ locally p.i. " show then that the all sorts of "purely infinite" C^*-algebras are residually antiliminary.

(2) ??? The free product A of countably many algebras A_n, $A_n \cong \mathrm{C}_0((0,1], \mathbb{K}(\ell_2(\mathbb{N}))$ has no finite-dimensional irreducible representation, but $\ell_\infty(A)$ has a character (and moreover irreducible representations of every dimension n for each $n \in \mathbb{N}$).

This is not proven completely, because we have only an example where representations $\rho_n \colon A \to \mathbb{K}$ "converge" to a character on some *-subalgebra of $\ell_\infty(A)/c_0(A)$ that contains in its kernel an ideal J of A such that A/J is commutative.

But A itself has no character. Thus, ??? $\rho_\infty(A) \subseteq c_0(A)$???...

It is not clear if ρ_ω itself has abelian image on all elements of $\ell_\infty(A)/c_0(A)$.

It is not clear if this A is residually antiliminary, or can be used to construct a residually antiliminary C^*-algebra B with the property that $\ell_\infty(B)$ has a character.

(3) M_n has the $n \times n$-matrix $[a_{jk}]$ with $1 = a_{12} = a_{23} = \cdots = a_{n-1,n}$ (and zero at all other places) as generator.

(4) Let I_n denote the ideal of A that is generated by all homomorphisms of $\mathrm{C}_0((0,1], M_n)$ into A,

Then A/I_n has only irreducible representations of dimension $\leq n-1$:

Suppose that A/I_n has an irreducible representation $d\colon A/I_n \to \mathcal{L}(\mathcal{H})$ with dimension of $\mathcal{H}$ being $\geq n$. Let $P \in \mathbb{K}(\mathcal{H})$ a projection of rank $= n$, then, by the generalized Kadison transitivity Lemma **??** and semi-projectivity of $\mathrm{C}_0((0,1], M_n)$, cf. by Proposition **??**, there exist a C^*-morphism $h\colon \mathrm{C}_0((0,1], M_n) \to A$ with $d \circ \pi_{I_n}(f_0 \otimes 1_n) = P$. But $h(\mathrm{C}_0((0,1], M_n)) \subseteq I_n$ by definition of I_n and therefore $d \circ \pi_{I_n}(f_0 \otimes 1_n) = 0$ (with $f_0(t) = t$ on $(0,1]$). This contradicts the existence of $P \in \mathbb{K}(\mathcal{H})$ of rank $= n$ and shows that the dimension of $\mathcal{H}$ is $\leq n-1$.

Moreover the ideal I_n has no irreducible representations of dimension $< n$: Indeed, there would be an irreducible representation $d\colon A \to \mathcal{L}(\mathcal{H})$ with $k := \dim(\mathcal{H}) < n$ and $d|I_n \neq 0$. But, by definition of I_n, there exists a C^*-morphism $h\colon \mathrm{C}_0((0,1], M_n) \to I_n$ such that $d \circ h\colon \mathrm{C}_0((0,1], M_n) \to \mathcal{L}(\mathcal{H})$ is not $= 0$. But there does not exist a C^*-morphism from $\mathrm{C}_0((0,1], M_n)$ onto onto M_k for $k < n$.

What is with the (perhaps bigger) ideal J_n generated by contractions a in A with $\|a^{n-1}\| = 1$ and $a^n = 0$? (Notice that J_n contains I_n!)

The universal C^*-algebra $A_n := C^*(a^*, a\,;\ \|a^{n-1}\| = 1 \geq \|a\|, a^n = 0)$ has no irreducible representations of dimension $\leq n-1$.

$A_2 := C^*(b^*, b\,;\ \|b\| = 1, b^2 = 0)$ has a C^*-morphism φ into A_n give by $\varphi(b) := a^{n-1}$, or by $\varphi(b) := a^\ell$ with $\ell \geq n/2$.

There must be an irreducible representation on a Hilbert space $\mathcal{H}$ and $x \in \mathcal{H}$ with $\|x\| = 1$, $\|a^{n-1}x\| = 1$, because $\|a^{n-1}\| = 1$. Consider the vectors $\{x, ax, a^2x, \ldots, a^{n-1}x\}$. They have all the norm $= 1$. It generates an a-invariant (i.e., with $aL \subseteq L$) linear subspace $L \subseteq \mathcal{H}$ of dimension $\leq n$. It contains the a-invariant subspaces a^kL generated by $\{a^kx, a^{k+1}x, \ldots, a^{n-1}x\}$ of dimension $\leq n-k$: $\{\mathbb{C} \cdot a^{n-1}x\} = a^{n-1}L \subseteq a^{n-2}L \subseteq \ldots \subseteq \ldots \subseteq a^2L \subseteq aL$.

If $k \in \{1, \ldots, n-2\}$ exists with $\mathrm{Dim}(a^kL) = \mathrm{Dim}(a^{k-1}L)$ then $a|a^{k-1}L$ is bijective on $a^{k-1}L$. Hence, $a^{k-1}L = a^kL$ and $a|a^kL$ is again bijective. This contradicts $a^nL = \{0\}$, and shows that linear span of $\{x, ax, a^2x, \ldots, a^{n-1}x\}$ is vector space of dimension $= n$.

In particular, $M_{n-1}(\mathbb{C})$ can not contain a contraction a with $\|a^{n-1}\| = 1$ and $a^n = 0$.

`Beginning from here, above considerations are not (!) integrated so far.`

Let $\mathcal{H}$ of dimension $m < n$, $a \in \mathcal{L}(\mathcal{H})$, with $\|a\| \leq 1$, $\|a^{n-1}\| = 1$ and $a^n = 0$. Can suppose that $C^*(a^*, a\,;\ \|a^{n-1}\| = 1 \geq \|a\|, a^n = 0)$ is there irreducible represented. The above considerations show that $\mathcal{H}$ must have dimension $\geq n$.

Find $x \in \mathcal{H}$ with $\|x\| = 1$, $\|a^{n-1}x\| = 1$. It must exists because $\|a^{n-1}\| = 1$. It follows that the vectors $x, ax, a^2x, \ldots, a^{n-1}x$ necessarily have all the norm $= 1$.

They can not be linearly independent, because the dimension of $\mathcal{H}$ is $= m < n$. Let $\mathcal{H}_0$ denote the linear span of $\{x, ax, a^2x, \ldots, a^{n-1}x\}$. It has some dimension $=: m < n$.

There is a linear map $T\colon \mathbb{C}^n \to \mathcal{H}$ defined by $T(e_1) := x$ and $T(e_k) := a^{k-1}x$ for $k = 2, \ldots, n$. The linear map T satisfies $TS_n = aT$ for the linear map $a \in \mathcal{L}(\mathcal{H})$ and the map $S_n \in \mathcal{L}(\mathbb{C}^n)$ defined by $S_n(e_k) := e_{k+1}$ $(k = 1, \ldots, n-1)$ and $S_n(e_n) := 0$. The map S_n satisfies $S_n^\ell(e_k) = e_{k+\ell}$ for $k + \ell \leq n$ and $S_n^\ell(e_k) = 0$ for $k + \ell > n$. In particular, $S_n^{n-1}(e_1) = e_n$, $S_n^{n-1}(e_k) = 0$ for $1 < k \leq n$ and $S_n^n = 0$. It implies $T(S_n(e_k)) = T(e_{k+1}) = a^k x = aT(e_k)$, for $k < n$ and $T(S_n(e_n)) = 0 = a^n x = aT(e_n)$, because $T(e_n) = a^{n-1}x$ and $a^n = 0$. Thus $TS_n = aT$ and $T\colon \mathbb{C}^n \to \mathcal{H}_0$ is surjective.

More?

Move it to some Appendix ??.

(5) The ideal I_n is identical with the hereditary C^*-subalgebra D_n of A that is build by convex combinations of all positive n-homogenous elements of A. (Because the D_n is invariant under inner automorphisms of A induced by unitaries in $\mathcal{U}_0(A + \mathbb{C}1)$.)

(6) Conjecture: If A is σ-unital and its asymptotic central sequence algebra $F(A) := (A' \cap A_\omega)/\mathrm{Ann}(A, A_\omega)$ has no characters, then A_ω is residual anti-liminary.

Attempt:
Let $h \in A_\omega$ a positive contraction. $D := \overline{hA_\omega h}$. Then there is a unital C^*-morphism from $F(A)$ into $\mathcal{M}(D)$ (? To be checked !!!?). The D can not have a character.

Thus A_ω is residual antiliminary.

(7) If A has only l.s.c. 2-quasi-traces that take the values 0 and $+\infty$ then A is residually antiliminary.

(8) All simple non-elementary C^*-algebras are residually antiliminary.

Equivalently expressed, cf. [**616**, sec. 6.1.1], B is "antiliminary" if B does not contain a non-zero "abelian element" $b \in B_+$. The element $b \in B_+$ is called "abelian" if bBb is a commutative subalgebra of B, cf. [**616**, sec. 5.5.1].

The following Proposition 2.7.7 and the Lemmata 2.7.3 and 2.7.13 will be used for the recognition and applications of residual antiliminary C^*-algebras.

Compare Remark A.5.8 and Lemma 2.1.7(o,v) with next Lemma and its proof.

LEMMA 2.7.3. *Let D a hereditary C^*-subalgebra of a C^*-algebra A. Then the map $J \mapsto J \cap D$ is a* surjective *map from the lattice $\mathcal{I}(A)$ of closed ideals of A onto $\mathcal{I}(D)$. In particular, $I = D \cap \overline{\mathrm{Span}(AIA)}$ for each closed ideal of D.*

PROOF. The latter identity can be seen easily with help of an approximate unit $\{e_\tau\}$ of D, by using that $DAD = D$, cf. Lemma 2.1.7(o). It shows the surjectivity of the map $J \mapsto J \cap D$, because $D \cap J = I$ for $J := \mathrm{Span}(AIA)$ if I is a closed ideal I of $D \subseteq A$. $\square$

Why should this non-zero character exist???

LEMMA 2.7.4. *Let D a C^*-algebra and $c \in D_+$ with $\|c\| = 1$ and suppose that*

$$\chi\colon E := \overline{cDc} \to \mathbb{C}$$

is a non-zero character.

Then $0 < \chi(c) \leq 1$, and, for each non-zero positive contraction $b \in D_+$ with $\|c - b\| < \chi(c)/3$ and $\delta \in (\|c - b\|, \chi(c)/3)$, the hereditary C^*-subalgebra $\overline{(b-\delta)_+ D(b-\delta)_+}$ of D has a non-zero character.

PROOF. By assumptions, the hereditary C^*-subalgebra $E := \overline{cDc}$ of D has non-zero character $\chi\colon E \to \mathbb{C}$ with kernel ideal $I \subset \overline{cDc}$, and $\|c\| = 1$. Since c is a strictly positive element of E it follows that $0 < \chi(c) \leq 1$.

Let $I \subseteq E$ the kernel ideal of the character χ, and let $J \subseteq D$ the closed ideal of D generated by I, i.e., $J := \overline{\mathrm{Span}(D \cdot I \cdot D)}$. It can be shown that $J \cap E = I$ by using an approximate unit of I, cf. Lemma 2.7.3.

It implies that $\pi_J(I) = \mathbb{C} \cdot p$ for some non-zero projection $p \in D/J$ that satisfies $p(D/J)p = \mathbb{C} \cdot p$ and $\pi_J(c) = \chi(c) \cdot p$. In particular, $\|\pi_J(c)\| = \chi(c)$.

The ideal K of D/J generated by the 1-dimensional hereditary C^*-subalgebra

$$\pi_J(E) = E/(J \cap E) = E/I = \mathbb{C} \cdot p = p(D/J)p$$

is equal to $\pi_J(\overline{\mathrm{Span}(DcD)})$. The ideal K is also equal to the closure of the linear span $\mathrm{Span}((D/J)p(D/J))$. Thus, K is isomorphic to the algebra of compact operators $\mathbb{K}(\mathcal{H})$ on some Hilbert space $\mathcal{H}$. The projection $p \in K$ has rank equal to one if considered as element in $\mathbb{K}(\mathcal{H}) \cong K$ because $pKp = \mathbb{C} \cdot p$.

Let $b \in D_+$ a with $\|b\| \leq 1$, $\|b - c\| < \chi(c)/3$ and $\delta \in (\|b - c\|, \chi(c)/3)$.
HERE XXX check again !!!

There exists a contraction $d \in D$ with $d^* c d = (b - \delta)_+$ by Lemma 2.1.9. It implies that in the ideal K of D/J the element $\pi_J((b-\delta)_+) = \chi(c)\pi_J(d)^* p \pi_J(d)$ has at most the rank one. It means that, if $\pi_J((b-\delta)_+) \neq 0$, then there exists a projection $q \in K \subseteq D/J$ with $q(D/J)q = \mathbb{C} \cdot q$ and

$$\pi_J((b-\delta)_+) = \|\pi_J((b-\delta)_+)\| q\,.$$

Thus, if $\pi_J((b-\delta)_+) \neq 0$ then the π_J defines a C^*-algebra epimorphism from the hereditary C^*-subalgebra $\overline{(b-\delta)_+ D(b-\delta)_+}$ of D onto the algebra $\mathbb{C} \cdot q$ in D/J. This shows that $\overline{(b-\delta)_+ D(b-\delta)_+}$ has a non-zero character if $\mathcal{I}(\pi_J((b-\delta))\| > 0$.

We finish the proof by showing that $\mathcal{I}(\pi_J((b-\delta))\| > 0$:
We have $\|(\pi_J((b-\delta)_+)\| = \|(\pi_J(b) - \delta)_+\| \geq \|\pi_J(b)\| - \delta$ and $\|\pi_J(b)\| \geq \|\pi_J(c)\| - \|\pi_J(c-b)\| \geq \chi(c) - \|c - b\|$. Thus,

$$\|(\pi_J((b-\delta)_+)\| \geq \chi(c) - \|c - b\| - \delta > \chi(c)/3\,.$$

In particular, $\|(\pi_J((b-\delta)_+)\| > 0$. □

The next Lemma 2.7.5 could be improved with respect to the possible estimates, but it is good enough for our applications.

LEMMA 2.7.5. *Let A a C^*-algebra and $B \subseteq A$ a C^*-subalgebra. If A contains a non-zero projection p with the properties $pAp = \mathbb{C} \cdot p$ and that the distance of p to B is less than $1/9$, i.e., $\operatorname{dist}(p, B) < 1/9$, then there exists a projection $q \in B$ with $\|p - q\| < 1$ and $qBq = \mathbb{C}q$.*

Moreover, there is a unitary $U \in \mathcal{U}_0(\mathcal{M}(A)) \cap (1 + A)$ with $q := U^*pU \in B$.

PROOF. Recall here that $\mathcal{U}_0(\mathcal{M}(A))$ denotes the in operator-norm connected component of 1 in the unitaries $\mathcal{U}(\mathcal{M}(A))$. There is a positive linear functional ψ on A with $\psi(a)p = pap$ for all $a \in A$, because $pAp = \mathbb{C} \cdot p$. It shows that ψ must be a pure state on A. Notice that there exists only one state on A with this property, and the property that the closed ideal $J \subseteq A$ of A generated by p is isomorphic to the compact operators $\mathbb{K}(\mathcal{H})$ of some Hilbert space $\mathcal{H}$, i.e., $J \cong \mathbb{K}(\mathcal{H})$.

By assumption, there exist $b \in B$ with $\|b - p\| < 1/9$. The selfadjoint $f := (1/2)(b^* + b) \in B$ is the real part of b and satisfies again $\|f - p\| < 1/9$. It says, for $\delta \in (0, 1/9 - \|s - p\|)$ and the unit $1 \in B^{**}$, that

$$-(1/9 - \delta)1 \;\leq\; p + f_- - f_+ \;\leq\; (1/9 - \delta)1\,.$$

Let χ a character on $C^*(f) \subseteq B \subseteq A$ with $\chi(f_-) = \|f_-\|$ and $\chi(f_+) = 0$. It extends to a pure state on B and then, – further on –, to a pure state on $\rho \colon A \to \mathbb{C}$ with the properties that $\rho(f_-) = \|f_-\|$ and $\rho(f_+) = 0$. If we apply it to above inequality, then we get $\rho(p) + \|f_-\| \leq (1/9 - \delta)_+$ and $0 \leq \rho(p) \leq 1$. Thus, $\|f_-\| < 1/9$ and positive part $c := f_+$ satisfies $\|c - p\| < 2/9$, and $c \geq 0$.

Let $\xi \in (\|c - p\|, 2/9)$. It satisfies the inequalities $\|c - p\| < \xi$ and, therefore, $1 - \xi < \|c\| < 1 + \xi$. In particular, $0 < \xi < \|c\|$ because $9\,\xi < 2$.

Lemma 2.1.9 gives a contraction $d \in A$ with $d^*pd = (c - \xi)_+ \neq 0$, because $\|c - p\| < \xi$ and $\|c\| > \xi$.

It implies that $q := (\|c\| - \xi)^{-1}(c - \xi)_+ \in B$ is a rank-one projection in the ideal $J \cong \mathbb{K}$ of A generated by p.

They imply following identities and estimates: $(\|c\| - \xi) \cdot q = (c - \xi)_+$, $1 - \xi < \|c\| < 1 + \xi$,

$$\|q - (c - \xi)_+\| = |1 - (\|c\| - \xi)| \;=\; 1 + \xi - \|c\| \;<\; 2\xi\,,$$

and

$$\|(c - \xi)_+ - p\| \;\leq\; \|c - p\| + \|c - (c - \xi)_+\| \;<\; 2\xi\,.$$

It gives the desired estimate:

$$\|q - p\| \;\leq\; \|q - (c - \xi)_+\| + \|(c - \xi)_+ - p\| \;<\; 4\xi \;< 1\,.$$

The inequality $\|p - q\| < 1$ implies for the two rank-one projections $p, q \in J \cong \mathbb{K}(\mathcal{H})$ that they are identical if they are linear dependent. But if they are not linear dependent then the support project Q of $p + q$ in J has rank two, i.e., $p, q \in QJQ \cong M_2$. Then there exists a unitary $V \in \mathcal{U}_0(QJQ)$ with $V^*pV = q$. The unitary $U := V + (1 - Q) \in 1_{\mathcal{M}(A)} + A$ has the proposed properties. □

Corollary 2.7.6. *Let A a C^*-algebra and $b_1, b_2, \ldots \in A_+$ a sequence contractions that converge to a contraction $c \in A_+$ with $\|c\| = 1$, i.e., $\lim_n \|c - b_n\| = 0$.*

If the hereditary C^*-subalgebras $\overline{(b_n - \rho)_+ A (b_n - \rho)_+}$ have no non-zero characters for every $n \in \mathbb{N}$ and every rational number $\rho \in (0, \|b_n\|)$, then the hereditary C^*-subalgebra $\overline{(cAc)_+}$ can not have a non-zero character.

Proof. If $\overline{cAc}$ has a non-zero character then infinitely many of the hereditary C^*-subalgebras $\overline{(b_n - \rho)_+ A (b_n - \rho)_+}$ must have a character, by Lemma 2.7.4. It would contradict the assumptions. □

Proposition 2.7.7. *Following properties of a C^*-algebras A are equivalent:*

(i) *A is residual antiliminary in the sense of Definition 2.7.2.*
(ii) *Each hereditary C^*-subalgebra D of A does not have a non-zero character.*
(iii) *Each non-zero hereditary C^*-subalgebra D of A does not have irreducible representations that contain non-zero compact operators in its image.*
(iv) *No irreducible representation $\rho\colon A \to \mathcal{L}(\mathcal{H})$ of A contains a non-zero compact operator in its image.*
(v) *There exists a norm-dense subset $S \subseteq \{a \in A_+ \,;\, \|a\| = 1\}$ with the property that for each $b \in S$ and each rational numbers $\rho \in (0, 1)$ the hereditary C^*-subalgebra $\overline{(b - \rho)_+ A (b - \rho)_+}$ of A has no non-zero character.*

Proof. We give indirect proofs for all implications, except for the trivial implications (ii)⇒(v) and (iii)⇒(iv).

(i)⇒(ii): Suppose that D is a hereditary C^*-subalgebra of A that has a non-zero character character $\chi\colon D \to \mathbb{C}$ and let I denote the kernel of χ. By Lemma 2.7.3 there exists a closed ideal J of A that satisfies $J \cap D = I$. Then $E := \pi_J(D) \cong \mathbb{C}$ is a hereditary C^*-subalgebra of A/J and there is a unique non-zero projection $p \in E$ with $E = \mathbb{C} \cdot p$. Then $E = \overline{p^*(A/J)p}$ is a non-zero commutative and hereditary C^*-subalgebra of the quotient A/J of A. It contradicts that A is residual antiliminary.

(ii)⇒(iii): Suppose that there exists a hereditary C^*-subalgebra D of A that admits an irreducible $\rho\colon D \to \mathcal{L}(\mathcal{H})$ with the property that $\rho(D)$ contains a non-zero compact operator $T \in \rho(D)$. Let $I \subset D$ denote the kernel of ρ.

Since irreducible representations of C^*-algebras are cyclic with respect to each non-zero vector, one can show that the non-zero C^*-subalgebra $\rho(D) \cap \mathbb{K}(\mathcal{H})$ of $\mathbb{K}(\mathcal{H})$ is an irreducible C^*-subalgebra of $\mathbb{K}(\mathcal{H})$. It implies that $\mathbb{K}(\mathcal{H}) \subseteq \rho(D)$. Thus, there exist a projection $p \in \mathbb{K}(\mathcal{H})$ of rank one with the property $p \in \rho(D)$. It implies $p\rho(D)p = \mathbb{C} \cdot p$. The C^*-subalgebra $E := \rho^{-1}(\mathbb{C} \cdot p) = \rho^{-1}(p\rho(D)p)$ of D is a hereditary C^*-subalgebra of D, – hence is also hereditary in A –, and $E/(I \cap E)$

is one-dimensional, i.e., E is a hereditary C^*-subalgebra of A that has a character. It contradicts that E can not have a character by (ii).

(iii)⇒(i): Suppose that A is not residual antiliminary in in the sense of Definition 2.7.2.

Then there exists a closed ideal $I \neq A$ of A and a non-zero element $b \in A/I$ such that the hereditary C^*-subalgebra $E := \overline{b^*(A/I)b}$ of A/I is commutative. Let $D := \pi_I^{-1}(E)$ and $\xi \colon E \to \mathbb{C}$ a non-zero character of E. Then D is a non-zero hereditary C^*-subalgebra of A, and $\chi := \xi \circ (\pi_I | D)$ is a non-zero character on D, contradicting Property (iii) on A.

(iii)⇒(iv): Consider $D := A$.

(iv)⇒(iii): Suppose that D is a hereditary C^*-subalgebra of A, $\rho_0 \colon D \to \mathcal{L}(\mathcal{H}_0)$ an irreducible representation and that $T \in \rho_0(D)$ is a non-zero compact operator on $\mathcal{H}_0$. Take $e \in D$ with $\rho_0(e) = T$. We can suppose that $e \geq 0$ and $T \geq 0$ by replacing them otherwise by e^*e and T^*T.

The irreducible representation ρ_0 of D "extends" to an irreducible representation $\rho_1 \colon A \to \mathcal{L}(\mathcal{H}_1)$ in the sense that there exists an isometry $I \colon \mathcal{H}_0 \to \mathcal{H}_1$ such that $\rho_1(d) \circ I = I \circ \rho_0(d)$ and $\rho_1(d)x = 0$ for all $x \in \mathcal{H}_1 \top I(\mathcal{H}_0)$ and for all $d \in D$. Thus, $e \in D \subseteq A$ satisfies that $\rho_1(e)$ is a non-zero compact operator on $\mathcal{H}_1$. This contradicts (iv).

(v)⇒(ii): The assumptions of Part (v) imply by Corollary 2.7.6 that $\overline{bAb}$ has no non-zero character for all $b \in A_+$ with $\|b\| = 1$.

It follows that each hereditary C^*-subalgebra D of A does not have a non-zero character:

Suppose that there exists a non-zero character ξ on D. Then there exists some $a \in D$ with $\xi(a) = 1$. Let $b := a^*a - (a^*a - 1)_+$, then $b \in D_+$, $\|b\| = 1$ and $\xi(b) = 1$. Thus, the restriction of ξ to $\overline{bAb}$ is a non-zero character. But this impossible. □

LEMMA 2.7.8. *A C^*-algebra B has no irreducible representation of dimension $\leq n$, if and only if, the closed ideal J_n of B generated by all elements $b \in B$ with the property $b^{m-1} \neq 0$ and $b^m = 0$ and $m \geq n$, is equal to B.*

If B has an irreducible representation of dimension $\geq n$ then B contains an element with $b^{n-1} \neq 0$ and $b^n = 0$.

If B contains an element with $b \in B$ with $b^{n-1} \neq 0$ and $b^n = 0$, then B has an irreducible representation with dimension $\geq n$.

Thus, if B has only irreducible representations of dimension $< n$, then B can not contain b with $b^{n-1} \neq 0$ and $b^n = 0$.

If B does not contain elements $b \in B$ with $b^{n-1} \neq 0$ and $b^n = 0$ then every irreducible representation of B has dimension $< n$.

Let J_n denote the closed ideal of B generated by all elements $b \in B$ with $b^{n-1} \neq 0$ and $b^n = 0$.

(1) B/J_n has only irreducible representation on Hilbert spaces of dimension $\leq n$.

It is equivalent to the property that for every irreducible representation $\rho\colon B \to \mathcal{L}(\mathcal{H})$ of dimension $\dim(\mathcal{H}) > n$ there exists a contraction $b \in B$ with $b^{n+1} = 0$, $b^n \neq 0$ and $\rho(b) \neq 0$. (Because this implies that $\rho|J_n$ is an irreducible representation of the J_n.)

Proof of (1):
Let $\rho\colon B \to \mathcal{L}(\mathcal{H})$ an irreducible representation and $\dim(\mathcal{H}) > n$.

By (sharpened form of) the generalized Kadison transitivity theorem there exists C^*-algebra homomorphism $\varphi\colon \mathrm{C}_0((0,1], M_{n+1}) \to B$ such that $f \to \rho \circ \varphi(f)$ has kernel $\mathrm{C}_0((0,1), M_{n+1})$, and defines a (non-zero) C^*-morphism $\eta\colon M_{n+1} \to \mathbb{K}(\mathcal{H})$ of M_{n+1} into $\mathbb{K}(\mathcal{H})$. Let $d := e_{1,2}+e_{2,3}+\cdots+e_{n-1,n}$ Then $b := \varphi(f_0 \otimes d) \in B$ satisfies $b^{n-1} \neq 0$ and $b^n = 0$.

(2) Every irreducible representation $\rho\colon B \to \mathcal{L}(\mathcal{H})$ of dimension $\dim(\mathcal{H}) \leq n$ contains J_n in its kernel ideal.

This is equivalent to the property of J_n that says that J_n is contained in the intersection of the kernels of all irreducible representations $\rho\colon B \to \mathcal{L}(\mathcal{H})$ with $\mathrm{Dim}(\mathcal{H}) \leq n$.

To show this, we have to prove that there does not exist an irreducible representation $\rho\colon B \to \mathcal{L}(\mathcal{H})$ on a Hilbert space $\mathcal{H}$ such that $\rho(b) \neq 0$ for some $b \in B$ in the given set of generators for J_n.

The generators of J_n are the elements $b \in B$ with the property $b^{n-1} \neq 0$ and $b^n = 0$.

Thus we have to determine: What is the dimension of a Hilbert space $\mathcal{H}$ if $\mathcal{L}(\mathcal{H})$ contains a contraction T with $T^n = 0$ and $T^{n-1} \neq 0$.

We show that for a Hilbert space $\mathcal{H}$ holds:

$\mathrm{Dim}(\mathcal{H}) \geq n$, if and only if, $\mathcal{L}(\mathcal{H})$ contains an operator of finite rank $T \in \mathcal{L}(\mathcal{H})$ with the property $T^n = 0$ and $T^{n-1} \neq 0$.

Equivalently this says that if $\mathrm{Dim}(\mathcal{H}) \leq n$ then there does not exists an operator $T \in \mathcal{L}(\mathcal{H})$ with $T^{m-1} \neq 0$ and $T^m = 0$ if $m > n$.

(There exists T with $T^{n-1} \neq 0$ and $T^n = 0$ if $\mathrm{Dim}(\mathcal{H}) = n$, but no T with $T^{m-1} \neq 0$ and $T^m = 0$ if $\mathrm{Dim}(\mathcal{H}) < m < \infty$)

The images $\mathcal{H}_k := T^k\mathcal{H}$ are linear subspaces for $k \in \{0, \ldots m\}$, where we let $T^0 := \mathrm{id}_{\mathcal{H}}$. They are closed subspaces of $\mathcal{H}$, because $\mathrm{Dim}(\mathcal{H}) \leq n$. Obviously $\mathcal{H}_{k+1} \subseteq \mathcal{H}_k$, and the $\mathcal{H}_k$ are invariant subspaces of T, i.e., $T\mathcal{H}_k \subseteq \mathcal{H}_k$.

If there is $k \in \{0, \ldots, m-1\}$ with $\mathcal{H}_k = \mathcal{H}_{k+1}$ and $\mathcal{H}_k$ then is $T|\mathcal{H}_k$ is a bijective linear map on $\mathcal{H}_k$. It implies that $T^\ell \neq 0$ for all $\ell \in \mathbb{N}$, if $\mathcal{H}_k = \mathcal{H}_{k+1}$ for some $k \in \{0, 1, \ldots, m-1\}$. It would contradict the assumption that $T^m = 0$.

Thus, $\mathrm{Dim}(\mathcal{H}_{k+1}) < \mathrm{Dim}(\mathcal{H}_k) \neq \{0\}$ for $k \in \{0, 1, \ldots, m-1\}$ and $\mathcal{H}_m = T^m\mathcal{H} = \{0\}$, because $T^{m-1} \neq 0$ and $T^m = 0$.

It follows that ????????????

Since $T^m = 0$, by assumption, this can not happen. Thus, $\mathrm{Dim}(T^{k+1}\mathcal{H}) < \mathrm{Dim}(T^k\mathcal{H})$ for all $k \in \{0, \ldots, m\}$. $\{0\} = \mathcal{H}_m$ and $\mathrm{Dim}(H_{k+1}) < \mathrm{Dim}(H_k)$ for $k \in \{0, 1, \ldots, m\}$.

It follows that $\mathrm{Dim}(Hi) \geq m - 1$???

(2) If B has an irreducible representation ρ of dimension $m > n$ then there exists an element

????????

If B/J_n has an irreducible representation $\rho \colon B/J_n \to M_n$

of dimension m or n here ?????

then the semi-projectivity of $\mathrm{C}_0((0,1], M_m)$ shows that there is a C^*-morphism $\psi \colon \mathrm{C}_0((0,1], M_m) \to B$ with $(\rho \circ \psi)(f) = f(1)$ for $f \in \mathrm{C}_0((0,1], M_m)$. Then $b := \psi(f_0 \otimes (p_{1,2} + p_{2,3} + \ldots + p_{n_1,n})$ satisfies $b^{m-1} \neq 0$ and $b^m = 0$. Thus, $m < n$ if $b \notin J_n$.

Need also to show that J_n has no irreducible representation of dimension $< n$ B/J_n has only irreducible representation of dimension $< n$. It is NOT clear if it is so!

We know only that if B has an irreducible representation $D \colon B \to M_k$ of dimension $k < n$ then B contains a contraction $b \in B$ with $\|b^\ell\| = 1$ for $\ell < k$ and $b^k = 0$, because B contains then an image $\psi(M_k(\mathrm{C}_0(0,1]))$ of $M_k(\mathrm{C}_0(0,1])$ by some C^*-morphism ψ with $D \circ \psi(f_0 \otimes 1_n) = 1_k$. In this (very special) situation one has moreover that $D(b)^\ell \neq 0$ for $1 \leq \ell < k$. The b is given by $\psi(f_0 \otimes Q)$ for $Q := \sum_{\ell=1}^{k-1} p_{\ell, 1+\ell}$.

But $b \in B$ with this properties can be found if B has any irreducible representation D of dimension $\geq k$. Simply by considering the the hereditary C^*-subalgebra that maps onto $M_k \oplus 0_{n-k} \subseteq M_k \oplus M_{n-k} \subseteq M_n$.

If B does not contain an element $b \in B$ with $b^{n-1} \neq 0$ and $b^n = 0$ then B can not have any irreducible representation of dimension $\geq n$.

The problem is, if the relations are "liftable", i.e., if B/J does not contain an element $c \in B/J$ with $c^{n-1} \neq 0$ and $c^n = 0$

(in particular B/J can not have an irreducible representation of dimension $\geq n$),

is then every element $b \in B$ with $b^{n-1} \neq 0$ and $b^n = 0$ contained in J?

The problem is, that it can be that $\pi_J(b) \neq 0$, but also $\pi_J(b^\ell) = 0$ for some $1 < \ell < n - 1$. This can happen in case $B = B_1 \oplus B_2$ if $b = b_1 \oplus b_2$ and

????. $b^n = 0$ for $n := \max(n_1, n_2)$ if

?????

REMARK 2.7.9. The property that the closed ideal $J_n(B)$, generated by all elements $b \in B$ with $b^{n-1} \neq 0$ and $b^n = 0$, is equal to B, like considered in Lemma 2.7.8 does not pass in general to $\ell_\infty(B)$ or its quotients, as e.g. the ultrapowers B_ω.

It is still not clear if this is a true counter examples!
Can a sequence of surjective (!) $C*$-morphisms $h_n : B \to \mathbb{K}$
produce a morphism from B_ω into $\mathbb{K}_\omega$ that is not surjective?

The ultrapower B_ω of the free product B of countably many copies of $\mathrm{C}_0((0,1], \mathbb{K}(\ell_2))$ could have a character, even if B has no irreducible representation of finite dimension?

It is only known that the restriction to $B \subset B_\omega$ is a character.

Is the ideal J_n different from the ideal generated by all n-homogenous positive elements?

Case $n = 2$, i.e., general $C^*(b^*, b)$ with $b^2 = 0$?

Then $C^*(b^*, b) \cong M_2 \otimes C^*(b^*b)$ by letting b correspond to $p_{1,2} \otimes (b^*b)^{1/2}$:

The polar decomposition $b = v(b^*b)^{1/2}$ in $C^*(b^*, b)^{**}$ has the property that $b = (bb^*)^{1/2}v$. In particular, $b^* = v^*(bb^*)^{1/2}$ is the polar decomposition of b^*, $v(b^*b)v^* = bb^*$ and $v^*(bb^*)v = b^*b$.

Let $f := (b^*b + bb^*)^{1/2} = (b^*b)^{1/2} + (bb^*)^{1/2}$ in $C^*(b^*, b)$. The partial isometry v commutes with f: $vf = v(v^*v)(b^*b)^{1/2} = b$ and $fv = (bb^*)^{1/2}v = b$. Notice that the *non-zero* values in the spectra of f and $(b^*b)^{1/2}$ are the same.

Thus, there is a C^*-morphisms ρ from $C^*(v^*, v) \otimes C^*(f)$ onto $C^*(b^*, b)$ with the property that $\rho(v \otimes f) = b$ and $\rho((vv^* + v^*v) \otimes f) = f$. Since $C^*(v^*, v) \cong M_2$, we get an isomorphism from $M_2(C^*(f))$ onto $C^*(b^*, b)$.

PROOF. Let $D_n \in M_n$ denote the matrix with entries $d_{k,k+1} = 1$ for $k = 1, \ldots, n-1$ and $d_{k,\ell} = 0$ on all other places. Then $D_n^{n-1} \neq 0$ but $D_n^n = 0$.

Let $J_n \subseteq B$ the closed ideal of B that is generated by all elements $b \in B$ with $b^n = 0$ and $b^{n-1} \neq 0$.

We show that B/J_n is sub-homogenous with irreducible *-representations of dimension $< n$, and that J_n has only irreducible representation of dimension $\geq n$.

Let $\rho \colon B \to M_m$ a *-morphism, and $b \in B$ with $b^{n-1} \neq 0$ but $b^n = 0$ with $\rho(b^{n-1}) \neq 0$...

Need: $C^*(b^*, b)$ is n-homogenous (or n-sub-homogenous C^*-subalgebra) if $b^n = 0$ and $b^{n-1} \neq 0$???

Suppose that $\rho \colon J_n \to \mathcal{L}(\mathcal{H})$ has an irreducible representation of dimension $m < n$, then exists an element $b \in B$ with $b^n = 0$ and $b^{n-1} \neq 0$, and $\rho(b) \neq 0$ ...

HERE IS SOMETHING wrong??

We need also to show that each irreducible representation with $\rho|J_n \neq 0$ has dimension $\geq n$.

This could be shown by proving directly that J_n is also generated by all n-homogenous elements of B.

At least, it is easy to see that the image of all non-zero C^*-morphisms $\psi\colon \mathrm{C}_0((0,1], M_n) \to B$ is contained in J_n, because $\psi(f_0 \otimes D_n)$ is contained in J_n, where D_n means the matrix with entries $d^{(n)}_{j,k} = 1$ for $k := j+1$ and $j = 1, \ldots, n-1$ and let $d^{(n)}_{j,\ell} := 0$ if $\ell - j \neq 1$. The element $f_0 \otimes D_n$ generates $\mathrm{C}_0((0,1], M_n)$ as a C^*-algebra, because $t \cdot D_n$ generates M_n as C^*-algebra for each $t \in (0,1]$ (Use here the variant of the classical Stone-Weierstrass theorem for type-I C^*-algebras, e.g. [**704**, cor. 4.7.8]).

The question is, if $b \in B$ with $b^n = 0$ and $b^{n-1} \neq 0$ generates an n-homogenous C^*-subalgebra?

What about $b - b^{n-1}$? Has it a good polar decomposition?

$(1-b)(b + b^2 + \ldots + b^{n-1}) = b - b^n$ and $b^n = 0$ if b is as above.

How about explicit construction?

$b(b^{n-1}\mathcal{H}) = \{0\}$.

Let $\rho\colon B \to \mathcal{L}(\mathcal{H})$ and irreducible with $\rho(J_n) = \{0\}$. Then the dimension of $\mathcal{H}$ is $< n$:

Suppose that the dimension of $\mathcal{H}$ is $\geq n$. Then there exists a subspace $L \subseteq \mathcal{H}$ of dimension n, a C^*-morphism λ from M_n into $\mathcal{L}(\mathcal{H})$ with $\lambda(1_n) = P_L$ the orthogonal projection onto L, and a C^*-morphism ψ from $\mathrm{C}_0((0,1], M_n)$ into B with the property $\rho \circ \psi = \lambda$ (by Kadison transitivity theorem and projectivity of cones over finite-dimensional C^*-algebras).

We take in B the element $C := \psi(f_0 \otimes D_n)$. It satisfies $C^{n-1} \neq 0$ but $C^n = 0$. Thus, $C \in J_n$ and $\rho(C) \neq 0$, in contradiction to the requirement $\rho(J_n) = \{0\}$.

The family of elements $b \in B$ with $b^n = 0$ and $b^{n-1} \neq 0$ is invariant under all automorphisms of B ... Thus, the hereditary C^*-algebra generated by them is an ideal. The same happens with n-homogenous elements.

Use Lemma 2.1.15(iii)

The case $n = 1$, i.e., $b^2 = 0$ is the interesting case.

Is the C^*-subalgebra generated by them an ideal of B? □

LEMMA 2.7.10. *The following properties of C^*-algebras A are equivalent:*

(i) *For every irreducible representation $d\colon A \to \mathcal{L}(\mathcal{H})$ the image $d(A)$ does not contain a nonzero compact operator on H, i.e., $d(A) \cap (C)(\mathcal{H}) = \{0\}$.*
(ii) *Every non-zero hereditary C^*-subalgebra D of A has no character.*
(iii) *For every non-zero hereditary C^*-subalgebra D of A, $k \in N$ and state ρ on D there exists a C^*-algebra morphism $h\colon C_0((0,1], M_k) \to D$ with $\rho(h((0,1] \otimes 1_k)) = 1$.*

LEMMA 2.7.11. *Let A a C^*-algebra. Following observations are nearly obvious:*

(i) *If $B \subseteq C \subseteq A$ are C^*-subalgebras of A and if an element $b \in B_+$ has the property that $\overline{bBb}$ has no non-zero character, then $\overline{bCb}$ and $\overline{bAb}$ have no non-zero characters.*

(ii) *If $c \in A_+$ and $\overline{cAc}$ has no non-zero character, $C \subseteq A$ is a separable C^*-subalgebra of A with $c \in C$, then there exists a separable C^*-subalgebra $B \subseteq A$ such that $C \subseteq B$ and $\overline{cBc}$ has no non-zero character.*

(iii) *Let $X \subseteq A_+$ be a countable subset of elements with the property that $\overline{xAx}$ has no non-zero character for each $x \in X$. Then there exists a separable C^*-subalgebra $C \subseteq A$ with $X \subseteq C$ and the property that $\overline{xCx}$ has no non-zero characters for each $x \in X$.*

(iv) *Let C a C^*-algebra and let $X \subseteq C_+$ a countable subset of contractions that is norm-dense in the set of positive contractions of C. If all elements $x \in X$ have the property that $\overline{(x-\rho)_+C(x-\rho)_+}$ has no nonzero character for all $\rho \in (0, \|x\|)$, then C^*-algebra C is residually antiliminary (and separable).*

PROOF. Part (i) is obvious, because the restriction to $\overline{bBb}$ of a character on $\overline{bCb}$ or $\overline{bAb}$ would be a (non-zero) character on $\overline{bBb}$.

(ii): TEXT(ii): If $c \in A_+$ and $\overline{cAc}$ has no non-zero character, $C \subseteq A$ is a separable C^*-subalgebra of A with $c \in C$, then there exists a separable C^*-subalgebra $B \subseteq A$ such that $C \subseteq B$ and $\overline{cBc}$ has no non-zero character.

If $c \in A_+$ and $D := \overline{cAc}$ has no non-zero character, then $\overline{cAc}$ is – as a C^*-algebra – generated by its 2-homogenous elements. They are determined by the elements $a \in \overline{cAc}$ with $a^2 = 0$ and $\|a\| = 1$. This is, because $C^*(a^*, a) \subseteq A$ is then a 2-homogenous C^*-algebra. And for every pure state ρ on $\overline{cAc}$ there is contraction $a \in \overline{cAc}$ with $\rho(a^*a) = 1$ and $a^2 = 0$. Indeed, let $\rho \in A^*$ a pure state with $\rho(c) \neq 0$ then the irreducible representation $d_\rho \colon A \to \mathcal{L}(\mathcal{H})$ with cyclic vector $x \in \mathcal{L}(\mathcal{H})$, i.e., $d_\rho(A)x = \mathcal{H}$, $\|x\| = 1$ and $\langle d_\rho(a)x, x\rangle = \rho(a)$ is not a character if an only if $\dim(\mathcal{H}) > 1$. Thus there exists $y \in \mathcal{H}$ with $\|y\| = 1$ and $\langle x, y\rangle = 0$.

By ???? some of above lemmata ???

Let $E \subseteq A$ a separable C^*-subalgebra of A that contains c, let $C := \overline{cEc} \subseteq D$.

If ????

C^*-subalgebra with $c \in C_+$???

(iii): remember TEXT(iii): Let $X \subseteq A_+$ be a countable subset of elements with the property that $\overline{xAx}$ has no non-zero character for each $x \in X$. Then there exists a separable C^*-subalgebra $C \subseteq A$ with $X \subseteq C$ and the property that $\overline{xCx}$ has no non-zero characters for each $x \in X$.

(iv): Let $c \in C_+$ with $\|c\| = 1$. Then there exists a sequence $x_1, x_2, \ldots \in X$ such that $\lim_n \|x_n - c\| = 0$. The assumption that $\overline{(x_n-\rho)_+C(x_n-\rho)_+}$ has no non-zero character for all rational numbers $\rho \in (0, \|x_n\|)$ implies that $\overline{cCc}$ has no non-zero character, cf. Corollary 2.7.6.

□

PROPOSITION 2.7.12. *The class* $\mathcal{RAL}$ *of the* 'residual anti-liminary' *C^*-algebras, defined in Definition 2.7.2, is invariant under each of following operations:*

(i) *Passage to non-zero quotients,*
(ii) *Passage to non-zero hereditary C^*-subalgebras (including closed ideals),*
(iii) *Forming of finite direct sums,*
(iv) *Inductive limits,*
(v) *Maximal tensor products $A \otimes_{\max} B$, ????,*
(vi) *Infinite direct c_0-sums $A_1 \oplus A_2 \oplus \cdots$,*
(Follows from (iii) and (iv))
(v) *Passage from A to $\ell_\infty(A)$.*

If A is residual anti-liminary, then for each countable subset S of A there exists a separable C^*-subalgebra $B \subseteq A$ such that $S \subseteq B$ and B is residual anti-liminary.

In particular, each residual anti-liminary C^*-algebra A is the inductive limit of its separable residual anti-liminary C^*-subalgebras (in its natural containment order as indices of the order).

WHAT ABOUT: tensor products?,

PROOF. The proposed *permanence properties* of the class of residual anti-liminary C^*-algebras A can be seen by following indirect arguments:

If A/J is a non-zero quotient of A and $E \subseteq A/J$ a closed hereditary C^*-subalgebra of A/J and has a non-zero character $\chi\colon E \to \mathbb{C}$ (i.e., if A/J does not satisfy (ii) in place of A), then $D := \pi_J^{-1}(E)$ is a non-zero hereditary C^*-subalgebra of A, and D has the non-zero character $\chi \circ \pi_J$. But this is impossible by property (ii) of A.

Thus, E must satisfies Part(ii) if A satisfies Part(ii), i.e., E must be residual anti-liminary if A is residually anti-liminary. □

Very important open Question:
Is $\ell_\infty(A)$ residual anti-liminary if A is residually anti-liminary?

(It seems to be very difficult to decide, despite it can be reduced to the case of separable A.)

Ques: Is every separable subset of a residual anti-liminary C^*-algebra A contained in a residual anti-liminary separable C^*-subalgebra of A?

Is a C^*-subalgebra of a residual anti-liminary separable C^*-algebra again residual anti-liminary?

Is the inductive limit of a sequence of residual antiliminary separable C^*-algebras again residual anti-liminary?

Has positive answer, using following obvious fact:

(The C can be generated by a countable family of – inside C – 2-homogenous contractions ????)

Combine this with following observation:

If $b \in A_+$ is an element such that $\overline{bAb}$ has no non-zero character, then there exists a separable C^*-subalgebra $B \subseteq A$ such that $b \in B$ and $\overline{bBb}$ has no character.

It shows then by countability of a dense subset of the positive contractions in a separable C^*-algebra C:

If C is a separable C^*-subalgebra of A and $X \subset C_+$ is a countable subset of the positive contractions that is dense in $\{c \in C_+ ; \|c\| = 1\}$ then there exists a separable C^*-subalgebra D of A such that $C \subseteq D$ and for each $x \in X$ and each rational number $\rho \in (0, \|x\|)$ the hereditary C^*-subalgebra $\overline{(x-\rho)_+ D (x-\rho)_+}$ has no non-zero character.

??? To be shown !!! ???

One can show that this implies that $\overline{cDc}$ has no non-zero character for every $c \in C_+$.

In this way we find a sequence $C_1 := C \subseteq C_2 \subseteq C_3 \ldots$ of separable C^*-subalgebras C_n of A, and a countable subset S of the positive contractions $D := \overline{\bigcap_n C_n} \subseteq A$ that is dense in $\{d \in D_+ ; \|d\| = 1\}$ and has the property that $\overline{cDc}$ has no non-zero character for each $c \in S$.

Ques: Is the inductive limit of residual antiliminary C^*-algebras again residually anti-liminary?

(Seems to be: $D \subset E$ hereditary, $E = \overline{\bigcup_\tau E_\tau}$ with E_τ residual anti-liminary, τ in upward directed net, $E_\tau \leq E_\sigma$ if $\tau < \sigma$... D with character ξ.

Then by Remark/Lemma **??** ???: If $D \subseteq E$ is a hereditary C^*-subalgebra of E and J is a closed ideal of D, the the ideal I of E generated by J satisfies $D \cap I = J$.

We consider ideal I of E generated by kernel of ξ (on D), and then the ideal J generated by the image of D in E/I. It would show that $\|\pi_I(f)\| = \|\pi_J(f)\|$ for every $f \in E_\tau$. This leads to a contradiction. Thus, D can not have a character.

Thus, we can consider the quotient $E/I \supseteq D/J$. But D/J is one-dimensional: there is a projection $p \in D/J \subseteq E/I$ with $\mathbb{C} \cdot p = D/J$. and $p(E/I)p = D/J$

Thus E/I contains a minimal projection p with $p(E/I)p = \mathbb{C} \cdot p$.

The ideal K of E/I generated by p is necessarily isomorphic to $\mathbb{K}(\mathcal{H})$ of some Hilbert space.

The C^*-algebras $\pi_I(E_\tau) \cong E_\tau/(E_\tau \cap I)$ are again residual anti-liminary by Prop. ????(??).

Therefore there intersections with K must be $= \{0\}$. It follows that $\|\pi_K(\pi_I(e))\| = \|\pi_I(e)\|$ for all $e \in E_\tau$ for each τ.

We use now that $\bigcup_\tau \pi_I(E_\tau)$ is dense in $\pi_I(E)$:

There exists τ and $e \in \pi_I(E_\tau)_+$ with $\|e\| \leq 1$ and $\|p-e\| < 1/4$. This implies that $\|e\| = \|\pi_K(e)\| < 1/4$ but $\|e\| \geq \|p\| - \|p-e\| \geq 1 - 1/4 = 3/4$ (because $1/2 = \|e\| + \|p-e\| \geq \|p\| = 1$) a contradiction.

Compare Remark 2.1.16(iv):
Item(iv):
If, moreover, A is *strictly antiliminary* (also called *residually antiliminary*, cf. Definition 2.7.2) in the sense that each non-zero quotient A/J of A is antiliminary in the sense of [**616**, sec. 6.1.1]

(Here footnote:

It is equivalent to the formally stronger assumption that no hereditary C^*-subalgebra of A has a non-zero character.),

then for every non-zero hereditary C^*-subalgebra D of A, every pure state ρ on D and every $n \in \mathbb{N}$ there exists a C^*-morphism $\psi\colon \mathrm{C}_0((0,1], M_n) \to D$ with $\rho(\psi(f_0 \otimes p_{11})) = 1$.

Big big QUESTION:
Does here exists a non-zero element $e \in A_+$ such that the *hereditary* C^*-subalgebra $\mathrm{Ann}(e) := \{a \in A\,;\; ae = 0\}$ of A generates A as an ideal of A if A is residually antiliminary ????

In the case of separable A one could look to $e := (\varphi(f_0 \otimes p_{11}) - \varepsilon)$ with φ and ε suitable...?

LEMMA 2.7.13. *Let $\rho\colon D \to \mathcal{L}(\mathcal{H})$ an irreducible representation that does not contain a non-zero compact operator in its image $\rho(D)$, and $(p_1, p_2, \ldots, p_m)$ a sequence of orthogonal projections $p_n \in \mathcal{L}(\mathcal{H})$ of finite rank $k_n \in \mathbb{N}$, $1 \leq n \leq m$.*

Then D contains k_n-homogenous positive contraction $e_n \in D_+$ with $p_n\rho(e_n) = \rho(e_n)p_n = p_n$.

If the $p_1, \ldots, p_m$ are mutually orthogonal, then the e_n can be found mutually orthogonal.

PROOF. Use the "advanced version" of Kadison transitivity in Lemma 2.1.15(ii).
The case of mutually orthogonal $p_1, \ldots, p_m$ can be studied by considering the projection $p_1 + \cdots + p_m$. □

The following Lemma 2.7.14 lists some later used reformulations of the Definition 2.7.2.

It could be that some items are only one-sided implications... Check it!

LEMMA 2.7.14. *Following properties of a C^*-algebra $A \neq \{0\}$ are equivalent (???):*

(i) *Any irreducible representation of A does not contain a non-zero compact operator in its image, i.e., for every irreducible representation $\rho\colon A \to \mathcal{L}(\mathcal{H})$ holds that $\rho(A) \cap \mathbb{K}(\mathcal{H}) = \{0\}$.*

(ii) *A is residual antiliminary in sense of Definition 2.7.2.*

(iii) *Each hereditary C^*-subalgebra D of A has no (non-zero) character.*

(iv*) *[Definition 2.7.2 of "residual antiliminary" !!!] Every non-zero quotient A/I of A is antiliminary for each closed ideal $I \neq A$ of A.*

[??? Follows immediately from [**616**, prop. 6.2.8]. *????*

???? Take $J := \pi^{-1}(\mathbb{K}(\mathcal{H}))$. If $x \in J$ then how to find an other representation ???] .

(v) *For each closed ideal $I \neq A$ and $x \in A \setminus I$ there exists an irreducible representation $\pi\colon A \to \mathcal{L}(\mathcal{H})$ with $\pi(I) = \{0\}$ and $\pi(x) \notin \mathbb{K}(\mathcal{H})$.*

(vi) *All non-zero quotients A/I of A do not contain a "minimal" projection $p \in A/I$ (i.e., with the property $p(A/I)p = \mathbb{C}p \neq \{0\}$).*

(viii) *Each non-zero hereditary C^*-subalgebra D of A has no non-zero quotient of Type I.*

What means Type I here?

(It implies (iii): D has no character.)

(Implies: Each non-zero quotient of D contains a non-zero n-homogenous positive contraction.)

(ix) *For each non-zero hereditary C^*-subalgebra D of A and each pure state λ on A with $\lambda(D) \neq 0$ and each $n \in \mathbb{N}$ there exists an n-homogenous element $e \in D_+$ with $\lambda(e) > 0$.*

(x) *For every $n \in \mathbb{N}$, every closed ideal I of A, and every hereditary C^*-subalgebra D of A with $\pi_I(D) \neq \{0\}$ there exists an n-homogenous positive contraction $a \in D$ with $\|\pi_I(a)\| = 1$.*

(xi ???) *More needed ???*

PROOF. To be filled in ??

The problems are ?: Given a non-zero hereditary Abelian C^*-subalgebra D of A. Does there exists an irreducible representation ρ of A such that $\rho(D)$ is 1-dimensional ????

(extend a character ξ of D to a pure state on A/I and use that $D \cap I$ the the ideal I of A generated by the kernel of the character ???????

Let D any hereditary C^*-subalgebra of A and ξ a character of D, $K \subseteq D$ the kernel of ξ.

Citation of Lemma for next is where ???:

The closed ideal of ideal J of A generated by K has the property that $J \cap D = K$.

Thus, $\pi_J(D) \cong D/K \cong \mathbb{C}$, and therefore, $\pi_J(D) = \mathbb{C} \cdot p$ for some projection $p \in A/K$ with $p(A/K)p = \mathbb{C} \cdot p$.

?(x)⇒(ix): trivial.

?(ix)⇒(x): indirect.

The equivalence of (?v) and (?vi) (= old ???) follows immediately from [**616**, prop. 6.2.8].

The other implications follow from the fact that for each closed ideal J of a hereditary C^*-subalgebra D of A the closed ideal $I := \overline{\mathrm{Span}(AJA)}$ of A satisfies $I \cap D \supseteq J$.

latter OK ????? □

LEMMA 2.7.15. *Let A a C^*-algebra, $C_n := \mathrm{C}_0((0,1], M_n) = M_n(\mathrm{C}_0((0,1])$ for $n > 1$, $C_\infty := \mathrm{C}_0((0,1], \mathbb{K}(\ell_2(\mathbb{N}))$ and D a hereditary C^*-subalgebra of A.*

Let $\kappa \in \{2, 3, \ldots\}$ or $\kappa = \infty$. Then the following properties (i) *and* (ii) *of A and D are equivalent (for the same fixed κ).*

(i) *For every* pure *state ρ on A with $\rho|D \neq 0$ there exists a C^*-morphism $\varphi\colon C_\kappa \to D$ with $\rho(\varphi(C_\kappa)) \neq \{0\}$.*
(ii) *For* every *non-zero positive functional ρ on A (or on D) with $\rho|D \neq 0$ there exists a C^*-morphism $\varphi\colon C_\kappa \to D$ with $\rho(\varphi(C_\kappa)) \neq \{0\}$.*

Moreover, if Part (i) *holds then D has no irreducible representation $\pi\colon D \to \mathcal{L}(\mathcal{H})$ with dimension $\mathrm{Dim}(\mathcal{H}) < \kappa$.*

In case of $\kappa \in \mathbb{N}$, i.e., with $\kappa < \infty$, this property of D is moreover equivalent to Part (i)*.*

PROOF. For the following we use that for each closed ideal J of D the ideal I of A generated by J satisfies $J = I \cap D$, cf. Lemma **??**.

Consider the closed ideal J_κ of D generated by the images $\varphi(C_\kappa)$ of all possible C^*-algebra morphisms $\varphi\colon C_\kappa \to D$.

If $J = D$ then clearly Part(ii) holds, – and implies Part(i).

Conversely, if Part (i) holds then $J_\kappa = D$ because, otherwise, there would exists a pure state λ on D with $\lambda(J_\kappa) = \{0\}$. The pure state λ has a unique extension to a pure state ρ on A.

This shows the equivalence of Parts (i) and (ii).

If Part (i) holds, then D has no irreducible representation $\pi\colon D \to \mathcal{L}(\mathcal{H})$ with dimension $\mathrm{Dim}(\mathcal{H}) < \kappa$:

Indeed, if $\pi\colon D \to \mathcal{L}(\mathcal{H})$ is an irreducible representation, then the vector state $\lambda(d) := \langle \pi(d)x, x\rangle$, for given $x \in \mathcal{H}$ with $\|x\| = 1$, is a pure state on D that uniquely extends to a pure state ρ on A. By Part (i) there exists a C^*-morphism $\varphi\colon C_\kappa \to D$ with $\rho(\varphi(C_\kappa)) \neq \{0\}$.

The positive functionals ρ and λ coincide on $\varphi(C_\kappa) \subseteq D$. Thus $\pi(\varphi(C_\kappa)) \subseteq \mathcal{L}(\mathcal{H})$ is isomorphic to a non-zero quotient C^*-algebra of $\mathrm{C}_0((0,1], M_\kappa)$ and has a dimension $\geq \kappa^2$, considered as vector space. Thus, $\mathcal{L}(\mathcal{H})$ has vector-space dimension $\geq \kappa^2$. But this me means that $\mathrm{Dim}(\mathcal{H}) \geq \kappa$.

In case $\kappa = \infty$ this should be read as: $\mathcal{H}$ must be of infinite dimension, because then $\rho(\varphi(C_\kappa))x$ is as a vector space infinite dimensional for each $x \in \mathcal{H}$ with $\rho(\varphi(C_\kappa))x \neq \{0\}$ ([40]).

Above we have seen that the property of $D \subseteq A$ and $2 \leq \kappa \leq \infty$, as stated in Part (i), implies that D has no quotient that is isomorphic to M_κ if $2 \leq \kappa < \infty$, i.e., D has no irreducible representation on a Hilbert space of dimension $< \kappa$.

The opposite direction of this implication holds in case of $1 < \kappa \in \mathbb{N}$, i.e., if D has no irreducible representation $\pi \colon D \to \mathcal{L}(\mathcal{H})$ with dimension $\mathrm{Dim}(\mathcal{H}) < \kappa$, then the hereditary subalgebra $D \subseteq A$ satisfies Part (i):

Let ρ a pure state on A with $\rho|D \neq 0$. Then there is an irreducible representation $\pi \colon A \to \mathcal{L}(\mathcal{H})$ with cyclic vector x such that $\mathcal{H} = \pi(A)x$ and $\rho(a) = \langle \pi(a)x, x\rangle$ for $a \in A$. The closed linear subspace $\mathcal{H}_0 := \pi(D)x$ is invariant under $\pi(D)$ and the restrictions $\psi(d) := \pi(d)|\mathcal{H}_0$ of $\pi(d)$ to $\mathcal{H}_0$ for $d \in D$ define an irreducible *-representation ot D on $\mathcal{H}_0$. We denote by P the orthogonal projection from $\mathcal{H}$ to $\mathcal{H}_0$ and let $y := \|Px\|^{-1/2} \cdot Px$. Then $\|Px\| = \|\rho|D\| > 0$ and $\lambda(d) := \langle \psi(d)y, y\rangle$ is pure state on D of norm $= 1$.

Now we use the assumption that D has no irreducible representation on a Hilbert space of dimension $< \kappa$, i.e., that D has no quotient D/I that is isomorphic to M_m for some $m < \kappa$. It follows that $\mathrm{Dim}(\mathcal{H}_0) \geq \kappa$. Let $P \in \mathcal{L}(\mathcal{H}_0) \subseteq \mathcal{L}(\mathcal{H})$ a projection with $\mathrm{Dim}(P\mathcal{H}) = \kappa$. By Lemma **??**

there exists a C^*-morphism $\varphi \colon C_\kappa \to D$ with $\varphi(C_\kappa) = P\mathcal{L}(\mathcal{H}_0)P = P\mathcal{L}(\mathcal{H})P$ and $\psi \circ \varphi(f_0 \otimes P) = P$. Thus, $\rho(\varphi(C_\kappa)) \neq \{0\}$ and $D \subseteq A$ fulfill Part (i).

Thus, in case where $2 \leq \kappa < \infty$, the non-existence of irreducible representations $\rho \colon D \to \mathcal{L}(\mathcal{H})$ with $\mathrm{Dim}(\mathcal{H}) < \kappa$ is equivalent to Part (i) with this κ. □

The following equivalent formulations l.p.i.(1) and l.p.i(2) of local pure infiniteness imply that l.p.i. C^*-algebras A are residually antiliminary in the sense of Definition 2.7.2 ????? where ????? :

l.p.i.(1):
The C^*-algebra A is locally purely infinite if, for every non-zero hereditary C^*-subalgebra B of A and every pure state ρ of B, there exists a σ-unital stable C^*-subalgebra $D \subseteq B$ with $\rho|D \neq 0$.

Indeed, if $B \subseteq A$ is a hereditary C^*-subalgebra of A and ρ is a pure state of B, then ρ can be uniquely extended to a pure state ρ_{ext} on A with $\rho_{ext}|B = \rho$ and there exists a positive contraction $e \in B_+$ with $\rho(e) = 1$.

Let $D := \overline{eAe}$. Then $D \subseteq B$ and $\rho_{ext}(a) = \rho(eae)$ for all $a \in A$.

By assumption there exists a a stable C^*-subalgebra $D \subseteq E$ with $\rho(D) \neq \{0\}$.

[40] Notice here that $\rho \circ \varphi$ is non-zero, but is not necessarily cyclic or even irreducible, because $\varphi(C_\kappa)$ is in general not necessarily hereditary in D.

It follows that ????

for every non-zero $a \in A_+$ and pure state ρ on A with $\rho(a) > 0$, there exists a stable C^*-subalgebra $D \subseteq \overline{aAa}$ with $\rho(D) \neq \{0\}$.

Thus, ?????

Conclusion:

This property implies in particular that every nonzero hereditary C^*-subalgebra B of A can not have a character ρ, because the non-zero restriction $\rho|D$ to any stable non-zero $D \subseteq B$ can not be character.

Thus, locally purely infinite C^*-algebras are residual antiliminary in sense of Definition 2.7.2.

l.p.i.(2): The C^*-algebra A is locally purely infinite if, for every $d \in A_+$ with $\|d\| = 1$ and every state ρ of A with $\rho(d) \neq 0$, there exists $b \in D := \overline{dAd}$ with the properties that $0 \leq b\,,\ \rho(b) > \|\rho|D\|/2\,,\ \|b\| = 1$ and $\overline{bAb}$ is stable.

`Here: One of the (old! last) estimate is not clear ?!`

Question: Carries the latter property over to $A_\infty := \ell_\infty(A)/c_0(A)$?

Can one at least show that A_∞ is residually antiliminary if A is residual antiliminary?

It can be reduced to the separable case, because one can consider finite free products of $\mathrm{C}_0((0,1], M_n)$, $n = 2, 3, \ldots$. And build suitable inductive limits ...? Look if ultrapowers of this inductive limits have ultra-powers with non-zero characters.

One could try to construct an inductive limit of free products of $\mathrm{C}_0((0,1], M_n)$ that is "universal" for residual antiliminary separable C^*-algebras.

Proof of l.p.i. $\Rightarrow$ l.p.i.(1):

Definition 2.0.3 implies l.p.i.(1): If ρ is a pure state on E then there exists, e.g. by cf. Lemma 2.1.15(ii), a contraction $a \in E_+$ with $\rho(a) = 1$. We can extend ρ to a pure state on A. Thus, there exists a stable C^*-subalgebra $D \subseteq \overline{aAa} \subseteq E$ with $\rho|D \neq 0$ by Definition 2.0.3.

`Next ques should be somewhere discussed`

Question:

Let A a residually antiliminary C^*-algebra and $b \in A_+$ with $\|b\| = 1$ and ρ a state on A with $\rho(b) > 2/3$. Does there exist a general continuous function $f(t) > 0$ with $\lim_{t\to 0} f(t) > 0$ such that there exist always an n-homogenous element $a \in A_+$ with $a \min((1 + 1/n)b, 1) = a$ and $\rho(a) > f(1/n)$?????

`Sort above Lemmata and its Proofs!`
`Until here some are on wrong place ??`

The following Proposition 2.7.16 shows that possible differences between the definitions of Properties pi-n and pi(n) disappear if the multiplier algebra $\mathcal{M}(A)$ of A has a properly infinite unit.

PROPOSITION 2.7.16.
Suppose that A satisfies the following properties (i) *and* (ii) *:*

(i) *For each n-homogenous element $a \in A_+$ and each $b \geq 0$ in the closed ideal $J(a)$ of A generated by a there exists a sequence of elements $d_1, d_2, \ldots \in A$ with $a + b = \lim_n d_n^* a d_n$.*

(ii) *A has no irreducible representations $\rho\colon A \to \mathcal{L}(\mathcal{H})$ of dimension $\leq n$ (of the Hilbert space $\mathcal{H}$).*

Then every non-zero n-homogenous positive element is properly infinite inside the C^*-algebra A .

We do *not* require in Part (i) that $ab = 0$ for the in Part (i) considered sums $a + b$.

The property in Part (i) holds for A if each n-homogenous element of A is properly infinite, but Part (ii) does not follow from Part (i), e.g. for the C^*-algebra $A := \mathcal{O}_2 \oplus M_{n-1}$. (Each non-zero n-homogenous element $a = x \oplus y$ satisfies $a = x \oplus 0$ with $x \neq 0$ and $J(a) = \mathcal{O}_2 \oplus 0$. Then there exists d with $d^* a d = 1 \oplus 0$.)

A trivial example is $A := M_{n-1}$, it satisfies condition (i) trivially, because only 0_{n-1} is n-homogenous in M_{n-1}, but A satisfies not (ii).

PROOF. The idea of the proof are the following:

(α) The assumptions (i) and (ii) pass to all non-zero quotients of all non-zero hereditary C^*-subalgebras of A.

(In particular, A is residually antiliminary in sense of Definition 2.7.2, because this permanence implies that non-zero hereditary C^*-subalgebras can not have contractions.)

(β) It follows from this permanence properties that it suffices to show that each non-zero n-homogenous positive contraction $X \in A_+$ is not finite in A (i.e., is infinite in A).

(γ) To show (β) we shall find for the given X non-zero n-homogenous positive contractions $T \leq S \leq X$ and $R \leq X$ such that $R + S = X$, $TS = T \neq 0$, S in the ideal generated by R and $TR = 0$.

Then it follows that $X \precsim R$, because $X = R + S$ is in the ideal generated by the n-homogenous R. This implies together with $R + T \leq R + S = X$, that $X \approx R$ and then that $R \approx T + R$.

The relations $R \approx T + R$, $T \neq 0$ and $TR = 0$ imply that R is infinite in A. Thus X is infinite in A.

Now we prove this claims and carry out this constructions explicitly:

The Part(i) says that if $\varphi\colon \mathrm{C}_0(0,1] \otimes M_n \to A$ is a C^*-morphism, then for $c := \varphi(f_0 \otimes 1_n)$ holds: If b is in the closed ideal generated by $a := \varphi(f_0 \otimes p_{11})$ then $b \precsim c$. Notice that c is MvN-equivalent in $M_n(A) \subset M_\infty(A)$ to the n-fold sum $\mathrm{diag}(a, a, \ldots, a) = a \oplus a \oplus \cdots \oplus a$.

If expressed in $W(A)$ it says:

If $b \in A$ satisfies $[b] \leq m[a]$ then this implies $[b] \leq \min(m, n)[a]$.

It implies that for every nonzero $n+1$-homogenous element $b := \psi(f_0 \otimes 1_{n+1})$ the n-homogenous element $c := \psi(f_0 \otimes 1_n)$ is properly infinite in A, because it says in $W(A)$ that $[b] = n[a] + [a] = [c] + [a] \leq n[a] = [c]$ and then inductively (over k) that $[c] + k[a] \leq [c]$ and finally that $[c] + [c] \leq [c]$, i.e., that c is properly infinite in A.

The arguments show also that A has the property that all n-homogenous elements $c = \psi(f_0 \otimes 1_n)$ of A "absorb" all elements $b \in A_+$ – in the sense that $b \oplus c \precsim c$ - with $bc = 0$ and and b is in the closed ideal of A that is generated by c ([41]).

It is easy to see that this property passes to all non-zero hereditary C^*-subalgebras $D \subseteq A$ of A.

The passage to the quotient goes as follows: Every selfadjoint contraction $b - c \in A/J$ (with $bc = 0$, and $0 \leq b \leq 1$ and $0 \leq c \leq 1$) can be lifted to a selfadjoint contraction in A, and every n-homogenous positive contraction in A/J can be lifted to an n-homogenous contraction in A, cf. Proposition A.8.4 (or [**540**, cor. 3.8]).

Now we show by an indirect argument that this implies that the C^*-algebra A is residually antiliminary in the sense of Definition 2.7.2 using the characterization in Part (iv) of Proposition 2.7.7:

Let $\rho \colon A \to \mathcal{L}(\mathcal{H})$ an irreducible representation of A. Suppose that there exists a positive contraction in $a \in A_+$ with $0 \neq \rho(a) \in \mathbb{K}(\mathcal{H})$. Then the dimension of $\mathcal{H}$ is $\geq n+1$ by assumption in Part (ii) of Proposition 2.7.16. Moreover then $\rho(A) \cap \mathbb{K}(\mathcal{H})$ is a non-zero C^*-subalgebra of $\mathbb{K}(\mathcal{H})$ that acts irreducibly on $\mathcal{H}$. Thus, $\rho(A) \cap \mathbb{K}(\mathcal{H}) = \mathbb{K}(\mathcal{H})$, and we find an projection $P = P^*P \in \mathbb{K}(\mathcal{H})$ of rank $n+1$.

It follows that there exists a C^*-subalgebra B of A such that $\rho|B$ is a epimorphism from B onto $P\mathbb{K}(\mathcal{H})P \cong M_{n+1}$. The projectivity of $\mathrm{C}_0((0,1], M_{n+1})$, cf. Proposition A.8.4 (or [**540**, cor. 3.8]), shows that there exists an $(n+1)$-homogenous element $b := \psi(f_0 \otimes 1_{n+1}) \in B \subseteq A$ with $\rho(b) = P$. But above we have seen that $[b] = (n+1)[\psi(f_0 \otimes p_{11})]$ satisfies $2[b] \leq [b]$, i.e., the b is properly infinite in A. It is easy to see that non-zero image P of the properly infinite element $b \in A$ are properly infinite. Since P is not properly infinite this contradicts the existence of P and that of non-zero elements in $\rho(A) \cap \mathbb{K}(\mathcal{H})$.

Hence, $\rho(A) \cap \mathbb{K}(\mathcal{H}) = \{0\}$ for every irreducible representation $\rho \colon A \to \mathcal{L}(\mathcal{H})$ of A, i.e., A is residually antiliminary.

Change notation, use only two functions f_1, f_2.!?
Remove blue repeat of assumptions?

Suppose that each n-homogenous element $a \in A_+$ has the following property:

[41] It seems that this property is not equivalent to the stated assumptions on A.

For every positive element $b \in \overline{\mathrm{span}(AaA)} =: J(a)$ *there exist* $d_1, d_2, \ldots \in A$ *with* $\lim_k d_k^* a d_k = a + b$*, and that* A *has no irreducible representation of dimension* $\leq n$*.*

We show the following observations (1.0)-(1.3), (2.1) and (2.2), and get finally in (3.0) the desired conclusion.

(1.0) The C^*-algebra A is residual antiliminary in sense of Definition 2.7.2.

(1.1) The properties (i) and (ii) of A pass to each non-zero hereditary C^*-subalgebra D of A, and to all quotients A/I for closed ideals $I \neq A$.

(It is done at the beginning ?)

(1.2) All non-zero $(n+1)$-homogenous elements of $(A/I)_+$ are infinite in A/I.

(It is done at the beginning ?)

(1.3) Non-zero quotients A/I of A can not contain a "minimal" projection $p \in A/I$ with $p(A/I)p = \mathbb{C}p$. (Should be equivalent to "A is residual antiliminary"???)

In particular, any irreducible representation of A does not contain a non-zero compact operator in its image, and each non-zero hereditary C^*-subalgebra D of A has no character.

`(1.3) has been discussed further above or below. Synchronize!`

(2.1) Every non-zero n-homogenous $a \in A_+$ is infinite in A.

(2.2) Every non-zero n-homogenous $a \in (A/I)_+$ is infinite in A/I for every closed ideal $I \neq A$ of A. [Follows immediately from (2.1) and (1.1) by replacing A by A/I.]

(3) Final conclusion from (2.1) and (2.2): Every non-zero n-homogenous element $a \in A_+$ is properly infinite in A, because it says equivalently – by Lemma 2.5.3(v) – that $\pi_I(a)$ is infinite in A/I or $a \in I$ for every closed ideal I of A.

Ad(1.1): Let $\{0\} \neq D \subseteq A$ a hereditary C^*-subalgebra of A and $0 \neq a \in D_+$, $b \in D_+$ in the closed ideal $\overline{\mathrm{span}(DaD)}$ of D generated by a. Then $b \in \overline{\mathrm{span}(AaA)}$ and there exist $d_1, d_2, \ldots \in A$ with $\lim_k d_k^* a d_k = a + b$. The elements $e_k := a^{1/m_k} d_k (a+b)^{1/k}$ are in D and satisfy $\lim_k e_k^* a e_k = a + b$ if the $m_k > k$ are chosen such that $\|a^{1/2} a^{1/m_k} - a^{1/2}\| < 2^{-n} \cdot (\|d_k\|^2 + 1)^{-1}$.

If $\rho \colon D \to \mathcal{L}(\mathcal{H})$ is an irreducible representation ??????????

properties (i) and (ii) of A pass to each non-zero

?? hereditary ??

C^*-subalgebras D of A:

Let $I \neq A$ a closed ideal of A. Then A/I can not have an irreducible representation ρ of dimension $\leq n$, because $\rho \circ \pi_I$ would be an irreducible representation of A on a Hilbert space of dimension $\leq n$, that we have excluded by assumption (ii).

Now let $0 \neq c \in (A/I)_+$ an n-homogenous element and $g \in (A/I)_+$ in the ideal generated by c. We can suppose that $\|c\| = 1$, otherwise replace c by $\|c\|^{-1}c$. Then there exists a C^*-morphism $\psi\colon \mathrm{C}_0((0,1], M_n) \to A/I$ with $c := \psi(f_0 \otimes 1_n)$.

The C^*-algebra $\mathrm{C}_0((0,1], M_n)$ is projective, cf. Proposition A.8.4. Thus there exists a C^*-morphism $\varphi\colon \mathrm{C}_0((0,1], M_n) \to A$ with $\pi_I \circ \varphi = \psi$. The element $a := \varphi(f_0 \otimes 1_n) \in A_+$ satisfies $\pi_I(a) = c$.

Let $\varepsilon \in (0,1)$. There are $h_1, h_2, \ldots, h_m \in A$ with $\|g - \sum_k \pi_I(h_k)^* c \pi_I(h_k)\| < \varepsilon/2$, because the element g is contained in the ideal generated by c.

Property (i) of n-homogenous $a \in A_+$ and that $b := \sum_k h_k^* a h_k$ give the existence of $d \in A$ with $\|(a+b) - d^*ad\| < \varepsilon/2$. Thus $\|(c+g) - \pi_I(d)^* c \pi_I(d)\| < \varepsilon$.

This shows Part (1.1), i.e., that A/I satisfies the assumptions (i) and (ii) – with c and A/I in place of a and A.

Ad(1.2): Let $c \in A_+$ an $(n+1)$-homogenous element. By Lemma 2.5.3(v) it suffices to show that $\pi_I(c)$ is infinite in A/I for all closed ideals I of A with $c \notin I$. By (1.1) the non-zero quotients A/I of A satisfy again conditions (i) and (ii) with $0 \neq \pi_I(a) \in (A/I)_+$ in place of $0 \neq a \in A_+$. Therefore, it suffices to show that each non-zero $(n+1)$-homogenous element in A_+ is infinite in A:

If $\psi\colon \mathrm{C}_0(0,1] \otimes M_{n+1} \to A$ is a non-zero C^*-morphism and $c := \psi(f_0 \otimes 1)$, then $a := \psi(f_0 \otimes (1 - p_{11}))$ is an n-homogenous element and $b := \psi(f_0 \otimes p_{11})$ is in the ideal generated by a, because $b = zz^*$ and $z^*z = \psi(f_0 \otimes p_{22}) \leq a$ for $z := \psi(f_0^{1/2} \otimes p_{12})$. Thus, $b + a = \lim_n d_n^* a d_n$ for a suitable sequence $d_1, d_2, \ldots \in A$ by assumptions on A and a. In particular $c = b + a \precsim a$, $ab = ba = 0$ and $b \neq 0$, i.e., a is infinite in sense of Definition 2.5.1. Then $a \leq c \precsim a$ shows that $c \approx a$, and c is infinite in A.

Ad(1.3): Suppose that $p \in A/I$ is a projection with $p(A/I)p = \mathbb{C} \cdot p$. Then the closed ideal K of A/I generated by p is isomorphic to $\mathbb{K}(\mathcal{H}) \cong K$ for some Hilbert space $\mathcal{H}$.

Suppose that $\mathrm{Dim}(\mathcal{H}) > n$. Then there exists an $n+1$-homogenous element in K (given by any projection $p \in K$ of rank $= n+1$). But this is not possible, because all $n+1$-homogenous elements in A/I are properly infinite by Step (1.2).

It follows that $\mathrm{Dim}(\mathcal{H}) \leq n$. Then $\mathbb{K}(\mathcal{H}) \cong K$ is unital and its unit is in the center of A/I. It would define an irreducible representation of A of dimension $\leq n$. But this has been excluded by the assumption (ii) on A. Hence, a minimal projection p can not exist in any quotient of A.

If D is a non-zero hereditary C^*-subalgebra of A ?????

Ad(1.4): Let $\{0\} \neq D \subseteq A$ a hereditary C^*-subalgebra of A and $0 \neq Y \in D_+$ an n-homogenous element and $b \in D_+$ in the ideal $J(Y)$ generated by Y.

(1.4.a) An element $b \in D$ is in the ideal of D generated by Y inside D, if and only if, b is in the ideal $J(Y)$ of A generated by Y, i.e., $D \cap J(Y) = I(Y)$ for the ideal of $I(Y)$ of D generated by Y.

Compare here also Remark A.5.8 or Lemma 2.7.3!

This is because if $f_1, \ldots, f_m \in A$ satisfy $\|b - \sum_k f_k^* Y f_k\| < \varepsilon$ then for suitable $\beta \in (0, 1/2)$ and $g_k := Y^\beta f_k b^\beta$ holds $\|b - \sum_k g_k^* Y g_k\| < \varepsilon$.

Moreover then there exists a sequence of elements $d_n \in A$ with $\lim_n d_n^* Y d_n = Y + b$. Again we can suppose that the d_n are in D, by replacing the d_n by $Y^{\beta_n} d_n (Y + b)^{\beta_n}$ for a suitable zero sequence $\beta_n \in (0, 1/2)$.

(1.4.b)

D has no irreducible representation of dimension $\leq n$:

An irreducible representation of D of finite dimension extends to an irreducible representation ρ of A that contains the compact operators in its image. Let I denote the kernel of ρ. It would imply that a quotient A/I of A contains a projection p with $p(A/I)p = \mathbb{C} \cdot p$. We have seen in

Ad(1.2)

that this is impossible.

Thus, D has no irreducible representation of finite dimension. In particular, D has no character.

Ad(2): Every nonzero n-homogenous $Y \in A_+$ is infinite in A:

Let $Y \in A_+$ non-zero and n-homogenous. Since $Y \approx \|Y\|^{-1} Y$, we can suppose that $\|Y\| = 1$. Then there exists $\psi\colon \mathrm{C}_0(0, 1] \otimes M_n \to A$ with $\psi(f_0 \otimes 1_n) = Y$, where $f_0(t) = t$ on $[0, 1]$.

Consider the functions $f_1(t) := \min(3t, 1)$, $f_2(t) := \min(\max(3t - 1, 0), 1)$, and $f_3(t) := \max(3t - 2, 0)$ in $\mathrm{C}_0(0, 1]_+$. They are increasing with $f_k(1) = 1$ and $f_k(0) = 0$ $(k = 1, 2, 3)$ and satisfy $f_0 \leq f_1 \leq 3f_0$, $f_2 f_1 = f_2$, $f_3 f_2 = f_3$, $f_1 + f_2 + f_3 = 3f_0$, $f_3 = (3f_0 - 2)_+$, $f_2 = (3f_0 - 1)_+ - (3f_0 - 2)_+$ and $f_1 = 3f_0 - (3f_0 - 1)_+$.

Let $X_1 := 3Y - (3Y - 1)_+ = \psi(f_1 \otimes 1_n)$, $X_2 := (3Y - 1)_+ - (3X - 2)_+ = \psi(f_2 \otimes 1_n)$ and $X_3 := (3Y - 2)_+ = \psi(f_3 \otimes 1_n)$. Then the X_k are all n-homogenous, have norms $\|X_k\| = 1$, and $X_{k+1} = X_{k+1} X_k$ (for $k = 1, 2$). Moreover $Y \leq X_1 \leq 3Y$, in particular $Y \approx X_1$.

The element $Z := \psi(f_3 \otimes p_{11})$ has norm $\|Z\| = \|X_3\| = 1$, because the elements $\psi(f_3 \otimes p_{jj})$ $(j = 1, \ldots, n)$ are pairwise orthogonal, are MvN-equivalent and their sum is $X_3 = \psi(f_3 \otimes 1_n)$. It implies $\|\psi(f_3 \otimes p_{jj})\| = \|X_3\| = 1$ for $1 \leq j \leq n$.

Moreover we get that $Z\psi(f_2 \otimes p_{11}) = Z = Z\psi(f_1 \otimes p_{11})$ because $f_3 f_2 = f_3 = f_3 f_1$. Let $D := \overline{ZAZ}$ the hereditary C^*-subalgebra of A generated by Z.

In Ad(2) we have seen that D has no character. In particular D is not Abelian.

A non-abelian C^*-algebra D contains a nonzero element $x \in D$ with $\|x\| = 1$ and $x^2 = 0$. I.e., D contains a 2-homogenous element $\varphi\colon \mathrm{C}_0(0, 1] \otimes M_2 \to D$ with $\varphi(f_0 \otimes p_{12}) = x$. In particular $\|\varphi(f_0 \otimes 1_2)\| = 1$.

(It can be seen from the existence of an irreducible representation of dimension ≥ 2 and a strong variant of the Kadison transitivity theorem, - Lemma 2.1.15(ii)-, and projectivity of $\mathrm{C}_0(0, 1] \otimes M_2$.

Give ref's or cite!?)

Now we use the natural isomorphism $\overline{X_3AX_3} \cong D \otimes M_n$ for $X_3 := \psi(f_3 \otimes 1_n)$ in a way that $\psi(f_3 \otimes p_{jk})$ corresponds to to $Z \otimes p_{jk} \in D \otimes M_n$. Notice that $X_2(Z \otimes p_{jk}) = (Z \otimes p_{jk}) = (Z \otimes p_{jk})X_2$ under this natural identification.

We build the elements $g_1, g_2 \in \mathrm{C}_0(0,1]$ by $g_1 := 2f_0 - (2f_0 - 1)_+ = \min(2f_0, 1)$ and $g_2 := 2f_0 - \min(2f_0, 1) = \max(2f_0 - 1, 0)$. Notice that $g_1 + g_2 = 2f_0$, $g_2 = (2f_0 - 1)_+$, $g_1 g_2 = g_2$ and $g_1(1) = g_2(1) = 1$. In particular $\|\varphi(g_1 \otimes e_{jk})\| = 1 = \|\varphi(g_1 \otimes 1_2)\|$, $\|\varphi(g_2 \otimes 1_2)\| = 1$ and $\varphi(g_1 \otimes 1_2)\varphi(g_2 \otimes 1_2) = \varphi(g_1 \otimes 1_2)$.

Let $E \subseteq A$ the hereditary C^*-subalgebra of A defined by

$$E := \overline{\psi(f_1 \otimes 1_n)A\psi(f_1 \otimes 1_n)}\,.$$

There is a natural isomorphism γ from E onto the C^*-algebra $F \otimes M_n$, where F is the hereditary C^*-subalgebra of A given by

$$F := \overline{\psi(f_1 \otimes p_{11})A\psi(f_1 \otimes p_{11})}\,.$$

Notice that $\psi(f_1 \otimes p_{11})\varphi(h) = \varphi(h)$ for all $h \in \mathrm{C}_0(0,1] \otimes M_2$, because $\psi(f_1 \otimes p_{11})d = d$ for all $d \in D$.

We define $S := \varphi(g_2 \otimes e_{11}) \otimes 1_n$, $T_1 := \varphi(g_1 \otimes e_{11}) \otimes 1_n$, $T_2 := \varphi(g_1 \otimes e_{22}) \otimes 1_n$, $R := X_1 - T_1 = [\psi(f_1 \otimes p_{11}) - \varphi(g_1 \otimes e_{11})] \otimes 1_n$. Notice that $T_1 S = S$ implies $RS = 0$, that $S \leq T_1 \sim_{MvN} T_2$ and $T_2 \leq R$. It follows that T_1 and S are in closed ideal generated by R. Since $\psi(f_1 \otimes p_{11})\varphi(g_1 \otimes e_{jj}) = \varphi(g_1 \otimes e_{jj})$ it follows that R is a positive n-homogenous element in A and that $RT_2 = T_2 = T_2 R$ implies that $T_2 \leq R$ and $\|R\| = 1$.

Clearly $R \leq X_1$ and $X_1 = R + T_1$. Thus $R \precsim X_1$. Since R is n-homogenous and $T_1 \approx T_2 \leq R$ it follows by assumption on n-homogenous elements in A that $X_1 = R + T_1 \precsim R$.

Thus, $X_1 \approx R$. It implies that the X_1 is infinite in A if and only if R is infinite in A. Since $Y \approx X_1$ (by $Y \leq X_1 = 3Y - (3Y - 1)_+ \leq 3Y$) this would cause also that Y is infinite in A.

Since $RS = 0$, $\|S\| = 1$ and $S \leq T_1 \approx T_2 \leq R$ we have by assumption on n-homogenous elements $R \in A_+$ that there exist $d_1, d_2, \ldots \in A$ with $S + R = \lim_n d_n^* R d_n$. This implies $S + R \precsim R$. On the other hand $(S + R) \oplus 0 = [S^{1/2}, R^{1/2}][S^{1/2}, R^{1/2}]^*$ and $S \oplus R = \mathrm{diag}(S, R) = [S^{1/2}, R^{1/2}]^*[S^{1/2}, R^{1/2}]$ in $M_2(A)$, i.e., $(S + R) \oplus 0 \sim_{MvN} S \oplus R$ in $M_2(A)$. It implies that $S \oplus R \precsim R \oplus 0$ in $M_2(A)$. Thus R, X_1 and Y are infinite elements of A_+.

Since the considered property of Y pass to each quotient A/I of A with $Y \notin I$, it follows finally that Y is properly infinite in A by Lemma 2.5.3(v). □

The following Corollaries 2.7.18 and 2.7.19 are consequences of Proposition 2.7.16.

But we have here inserted also other permanence properties.
Move this to other places.

PROPOSITION 2.7.17. *The Property pi-n of a C^*-algebra A implies that A has Property pi(n).*

Both properties imply that all non-zero n-homogenous elements in A are properly infinite.

Both properties pass to non-zero hereditary C^*-subalgebras and to non-zero quotients.

If, for each $a \in A_+$ and $\varepsilon \in (0, \|a\|)$, there exists elements $d_1, \ldots, d_n \in A$ with $d_j^* d_k = \delta_{jk}(a - \varepsilon)_+$, then Property pi($n$) implies also Property pi-n.

`Not verified, needs special topology of` prime(A)`!:`

??? And then both are equivalent to the property that A has no irreducible representation of dimension $\leq n$ and all n-homogenous elements are properly infinite.???

The Property pi(n) (and therefore also the Property pi-n) implies that A is residually antiliminary in sense of Definition **??**.

The algebra $\mathbb{K}(\mathcal{H})$ of compact operators in any Hilbert space $\mathcal{H}$ can not have one of the properties pi-n or pi(n). In particular, C^*-algebras with this properties have no irreducible representations of finite dimension.

PROOF. The Property pi-n implies Property pi(n):

Let $a \in A_+$, $b \in A_+$ in the closed ideal generated by a, and $\varepsilon > 0$, then there exists $\delta > 0$ and $d_1, \ldots, d_m \in A$ with $\sum_{k=1}^{m} d_k(a - 2\delta)_+(d_k)^* = (b - \varepsilon)_+$. Let $\ell \in \mathbb{N}$ with $n \leq (\ell - 1) \cdot n \leq m \leq \ell \cdot n$. Then the row-matrix $D \in M_{1,m}$ with entries $[d_1, \ldots, d_m]$ in $M_{1,m}$ satisfies $D((a - 2\delta)_+ \otimes 1_m)D^* = (b - \varepsilon)_+$.

By assumption of Property pi-n, the diagonal matrix

$$\operatorname{diag}((a - \gamma)_+, \ldots, (a - \gamma)_+) = (a - \gamma)_+ \otimes 1_n$$

is properly infinite inside $M_n(A)$ for each $\gamma \in (0, \|a\|)$. Thus, there exists an operator matrix $R \in M_{m,n}(A)$ with

$$R((a - \delta)_+ \otimes 1_n)R^* = (a - 2\delta)_+ \otimes 1_m\,.$$

The row matrix $D \cdot R \in M_{1,n}(A)$ satisfies $(D \cdot R)((a - \delta)_+ \otimes 1_n)(D \cdot R)^* = (b - \varepsilon)_+$. This shows that an element b in the in the in closed ideal generated by a non-zero element $a \in A$ can be approximated by sums of n products $cad \in A \cdot a \cdot A$.

The Properties pi-n and pi(n) pass to non-zero hereditary C^*-subalgebras D, in particular to non-zero closed ideals J, and they pass to all non-zero quotients.

`What happens with stabilizations?` $A \otimes M_n$?

The algebra $\mathbb{K}(\mathcal{H})$ of compact operators in any Hilbert space $\mathcal{H}$ can not have one of the properties pi-n or pi(n). In particular, C^*-algebras with this properties have no irreducible representations of finite dimension. □

COROLLARY 2.7.18. *If the C^*-algebra A has Property pi-n of Definition **??** or Property pi(n) of Definition 2.0.4, then every non-zero n-homogenous element of A_+ is properly infinite.*

PROOF. The Property pi-n implies Property pi(n) by Lemma 2.1.2

Let $a \in A_+$, $b \in A_+$ in the closed ideal generated by a, and $\varepsilon > 0$, then there exists $\delta > 0$ and $d_1, \ldots, d_m \in A$ with $\sum_{k=1}^{m} d_k(a-2\delta)_+(d_k)^* = (b-\varepsilon)_+$. Let $\ell \in \mathbb{N}$ with $n \leq (\ell - 1) \cdot n \leq m \leq \ell \cdot n$. Then the row-matrix $D \in M_{1,m}$ with entries $[d_1, \ldots, d_m]$ in $M_{1,m}$ satisfies $D((a-2\delta)_+ \otimes 1_m)D^* = (b-\varepsilon)_+$.

By assumption of Property pi-n, the diagonal matrix

$$\mathrm{diag}((a-\gamma)_+, \ldots, (a-\gamma)_+) = (a-\gamma)_+ \otimes 1_n$$

is properly infinite inside $M_n(A)$ for each $\gamma \in (0, \|a\|)$. Thus, there exists an operator matrix $R \in M_{m,n}(A)$ with

$$R((a-\delta)_+ \otimes 1_n)R^* = (a-2\delta)_+ \otimes 1_m .$$

The row matrix $D \cdot R \in M_{1,n}(A)$ satisfies $(D\cdot R)((a-\delta)_+ \otimes 1_n)(D\cdot R)^* = (b-\varepsilon)_+$. This shows that an element b in the closed ideal generated by a non-zero element $a \in A$ can be approximated by sums of n elements *cad* in $A \cdot a \cdot A$.

The Properties pi-n and pi(n) pass to non-zero hereditary C^*-subalgebras D, in particular to non-zero closed ideals J, and they pass to all non-zero quotients.

`What happens with stabilizations?` $A \otimes M_n$?

The algebra $\mathbb{K}(\mathcal{H})$ of compact operators in any Hilbert space $\mathcal{H}$ can not have one of the properties pi-n or pi(n). In particular, C^*-algebras with this properties have no irreducible representations of finite dimension.

Let ρ a pure state on A, $L := \{a \in A\,;\ \rho(a^*a) = 0\}$, $\mathcal{H} := A/L$, and $D\colon A \to \mathcal{L}(\mathcal{H})$ the corresponding irreducible representation. Then there exists a contraction $e \in A_+$ with $\rho(e) = 1 = \|\rho\|$. By Property pi-n, the diagonal matrix $\mathrm{diag}(e, \ldots, e)$ is infinite in $M_n(A)$.

In case of Property pi-n, the Definition **??** rather directly implies that all n-homogenous non-zero elements in A with Property pi-n are properly infinite in A:

If $a \in A_+$ is n-homogenous and $\|a\| = 1$, then there exists a C^*-morphism $\psi\colon \mathrm{C}_0(0,1] \otimes M_n \to A$ with $\psi(f_0 \otimes 1_n) = a$, where $f_0(t) = t$ for $t \in [0,1]$.

Let $F := f_0 \otimes 1_n$ $G := f_0 \otimes e_{11}$ in $\mathrm{C}_0(0,1] \otimes M_n$, the equivalence $\psi(F) \otimes e_{11} \sim_{MvN} \psi(G) \otimes 1_n$ in $A \otimes M_n$ and an isomorphism

$$A \supseteq \overline{\psi(F)A\psi(F)} \cong M_n(\,\overline{\psi(G)A\psi(G)}\,) \subseteq M_n(A)$$

that maps the n-homogenous element $\psi(F) \in \overline{\psi(F)A\psi(F)} \subseteq A$ to the element $\psi(G) \otimes 1_n \in A \otimes M_n$. The element $\psi(G) \otimes 1_n$ is properly infinite in $A \otimes M_n$ by Definition **??**. It is then automatic also properly infinite inside the hereditary C^*-subalgebra $\overline{\psi(G)A\psi(G)} \otimes M_n$ of $A \otimes M_n$ generated by $\psi(G) \otimes 1_n$. But there is an isomorphism from the C^*-algebra $M_n(\overline{\psi(G)A\psi(G)}$ onto the hereditary C^*-subalgebra $\overline{aAa} = \overline{\psi(F)A\psi(F)}$ with the n-homogenous element $\psi(F) = a$ corresponding to the in $\overline{\psi(G)A\psi(G)} \otimes M_n$ properly infinite $\psi(G) \otimes 1_n$. Thus, the n-homogenous $a \in A_+$ is properly infinite in A, and this shows that the property pi-n of A implies that each non-zero n-homogenous element $\psi(F) \in A$ is properly infinite in A.

In the case of Property pi(n) the proper infiniteness of non-zero n-homogenous elements can be derived with help of the (not so trivial) Proposition 2.7.16:
The Definition 2.0.4 requires (!) that A has no irreducible representation on a Hilbert space of dimension $\leq n$ and that A has the property that each element c in the closed ideal $J(a)$ generated by $a \in A$ satisfies $[c] \leq n[a]$ in the (large) Cuntz algebra $\mathrm{Cu}(A)$.

If moreover $a, c \in A_+$ are non-zero then the latter means that, for each $\varepsilon > 0$ there exists $\delta \in (0, \|a\|)$ and $d_1, \ldots, d_n$ such that

$$(c - \varepsilon)_+ \,=\, d_1^*(a - \delta)_+ d_1 + \ldots + d_n^*(a - \delta)_+ d_n \,.$$

In special case where $a \in A_+$ is n-homogenous and $\|a\| = 1$, there exists $\psi \colon \mathrm{C}_0(0,1] \otimes M_n \to A$ such that $a = \psi(F)$ for $F := f_0 \otimes 1_n$. Let $b := \psi(f_0 \otimes p_{11}) \in A_+$. Then the element $c \in J(a) = J(b)$ satisfies also that $c \in J(b)$ and now $[c] \leq n[b] = [a]$.

Thus, we can in this special case the above defined n-homogenous element $a := \psi(F)$, the element $b := \psi(G)$ and get for every $c \in J(a)_+$, that $c + a \in J(a) = J(b)$ and $[c + a] \leq n[b] = [a]$. It gives that $c + a \precsim a$ in A for all n-homogenous $a \in A_+$ and $c \in J(a)_+$. The additional requirement that A has no irreducible representation of dimension $\leq n$ allows to apply Proposition 2.7.16 to get that all non-zero n-homogenous elements of A are properly infinite in A. □

The Corollary 2.7.18 implies immediately the following Corollary:

COROLLARY 2.7.19. *If the unit element $1_{\mathcal{M}(A)}$ of the multiplier algebra is properly infinite, i.e., if there exists isometries $S, T \in \mathcal{M}(A)$ with $S^*T = 0$, then A has Property pi-n of Definition* **??**, *if and only if, A has Property pi(n) of Definition 2.0.4.*

`Check next proof again. Something not clear?`

PROOF. Since $\mathcal{M}(A)$ is unitally contained in $\mathcal{M}(\ell_\infty(A))$, $\mathcal{M}(A_\infty)$ and $\mathcal{M}(A_\omega)$, it follow that this algebras have no finite-dimensional quotient C^*-algebras.

In fact, the properties pi-n and pi(n) are equivalent if for every element $a \in A_+$ and $\varepsilon \in (0, \|a\|)$ there exist elements $b_1, \ldots, b_n \in A$ with $b_j^* b_k = \delta_{j,k}(a - \varepsilon)_+$. In case of Corollary 2.7.19 one can use $b_k := S^k T \cdot (a - \varepsilon)_+^{1/2}$, for $k = 1, \ldots, n$.

The $b := \sum_{k=1}^n b_k b_k^* \in A_+$ is a properly infinite n-homogenous element and $b \otimes p_{11}$ is approximately equivalent in $M_n(A)$ to the diagonal $n \times n$-matrix $C := \mathrm{diag}((a - \varepsilon)_+, \ldots, (a - \varepsilon)_+) \in M_n(A)$.

But the question is if C is properly infinite in $M_n(A)$, i.e., if $C\oplus 0 \approx C\oplus (a-\varepsilon)_+$ in $M_{n+1}(A)$.

If $c=\sum_{k=1}^m d_k^* a d_k$, then for every $\varepsilon>0$ there exists $\delta>0$ and $e_j\in A$ such that $(c-\varepsilon)_+ = \sum_{j=1}^n e_j^*(a-\delta)_+ e_j$.

Thus ??????

Then $\sum_k (b_k)^* b_k = n\cdot (a-\delta)_+$ and $\sum_k b_k(b_k)^*$ is an n-homogenous element that is equivalent to $(a-\varepsilon)_+\otimes 1_n$ in $M_n(A)$.

???? □

Next BLUE is not proven yet. Perhaps it is wrong ...

The free product $A:=C_1 * C_2 * \cdots$ of a sequence of $C_1, C_2, \ldots$, where the C_n are copies $C_n\cong \mathrm{C}_0((0,1],\mathbb{K}(\ell_2(\mathbb{N})))$ of the cones over the compact operators, has no irreducible representation of finite dimension but the ultrapower A_ω of A has a character (and has irreducible representation of each finite dimension). But this example A is not residually antiliminary:
A has e.g. the compact operators $\mathbb{K}$ on $\ell_2(\mathbb{N})$ as its quotient, because $\mathbb{K}$ is the quotient of one of the freely generating copies C_n of $\mathrm{C}_0((0,1],\mathbb{K})$.

If there is an example of a separable C^*-algebra A that has no characters but A_∞ has (non-zero) characters then the free product F of countably many copies of $M_2(\mathrm{C}_0(0,1])$ must have this property: The algebra A must be a quotient of F, because the C^*-subalgebra B of A generated by a dense sequence in the set of all 2-homogenous contractions contains all 2-homogenous elements in A_+. It is then not difficult to see that for each $a\in A_+$ the closed hereditary C^*-subalgebra $\overline{aAa}$ contains a positive contraction $b\in B_+$ such that $B\cap \overline{aAa}=\overline{bBb}$ and that alternatively $\overline{bAb}=\overline{aAa}$ or $\overline{bAb}$ is an ideal of $\overline{aAa}$ with the property that $\overline{aAa}/\overline{bAb}$ is commutative.

The convex cone K_2 in A_+ generated by all 2-homogenous positive contractions in A should be identical with A_+ , and F has no characters.

It follows from the invariance of K_2 under automorphisms of A and that the (norm-) closure of K_2 is hereditary and K_2 separates the pure states of A (by Kadison transitivity theorem, cf. Lemma **??**).

It needs a Lemma that says if $\overline{aAa}$ has no characters and $0\leq a\leq b_1+\ldots+b_n$, with b_k all 2-homogenous and positive, than a can be approximated by convex combinations of positive 2-homogenous elements in $\overline{aAa}$ (In case that A is residually antiliminary this happens for every non-zero $a\in A_+$).

8. Basics on quasi-traces

Begin of eksec2-Part2.tex !!!

The main destinations are:

1) If $A \otimes C^*_{red}(F)$ has no non-trivial l.s.c. (additive) trace, then $A \otimes C^*_{red}(F)$ is s.p.i., if F is one of the free groups F_n, $n \in \{2, 3, \ldots\} \cup \{\infty\}$.

(The exactness of the reduced group C^*-algebra $C^*_{red}(F)$ ensures that the questions are reduced to the observation that all quasi-ideals of $M \otimes C^*_{red}(F)$ are ideals and to the non-existence of central states on M if $M \otimes C^*_{red}(F)$ has no non-zero central state.)

2) If A_ω has no non-trivial l.s.c. 2-quasi-trace then A_ω is weakly purely infinite (it implies that A is weakly p.i.).

3) If $A \otimes \mathcal{Z}$ has no non-trivial l.s.c. quasi-trace, then $A \otimes \mathcal{Z}$ is s.p.i.

Work here with Rørdam condition on the Cuntz semi-group $\mathrm{Cu}(A)$ and using central sequences of the join algebra $\mathcal{E}(M_p, M_q)$ in $\mathcal{Z}$.

4) Permanence properties for s.p.i. algebras (including extensions, coronas etc.) tensor with exact C^*-algebras ...

5) Special cases of continuous fields with s.p.i. fibres ...

6) $A \otimes \mathcal{O}_\infty \cong A$ if A is separable, nuclear and s.p.i.

More ?????

Before we give in the next section some results concerning the relations between 2-quasi-traceless C^*-algebras and purely infinite C^*-algebras, we report some basic knowledge on 2-quasi-traces, give necessary definitions and explain results that we apply here.

`We have all the Definitions in the first section`
`of Chapter 2 or in the Introduction`

DEFINITION 2.8.1. A map $\tau\colon A_+ \to [0, \infty]$ is a **quasi-trace** if $\tau(0) = 0$ and $\tau(a + b) = \tau(a) + \tau(b)$ for all *commuting* $a, b \in A_+$, and $\tau(a^*a) = \tau(aa^*)$ for all $a \in A$. It is **lower semi-continuous** (l.s.c.) if $\tau(a) = \sup_{\delta>0} \tau((a - \delta)_+)$ for each $a \in A_+$ ([42]). If $\mu\colon A_+ \to [0, \infty]$ is any quasi-trace then $\mu_*(a) := \sup_{\delta>0} \mu\big((a-\delta)_+\big)$ is an l.s.c. quasi-trace. It satisfies $\mu_* \le \mu$

`Check this:` and $\mu(a) = \mu_*(a)$ for all $a \in A_+$ with $\mu(a) < \infty$.

The quasi-trace τ is a **2-quasi-trace** if there is a quasi-trace

$$\tau_2\colon M_2(A)_+ \to [0, \infty]$$

such that $\tau(a) = \tau_2(a \otimes p_{11})$ for all $a \in A$.

We say that A is **(2-quasi-) traceless** (respectively A is **traceless**) if all *lower semi-continuous* 2-quasi-traces (respectively all l.s.c. and additive τ) on A_+ take only the values 0 and $+\infty$.

[42] Then τ is an l.s.c. function from A_+ into $[0, +\infty]$ in the ordinary sense with respect to the norm-topology on A_+ and the Hausdorff topology on $[0, +\infty] \cong [0, 1]$.

```
Hold next ready for later needed reference!

Including all hints for proofs.
```

PROPOSITION 2.8.2. *Let* $\tau\colon A_+ \to [0,\infty]$ *a lower semi-continuous* 2*-quasi-trace. Then*

(1) $\tau\colon A_+ \to [0,\infty]$ *is an order-monotone map on* A_+*,*
(2) $\tau(a+b) \le 2(\tau(a)+\tau(b))$ *for all* $a, b \in A_+$*,*
(3) $\{a \in A\,;\ \tau(a^*a) = 0\}$ *is a closed ideal of* A*,*
(4) $\{a \in A\,;\ \tau(a^*a) < \infty\}$ *is an algebraic* **-ideal of* A*.*
(5) *If* $\mathcal{U} := M_2 \otimes M_3 \otimes \cdots$ *denotes the universal UHF algebra then there exists a unique l.s.c. "local" quasi-trace* $\mu\colon (\mathcal{U}\otimes A)_+ \to [0,\infty]$ *with* $\mu(1\otimes a) = \tau(a)$ *for all* $a \in A_+$ *.*
(6) *For each* $n \in \mathbb{N}$ *there exists a unique lower s.c. quasi-trace*
$$\tau_n\colon (A\otimes M_n)_+ \to [0,\infty]$$
with $\tau(a) = \tau_n(a\otimes e_{11})$ *for all* $a \in A$*.*

Every l.s.c. "local" quasi-trace on a C^*-algebra A of real rank zero, e.g. on an AW*-algebra or a Rickard algebra, is a 2-quasi-trace. (And it can be interpreted as some sort of evaluations on the J. von Neumann "perspectives" for the related affine geometry.)

It is (2019?) a still open question if unital 2-quasi-traces on AW*-algebras are always additive, i.e., are unital traces.

The minimal requirements on a C^*-algebra A for having the property that all quasi-traces on A are 2-quasi-traces has to do with the question if all quasi-ideals of $\ell_\infty(A)/c_0(A)$ are ideals ... (Consider here also the quasi-traces that take only the values 0 and ∞ ...

But there exists a unital l.s.c. quasi-traces on $C([0,1]) * C([0,1])$ and on $C^*(F_2) = C(S_1) * C(S_1)$ that are not a 2-quasi-traces, – do not mix it up here with the reduced group C^*-algebra $C^*_{red}(F_2)$, which is an exact C^*-algebra.

Notice here that e.g. $t \in [0,1] \to e^{it} \in S_1$ defines a unital epimorphism from $C(S_1)$ onto $C([0,1])$. Thus we have only to give a ???

The τ_2-existence condition in Definition 2.8.1 of 2-quasi-trace τ is equivalent to each of the two following inequalities for all $a, b \in A_+$:

$$\tau(a+b)^{1/2} \le \tau(a)^{1/2} + \tau(b)^{1/2}\,,$$

(which was 1991 observed by U. Haagerup [**342**]), and the 2-sub-additivity:

$$\tau(a+b) \le 2(\tau(a)+\tau(b))\,.$$

The 2-sub-additivity follows from Haagerup's inequality, because for $x, y, z \in [0,+\infty]$ the inequality $x \le y+z$ implies $x^2 \le 2(y^2+z^2)$. But it can be seen also directly from the τ_2-existence by considering the matrix $C := a^{1/2}\otimes p_{11} + b^{1/2}\otimes p_{21}$

by using that $C^*C = (a+b)\otimes p_{11}$, $CC^* \leq 2(a\otimes p_{11} + b\otimes p_{22})$ and that $\tau_2(a\otimes p_{11} + a\otimes p_{22}) = \tau(a)+\tau(b)$ for all $a,b\in A_+$.

A now classical result of U. Haagerup [**342**], says that all 2-sub-additive states on exact C^*-algebra are additive.

The question if every l.s.c. 2-quasi-trace on a C^*-algebra A is additive is an open question. A possible positive answer is equivalent to the likely more than 65 (?) years old conjecture of I. Kaplansky that every finite AW*-factor is a W*-factor.

`Next requires details ...`

J.F. Aarnes [**3**] has described a rather natural quasi-state τ on $\mathrm{C}([0,1]^2)_+$ that has the property that $\tau|C^*(1,f)_+$ is additive if all winding numbers $w(\sigma,f,z)$ of $f\in \mathrm{C}([0,1]^2)$ are zero for all Jordan curves $\sigma\colon S^1\to[0,1]^2$ and all $z\in\mathbb{C}\setminus f(S^1)$.

There exists unital type-I C^*-algebras A, given by a suitable extension $0\to c_0(\mathbb{K})\to A\to \mathrm{C}([0,1]^2)\to 0$, and a unital map $\mu\colon A_+\to[0,\infty)$, defined by the Aarnes quasi-state on $\mathrm{C}([0,1]^2)$, that has the property that the restriction $\mu|C_+$ for each commutative C^*-subalgebra $C\subset A$ is additive on C_+, $\mu(a^*a)=\mu(aa^*)$ for all $a\in A$, but there exists $a,b\in A_+$ with $\mu(a)=0$, $\mu(b)=0$ and $\mu(a+b)>2$. In particular this implies that μ is a quasi-trace state that is not a 2-quasi-trace.

An other example is the free unital product $B:=\mathrm{C}([0,1])\star\mathrm{C}([0,1])$ and the unital quasi-trace given by $\tau_A\circ\pi$, π denotes here the canonical unital epimorphism $\pi\colon B\to\mathrm{C}([0,1]^2)$ and τ_A is the Aarnes quasi-state on $\mathrm{C}([0,1]^2)$, cf. [**3**].

(Compare Section **??** for more information on the existence of non-2-sub-additive quasi-traces!)

In general an l.s.c. quasi-trace $\tau\colon A_+\to[0,\infty]$ is sub-additive (= 1-sub-additive), if and only if, τ is additive, if and only if, τ "extends" to $A\otimes C^*_{red}(F_2)$ in the sense that there exists an l.s.c. quasi-trace ρ on $(A\otimes C^*_{red}(F_2))_+$ with $\rho(a\otimes b)=\tau(a)\mathrm{tr}(b)$, where tr is the unique trace state on the reduced group C^*-algebra $C^*_{red}(F_2)_+$ of the free group F_2 on two generators.

(Here it is important to remind that $C^*_{red}(F_n)$, for $n=2,3,\ldots$ and $C^*_{red}(F_\infty)$ contain the Jiang-Su algebra $\mathcal{Z}$ unitally, cf. [**667**, section 6.3].)

`Give reference for above`

Every l.s.c. 2-quasi-trace $\tau\colon A_+\to[0,\infty]$ on an *exact* C^*-algebras A is additive, because it "extends" to an l.s.c. quasi-trace ρ on $(A\otimes C^*_{red}(F_2))_+$ with $\rho(a\otimes b)=\tau(a)\mathrm{tr}(b)$. (Here we use only that $C^*_{red}(F_2)$ is simple, has a unique trace state and is unitally contained in M_ω.)

`Where is` M_ω `defined?`

`Give example for next blue text??`

Notice that on *traceless* C^*-algebras A there can still exist non-zero 2-quasi-traces τ on the positive part D_+ of some hereditary C^*-subalgebras D of A that have also non-zero finite values on D_+, but those 2-quasi-traces can not have lower semi-continuous extensions to A_+ as 2-quasi-traces.

`Examples for above green text?  Case of ideal?`

IS IT REALLY TRUE, e.g. for simple C^*-algebras and degenerate quasi-traces?

If D is a hereditary C^*-subalgebra of A with l.s.c. 2-quasi-trace τ on $D_+ \cap A$, then τ should extend to A.

First extend to $E := I(D)_+$ for the ideal $E := I(D)$ generated by D by extending to $D \otimes \mathbb{K}$ and then using that $D \otimes \mathbb{K} \cong E \otimes \mathbb{K}$ for σ-unital hereditary C^*-subalgebras D and E that generate the same closed ideal of A.

Is it really on $D \cong D \otimes p_{11}$ the same 2-q-trace?

We recall here that not necessarily bounded lower semi-continuous 2-quasi-traces are in one-to-one correspondence to lower semi-continuous dimension functions D (= sub additive rank functions), and, therefore, are always order monotone maps.

(what we can see directly from the definition???) See Section 7 in Appendix A, ????? e.g. [**342**] and [**93**, sec. 2.9] more precise in BlanKir2 ???? or Appendix A??? for more details.

REMARK 2.8.3. The C^*-algebra A is (2-quasi-) *traceless*, if and only if, A has the property that

(*) for every $a \in A_+$ and $\varepsilon > 0$ there exists $n := n(a, \varepsilon) \in \mathbb{N}$ with

$$(a - \varepsilon)_+ \otimes 1_{2n} \precsim a \otimes 1_n \quad \text{for all} \quad n \geq n(a, \varepsilon)\,.$$

.

Compare Corollaries A.13.10 and A.7.3, or [**462**, prop. 5.7] for a proof.

Notice that this can be expressed equivalently in the Cuntz semigroup $W(A)$ as $2n \cdot [(a - \varepsilon)_+] \leq n \cdot [a]$ for all $n \geq n(a, \varepsilon)$.

Variation of ε and using that $((a - \varepsilon)_+ - \delta)_+ = (a - (\varepsilon + \delta))_+$ shows that

(**) for each $a \in A_+$, $\varepsilon > 0$ and $k > 1$ there exist a number $n(a, \varepsilon, k)$ such that $kn \cdot [(a - \varepsilon)_+] \leq n[a]$ for all $n \geq n(a, \varepsilon, k)$.

In particular there exists, for $n \geq n(a, \varepsilon, k)$, an element $d \in M_{1,k}(A \otimes M_n)$ with

$$d^*(a \otimes 1_n)d = ((a - 2\varepsilon)_+ \otimes 1_n) \otimes 1_k\,.$$

9. Pure infiniteness versus (2-quasi-) traceless.

LEMMA 2.9.1. *Let A and B C^*-algebras, and denote by $A \otimes B$ the minimal C^*-algebra tensor product, and by $P^\times$ the natural continuous map from the cartesian product of T_0-spaces* $\mathrm{prime}(A) \times \mathrm{prime}(B)$ *into the T_0-space* $\mathrm{prime}(A \otimes B)$*, that is defined by*

$$P^\times(I, J) := (I \otimes A) + (B \otimes J)\,.$$

(i) *If A or B is exact, then $P^\times$ is a (surjective) homeomorphism.*

(ii) *Suppose that $P^{\times}$ is surjective, D is a hereditary C^*-subalgebra of $A \otimes B$ and $I \in \mathcal{I}(A \otimes B)$ is a prime ideal*

`Or I must it be primitive ?? Check original!`

that does not contain D.

Then there exist $a \in A_+$, $b \in B_+$, $c \in A \otimes B$, pure states λ on A, and ρ on B such that

(α) $\lambda \otimes \rho(I) = \{0\}$,

(β) $c c^* \in D$ *and* $c^* c = a \otimes b$,

(γ) $\lambda(a) = \|a\| = 1$ *and* $\rho(b) = \|b\| = 1$.

(iii) *Suppose that the C^*-algebras A and B have the property that $P^{\times}$ is surjective.*

If A or B is (2-quasi-)-traceless then $A \otimes B$ is (2-quasi-)-traceless.

Notice that Part (ii) implies that – in case where $P^{\times}$ is surjective – the set of elements $\mathcal{F} := \{a \otimes b\, ;\; a \in A_+\, ,\; b \in B_+\}$ is a *filling family* for $A \otimes B$ in sense of [**469**, def. 4.2].

`Not.published? No!: It is now published, see [469]. But one has to pay 30 British pound.`
`But arXiv:1503.08519v2 is fairly readable... Check typos again?`
`Check new references !!!`

PROOF. (i): See [**93**, prop. 2.16 and prop.2.17(2)].

(ii): See Lemma 2.2.3 (cf. also [**93**, lem. 2.18]),

`Lemma 2.2:`

Let D be a non-zero hereditary C^*-subalgebra of the minimal C^*-algebra tensor product $A \otimes B$ of C^*-algebras A and B.

Then there exists $0 \neq z \in A \otimes B$ with $zz^* \in D$ and $z^*z = e \otimes f$ for some non-zero $e \in A_+$ and $f \in B_+$.

If $d \in D_+$ and pure states $\varphi \in A^*$, $\psi \in B^*$ are given with $(\varphi \otimes \psi)(d) > 0$, then the element $z \in A \otimes B$ can be found such that, moreover, $\varphi(e)\psi(f) > 0$.

(iii): By symmetry it suffices to consider the case where B is (2-quasi-) traceless. For each fixed $a \in A_+$, the map

$$\tau_a \colon b \in B_+ \mapsto \tau(a \otimes b) \in [0, \infty]$$

is an l.s.c. 2-quasi-trace on B_+. The τ_a can only take the values 0 and $+\infty$, because B is (2-quasi-) traceless. We show that this implies that τ can take only the values 0 and $+\infty$ by lower semi-continuity of τ:

The set of $g \in (A \otimes B)_+$ with $\tau(g) = 0$ is the positive part J_+ of a closed ideal J of $A \otimes B$ by Proposition 2.8.2.

Let $e \in (A \otimes B)_+$ with $\tau(e) < \infty$. To prove that $\tau(e) = 0$ it suffices by lower semi-continuity of τ to show that, for each $\varepsilon > 0$, the hereditary C^*-subalgebra D generated by $(e - \varepsilon)_+$ is contained in J.

Suppose that D is *not* contained in J. Then there exists a primitive ideal of I $A \otimes B$ such that $J \subseteq I$ and $D \not\subseteq I$.

Let $a \in A_+$, $b \in B_+$, $c \in A \otimes B$, $\lambda \in A^*$, and $\rho \in B^*$ as in Part (ii). Then $a \otimes b = c^*c \notin I$ but $cc^* \in D$, in particular $a \otimes b \notin J$, i.e., $0 < \tau(a \otimes b) \leq \infty$ and $\tau_a \colon x \in B_+ \mapsto \tau(a \otimes x)$ is an l.s.c. 2-quasi-trace on B_+.

The latter contradicts the assumption that B is traceless. Thus, $D \subseteq J$ and $\tau(e) = 0$ for each $e \in (A \otimes B)_+$ with $\tau(e) < \infty$. □

The Remark 2.8.3 has the following consequences for tensor products of A with UHF algebras, and for algebras A with (2-quasi-) traceless ultra-powers of A:

Corollary 2.9.2. *Let A a (2-quasi-) traceless C^*-algebra, E an exact C^*-algebra and B an UHF algebra (of infinite dimension) then $E \otimes A \otimes B$ is a purely infinite C^*-algebra.*

In fact $E \otimes A \otimes B$ is also *strongly* purely infinite, because one can decompose B into a tensor product $B = B_1 \otimes B_2$ with B_1 and B_2 UHF-algebras of infinite dimensions, cf. Proposition **??**.

Proof. By Lemma 2.9.1(iii) $E \otimes A$ is (2-quasi-) traceless. Thus we can rename $E \otimes A$ by A for the following.

We express B as a tensor product $B = C_1 \otimes C_2 \otimes \cdots$ with $C_k = M_{n_k}$ such that $n_{k+1} > 2 \cdot n_1 \cdot n_2 \cdot \ldots \cdot n_k$. The union of the increasing sequence of C^*-subalgebras

$$A_m := A \otimes C_1 \otimes C_2 \otimes \cdots \otimes C_m \otimes 1_{n_{m+1}} \otimes 1_{n_{m+2}} \otimes \cdots$$

of $A \otimes B$ is dense in $A \otimes B$. To simplify notation we write simply C_m for

$$1_{\mathcal{M}(A)} \otimes 1_{n_1} \otimes \cdots 1_{n_{m-1}} \otimes C_m \otimes 1_{n_{m+1}} \otimes \cdots .$$

The algebras A_m are matrix algebras over A and are q-trace-less because A is q-trace-less. Thus $A \otimes B$ must be q-trace-less. (We can use here also exactness of B and Part (iii) of Lemma 2.9.1.)

By Remark 2.8.3 we get that for each positive $a \in A_m$ and $\varepsilon > 0$ there exists $n(a, \varepsilon) \in \mathbb{N}$ with $(a - \varepsilon)_+ \otimes 1_{2n} \precsim a \otimes 1_n$ for all $n \geq n(a, \varepsilon)$.

It implies $2n[(a - \varepsilon)_+] \leq n[a]$ for all $n \geq n(a, \varepsilon)$.

One needs here that the numbers $n(a, \varepsilon)$ for given $\varepsilon > 0$ can be chosen in the list of finite products of "remaining" numbers $n_k = \mathrm{Dim}(C_k)^{1/2}$ starting from $k := m + 1$.

```
???? Next not correct !!! ???
```

For each $a \in A_m$ there exists $n \geq m$ such that $(n + 1)[a] \leq n[a]$ in $\mathrm{Cu}(A_m)$. Then for all $k \geq n$ and $\ell > 1$ holds $k[a] \geq k\ell[a]$.

Indeed: We get by induction $(n + r)[a] \leq n[a]$ for all $r \in \mathbb{N}$. Let $r := (k \cdot \ell) - n$. Then $k\ell[a] \leq n[a] \leq k[a]$.

In particular, it follows that for each $\varepsilon > 0$ there exist sufficiently big $k := k(a, \varepsilon) \in \mathbb{N}$, $\delta > 0$ and $d_1, d_2 \in A_k \subset A \otimes B$ such that $d_i^* a d_j = \delta_{ij}(a - \varepsilon)_+$.

This is the case because the relative commutant

$$(A_m)' \cap \mathcal{M}(A) \otimes B \subseteq (A_m)' \cap \mathcal{M}(A \otimes B)$$

of $A_m \subseteq A \otimes B$ in $\mathcal{M}(A) \otimes B$ contains sufficiently big unital matrix algebras C_m, and there is $n \in \mathbb{N}$ with $a \otimes 1_{2k} \precsim a \otimes 1_k$ for all $k \geq n$.

It follows that $A \otimes B$ is purely infinite by Lemma 2.5.17(ii), because the positive elements in $\bigcup_{m \in \mathbb{N}} A_m$ are dense in $(A \otimes B)_+$ and are spectral properly infinite in $A \otimes B$. □

M. Rørdam [**690**, prop. 2.2] gets the following observation using results in the Jiang-Su paper [**391**]: *There is a unital embedding of $E(m, n) := \mathcal{E}(M_m, M_n)$ into $\mathcal{Z}$ for every pair of natural numbers $m < n$ that are relatively prime.*

Recall that a C^*-algebra B is called "**(2-quasi)-traceless**" if every l.s.c. 2-quasitrace $\tau \colon B_+ \to [0, \infty]$ takes only the values 0 or $+\infty$. The lower semi-continuity of the 2-quasitrace and the 2-sub-additivity are important ingredients of this terminology, because the l.s.c. 2-sub-additive maps τ on A_+ with values in $\{0, \infty\}$ and $\tau(a^*a) = \tau(aa^*)$ correspond one-to-one to the lattice of closed ideals $J \triangleleft A$. The bijection is given by $\tau_J(a) := \|\pi_J(a)\| \cdot \infty$ and $J_\tau := \{a \in A\,;\ \tau(a^*a) = 0\}$.

Proposition 2.9.3 ([**463**]). *The ultra-power A_ω of a C^*-algebra A is (2-quasi)-traceless, if and only if, there exists general $n \in \mathbb{N}$ such that $a \otimes 1_n$ is properly infinite in $A \otimes M_n$ for every non-zero $a \in A_+$, i.e., A has property pi-n in sense of Definition* **??**.

In this case A is also pi(m) in sense of Definition 2.0.4, with $m \leq n$ (cf. Proposition **??** *NO other !).*

??? Strange formulation:

Recall that A has property pi-n if and only if A is m-purely infinite for some $m \leq n$

and that pi-n implies pi(n),

but nothing is known over the converse ...

or $m \leq n^2$?

by Proposition **??**, i.e., A is pi(m) in sense of Definitions 2.0.4 with $m \leq n$.

Proof. Suppose that A_ω has no non-zero 2-quasitrace. By Remark 2.8.3 we get that for each positive $b \in A_\omega$ and $\varepsilon > 0$ there exists $n(b, \varepsilon) \in \mathbb{N}$ with $(b - \varepsilon)_+ \otimes 1_{2n} \precsim b \otimes 1_n$ for all $n \geq n(b, \varepsilon)$.

Give reference

Suppose that there does not exist an $n \in \mathbb{N}$ such that $a \otimes 1_n$ is properly infinite in $A \otimes M_n$ for every $a \in A_+$.

Then there exists a sequence of positive contractions $a_k \in A_+$ and and $n_k \in \mathbb{N}$ such that $n_k < n_{k+1}$, and $a_k \otimes 1_{n_k}$ is not properly infinite in $A \otimes M_{n_k}$ for each $k \in \mathbb{N}$.

If we use observation (x) of Lemma 2.5.3 then we find $\varepsilon_k \in (0,1)$ with $\varepsilon_{k+1} < \varepsilon_k$ such that

$$(a_k \otimes 1_{2n_k} - \varepsilon_k)_+ \not\precsim a_k \otimes 1_{n_k} \,.$$

There are $m_k \in \mathbb{N}$ such that $(\varepsilon_k)^{1/m_k} > 1/2$ for each $k \in \mathbb{N}$. Let $b_k := a_k^{1/m_k} \in A$ and $b := \pi_\omega(b_1, b_2, \ldots)$ in A_ω. It satisfies

$$(b - 1/4)_+ \otimes 1_{2n} \not\precsim b \otimes 1_n \,.$$

This contradicts that A_ω admits no l.s.c. 2-quasi-trace. □

It is not clear if the following Definition 2.9.4 is useful for general study:

Definition 2.9.4. Let C a unital C^*-algebra and suppose that there exist contractions $e_1, e_2 \in C_+$ and $d_{1,1}, \ldots, d_{1,m}, d_{2,1}, \ldots, d_{2,m} \in C$ such that $e_1 e_2 = 0$ and $\sum_{k=1}^m d_{j,k}^* e_j d_{j,k} = 1$ for $j = 1, 2$.

The smallest number $m \in \mathbb{N}$ with the property that such $(e_j, d_{j,k})$ exist will be denoted by $m(C) \in \mathbb{N} \cup \{+\infty\}$. We call $m(C)$ the "**minimal orthogonality**" of C.

And we define a *universal* unital C^*-algebra

$$G_m := C^*(e_j, d_{j,1}, \ldots, d_{j,m};\, j = 1, 2, \langle R \rangle\,)$$

with above considered relations (R) on the e_j and $d_{j,k}$.

Next Lemma 2.9.5 and its proof are wrong because we can take $V := \mathrm{id}_{M_n}$, but there does not exist a unitary $U \in M_n$ with $U^* p_{11} U = (1/n) 1_n$, because the of norms $(1, 1/n)$ and ranks $(1, n)$ are different.

Lemma 2.9.5. *Let $V \colon M_n \to A$ a completely positive map.*

Then there exists a unitary $U \in M_n$ such that $V(U^* p_{11} U) = 1/n V(1_n)$, $V(U^* p_{22} U) = 1/(n-1) V(1_n - p_{11})$ for $1 \le k \le n$.

Lemma 2.9.6. *Let A a unital C^*-algebra. Then A has no character, if and only if, there exists $m \in \mathbb{N}$ and contractions $e_{j,k} \in A$, $j = 1, \ldots, m$, $k \in \{1, 2\}$, that satisfy the relations: $\sum_j e_{j,k}^* e_{j,k} = 1$, $e_{j,1}^* e_{j,2} = 0 = e_{j,2}^* e_{j,1}$ and*

????? Look also to centalseq. paper with M.Rordam!// Perhaps this can not be realized?:

$e_{j,1}^* e_{j,1} = e_{j,2}^* e_{j,2}$????? because it is likely that

$T^{-1/2} p_{1,1} T^{-1/2} \neq T^{-1/2} p_{2,2} T^{-1/2}$

It is even not an estimate available !!!

([43]).

[43] The relations do not imply – or require – that $e_{i,k}^* e_{j,k} = 0$ for $i \neq j$.

PROOF. To be filled in ! ??

Let S denote the set of all finite sums $n^{-1}\sum_{k=1}^{n} a_k \in A_+$ of $a_k := \psi_k(f_0 \otimes 1_2)$ where ψ_k denote any non-zero *-homomorphism from $\mathrm{C}_0((0,1], M_2) \cong M_2(\mathrm{C}_0(0,1])$ into A. The set $S \subseteq A_+$ is a convex subset of the contractions in A that is invariant under automorphisms of A. In particular the hereditary convex sub-cone of A_+, i.e., the set of $a \in A_+$ with the property that there exists $b \in A_+$ and $\gamma \in [0,\infty)$ with $a+b \in \gamma \cdot S$, i.e., is generated by S, has as its norm-closure a hereditary closed convex cone that invariant under all automorphisms of A and is generated by all 2-homogenous elements of A_+.

By Lemma ??

Says/should say:

(1) the closures C of a hereditary sub-cone of A_+, defined by a subset $X \subset A_+$ of contractions in A_+, is a hereditary (!!) sub-cone of A_+. It is the positive part $D_+ = C$ of a hereditary C^*-subalgebra D of A.

The D is invariant under conjugation by all unitaries of A (= inner automorphisms) if C it is invariant under conjugation by all $\exp(ih)$ with $h^* = h \in A$ and $\|h\| < 1$.

(2) If a hereditary C^*-subalgebra D is invariant under conjugation by all $\exp(ih)$ with $h^* = h \in A$ and $\|h\| < 1$ then D is a closed ideal of A.

(3) For every element $d \in D_+$ and $\varepsilon > 0$ there exists f in the convex span of X and $\lambda \in (0,\infty)$ with $(d-\varepsilon)_+ \leq \lambda x$. ???? (at least if X is invariant under inner automorphisms of A.)

It is the positive part of the closed ideal of A generated by all images $\psi(f_0 \otimes 1_2)$.

The quotient A/J can not contain a non-zero 2-homogenous element, because $\mathrm{C}_0((0,1], M_k)$ is a projective C^*-algebra for all $k \in \mathbb{N}$, cf. Proposition A.8.4 or [**540**, cor. 3.8].

Thus, J is also the closed ideal of A generated by all commutators $ab - ba$, i.e., is the intersection of the kernels of all characters on A.

By assumption, A has no character. It shows that $A = J$ and $1 \in J$.

By the above study of J_+ there exists $r \in \mathbb{N}$ and a finite sum $\sum_{q=1}^{r} a_q \in A_+$ of 2-homogenous positive elements $a_q := \psi_q(f_0 \otimes 1_2) = \psi_q(f_0 \otimes p_{11}) + \psi_q(f_0 \otimes p_{22})$

such that

$1_A \leq \sum_{q=1}^{r} a_q =: T$. Then $\sum_{q=1}^{r} T^{-1/2} a_q T^{-1/2} = 1$.

But this T is imbalanced with respect to the entries $\psi_q(f_0 \otimes p_{j,k})$ if $a_q = \psi_q(f_0 \otimes p_{1,1})$.

$\psi_q(f_0^{1/2} \otimes p_{11}) + \psi_q(f_0^{1/2} \otimes p_{12}) = \psi_q(f_0^{1/2}, p_{11} + p_{12})$

Let $x := (1/\sqrt{2})(p_{11} + p_{12})$ gives $x^* \neq x$ $x^*x = 1/2(p_{11} + p_{12} + p_{2,1} + p_{2,2})$, and for $y := (1/\sqrt{2})(p_{22} - p_{21})$ gives $y^*y = 1/2(p_{11} - p_{12} - p_{2,1} + p_{2,2})$ and $y^*x = 0$.

Can we find some estimate for x^*x ? $x^*x \leq p_{11} + p_{22}$ because $x^*x + y^*y = p_{11} + p_{22}$

The elements $T^{-1/2}\psi_q(f_0 \otimes 1_2)T^{-1/2} \in A$ with properties $\psi_q \colon \mathrm{C}_0((0,1], M_2) \to A$, $1 \leq q \leq r$ imply the statement ... ???

(Likely ???: $m := 2r$, ???? $e_{j,1} := \psi_j(f_0^{1/2} \otimes p_{11})T^{-1/2}$ for $1 \leq j \leq n$ and $e_{n+j,1} := \psi_{j-n}(f_0 \otimes p_{22})T^{-1/2}$ for $n+1 \leq j \leq 2r$????)

But, what can we show ??? It is:

If unital A has no non-zero character, then there exist m contractions $z_1, \ldots, z_m \in A$ with the properties $z_k^2 = 0$ and

$$\sum_{k=1}^{m} (z_k (z_k)^* + z_k^* z_k) \geq 1 \,.$$

In case of only σ-unital A, with strictly positive element $e \in A_+$ that satisfies $\|e\| = 1$ and has no non-zero character, this should have similar properties:

Likewise this:

For every $\varepsilon > 0$ there exists $\delta \in (0, \varepsilon)$, and $m \in \mathbb{N}$ such that there are exist m contractions $z_1, \ldots, z_m \in \overline{(e-\delta)_+ A (e-\delta)_+}$ with the properties $z_k^2 = 0$, and

$$\sum_{k=1}^{m} (z_k (z_k)^* + z_k^* z_k) \geq (e-\varepsilon)_+ \,.$$

There exists $m \in \mathbb{N}$ and contractions $e_{j,k} \in A$, $j = 1, \ldots, m$, $k \in \{1, 2\}$, that satisfy the relations: $\sum_j e_{j,k}^* e_{j,k} \geq 1$, $e_{j,k}^* e_{j,\ell} = 0$ and $e_{j,k}^* e_{j,k} = e_{j,\ell}^* e_{j,\ell}$ for $k \neq \ell$, (The relations do not imply or require that $e_{i,k}^* e_{j,k} = 0$ for $i \neq j$). □

`Remarks:` The Lemma 2.9.6 implies immediately the following ??????

If B is a σ-unital C^*-algebra, then the unital C^*-algebra

$$F(B) := (B' \cap B_\omega) / \operatorname{Ann}(B, B_\omega)$$

has no character, if and only if there exist $d_{j,k} \in B' \cap B_\omega$ $j = 1, \ldots, m$, $k \in \{1, 2\}$, $d_{j,k}^* d_{j,\ell} = 0$ and $d_{j,k}^* d_{j,k} = d_{j,\ell}^* d_{j,\ell}$ for $k \neq \ell$ and $\sum_j d_{j,k}^* d_{j,k} \in 1 + \operatorname{Ann}(B, B_\omega)$.

Notice that for $\mathcal{E}(M_2, M_3) \subseteq \mathcal{Z} \subseteq \mathcal{O}_\infty$ we get $m(\mathcal{E}(M_2, M_3)) \leq 3$.

`Or` $m(\ldots) \leq 2$ `???`

One can see that the infinite unital free product $C *_1 C *_1 C *_1 \cdots$ of the unital cones $C := \{ f \in \mathrm{C}([0,1], M_2) \, ; \; f(0) = 1_2 \}$ (with unit element $1_C(t) := 1_2$ for all $t \in [0,1]$) has only one character χ given by $f \mapsto f(0) \in \mathbb{C} \cdot 1_2$.

It has to be considered in a natural way as the C^*-algebra inductive limit by the injective maps

$$C \mapsto C *_1 1 \subset C * C \mapsto C *_1 C *_1 1 \subset C *_1 C *_1 C \ldots$$

The unital character χ then extends step by step to a character of

$$C *_1 C *_1 C * \cdots .$$

This should be the only character on it ???

Let D denote the kernel ideal of the character χ. Then $D *_1 1_C$ and $1_C *_1 D$ together generate $C *_1 C$ .....????

PROPOSITION 2.9.7. *Let A a purely infinite C^*-algebra. If there exists $m \in \mathbb{N}$ such that for every finite subset $F \subseteq A$ and $\delta > 0$ there exists a unital C^*-morphism $\phi\colon G_m \to \mathcal{M}(A)$ with $\|[x, \phi(e_j)]\| < \delta$ and $\|[x, \phi(d_{j,k})]\| < \delta$ for $x \in F$, $j = 1, 2$ and $k = 1, \ldots, m$. Then A is strongly p.i.*

PROOF. In the general case, e.g. where A is only pi-n, we get at least that all matrices with n-homogenous diagonal entries are approximately diagonalizable by n-homogenous entries in the diagonal.

The assumptions imply that, for every separable C^*-subalgebra B of A, there exist a unital C^*-morphism $\psi\colon G_m \to \mathcal{M}(A)_\omega$ with zero commutators $[b, \psi(e_j)] = 0$ and $[b, \psi(d_{j,k})] = 0$ for all $b \in B$.

Let $a, b \in A_+$ properly infinite elements and consider the C^*-subalgebra $C^*(a, b)$ of A generated by a and b. Find in A a separable C^*-subalgebra B with the following properties:

(1) $a, b \in B_+$ and a, b are inside B properly infinite.

(2) B contains sequences that represent the generating elements of $\psi(G_m)$ such that $\psi(G_m)$ commutes with B and is in B_ω.

Now we consider the 2×2-matrix $C := [c_{p,q}] = [a, b]^\top [a, b]$ with entries $c_{11} = a^2$, $c_{22} = b^2$, $c_{1,2} = ab$ and $c_{2,1} = ba$. If a and b are properly infinite in A, then they are also properly infinite in A_ω.

This happens also for elements be_1 and ae_2 in A_ω if $be_1 = e_1 b$ and $ae_2 = e_2 a$ if ?????.

?????? IS THE LATTER TRUE ??

More generally let $d_{j,k} \in B' \cap B_\omega$ $j = 1, \ldots, m$, $k \in \{1, 2\}$, $d_{j,k}^* d_{j,\ell} = 0$ and $d_{j,k}^* d_{j,k} = d_{j,\ell}^* d_{j,\ell}$ for $k \neq \ell$ and $\sum_j d_{j,k}^* d_{j,k} \in 1 + \mathrm{Ann}(B, B_\omega)$.

Define properly infinite $a, b \in A_+$ by elements $f_1, \ldots, f_m, g_1, \ldots g_m \in A$ with $f_j^* a^2 f_k = \delta_{j,k}(a^2 - \varepsilon)_+$ and $g_j^* b^2 g_k = \delta_{j,k}(b^2 - \varepsilon)_+$.

Then define $h_1 := \sum_{j=1}^m f_j d_{j,1} \in B_\omega$ and $h_2 := \sum_{j=1}^m g_j d_{j,2} \in B_\omega$

????

Notice that $h_1^* a^2 h_1 = (a^2 - \varepsilon)_+$ and $h_2^* b^2 h_2 = (b^2 - \varepsilon)_+$, but to get $h_1^* ab h_2 = 0$, one needs in addition that $d_{j,k}^* d_{i,\ell} = 0$ for all $j \neq i$ and all $k, \ell \in \{1, 2\}$.

`To be filled in` ?? □

COROLLARY 2.9.8. *Let $\mathcal{Z}$ denote the Jiang-Su algebra. If A is a (2-quasi-) traceless C^*-algebra, then $A \otimes \mathcal{Z}$ is strongly purely infinite.*

PROOF. By Proposition n?? $A \otimes \mathcal{Z}$ is purely infinite.

By [**391**], the algebra $\mathcal{Z}$ contains $\mathcal{E}(M_2, M_3)$ and $\mathcal{Z} \cong \mathcal{Z} \otimes \mathcal{Z} \otimes \cdots$. Since $m(\mathcal{E}(M_2, M_3)) \leq 3$ it follows that there is a unital C^*-morphism from G_3 into $\mathcal{Z}$.

The isomorphism $\mathcal{Z} \cong \mathcal{Z} \otimes \mathcal{Z} \otimes \cdots$ implies that there exists a "central" sequence of unital C^*-morphisms from G_3 into $\mathcal{M}(A) \otimes \mathcal{Z} \subset \mathcal{M}(A \otimes \mathcal{Z})$. Now Proposition 2.9.7 applies and shows that $A \otimes \mathcal{Z}$ is strongly purely infinite.

Alternatively one can $\mathcal{Z}$ represent as inductive limit of $\mathcal{E}(M_{2^\infty}, M_{3^\infty})$ given by a suitable endomorphism of $\mathcal{E}(M_{2^\infty}, M_{3^\infty})$. The latter can be described as inductive limit of $\mathcal{E}(M_{2^n}, M_{3^n})$. But $\mathcal{E}(M_{2^n}, M_{3^n})$ contains obviously a central sequence of copies of $\mathcal{E}(M_2, M_3)$.

□

DEFINITION 2.9.9. Let A, B unital C^*-algebras. The **tensorial joint algebra** (also called **joining algebra** , or **winding around algebra**) of A and B is defined in [**448**, following Prop. 1.17] as the C^*-subalgebra of $\mathrm{C}([0,1], A \otimes^{\max} B)$ defined by:

$$\mathcal{E}(A, B) := \{ f \in \mathrm{C}([0,1], A \otimes^{\max} B)\, ;\ f(0) \in A \otimes 1\, ,\ f(1) \in 1 \otimes B \} \tag{9.1}$$

In cases where $A := M_m$ and $B := M_n$, this algebras also are called *dimension-drop* C^*-algebras.

COROLLARY 2.9.10. *If A is a (2-quasi-) traceless C^*-algebra, and if $B := M_p$ and $C := M_q$ are UHF-algebras with infinite supernatural numbers p and q, then the tensor product*

$$A \otimes \mathcal{E}(B, C) \subseteq A \otimes \mathrm{C}([0,1], B \otimes C)$$

of A with the "tensorial joint" algebra $\mathcal{E}(B, C)$ of Definition 2.9.9 is strongly purely infinite.

PROOF. Consider unital C^*-algebras B and C. Let H_1 denote the sub-algebra of $\mathrm{C}[0,1/2] \otimes C$ defined by the maps $f \in \mathrm{C}([0,1/2], C)$ with $f(0) = 1$, and H_2 the sub-algebra of maps $g \in \mathrm{C}[1/2,1] \otimes B$ with $g(1) = 1$. Then there are natural C^*-epimorphisms ϕ_1 from $B \otimes H_1$ onto $B \otimes C$ with $\phi_1(b \otimes f) = b \otimes f(1/2)$ and $\phi_2 \colon H_2 \otimes C \to B \otimes C$ with $\phi_2(g \otimes c) = g(1/2) \otimes c$.

It is easy to see that $\mathcal{E}(B, C) \subseteq \mathrm{C}([0,1], B \otimes C)$ is naturally isomorphic to the pull-back of ϕ_1 and ϕ_2.

It follows that $A \otimes \mathcal{E}(B, C)$ is the pull-back of the epimorphisms $\mathrm{id}_A \otimes \phi_1$ and $\mathrm{id}_A \otimes \phi_2$ onto $A \otimes B \otimes C$. In particular, it is an extension of $A \otimes B \otimes C$ by the ideal $(A \otimes \phi_1^{-1}(0)) \oplus (A \otimes \phi_2^{-1}(0))$ of $A \otimes \mathcal{E}(B, C)$.

Notice that $\mathcal{E}(\mathbb{C}, B)$ is the C^*-subalgebra of $\mathrm{C}([0,1], B)$ of continuos functions $f \colon [0,1] \to B$ wit $f(0) = 1_B$. Notice that $\phi_1^{-1}(0) \cong B \otimes \mathcal{E}(\mathbb{C}, C)$ and $\phi_2^{-1}(0) \cong \mathcal{E}(\mathbb{C}, B) \otimes C$.

For this ideals and for the $A \otimes B \otimes C$ the Lemma **??** applies if $B := M_{2^\infty}$ and $C := M_{3^\infty}$, because all tensorial absorb UHF algebras. Thus they are purely infinite infinite if A is (2-quasi-) traceless.

By Proposition 2.9.12 they are moreover strongly purely infinite because they have central sequences of matrix algebras.

Thus, $A \otimes \mathcal{E}(B, C)$ is an extension of strongly p.i. C^*-algebras if A is (2-quasi-) traceless. By Proposition **??** it follows that $A \otimes \mathcal{E}(B, C)$ is p.i., because the class of purely infinite C^*-algebras is invariant under extensions.

`next Ext.part of Thm. is not present here. Only cited.`

Since extensions of s.p.i. algebras are s.p.i. by Theorem 2.9.13, we get moreover that $A \otimes \mathcal{E}(B, C)$ is strongly p.i.

□

Corollary 2.9.11. *Let A a (2-quasi-) traceless C^*-algebra and $\mathcal{Z}$ the Jiang-Su algebra, then $A \otimes \mathcal{Z}$ is strongly purely infinite.*

Proof. If B is a unital C^*-algebra and $\psi \colon B \to B$ a unital C^*-morphism. The map ψ is called "trace-collapsing" if $\tau_1 \circ \psi = \tau_2 \circ \psi$ for any trace state on B, i.e., $\psi^*(T(A))$ consists of a fix-point of $T(A)$.

By [**693**, thm. 3.4], $\mathcal{Z}$ is the inductive limit

$$\mathrm{indlim}_n \left(\phi_n \colon \mathcal{E}(M_{2^\infty}, M_{3^\infty}) \to \mathcal{E}(M_{2^\infty}, M_{3^\infty}) \right),$$

where $\phi_n := \phi$ is a suitable fixed "trace-collapsing" unital endomorphism ϕ of $\mathcal{E}(M_{2^\infty}, M_{3^\infty})$. "Trace-collapsing" means here that for each trace state ρ on $\mathcal{E}(M_{2^\infty}, M_{3^\infty})$ the state $\rho \circ \phi$ is identical with the state induced on $\mathcal{E}(M_{2^\infty}, M_{3^\infty}) \subseteq \mathrm{C}([0,1], M_{2^\infty} \otimes M_{3^\infty})$ by $\mu(f) = \int_0^1 \tau(f(t))\, dt$, where τ is the unique trace state on $M_{2^\infty} \otimes M_{3^\infty}$.

We have seen above (in a more general case) that $A \otimes \mathcal{E}(M_{2^\infty}, M_{3^\infty})$ is s.p.i. because there exists a "central" sequence of unital C^*-morphisms $\psi_k \colon \mathcal{E}(M_p, M_q) \to \mathcal{E}(M_{2^\infty}, M_{3^\infty})$, where $p := 2^k$ and $q := 3^\ell$ for suitable $k, \ell \in \mathbb{N}$.

?????????

The classes of the purely infinite C^*-algebras and of the strongly purely infinite C^*-algebras are both invariant under inductive limits.

By Theorem **??**(????) the class of s.p.i. algebras is invariant under inductive limits. □

Proposition 2.9.12. *If A is (2-quasi-) traceless and B is a UHF algebra (of infinite dimension), then $A \otimes B$ is s.p.i.*

Proof. We can split B into a tensor-product $B = B_1 \otimes B_2$ where B_1 and B_2 are UHF-algebras of infinite dimension. Then $A \otimes B_1$ is purely infinite by Lemma **??**. Thus we can suppose that A is purely infinite. Let $a, b \in (A \otimes B)_+$

contractions and $\varepsilon > 0$ There exist contractions $c, d \in (A \otimes B)_+$ with $\|a - c\| < \varepsilon/2$ and $\|b - d\| < \varepsilon/2$

???? ???? □

THEOREM 2.9.13. *The class of s.p.i. C^*-algebras is permanent under extensions.*

(But only citation. The known proof is complicate.)

Other operations.?

PROOF. ??? □

COROLLARY 2.9.14. *If A is (2-quasi)-trace-less then $A \otimes \mathcal{Z}$ is strongly p.i.*

PROOF. Use that $\mathcal{Z}$ has central sequences of copies of $\mathcal{E}(M_2, M_3)$. □

Below we give later some results on tensor products that are farer going than those in Corollaries 2.9.2 and 2.9.10, e.g. we show that the tensor products $A \otimes B$ and $A \otimes \mathcal{E}(M_{2^\infty}, M_{3^\infty})$ considered in this corollaries are moreover strongly p.i.

PROOF. to be filled in ?? □

Give extra Definitions (!) for all sorts of pure infiniteness!!!

REMARKS 2.9.15.

(i) If $a \in A_+$, $b \in M_n(A)_+$ and suppose that there is a matrix $e \in M_{m,n}(A)$ with $\|b - e^*(a \otimes 1_m)e\| < \varepsilon$ for some $\varepsilon > 0$, then

$$(b - \varepsilon)_+ = f^*((a - 2\eta)_+ \otimes 1_m)f$$

for some matrix $f \in M_{m,n}(A)$ with $\|f\| \leq \|e\|$ and some $\eta \in (0, \varepsilon/2)$.

The def's (ii) of p.i. etc. are given earlier in Section 1, later again !!! where???

(ii) An element $a \in A_+ \setminus \{0\}$ in a (not necessarily purely infinite) C^*-algebra A is **properly infinite** if, for every $\varepsilon > 0$, there exists a row $d = [d_1, d_2] \in M_{1,2}(A)$ (depending on a and ε) such that $\|d^*ad - a \otimes 1_2\| < \varepsilon$, cf. [**462**, def. 3.2].

This property of a is equivalent to $[a] + [a] \leq [a]$ in $\mathrm{Cu}(A)$, i.e., $a \oplus a \precsim a$, or to $a \in I(a)$ by definition of $I(a)$ in Definition 2.5.1, cf. also Lemma 2.5.3(i).

An element $a \in A_+$ is **properly infinite** if for every closed ideal J of A – that does not contain a – there is an element $h \neq 0$ in $(A/J)_+$ such that for every $\delta > 0$ there exists a row matrix $d = [d_1, d_2] \in M_{1,2}(A/J)$ with $\|d^*\pi_J(a)d - (\pi_J(a) \oplus h)\| < \delta$, cf. Part (v) of Lemma 2.5.3 or [**462**, prop. 3.14].

The latter says that $[h] + [\pi_J(a)] \leq [\pi_J(a)]$ in $\mathrm{Cu}(A/J)$, i.e., $I(\pi_J(a)) \neq 0$ for all $J \in \mathcal{I}(A)$ with $a \notin J$, where $I(b)$ for $b \in \pi_J(A)$ is defined by Definition 2.5.1.

This definition of properly infinite infinite (positive) elements coincides with Definition 2.5.1 of a properly element $a \in A$ by $a \oplus a \precsim a$.

(iii) A C^*-algebra A is purely infinite in the sense of Definition 1.2.1, if and only if, every element $a \in A_+ \setminus \{0\}$ is properly infinite, [**462**, thm. 4.16].

`there is also Ref. in ???? to place here!!`

(iv) All purely infinite C^*-algebras A have the *global* Glimm halving property of Definition *2.15.9*.

Proof. (i): We find $\eta \in (0, \varepsilon/2)$ such that we have $\|b - e^*((a-\eta)_+ \otimes 1_m)e\| < \varepsilon$. By Lemma 2.1.9 there is a contraction $d \in M_n(A)$ such that $f := ed$ is as desired.

(ii?): ??

The element $\pi_{I(a)}(a) = a + I(a)$ is always finite in $A/I(a)$ by Part (iii) of Lemma 2.5.3. Thus above property of $a \in A_+$ implies that $a \in I(a)$, i.e., $a \oplus a \precsim a$.

(ii?): ?? If one applies (i) with $m = 1, n = 2$ then one finds $u, v \in aAa$ with $u^*u = v^*v = (a-\varepsilon)_+$ and $u^*v = 0$ ([**462**, prop. 3.3(v)]), i.e., there exists a row $w = [u, v] \in M_{1,2}(aAa)$ satisfying

$$w^*w = (a-\varepsilon)_+ \otimes 1_2 \quad \text{in } \; A \otimes M_2 \,,$$

cf. also Lemma 2.5.3(ix,xi)

(iv): ??

For each $a \in A_+ \setminus \{0\}$ and $\varepsilon > 0$, then $b = vu^* \in aAa$ with u, v from (ii??) verifies $b^2 = 0$ and $\big((a-\varepsilon)_+\big)^2 = v^*bu$, so that $(a-\varepsilon)_+ \in AbA$. □

`How often is` f_ε `defined and mentioned??`

In the following, recall that $f_\varepsilon(t) := \min(1, \max(0, 2t/\varepsilon - 1))$ for $t \geq 0$ and $\varepsilon > 0$. Those special pice-wise linear functions have been used fist in Glimm's paper [**324**] for his pioneering study of C^*-algebras of Type I.

Notice that the Part (i) of the next Lemma 2.9.16 applies in particular to all non-zero elements $a \in A_+$ that are *spectral properly infinite* in sense of Definition 2.5.16.

`Later appears a similar remark!!!`

Lemma 2.9.16. *Let $a \in A_+$ with $\|a\| = 1$, $0 < \delta < \varepsilon < 1$, and let $B := \overline{aAa}$.*

Suppose that for every $\nu \in (\delta, \varepsilon)$, the element $(a-\nu)_+$ is properly infinite *in the sense of Definition 2.5.1.*

(i) *There exists an infinite sequence $w_1, w_2, \ldots \in (a-\delta)_+ A (a-\varepsilon)_+^{1/3}$ such that*

$$w_n^* w_m = \delta_{n,m}\,(a-\varepsilon)_+ \quad \textit{for all } \; m, n \in \mathbb{N}\,.$$

The element $d := \sum_{n \in \mathbb{N}} 2^{-n} w_n w_n^* \in B$ generates a stable *hereditary C^*-subalgebra $E_\varepsilon := \overline{dAd}$ of $(a-\delta)_+ A (a-\delta)_+$ that is naturally isomorphic to $D \otimes \mathbb{K}$ for $D := \overline{(a-\varepsilon)_+ A (a-\varepsilon)_+}$.*

In particular the algebra E_ε is a full hereditary C^*-subalgebra of the closed ideal of A that is generated by $(a-\varepsilon)_+$.

(ii) *If, moreover,* every *non-zero element of B is properly infinite, then there are elements $w_n \in B$ such that $w_n^* w_m = \delta_{n,m} \cdot (a - 2^{-n})_+$ for all $n \geq m \in \mathbb{N}$.*

(iii) *Let $d := \sum_{n\in\mathbb{N}} 2^{-n} w_n w_n^* \in B := \overline{a\,A\,a}$ where the elements $w_1, w_2, \ldots \in B$ are the elements from Part* (ii).

The hereditary C^*-subalgebra $D := \overline{d\,A\,d}$ is contained in B, and there exist elements $z_1, z_2, \ldots \in B$ with $z_j^* z_k = \delta_{j,k} a$ and $z_k z_j^* \in D$.

In particular, the contraction $e := \sum_n 2^{-n} z_n z_n^*$ generates a hereditary C^*-subalgebra $E := \overline{e\,D\,e} = \overline{e\,A\,e}$ of D that is full in B.

(iv) *The hereditary C^*-subalgebra $B := \overline{a\,A\,a}$ is itself stable if each element of B is properly infinite and the annihilators $\mathrm{Ann}((a-1/n)_+, B)$ of $(a-1/n)_+$ are full in B for each $n \in \mathbb{N}$.*

(v) *The annihilators $\mathrm{Ann}((a-1/n)_+, B)$ are full in B for each $n \in \mathbb{N}$ if B has no unital quotient.*

(vi) *The hereditary C^*-subalgebra $B := \overline{a\,A\,a}$ is stable if B has no unital quotient and a is "spectral" properly infinite, i.e., $\psi(a)$ is properly infinite or zero for every function $\psi \in \mathrm{C}_0(0, \|a\|]_+$.*

PROOF. Recall that an element a itself is properly infinite if $(a-\nu)_+$ is properly infinite for every $\nu \in (0, \delta)$ for some $\delta > 0$, and that the elements b^*b, bb^* and $(b^*b)^{1/2}$ are all properly infinite if one of its is properly infinite, cf. Lemma 2.5.3(xi,xii).

by Remark 2.9.15(ii) ?

Find precise Ref.s for next.

(i): We can take $\delta < \delta' < \varepsilon' < \varepsilon$, replace a by $(a-\delta')_+$ and then show moreover that there are elements $c_1, c_2, \ldots$ in the closure of $(a-\delta')_+ A (a-\varepsilon')_+$ such that $c_n^* c_m = \delta_{n,m} (a-\varepsilon')_+$ for $m, n \in \mathbb{N}$. We get the desired w_n as $w_n := c_n \cdot \varphi(c_n^* c_n)^{1/2}$ for the function $\varphi(t) := (t-\varepsilon)/(t-\varepsilon')$ for $t \geq \varepsilon$ and $\varphi(t) = 0$ for $t < \varepsilon$.

Hence, we can rename $(a-\delta')_+$ by a and $\varepsilon' - \delta'$ by ε and show only the existence of $w_k \in \overline{aA(a-\varepsilon)_+}$ with $w_k^* w_j = \delta_{j,k} (a-\varepsilon)_+$.

For $n \in \mathbb{N}$, let $\varepsilon_n := 2^{-n-1}\varepsilon$ and $\mu_n := \sum_{0\leq k\leq n} \varepsilon_k = (1-2^{-n-1}) \cdot \varepsilon < \varepsilon$.

Recall that, if $(a-\delta)_+$ is properly infinite, then, for each $\mu > \delta$, there exist $\tau \in (\delta, \mu)$ and $u, v \in A$ with

$$u^*v = 0\,, \quad u^*u = v^*v = (a-\mu)_+ \quad \text{and} \quad uu^* + vv^* \in (a-\tau)_+ A (a-\tau)_+\,. \tag{9.2}$$

Compare Remark 2.9.15(ii) or Lemma 2.5.3(ix,xi). `or other reference ?`

If we let $v_{-1} := a^{1/2}$, then we can find for each $n \in \mathbb{N}$ inductively – by repeated use of Equation (9.2) – elements $u_n, v_n \in aAa$ such that

(1) u_n, v_n in $v_{n-1} A v_{n-1}^* \subseteq \overline{aAa}$ $(n \in \mathbb{N})$

(2) for every $\nu \in (0, \varepsilon - \nu_n)$, the element $(v_n^* v_n - \nu)_+$ is either zero or properly infinite,
(3) $u_n^* u_n = v_n^* v_n = (v_{n-1}^* v_{n-1} - \varepsilon_n)_+ = (a - \mu_n)_+ \geq (a - \varepsilon)_+$ and
(4) $u_n^* v_n = 0$,

Induction over m shows that condition (1) implies that $v_{n-1} A v_{n-1}^* \subseteq v_{m+1} A v_{m+1}^* \subseteq v_m A v_m^*$ for $m = 1, \ldots, n-2$.

Thus, $u_m^* v_{n-1} A v_{n-1}^* = 0$ and $u_m^* u_n = 0$ for $m < n$ by (1) and (4). Hence, $u_m^* u_n = \delta_{m,n}(a - \mu_n)_+$ for $m, n \in \mathbb{N}$ by (3).

Notice that (1) and (3) imply $u_n, v_n \in v_{n-1} A (a - \mu_{n-1})_+ \subseteq aAa$.

For $n \in \mathbb{N}$, let $\varphi_n \colon \mathbb{R}_+ \to [0,1]$ be the continuous function with $\varphi_n(t) := 0$ for $t < \varepsilon$ and $\varphi_n(t) := (t - \varepsilon)/(t - \mu_n)$ for $t \geq \varepsilon$.

The elements $w_n = u_n f_n(a)^{1/2} \in \overline{aA(a - \varepsilon)_+}$ satisfy the requested relations, because $(t - \mu_n)_+ \varphi_n(t) = (t - \varepsilon)_+$.

Let $B := \overline{(a - \varepsilon)_+ A (a - \varepsilon)_+}$. The relations $w_k^* w_\ell = \delta_{k,\ell}(a - \varepsilon)_+$ imply that the polar decomposition of the w_k define a natural isomorphism $B \cong \overline{w_1 A w_1^*}$ and that the C^*-subalgebra $D := C^*(w_m b w_n^* \, ; \; n, m \in \mathbb{N}, \; b \in A)$ of $\overline{aAa}$ is naturally isomorphic to $B \otimes \mathbb{K}$. In particular D is stable.

The algebra D contains $d := \sum_{n \in \mathbb{N}} 2^{-n} w_n w_n^*$ and is identical with the hereditary C^*-subalgebra $\overline{dAd} \subseteq B$, with d as strictly positive element.

The hereditary subalgebra D generates the same closed ideal of A as the element $(a - \varepsilon)_+$ because $2 w_1^* d w_1 = (w_1^* w_1)^2 = (a - \varepsilon)_+^2$.

(ii): Let $a \in A_+$ with $\|a\| = 1$, and suppose that *every* non-zero element of $B := \overline{aAa}$ is properly infinite and let $D \subseteq B$ (any) *full* hereditary C^*-subalgebra of B.

(α) Suppose that $D \subseteq B := \overline{aAa}$ (with $a \in A_+$, $\|a\| = 1$) is a full hereditary C^*-subalgebra of B and that each non-zero $e \in D_+$ is properly infinite.

Then for each $\gamma \in (0,1)$ there exists elements $u, v \in B$ with $u^* u = v^* v = (a - \gamma/2)_+$, $v^* u = 0$ and $vv^*, uu^* \in D$.

(β) If D is any full hereditary C^*-subalgebra of $B := \overline{aAa}$, where $a \in A_+$ with $\|a\| = 1$, and if

`check here if a weaker property also works!`

every element of D_+ is properly infinite, then for each $\gamma \in (0,1)$ there exists an element $w \in B$ that satisfies $w^* w = (a - \gamma)_+$, $ww^* \in D$, and that the annihilator $\mathrm{Ann}(ww^*, D)$ of ww^* in D is again a *full* hereditary C^*-subalgebra of B.

We postpone the proof of (α) and (β) and show that (β) allows to construct the in Part (ii) requested elements $w_1, w_2, \ldots \in B := \overline{aAa}$ with the relations $w_n^* w_m = \delta_{n,m} \cdot (a - 2^n)_+$ for $n \geq m$.

We proceed by induction using (β):

We find by (β) an element $w_1 \in D_0 := B$ with $w_1^* w_1 = (a - 1/2)_+$ such that $D_1 := \mathrm{Ann}(w_1 w_1^*, B)$ is a full hereditary C^*-subalgebra of B.

Suppose we have selected $w_1, \ldots, w_n \in B$ that satisfy

$$w_k^* w_\ell = \delta_{k,\ell} \cdot (a - 2^{-\ell})_+$$

for $k \leq \ell \leq n$, and that

$$D_n := \mathrm{Ann}(w_1 w_1^* + \cdots + w_n w_n^*, B) = \mathrm{Ann}(w_n w_n^*, D_{n-1})$$

is full in B.

Recall here that $\mathrm{Ann}(e, D) = \mathrm{Ann}(e, B) \cap D$ for hereditary $D \subseteq B$ and $e \in D_+$.

Thus, we can apply (β) to $D := D_n$ and $\gamma := 1/2^{n+1}$ and get $w_{n+1} \in D_n$ with $w_{n+1}^* w_{n+1} = (a - 2^{-(n+1)})_+$ and

$$D_{n+1} := \mathrm{Ann}(w_{n+1} w_{n+1}, D_n) = \mathrm{Ann}(w_1 w_1^* + \cdots + w_{n+1} w_{n+1}^*, B)$$

is full in B. It implies that

$$w_{n+1}^* w_k = \delta_{n+1,k} (a - 2^{-(n+1)})_+ \quad \text{for} \quad k = 1, \ldots, n+1 \ .$$

Proof of observation (α): Let $\gamma \in (0,1)$. Since D is full in B and $a \in B_+$ there exists $d_1, \cdots, d_n \in B$ with $d_k d_k^* \in D$ for $k = 1, \ldots n$ and

$$d_1^* d_1 + \cdots + d_n^* d_n = (a - \gamma/4)_+ \, .$$

It follows $n[e] \geq [(a - \gamma/4)_+]$ in $\mathrm{Cu}(B)$, for $e := d_1 d_1^* + \cdots + d_n d^* \in D$.

Since, by assumptions, $e \in D_+$ is a properly infinite element of B, we get $[e] \geq 2n[e] \geq 2[(a - \gamma/4)_+]$, i.e.,

$$(a - \gamma/4)_+ \oplus (a - \gamma/4)_+ \precsim e \oplus 0 \, .$$

In particular there exists $f_1, f_2 \in B$ and $\mu > 0$ with

$$[f_1^*, f_2^*](e - \mu)_+ [f_1, f_2]^\top = \mathrm{diag}(a - \gamma/2)_+ \oplus (a - \gamma/2)_+ \, .$$

The elements $u := (e - \mu)_+^{1/2} f_1$ and $v := (e - \mu)_+^{1/2} f_2$ satisfy $uu^*, vv^* \in D$, $u^* v = 0$ and $u^* u = v^* v = (a - \gamma/2)_+$.

Proof of observation (β): Each hereditary C^*-subalgebra D of $B := \overline{aAa}$ that is full in B and is purely infinite fulfills the assumptions for Part (α).

Let $\gamma \in (0,1)$ and let $u, v \in B$ the elements from Part (α), i.e., $u^* u = v^* v = (a - \gamma/2)_+$, $u^* v = 0$ and $uu^*, vv^* \in D$.

The function ψ_γ defined by $\psi_\gamma(t) := (t - \gamma)/(t - \gamma/2)$ for $t \geq \gamma$ and $\psi_\gamma(t) := 0$ for $t \leq \gamma$ is in $\mathrm{C}_0(0,1]_+$ and satisfies $\psi_\gamma(t) \leq 1$. Clearly

$$\psi_\gamma(a)(a - \gamma/2)_+ = (a - \gamma)_+ = ((a - \gamma/2)_+ - \gamma/2)_+ \, .$$

Define $w := v \psi_\gamma(a)^{1/2} \in B$. It satisfies $w^* w = (a - \gamma)_+ = (v^* v - \gamma/2)_+$ and $ww^* = (vv^* - \gamma/2)_+$. The latter equation can be seen with help of the polar decomposition $v = z_v (v^* v)^{1/2} = z_v (a - \gamma/2)_+$ using that $f(vv^*) z_v = z_v f(v^* v)$ for $f \in \mathrm{C}_0(0, \|v\|^2]$.

The elements ww^*, vv^* and $d := uv^*$ are in D and satisfy $ww^* = (vv^* - \gamma/2)_+$, $d^*(vv^* - \gamma/2)_+ = vu^*ww^* = 0$ and $[d] = [vv^*]$ in $\mathrm{Cu}(D)$. The latter because $d^*d = vu^*uv^* = v(a - \gamma/2)_+v^* = (vv^*)^2$. Thus, the hereditary C^*-subalgebra $\mathrm{Ann}(ww^*, D)$ is full in D by the last observation in Part (ii) of Lemma 2.5.14. Since D is full in B it implies that $\mathrm{Ann}(ww^*, D)$ is a hereditary C^*-subalgebra of B that is full in B.

(iii): TEXT:

Let $d := \sum_{n\in\mathbb{N}} 2^{-n} w_n w_n^* \in B := \overline{a\,A\,a}$ where the elements $w_1, w_2, \ldots \in B$ are the elements found in Part (ii).

The hereditary C^*-subalgebra $D := \overline{d\,A\,d}$ is contained in B, and there exist elements $z_1, z_2, \ldots \in B$ with $z_j^* z_k = \delta_{j,k} a$ and $z_k z_j^* \in D$.

In particular, the contraction $e := \sum_n 2^{-n}\, z_n\, z_n^* \in B$ generates a hereditary C^*-subalgebra $E := \overline{e\,D\,e} = \overline{e\,A\,e}$ of D that is full in B.

We define for $t \geq 0$ and $m, n \in \mathbb{N}$, $m < n$, the increasing function $\varphi(m, n; \cdot) \in \mathrm{C}_0(0, 1]$ with $\varphi(m, n; t) := 0$ on $[0, 2^{-m}]$ and $\varphi(m, n; t) := \max(t - 2^{-m}, 0)/\max(t - 2^{-n}, 0)$ for $t \geq 2^{-m}$.

Let $\lambda \colon \mathbb{N} \to \mathbb{N}\times\mathbb{N}$ a bijective map from $\mathbb{N}$ onto $\mathbb{N} \to \mathbb{N}$ and let $M_k := \lambda^{-1}(\{k\} \times \mathbb{N})$.

Notation M_k is not good,
NEXT property HERE necessary?

We can re-index the infinite subsets M_k of $\mathbb{N}$ such that they have the property that $\min(M_k) < \min(M_{k+1})$ for $k \in \mathbb{N}$.

The map λ defines a unique increasing injective map $\mu_k \colon \mathbb{N} \to \mathbb{N}$ with $\mu_k(\mathbb{N}) = M_k$.

We let $a[k, 1] := 1 \in C^*(a, 1) \subseteq \mathcal{M}(B)$,

$$a[k, n+1] := 1 - \varphi(\mu_k(n), \mu_k(n+1); a) \ \in C^*(a, 1)_+\,,$$

and define elements $v_k \in B$ for $k \in \mathbb{N}$ by

$$v_k := \sum_{n\in\mathbb{N}} w_{\mu_k(n)} \cdot a[k, n]^{1/2}\,.$$

The sum converges in B, because $w^*_{\mu_k(n)} w_{\mu_k(m)} = \delta_{m,n}(a - 2^{-n})_+$ and, for $n > 1$,

$$a[k, n]^{1/2} \cdot w^*_{\mu_k(n)} w_{\mu_k(n)} \cdot a[k, n]^{1/2} = (a - 2^{-\mu_k(n)})_+ - (a - 2^{-\mu_k(n-1)})_+\,.$$

It has norm $\leq 2^{-\mu_k(n-1)} - 2^{-\mu_k(n)} < 2^{-\mu_k(n-1)}$. The series $\sum_{n>1}(2^{-\mu_k(n-1)} - 2^{-\mu_k(n)})$ is absolutely convergent with sum $= 2^{-\mu_k(1)}$.

One gets from $w_\ell^* w_m = 0$ for $\ell \neq m$ that

$$v_k[n]^* v_k[n] = (a - 2^{-\mu_k(n)})_+$$

for the partial sums

$$v_k[n] := \sum_{m=1}^{n} w_{\mu_k(m)} \cdot a[k, m]^{1/2}\,.$$

It follows that

$$v_k^* v_k = \sum_n (a - 2^{-\mu_k(n)})_+ a[k,n] = a\,.$$

Since $w_m^* w_n = 0$ and $w_n w_m^* \in D$ for $m \neq n$ and $\mu_k(\mathbb{N}) \cap \mu_\ell(\mathbb{N}) = \emptyset$ for $k \neq \ell$, it follows that $v_k^* v_\ell = \delta_{k,\ell} a$. and $v_\ell v_k^* \in D$.

(iv):

TEXT:

The hereditary C^*-subalgebra $B := \overline{a\,A\,a}$ is itself stable if each element of B is properly infinite and the annihilators $\mathrm{Ann}((a-1/n)_+, B)$ of $(a-1/n)_+$ are full in B for each $n \in \mathbb{N}$.

to be filled in ??

We show that it implies that there exists a zero sequence $\|a\| > \gamma_1 > \gamma_2 > \cdots > 0$ and elements $u_n \in B$ with

(1) $u_n^* u_n = (a - \gamma_n)_+$,
(2) $u_{n+1}^*(a - \gamma_n)_+ = 0$, and
(3) $u_n = \lim_{n\to\infty} u_n (a - \gamma_{n+1})_+^{1/n}$.

What can be done with it ?

Since a is a strictly positive element of B it follows that the criteria for stability of B is satisfied for B. Alone from (1) and (2)?

Indeed we can define for the exhausting family of order preserving injective maps $???_k \colon \mathbb{N} \to M_k := \lambda^{-1}(\{k\} \times \mathbb{N})$ from a partition $\lambda\colon \mathbb{N} \to \mathbb{N} \times \mathbb{N}$

(v): Let J denote the closed ideal of B generated by $\mathrm{Ann}((a-1/n)_+, B)$. By Lemma 2.5.14, B/J is unital and $\pi_J(a)$ is invertible in B/J if $J \neq B$. Thus, $J = B$ if B has no unital quotients. □

REMARK 2.9.17. Let $a \in A_+$ with $\|a\| = 1$. The hereditary C^*-subalgebra $\overline{aAa}$ contains a full stable hereditary C^*-subalgebra D, if and only if, *there exists a sequence of elements* $b_n \in \overline{aAa}$ *with* $b_m^* b_n = \delta_{m,n}(a - 2^{-n})_+$ *for* $m, n \in \mathbb{N}$.

Here "full" – equivalently – means that a is in the closed ideal generated by D, i.e., that $a \in A \cdot D \cdot A = \overline{\mathrm{span}(ADA)}$ by stability of D.

It implies that there are $g_1, g_2, \ldots \in A$ with $g_m^* g_n = \delta_{m,n} a$ and $g_m g_m^* \in D$.

It is not clear when $C^*(b_n b_m^*\,;\ m, n \in \mathbb{N})$ itself is stable.

PROOF. The existence of the quoted sequence $d_1, d_2, \ldots$ is necessary:
If D is a stable and full hereditary C^*-subalgebra of $B := \overline{aAa}$ then there exists $d \in B$ with $d^* d = a$ and $dd^* \in D$, cf. Lemma ??(ii).

Since D is stable, its multiplier algebra $\mathcal{M}(D)$ contains a unital copy of $\mathcal{L}(\ell_2) \supset \mathcal{O}_\infty = C^*(s_1, s_2, \ldots\,;\ s_m^* s_n = \delta_{m,n} 1)$, cf. Remark 5.1.1(8). We can take $b_n := s_n d g_n(a)$, where $g_n(0) := 0$ and $g_n(t) := ((t - 2^{-n})_+/t)^{1/2}$ with $(t-\mu)_+ := \max(0, t-\mu)$ for $t > 0$.

Conversely, the existence of elements $b_n \in \overline{aAa}$ with $b_m^* b_n = \delta_{m,n}(a - 2^{-n})$ (for $m \leq n$) is sufficient for the existence of a full stable hereditary C^*-subalgebra $D \subseteq \overline{aAa}$ that contains a in the ideal ADA of A, because by the below given calculations $C^*(b_m b_n^*\,;\ m,n \in \mathbb{N}\,)$ is isomorphic to the hereditary C^*-subalgebra $E := \overline{d(C^*(a) \otimes \mathbb{K})d}$ of $C^*(a) \otimes \mathbb{K}$ where

$$d := \operatorname{diag}((a - 1/2)_+, (a - 1/4)_+, \ldots)^{1/2} \in \ell_\infty(C^*(a)) \subset \mathcal{M}(C^*(a) \otimes \mathbb{K})\,,$$

i.e., $e := \operatorname{diag}(1/2(a - 1/2)_+, \ldots, 2^{-n}(a - 2^{-n})_+, \ldots)$ is a strictly positive element of $C^*(a) \otimes \mathbb{K}$.

An isomorphism from E onto $C^*(b_m b_n^*\,;\ m,n \in \mathbb{N}\,)$ can be defined as follows:

First define $\lambda\colon C^*(a) \otimes \mathbb{K} \to B \otimes \mathbb{K}$ as the natural embedding. The λ is non-degenerate because $B = \overline{a\,B\,a}$. Therefore the strictly continuous $\mathcal{M}(\lambda)\colon \mathcal{M}(C^*(a) \otimes \mathbb{K}) \to \mathcal{M}(B \otimes \mathbb{K})$ exists and is injective natural inclusion of $\mathcal{M}(C^*(a) \otimes \mathbb{K})$ into $\mathcal{M}(B \otimes \mathbb{K})$. Let $g := \mathcal{M}(\lambda)(d)$ and $h := \lambda(e) = 1/2(a - 1/2)_+ \otimes p_{1,1} + 1/4(a - 1/4)_+ \otimes p_{2,2} + \cdots$. Then $\lambda(E)$ is a non-degenerate C^*-subalgebra of the hereditary C^*-subalgebra $\overline{g(B \otimes \mathbb{K})g} = \overline{h(B \otimes \mathbb{K})h} =: F$. It is easy to see that $\lambda(E) := F \cap \lambda(C^*(a) \otimes \mathbb{K})$, because it is generated by the elements $(a - 2^{-m})^{1/2}(a - 2^{-n})_+^{1/2} \otimes p_{m,n}$, and, even by definition of h, $h = \lambda(e) \in F_+$ is a strictly positive contraction of F and $\lambda(E)$.

The element $P := \sum_n 2^{-n} b_n b_n^* \in B$ is a strictly positive contraction of $C^*(b_m b_n^*\,;\ n,m \in \mathbb{N})$.

Let $T := \sum_n 2^{-n/2} b_n \otimes p_{1,n} \in B \otimes \mathbb{K}$. Then $TT^* = P \otimes p_{1,1}$ and

$$T^*T = \sum_n 2^{-n}(a - 2^{-n})_+ \otimes p_{n,n} = h\,.$$

The polar decomposition $T = U(T^*T)^{1/2}$ of T is given by the partial isometry

$$U := \sum_n v_n \otimes p_{1,n} \;\in\; B^{**} \overline{\otimes} \mathcal{L}(\ell_2) \cong (B \otimes \mathbb{K})^{**}\,,$$

where $(T^*T)^{1/2} = h^{1/2}$ and $(b_n b_n^*)^{1/2} v_n = v_n (b_n^* b_n)^{1/2} = b_n$. Notice that $U^*U = \sum_n v_n^* v_n \otimes p_{n,n}$, and $UU^* = \sum_n v_n v_n^* \otimes p_{1,1}$, the element $v_n^* v_n \in B^{**}$ is equal to the open support projection P_n of $(a - 2^{-n})_+$ in B^{**}, $v_n(a - 2^{-n})_+^{1/2} = b_n$ and $v_m^* v_n = \delta_{m,n} P_n$. In particular $U^*(b_n b_m^* \otimes p_{1,1})U = (a - 2^{-n})_+^{1/2}(a - 2^{-m})_+^{1/2} \otimes p_{n,m}$. Thus

$$U^*(C^*(b_n b_m^*\,;\ m,n \in \mathbb{N}) \otimes p_{1,1})U \;=\; \lambda(E)\,.$$

The C^*-algebra E is isomorphic to a C^*-subalgebra of $C^*(a) \otimes \mathbb{K}$ of the sort considered in Lemma 2.9.18 and contains therefore a full stable C^*-subalgebra by Lemma 2.9.18. □

LEMMA 2.9.18. *Let $\mu_1 > \mu_2 > \cdots$ a strictly decreasing zero sequence in $(0,1)$ and define a positive contraction $d \in \mathrm{C}_0(0,1] \otimes \mathbb{K}$ by*

$$d := \operatorname{diag}(2^{-1}(f_0 - \mu_1)_+\,,\ 2^{-2}(f_0 - \mu_2)_+\,,\ \ldots)^{1/2} \in \mathrm{C}_0(0,1] \otimes c_0 \subset \mathrm{C}_0(0,1] \otimes \mathbb{K}\,,$$

where $f_0 \in \mathrm{C}_0(0,1]$ is given by $f_0(t) := t$.

The hereditary C^*-subalgebra $E := \overline{d\,(\mathrm{C}_0(0,1]\otimes\mathbb{K})\,d}$ of $\mathrm{C}_0(0,1]\otimes\mathbb{K}$ contains a full stable C^*-subalgebra D of E.

PROOF. Let $\lambda\colon \mathbb{N}\to\mathbb{N}\times\mathbb{N}$ a bijective map from $\mathbb{N}$ onto $\mathbb{N}\times\mathbb{N}$.

Then λ defines a decomposition of $\mathbb{N}$ into countably many pairwise disjoint infinite subsets $M_n := \lambda^{-1}(\{n\}\times\mathbb{N})$. The natural order in M_n leads to bijective order-preserving surjective maps $\psi_n\colon \mathbb{N}\to M_n$ from $\mathbb{N}$ onto M_n. Let $n_0, n_1\in\mathbb{N}$ with $1\in M_{n_0}$ and with $\min(\mathbb{N}\setminus M_{n_0})\in M_{n_1}$. Then $\psi_{n_0}(k)=k$ for $k=1,\ldots,\psi_{n_1}(1)-1$ and $\psi_n(k)>k$ for all other pairs (n,k).

We define isometries $T_n\in\mathcal{L}(\ell_2)\cong\mathcal{M}(\mathbb{K})$ by $T_n(\eta_k):=\eta_{\psi_n(k)}$ for the canonical ONB $\{\eta_1,\eta_2,\ldots\}$ of $\ell_2(\mathbb{N})$. The T_n satisfy the relations $T_m^*T_n=\delta_{m,n}1$ and $\sum_n T_nT_n^*$ converges strictly to $1\in\mathcal{M}(\mathbb{K})$.

We define $d_k := (1\otimes T_k)d$, then $d_j^*d_k = \delta_{j,k}d^2\in E$ and `Check next`

$$d_kd_k^* = \sum_n 2^{-n}(f_0-\mu_n)_+\otimes e_{\psi_k(n),\psi_k(n)}\,.$$

Since $2^{-n}(f_0-\mu_n)_+ \le 2^{-\psi_k(n)}(f_0-\mu_{\psi_k(n)})$???

$d_kd_k^* =$?????

We get $d_kd_k^*\in E$ and $d_k\in E$, because always $n\le\psi_k(n)$, E is hereditary and $d_k^*d_k = d^2\in E$.

Thus $D := C^*(d_jd_k^*\,;\; j,k\in\mathbb{N})$ is a full and stable C^*-subalgebra of E. □

REMARK 2.9.19. The algebra $E := \overline{d(\mathrm{C}_0(0,1]\otimes\mathbb{K})d}$ of Lemma 2.9.18 is the inductive limit of the hereditary C^*-subalgebras
$E_n := \overline{g_n(\mathrm{C}_0(0,1]\otimes\mathbb{K})g_n}$ with positive contractions $g_n\in\ell_\infty(\mathrm{C}_0(0,1]\otimes\mathbb{K})\subset\mathcal{M}(\mathrm{C}_0(0,1]\otimes\mathbb{K})$ given by the sequences

$$g_n := \mathrm{diag}(2^{-1}(f_0-\mu_1)_+\,,\,\ldots\,,\;2^{-n}(f_0-\mu_n)_+\,,\;2^{-n}(f_0-\mu_n)_+\,,\ldots)^{1/2}\,,$$

that are stationary beginning from n-th entry.

It is likely that the E_n are stable because each $\mathcal{M}(E_n)$ is properly infinite and E_{n+1} is a extensions of $\mathbb{K}$ by

$$E_n\oplus(0_n\oplus\mathrm{C}_0(\mu_{n+1},\mu_n)\otimes\mathbb{K})\,.$$

REMARK 2.9.20. The algebra $D := \overline{d\,A\,d}$ of Part (iii) of Lemma 2.9.16

`give reason for`
`''HAS NO UNITAL QUOTIENT''`

has no unital quotient and, for each element $b\in D_+$ and $\varepsilon>0$, there exist $c := c(b,\varepsilon)\in D$ such that $\|c^*bc\|<\varepsilon$ and $\|c^*c-b\|<\varepsilon$. By a criterium of J. Hjelmborg and M. Rørdam in [**373**], this properties of D imply that D itself is a stable σ-unital full C^*-subalgebra of $\overline{a\,A\,a}$. (Compare also Corollary 5.5.2 for an alternative proof of this stability criterium.)

It follows that *every σ-unital purely infinite C^*-algebra A contains a stable σ-unital hereditary C^*-subalgebra D that is full in A.* (cf. J. Hjelmborg, M. Rørdam, [**373**], [**688**, prop. 5.4]).

10. Local stability and properly infinite full projections

Recall that a non-zero element $a \in A$ is **stable** if $\overline{a^*Aa}$ is stable, cf. Definition 2.1.1 of stable elements and Definition 2.0.3 of locally purely infinite C^*-algebras.

(Perhaps one can here moreover take 1-stable elements or even n-stable elements in sense of Definition 2.1.3?)

Lemma 2.10.1. *A C^*-algebra B is* locally purely infinite *in the sense of Definition 2.0.3, if and only if, for every non-zero $b \in B_+$ and $\varepsilon \in (0, \|b\|)$, there exist $n = n(b, \varepsilon) \in \mathbb{N}$ and* stable *positive elements $a_1, \ldots, a_n$ in the hereditary C^*-subalgebra $\overline{bBb}$ such that $(b-\varepsilon)_+$ is in the ideal of B generated by $\{a_1, \ldots, a_n\}$.*

Proof. Consider the algebraic ideal J_0 that is generated by all stable positive element of $\overline{bBb}$. The closure J of the $*$-ideal J_0 is an ideal of B. We show that $b \in J$:

Suppose $\gamma := \|\pi_J(b)\| > 0$. Then there is a pure state ρ on B/J with $\rho(\pi_J(b)) = \gamma$, simply by extending a character χ on $C^*(\pi_J(b))$ with $\chi(\pi_J(b)) = \|\pi_J(b)\|$ to a pure state ρ on B/J.

Then $\lambda := \rho \circ \pi_J$ is a pure state on B that satisfies $\lambda(b) = \gamma > 0$ and $\lambda(J) = \{0\}$.

Let K the kernel of the irreducible representation $D_\lambda \colon B \to \mathcal{L}(L_2(B, \lambda))$ corresponding to λ. Clearly $J \subseteq K$ follows from $\lambda(J) = 0$.

By Definition 2.0.3 there is a non-zero stable hereditary C^*-subalgebra $D \subseteq \overline{bBb}$ which is not contained in K. Therefore, D is not contained in J. The isomorphism $D \cong F \otimes \mathbb{K}$ (for some C^*-algebra F) shows that there is a separable stable C^*-subalgebra $D_1 \subseteq D$ with $D_1 \not\subseteq J$. Then a strictly positive contraction $a \in (D_1)_+$ is not in J, but a is stable, because $\overline{aBa} = D_1$. This contradicts the assumption $b \notin J$.

The algebraic ideal J_0 generated by the positive stable elements $a \in \overline{bBb}$ is dense in $J \supset \overline{bBb}$ and (therefore) contains the Pedersen ideal of $\overline{bBb}$. In particular, $(b-\varepsilon)_+ \in J_0$ for all $\varepsilon > 0$. □

Lemma 2.10.2. *Each non-zero locally purely infinite C^*-algebra A (in the sense of Definition 2.0.3) is (2-quasi-) traceless.*

Proof. Let $\tau \colon A_+ \to [0, \infty]$ a lower s.c. 2-quasi-trace. If $a \in A_+$ is a non-zero contraction with $\tau(a) \neq \infty$ and if $\delta \in (0, \|a\|)$ then $D := \overline{(a-\delta)_+ A (a-\delta)_+}$ is a hereditary C^*-subalgebra of A with $(a-\delta)_+ \in D_+$, $d\varphi_\delta(a) = \varphi_\delta(a)d = d$ for all $d \in D$, where

$$\varphi_\delta(t) := \min(1, \max(0, 2t/\delta - 1)) \leq 2t/\delta\,,$$

and

$$\tau(d) \leq \|d\| \cdot 2\tau(a)/\delta \quad \text{for all } d \in D_+ . \tag{10.1}$$

We show below that the Inequalities (10.1) yield that $\tau(d) = 0$ for all $d \in D_+$, in particular that $\tau((a-\delta)_+) = 0$. The lower semi-continuity of τ shows then in general that $\tau(a) = 0$ if $\tau(a) < \infty$, i.e., that τ takes only the values 0 and $+\infty$ on A_+. This holds for all l.s.c. 2-quasi-traces τ on A_+ and means that A is traceless.

The Inequalities (10.1) show that τ is bounded on the set of contractions in $D_+ \neq \{0\}$.

`Next similar to above said!!?`

The Inequalities 10.1 hold because $d \leq \|d\|\varphi_\delta(a) \leq \|d\|(2/\delta)a$ for $\varphi_\delta(t) := \min((2/\delta)(t-\delta/2)_+, 1)$, and $C^*(d, \varphi_\delta(a))$ and $C^*(a)$ are commutative C^*-subalgebras of A.

`Compare next with above`
`and Lemma on stably generated C*-alg's.`

If $b \in D_+$ is a non-zero stable contraction, then the multiplier algebra of $\overline{bDb}$ contains a copy of $\mathcal{O}_\infty$ unitally. Thus, there are $d_1, d_2, \ldots \in \overline{bDb}$ with $d_j^* d_i = \delta_{i,j} b$. It implies that $n\tau(d) = \tau(\sum_{j=1}^n (d_j)(d_j)^*) \leq (2/\delta)\tau(a)$ for each $n \in \mathbb{N}$. Thus $\tau(d) = 0$.

Since the set of $d \in D_+$ with $\tau(d) = 0$ is the positive part of some closed ideal of D, and since the ideal generated by the stable elements in D_+ is dense in D by Lemma 2.10.1, we get that $\tau(D_+) = \{0\}$. It shows that, $\tau((a-\delta)_+) = 0$ for every $\delta > 0$. Since τ is lower semi-continuous, we get $\tau(a) = 0$ for all $a \in A_+$ with $\tau(a) \neq \infty$. □

LEMMA 2.10.3. *The primitive ideal space* Prim(A) *can be covered by a countable family of quasi-compact subsets – i.e.,* Prim(A) *is σ-compact –, if and only if, there exists $a \in A_+$ with $J(a) := \overline{\text{span}(AaA)} = A$ (i.e., if and only if, A contains a full σ-unital hereditary C^*-subalgebra $D := \overline{aAa}$).*

The space Prim(A) *is quasi-compact, if and only if, there exists $a \in A_+$ with $\|a + J\| = 1$ for all primitive ideals $J \in$* Prim(A)

PROOF. For $b \in A_+$ with $\|b\| \leq 1$, the **generalized Gelfand transformation** $\widehat{b}\colon \text{Prim}(A) \to \mathbb{R}_+$ is defined by $\widehat{b}(J) := \|b + J\|$ for all $J \in \text{Prim}(A)$. (It is called $\check{b}$ and $\check{A}$ in [**616**].)

Notice here that the function $\widehat{b}$ is lower semi-continuous on the topological space Prim(A), i.e., the $J \in \text{Prim}(A)$ with $\widehat{b}(J) > s \geq 0$ build an open subset of Prim(A).

Let $b \in A$ and $t \in (0, \infty)$. We denote by $C_t(b) \subseteq \text{Prim}(A)$ the set of $J \in \text{Prim}(A)$ with $(\|b + J\| =)\|\pi_J(b)\| \geq t$.

`Relate next together:`

It is known that $C_t(b)$ is a (quasi-) compact subset of Prim(A), cf. [**217**, prop. 3.3.7], [**616**, prop. 4.4.4].

Then $\widehat{b}^{-1}[t, \|b\|] = C_t(b)$, and, therefore, $C_t(b)$ is a quasi-compact subset of $\mathrm{Prim}(A)$.

Let $a \in A$ with $I(a) = A$, then $\| a + J \| := \| \pi_J(a) \| > 0$ for any closed ideal J of A with $J \neq A$.

It follows $\mathrm{Prim}(A) = \bigcup_n C_{1/n}(a)$. Now use that the sets $C_{1/n}(a)$ are quasi-compact. Thus, $\mathrm{Prim}(A)$ is σ-quasi-compact.

Conversely: Let K_n quasi-compact subsets of $\mathrm{Prim}(A)$ such that $\mathrm{Prim}(A) = \bigcup_n K_n$. The supports in $\mathrm{Prim}(A)$ of the functions $\widehat{b}$ with $b \in A_+$ and $\|b\| < 1$ build an upward directed system of open subsets of $\mathrm{Prim}(A)$, because for $b_1, b_2 \in A_+$ with $\|b_i\| < 1$ there is $b_3 \in A_+$ with $\|b_3\| < 1$ and $b_i \leq b_3$ $(i = 1, 2)$, cf. proof of [**616**, thm. 1.4.2], and the generalized Gelfand transformation $b \mapsto \widehat{b}$ is monotone on A_+. For each primitive ideal J of A there is $b \in A_+$ with $\|b\| < 1$ and $\widehat{b}(J) = \|b + J\| > 0$. Thus, by quasi-compactness of K_n, there are $b_n \in A_+$ with $\|b_n\| < 1$ such that K_n is contained in the support of $\widehat{b_n}$. It follows that $a := \sum_n 2^{-n} b_n \in A_+$ satisfies $\|a + J\| > 0$ for all $J \in \mathrm{Prim}(A)$, i.e., $J(a)$ is not contained in any primitive ideal of A. Thus $J(a) = A$.

`Notation overlap:`
`former notation` $I(a)$ `had two different meanings!!!`
`Here we have changed to` $J(a) := \overline{\mathrm{span}(A\,a\,A)}$.

If, moreover, $\mathrm{Prim}(A)$ is quasi-compact, then the open subsets $U_n := \widehat{a}^{-1}(1/n, \infty)$ of $\mathrm{Prim}(A)$ cover $\mathrm{Prim}(A)$. It follows that $U_p = \mathrm{Prim}(A)$ for some $p \in \mathbb{N}$. We can replace a by $f(a)$ for the function $f(t) := \min(p \cdot t, 1)$. Then $\widehat{a} = 1$. □

`Is here the right place to show semi-projectivity of` $\mathcal{E}_n$`?`
`Better put it in the appendices. Near to other` $\mathcal{E}_n$ `stuff?`

For later applications of the next result, recall that locally p.i. algebra are traceless, cf. Lemma 2.10.2.

PROPOSITION 2.10.4. *Suppose that A is traceless (respectively that A is purely infinite) and that* $\mathrm{Prim}(A)$ *is quasi-compact.*

`Give ref. to Def. of "quasi-compact"` (T_0 `spaces)`

Then there exists $n \in \mathbb{N}$ and a full properly infinite projection $p \in M_n(A)$ (respectively a full properly infinite projection $p \in A$).

PROOF. At first, we consider the case where A is purely infinite, i.e., we consider case where the element a is properly infinite for all non-zero $a \in A$. Later we reduce the case of traceless A to the case of p.i. A.

Since $\mathrm{Prim}(A)$ is quasi-compact (by assumption), there exists a positive contraction $a \in A_+$ with $\|a + I\| = 1$ for all primitive ideals $I \in \mathrm{Prim}(A)$ (cf. Lemma 2.10.3).

It follows that $(a-t)_+$ is a full positive contraction in A for all $t \in [0,1)$, i.e., $J((a-t)_+) := \overline{\mathrm{span}(A(a-t)_+A)} = A$.

Since every $(a-t)_+$ is properly infinite and full, there are $d_1, d_2 \in A$ with $d_k^*(a-2/3)_+ d_k = (a-1/4)_+$ $(k=0,1)$ and $d_1^*(a-2/3)_+ d_2 = 0$.

Let $e := (a-2/3)_+^{1/2} d_2 d_2^* (a-2/3)_+^{1/2}$ and $z := (a-2/3)_+^{1/2} d_1 h(a)^{1/2}$ for the continuous function $h(t)$ with $h(t) := 8t$ for $0 \le t \le 1/2$, and $h(t) =: (t-1/4)^{-1}$ for $1/2 \le t \le 1$. It follows, $(z^*z)(zz^*) = zz^*$, $e \ge 0$, $zz^* + e \le 1$, and $J(e) = J((a-1/4)_+) = A$. Let $V := z + (1-z^*z)^{1/2}$. Then V is an isometry in the unitization $\widetilde{A}$ of A with $V^*eV = 0$, i.e., $e \le p := 1 - VV^* \in A$. We get that p is a full projection in A.

Since p is properly infinite, there exists a C^*-morphism $\psi\colon \mathcal{E}_2 \to A$ with $\psi(1) = p$.

We consider now the general case where A itself is only traceless:
The algebra $A \otimes M_{2^\infty}$ is purely infinite if A is traceless (cf. [**462**, thm. 5.9], or Theorem ??).

Thm. on p.i. tensor products ?!

Above we have seen that there exists a C^*-morphism $\psi\colon \mathcal{E}_2 \to A \otimes M_{2^\infty}$ such that $\psi(1) =: p$ is a full projection of $A \otimes M_{2^\infty}$.

Since the union of the C^*-subalgebras $A \otimes M_{2^n}$ is dense in $A \otimes M_{2^\infty}$, we get from Lemma A.2.1 that there are $n \in \mathbb{N}$, a C^*-morphism $\psi_n\colon \mathcal{E}_2 \to A \otimes M_{2^n}$ and a partial isometry $v_n \in A \otimes M_{2^\infty}$ with $v_n v_n^* = \psi(1)$ and $v_n^* v_n = \psi_n(1)$.

Let I denote the closed ideal of $A \otimes M_{2^n}$ generated by $v_n^* v_n$. Then $I = J \otimes M_{2^n}$ for some closed ideal J of A, and $\psi(1) = v_n v_n^*$ is in the closed ideal $J \otimes M_{2^\infty}$ of $A \otimes M_{2^\infty}$. Since $\psi(1)$ is a full projection of $A \otimes M_{2^\infty}$, it follows $J = A$ and that $\psi_n(1) = v_n^* v_n$ must be a full projection of $A \otimes M_{2^n}$. □

COROLLARY 2.10.5. *If A is locally purely infinite and unital, then there is $n \in \mathbb{N}$ such that the unit element $1_A \otimes 1_n$ of $M_n(A)$ is properly infinite.*

PROOF. Locally p.i. algebras are traceless by Lemma 2.10.2. If A is unital, then $\mathrm{Prim}(A)$ is quasi-compact. Thus, by Proposition 2.10.4, there exists $n \in \mathbb{N}$ such that $M_n(A)$ contains a properly infinite full projection p. It follows $p \le 1_A \otimes 1_n \precsim p$, i.e., $1_A \otimes 1_n \approx p$ is properly infinite in $M_n(A)$. □

LEMMA 2.10.6. *If A is locally purely infinite, then for $a \in A_+$ and $\varepsilon > 0$ there exist $n := n(\varepsilon) \in \mathbb{N}$ and a σ-unital stable hereditary C^*-subalgebra $D \subseteq A \otimes M_n$ with $ed = d$ for all $d \in D$ and $e := f_\varepsilon(a) \otimes 1_n$, such that $(a-2\varepsilon)_+ \in (A \otimes M_n) D (A \otimes M_n)$.*

If A has property pi-m, then one can find the $n(\varepsilon)$ such that $n(\varepsilon) \le m$.

In particular, if A is purely infinite, then there is a stable σ-unital hereditary C^*-subalgebra $D \subseteq A$ with $(a-2\varepsilon)_+ \in ADA$ and $f_\varepsilon(a) d = d$ for $d \in D$.

PROOF. Let $B := B_\varepsilon := \overline{(a-\varepsilon)_+ A (a-\varepsilon)_+}$. By definition of l.p.i. algebras, there are $n \in \mathbb{N}$ and stable hereditary C^*-subalgebras $D_k \subseteq B$, $k = 1, \ldots, n$, such that $(a - (3/2)\varepsilon)_+$ is in the closed ideal J generated by $D_1 \cup D_2 \cup \cdots \cup D_n$.

The direct sum $F := D_1 \oplus D_2 \oplus \cdots \oplus D_n$ is stable and is naturally contained in $M_n(B) \cong B \otimes M_n \subseteq A \otimes M_n$.

The algebra $D := F(A \otimes M_n)F \subseteq B \otimes M_n$ is a stable hereditary C^*-subalgebra of $A \otimes M_n$, and D generates the closed ideal $J \otimes M_n$ of $A \otimes M_n$. The element $(a-(3/2)\varepsilon)_+ \otimes 1_n$ is contained in $J \otimes M_n$, and $(f_\varepsilon(a) \otimes 1_n)x = x$ for all $x \in B \otimes M_n$.

If A has property pi-m, then $g(a) \otimes 1_m = g(a \otimes 1_m)$ is properly infinite for all non-zero $g \in \mathrm{C}_0(0, \|a\|]$. Then Lemma **??** says that there is a stable hereditary C^*-subalgebra $D \subseteq B \otimes M_m$ such that the ideal $J \otimes M_m$ generated by D contains $(a - (3/2)\varepsilon)_+ \otimes 1_n$.

`to be filled in` ?? □

LEMMA 2.10.7. *If A is p.i. then for each $a \in A_+$, $\varepsilon > 0$, $n \in \mathbb{N}$ there exists a row $d \in M_{1,n}(A)$ with $dd^* f_\varepsilon(a) = dd^*$ and $d^*d = (a-\varepsilon)_+ \otimes 1_n$.*

Here $f_\varepsilon(t)$ is the continuous function on $[0,\infty)$ with $f_\varepsilon(t) = 1$ on $[\varepsilon, \infty)$, $f_\varepsilon(t) = 0$ on $[0, \varepsilon/2]$ and $f_\varepsilon(t) = 2t/\varepsilon - 1$ on $[\varepsilon/2, \varepsilon]$.

PROOF. Recall $f_\varepsilon(t) := \min\big(1, (2/\varepsilon)\max(0, t-\varepsilon/2)\big)$ for $t \geq 0$ and $\varepsilon > 0$.

Then $(a-\varepsilon)_+$ is contained in the annihilator $\mathrm{Ann}(D)$ of the hereditary C^*-subalgebra $^D := \overline{(1-f_\varepsilon(a))A(1-f_\varepsilon(a))}$ of A.

?? By the observation of M. Rørdam [**688**, prop. 5.4], see also Proposition ??, there is a σ-unital stable hereditary C^*-subalgebra E in $\overline{(a-\varepsilon)_+ A (a-\varepsilon)_+} \subseteq \mathrm{Ann}(D)$, such that $(a-\varepsilon)_+$ is contained in the closed ideal of $\mathrm{Ann}(D)$ generated by E.

It follows from Lemma **??** that there exists $d_1, d_2 \in \mathrm{Ann}(D)$ with $d_1 d_1^* + d_2 d_2^* \in E$, $d_1^* d_2 = 0$ and $d_1^* d_1 = (a-\varepsilon)_+ = d_2^* d_2$. □

`Move to suitable places !!!`

11. Weak pure infiniteness for non-simple C^*-algebras

We have seen in Part (?????) ???? The properties pi(n) and pi-n are the same for C^*-algebras A with the additional property that $1_{\mathcal{M}(A)}$ is properly infinite in $\mathcal{M}(A)$, e.g. as it isthe case if A is stable. Moreover, then both properties coincide with the property that all non-zero n-homogenous elements $a \in A_+$ are properly infinite. This is because,

a) the algebra $\ell_\infty(A)$ is an ideal of $\ell_\infty(\mathcal{M}(A))$ and – therefore – has no quotient of finite dimension if $\mathcal{O}_\infty$ is unitally contained in $\mathcal{M}(A)$ (– more general if $\mathcal{M}(A)$ has no quotient of finite dimension –) and

b) the property pi(n) always implies that an element $a \in A_+$ is *properly infinite* (as defined in Section **??**) if a is n-homogenous.

`Give ref's to ''new'' places where it (= which ??) is proved !`

There could be a considerable shift between the numbers n and the m in general. Notice here that the numbers m and n are only upper estimates. Even in case of separable amenable (non-simple) C^*-algebras we do not know the possible minimal values, except in special cases, e.g. if the algebras absorb the Jiang-Su algebra tensorial.

An estimate for the $n \in \mathbb{N}$ of property pi-n for $A \otimes \mathbb{K}$ for A with property pi-m was given by $n \leq m^2$ in [**463**, prop. 4.5(vi)]. But it is unknown for which $n \in \mathbb{N}$ the stabilization $A \otimes \mathbb{K}$ is pi(n) (and is then there equal to pi-n) if A has property pi(m). It seems to be related to topological properties of the space prime(A) of prime ideals of A.

If A is pi(k) or pi-ℓ for some $k, \ell \in \mathbb{N}$ then there exist a number $n \in \mathbb{N}$ with $n \leq \min(k, \ell)$ such that every quasi-compact subset X of the space of prime ideals prime(A) is covered by (finitely many) open subsets that are dense in prime(A) and correspond to (stable) closed ideals $J \triangleleft A \otimes \mathbb{K}$ that are generated by an n^2-homogenous element of A such that J has property pi(n) and pi-n at the same time as stated in Proposition 2.11.1. It indicates that the relation between between pi(n) and pi-n has something to do with the topology of prime(A) (= prim-ideal space = point-wise completion of Prim(A)).

A partial converse and the passage to stabilization is given in Proposition 2.11.1. Unfortunately we get only "local" equality, despite of the different focus of the definitions.

`Next is in parts only a conjecture!!`

PROPOSITION 2.11.1. *Let A a non-zero C^*-algebra.*

Consider the following properties

(i,a) *A is a pi(n) algebra in sense of Definition 2.0.4.*

(i,b) *$A \otimes \mathbb{K}$ is "locally" a pi(n) algebra, i.e., for each n-homogenous element $b \in A_+$ the ideal $J(b) := \overline{\mathrm{span}(AbA)}$ of A generated by b has the property that $J(b) \otimes \mathbb{K}$ has property pi-n.*

It is known that it is true if b is instead n^2-homogenous in A.

Suppose that A has property pi(n). And that $b \in A_+$ is n-homogenous. Then $(b-\delta)_+$ is n-homogenous for every $\delta \in [0, \|c\|)$ and is properly infinite. Thus, for every $\varepsilon \in (0, \|c\|)$ there exists in $D := \overline{(b-\varepsilon)_+ A (b-\varepsilon)_+}$ an n^2-homogenous element $c \in D_+$ such that $(b-2\varepsilon)_+$ is contained in the ideal $J(c)\overline{AbA}$ of A. Thus $J((b-2\varepsilon)_+) \subseteq J(c) \subseteq J(b)$ and $J((b-2\varepsilon)_+) \otimes \mathbb{K}$ has property pi-n. (The latter because property pi-n passes to hereditary C^*-subalgebras.) Property pi-n is preserved under inductive limits and $J(b) \otimes \mathbb{K}$ is the inductive limit of $J((b-1/n)_+) \otimes \mathbb{K}$, $n \in \mathbb{N}$.

Thus:

If A has property $\mathrm{pi}(n)$ *and* $b \in A_+$ *is* n*-homogenous then than* $J(b) \otimes \mathbb{K}$ *has property* $\mathrm{pi}\text{-}n$*.*

(ii) $A \otimes \mathbb{K}$ *has property* $\mathrm{pi}(n)$*.*

(iii) $A \otimes \mathbb{K}$ *has property* $\mathrm{pi}\text{-}n$ *in sense of Definition* **??**.

(iv) A *has property* $\mathrm{pi}\text{-}n$*.*

(v) $\ell_\infty(A)$ *has property* $\mathrm{pi}\text{-}n$*.*

(vi) $\ell_\infty(A)$ *is locally p.i. in sense of Definition 2.0.3.*

(vii) *If* $J \triangleleft A$ *is a closed ideal of* A*, then* A *has* $\mathrm{pi}\text{-}n$ *(respectively* $\mathrm{pi}(n)$*) with* $n \leq k + \ell$ *if* J *and* A/J *have* $\mathrm{pi}\text{-}k$ *(respectively* $\mathrm{pi}\text{-}k$*) and* $\mathrm{pi}\text{-}\ell$ *(respectively* $\mathrm{pi}\text{-}\ell$*).*

Then (ii) and (iii) are equivalent and imply both of (i,a) and (iv).

If A has property $\mathrm{pi}\text{-}n$ *then* $\ell_\infty(A)$*, all non-zero quotients of A and all non-zero hereditary C^*-subalgebra of A have Property* $\mathrm{pi}\text{-}n$*.*

In particular, A is purely infinite in the sense of Definition 1.2.1, if and only if, each non-zero element $0 \neq a \in A$ *is properly infinite, i.e.,* $a \oplus a \precsim a$ *for each* $a \in A$ *(and means that A has property* $\mathrm{pi}\text{-}1$*).*

Ideas of a proof of Proposition 2.11.1 will be given farer below after we have stated and proven the needed lemmata.

Clearly ???? the trivial implications are ??? (ii)⇔(iii), ??? ??? (ii)⇒(i), and ??? (iii)⇒(iv), the implication (iv)⇒(i) requires only some simple and obvious matrix reformulation of the property $\mathrm{pi}(n)$ in Definition 2.0.4.

The nontrivial implication ??? (i)⇒(ii)? need some more work and preparation.

LEMMA 2.11.2. *Suppose that A has no irreducible representation of dimension* $\leq n$*.*

If A satisfies Part (i) of property $\mathrm{pi}(n)$*, then each non-zero element* $a \in A_+$ *in the ideal J generated by some* $(n+1)$*-homogenous element* $b \in A_+$ *satisfies that* $a \otimes 1_n$ *is properly infinite in* $A \otimes M_n$*.*

(Alternatively, we could require here that $b \in A_+$ *is n-homogenous and that for each* $\varepsilon > 0$ *the ideal generated by* $\mathrm{Ann}((b-\varepsilon)_+, A)_+ := \{c \in A_+ \,;\, c(b-\varepsilon)_+ = 0\}$ *contains* $(b - 2\varepsilon)_+$*.)*

There is (somewhere farer below) a new result that says every non-zero n-homogenous element $b \in A_+$ *is properly infinite in A if A is* $\mathrm{pi}(n)$*. I.e., the latter annihilator condition on* $(b-\varepsilon)_+$ *is not needed.*

If A is pi-n, then for each element $a \in (A \otimes \mathbb{K})_+$ *and* $\varepsilon > 0$ *there exists* $b \in A_+$*,* $d \in A \otimes \mathbb{K}$ *such that* $d^*(b \otimes 1_n)d = (a - \varepsilon)_+$*. It follows that* $c := a \otimes 1_{n^2}$ *is "spectrally properly infinite" for each* $a \in A \otimes \mathbb{K}$*, i.e.,* $\varphi(c^*c)$ *is properly infinite for each* $\varphi \in \mathrm{C}_0((0, \|c\|^2])$*.*

Properties pi(n) and pi-n coincide on stable C^*-algebras.

Holds in general for all C-algebras A with properly infinite* 1 *in* $\mathcal{M}(A)$.

If A has Property pi(n) $\varphi\colon B := \mathrm{C}_0((0,1], M_{n^2+1}) \to A$ *is a* C^**-morphism, then the closed ideal* J *of* A *generated by* $\varphi(B)$ *has the property that* $J \otimes \mathbb{K}$ *has property pi-n and this property coincide there with property pi*(n)*, as for all stable* C^**-algebras.*

In Proposition **??** we list some permanence properties of the class of weakly purely infinite C^*-algebras. We consider weak versions of pure infiniteness because it is usually easier to recognize if a C^*-algebra A is locally or weakly purely infinite in the sense of Definitions 2.0.3 and 2.0.4 e.g. if one considers tensor products, crossed products or continuous fields. Only strongly purely infinite algebras have properties that in good cases allow to classify them by functors into Abelian types of categories. Usually one gets the needed stronger assumptions by combination – say of weak pure infiniteness with corona factorization properties or with the existence of reasonable central sequences.

A basic open question is if property pi(n) or even property l.p.i. for A implies that A has property pi(1) or moreover that A has the in applications needed property that A is *strongly* purely infinite in sense of Definition 1.2.2.

We do not know any example where A is weakly purely infinite but is not pi(1) or where A is l.p.i. but is not weakly purely infinite, and we do not know an example where A is purely infinite in sense of Definition 1.2.1, i.e., is pi(1) in sense of Definition 2.0.4 but is not strongly purely infinite.

It is not difficult to see that $\mathrm{C}([0,1], A)$ is pi(2) if A is purely infinite. More generally, $\mathrm{C}_0(X, A)$ is pi(n) with $n \leq m + \dim(X)$ if A is pi(m) and X is a finite-dimensional and locally compact.

Reference for above? Formula OK?

For the following we need a definition and two lemmata:

DEFINITION 2.11.3. An element $a \in A$ is *spectral properly infinite* inside A if for each $\varepsilon > 0$ the cut down $(a^*a - \varepsilon)_+$ of a^*a is properly infinite in A.

$E_{\mathrm{Spec}}(A) \subseteq A$ (or simply E_{Sp}) will denote the set of all spectral properly infinite elements in A.

$E_{\mathrm{Funct}}(A) \subseteq A$ (or simply E_{Funct}) denotes the set of all elements $a \in A$ with the property $\psi(a^*a) \in E_{\mathrm{Spec}}(A)$ for all functions $\psi \in \mathrm{C}_0(0, \|a\|^2)_+$ with $\psi(a^*a) \neq 0$.

LEMMA 2.11.4. *Let* $E_{\mathrm{spec}}(A) \subseteq A$*, (respectively* $E_{\mathrm{funct}}(A) \subseteq A$*) the sets of all "spectral" (respectively "functional") properly infinite elements in sense of Definition 2.11.3.*

Then $E_{\mathrm{Spec}}(A)$ *and* $E_{\mathrm{Funct}}(A)$ *are closed subsets of* $A \setminus \{0\}$.

PROOF. To be filled in ?? ∎

`Next is still a conjecture ... !!!`

`Good for what? ... replace by other idea !!!`

LEMMA 2.11.5. *Let $a, b \in A$ elements such that $\psi(a^*a)$ is properly infinite in A for every $\psi \in \mathrm{C}_0(0, \|a\|^2]_+$ with $\psi(a^*a) \neq 0$. Let $a = v(a^*a)^{1/2}$ the polar decomposition of a in A^{**}. Then there exists for each $\delta \in (0, \|a\|^2)$ a continuous path of elements $t \in [0,1] \mapsto b(t) \in A$ with $b(t)^*b(t) = ((a^*a) - \delta)_+$ for all $t \in [0,1]$, $b(0) = v((a^*a) - \delta)_+^{1/2}$ and $b(1) = ((a^*a) - \delta)_+^{1/2}$.*

It is *wrong* in this formulation:

Let $A := \mathcal{O}_2 = C^*(s,t\,;\ s^*t = 0, ss^* + tt^* = 1, s^*s = 1 = t^*t)$

and $a := s$, $\delta = 1/2$. Then $v((a^*a - 1/2)_+^{1/2} = 2^{-1/2}s$. There is no continuous path $t \to b(t)$ with $b(t)^*b(t) = 1/2$, $b(0) = 2^{-1/2}s$ and $b(1) = 2^{-1/2}$, because there is no continuous path from s to 1 inside the the set of isometries of $\mathcal{O}_2$.

But if there enough "stable room" orthogonal to $(a^*a - \delta)_+$ and $(aa^* - \delta)_+$ (perhaps moving with the parameter) then there is some hope.

PROOF. (The definition of g_δ has to made precise.) The idea is: For each $\mu, \gamma \in (0, \|a\|^2)$ there exist contractions $s_1, s_2 \in A$ with $s_1^*s_2 = 0$, $s_1^*s_1 = g_{2\delta}(a^*a) = s_2^*s_2$ and $s_1s_1^* + s_2s_2^* \leq g_\delta(a^*a)$ (a "soft" version of $\mathcal{E}_2$ with $g_\delta(t) = 1$ for $t \geq \delta$ and $g_\delta(t) = 0$ for $t \leq \delta/2$ linear on $[\delta/2, \delta]$.) and

$$(a^*a - \gamma)_+^\mu s_k^* s_k (a^*a - \gamma)_+^\mu = (a^*a - \gamma)_+^{2\mu} g_{2\delta}(a^*a)\,.$$

Now consider (with suitable δ), $X := v\cdot((a^*a)^{1/2} - \delta)_+^{1/2} s_1^*$, $Y := ((a^*a)^{1/2} - \delta)_+^{1/2} s_2^*$ and $Z_1 := s_2s_1^* - s_1s_2^*$ (or + ?) $XZ_1Y^* = v((a^*a)^{1/2} - \delta)_+^{1/2} s_1^*s_1s_2^*s_2((a^*a)^{1/2} - \delta)_+^{1/2} =$

$= v((a^*a)^{1/2} - \delta)_+ g_{\delta/2}(a^*a)^2$ ("nearly" XY^*)

$Z_2 := s_1s_1^* + s_2s_2^*$

Has to study $(X + Y)Z_kX^* =$??????

`Idea does not work??`

`To be filled in ??` □

We do not know (2019) if A is purely infinite for separable A if A has the property that there exists a unital C^*-morphism $\psi\colon \mathrm{C}[0,1] \to \mathcal{M}(A)$ into the center of $\mathcal{M}(A)$ such that the "fibers" $A_t := A/I_t$ are all purely infinite. Here the the ideal I_t of A is the closed linear span of $\psi(\mathrm{C}_0([0,1] \setminus \{t\})) \cdot A)$.

(Perhaps, one gets an answer if A has the "corona factorization" property (CFP) in addition? But what have they to do with (CFP)?)

But we know that $\mathrm{C}_0(X, A)$ ($\cong A \otimes \mathrm{C}_0(X)$) is pi-$n$ if A is pi-n and X is any locally compact Hausdorff space:

It reduces to the case of $\mathrm{C}([0,1], A)$, because then one can step up by induction over $m \in \mathbb{N}$ to $\mathrm{C}([0,1]^{2m+1}, A)$. $\mathrm{C}_0(X, A)$ with $\dim(X) \leq m$ is an ideal of a quotient of $\mathrm{C}([0,1]^{2m+1}, A)$, and $\mathrm{C}_0(X, A)$ of an arbitrary (not necessarily metrizable) l.c. Hausdorff spaces X is an inductive limit of an upward directed net of C^*-subalgebras isomorphic to $\mathrm{C}_0(X_\lambda, A)$ with X_λ of finite dimension.

Thus, it reduces to the case of $\mathrm{C}([0,1], A)$, and it is easy to see that is suffices to consider only those elements of $\mathrm{C}([0,1], A)$ that are given by pice-wise linear map ϕ from $[0,1]$ into A_+ with $\|\phi(t)\| \leq 1$, i.e., have to check pice-wise linear maps ϕ from $[0,1]$ into positive contractions in A. In fact it suffices to consider those maps $\phi\colon [0,1] \to A_+$ for given $\delta > 0$ with break points $t_\ell \in [0,1]$ with $t_\ell < t_{\ell+1}$, $t_1 = 0$, $t_m = 1$ and $\|\phi(t_\ell) - \phi(t_{\ell+1})\| < \delta$, but it suffices to consider those paths that satisfy moreover $\phi(t_{2k}) = \phi(t_{2k+1})$ for $n = 2k$, i.e., with $\phi(t) = \phi(t_{2k})$ for $t \in [t_{2k}, t_{2k+1}]$ and only $\phi(t_{2k-1}) \neq \phi(t_{2k})$. This is because any continuous map ψ from $[0,1]$ into the contractions in A_+ can be approximated by such continuous maps ϕ arbitrarily well.

We can go with $\phi(t)$ to the next break point with a constant pice of "path" between.

Let $I_k := [t_{2k-1}, t_{2k}] \subseteq [0,1]$. Then we can "compress" the path $\phi(I_k)$ by a continuous map $c\colon I_k \to A$, given by a path $\{c(t)\,;\ t \in I_k\} \subseteq A$ for I_k of contractions in A to

$$X_k := \big(2^{-1}(\phi(t_{2k-1}) + \phi(t_{2k})) - \delta/2\big)_+\,,$$

i.e., find a contraction $c_k \in \mathrm{C}(I_k, A)$ such that $c_k(t)^*\phi(t)c_k(t) = X_k$ for $t \in I_k$. Here we can apply Lemma 2.1.9 to the elements $a := \phi|I_k$ and $b := 2^{-1}(\phi(t_{2k-1}) + \phi(t_{2k}))$ in the C^*-algebra $\mathrm{C}(I_k, A)$ because

$$\|\phi(t) - 2^{-1}(\phi(t_{2k-1}) + \phi(t_{2k}))\| < \delta/2 \quad \text{for all} \quad t \in I_k\ .$$

Then $\|X_k - \phi(t)\| < \delta$ for $t \in I_k = [t_{2k-1}, t_{2k}]$.

Then we can go back "up to δ" from the "constant" path $(X_k - \delta)_+$ on I_k to $\phi(I_k) \in \mathrm{C}(I_k, A)$, i.e., find by a contraction in $e = \{e(t)\} \in \mathrm{C}(I_k, A)$ with $e(t)^*(X_k - \delta)_+ e(t) = (\phi(t) - 2\delta)_+$ for $t \in [t_{2k-1}, t_{2k}]$. This is possible by Lemma 2.1.9 because $\|(X_k - \delta)_+ - \phi(t)\| < 2\delta$.

We find for the properly infinite element $1_n \otimes X_k \in M_n(A)$ elements $d_k \in M_{2n}(A)$ with $d_k^*((1_n \otimes X_k) \oplus 0_n)d_k = 1_{2n} \otimes (X_k - \delta)_+$, because A has property pi-n.

We define $D_k(t) := ((1_n \otimes c(t)) \oplus 0)d_k(1_{2n} \otimes e_k(t))$.

Then $D_k \in \mathrm{C}([t_{2k-1}, t_{2k}], M_{2n}(A))$ and

$$D_k(t)^*(1_n \otimes \phi(t) \oplus 0_n)D_k(t) = 1_{2n} \otimes (\phi(t) - 2\delta)_+\,.$$

But we do not know if $\mathrm{C}([0,1], A)$ is pi(1) if A is pi(1). By Proposition **??** for every compact space X the algebra $\mathrm{C}(X, A)$ is pi-n (respectively is s.p.i.) if and only if A is pi-n (respectively is s.p.i.). For simple A *all* up to now given definitions of pure infiniteness coincide with strong pure infiniteness.

But for A with property pi(n) we get only that $\mathrm{C}(X, A)$ has pi(m) with estimate $m \leq n \cdot (\mathrm{Dim}(X) + 1)$. ???? (If $X = [0, 1]$ then $m \leq 2n$.)

It would be sufficient to prove that $\mathrm{C}([0, 1], A)$ is pi-n if A is pi-n, cf. proof of Proposition **??**.

OLD or NEW or REMAINING?: The question, if $\mathrm{C}([0, 1], A)$ is pi(1) for purely infinite A, is equivalent to the following:

Let A a purely infinite C^*-algebra, $a, b \in A_+$ positive contraction, $\varepsilon > 0$, $\tau > 0$ and $d_1, d_2 \in A$ with $d_j^* a d_k = \delta_{jk}(a - \varepsilon)_+$ ($j, k \in \{1, 2\}$).

Try to find $e_1, e_2 \in \mathrm{C}([0, 1], A)$ with $\|d_j - e_j(0)\| < \tau$ for $j \in \{1, 2\}$ and

$$e_j(t)^*((1-t)a + tb)e_k(t) = \delta_{jk}\big(((1-t)a + tb) - \varepsilon\big)_+ \qquad \text{for} \quad t \in [0, 1]\,.$$

One can separate the question into the intervals $[0, 1/2]$ and $[1/2, 1]$. $a \leq a + b$, there exist contractions $T, S \in \mathrm{C}([0, 1/2], A)$ with $T(t)^*((1-t)a + tb)T(t) = (1-t)a$ and $S(t)^*((1-t)a + tb)S(t) = tb$, as e.g. the

`Not ready?`

strict ??? limit in ??? $\mathrm{C_b}([0, 1/2], A)$

$$T(t) := \lim_n ((1-t)a + tb + 1/n)^{-1/2}(1-t)^{1/2}a^{1/2}$$

More likely is that one can find a contraction $T \in \mathrm{C}([0, 1/2], A)$ with $T(t)^*(a + t/(1-t)b)T(t) = (a - \varepsilon)_+$ and use this locally ???

It suffices to consider the case of small $\|a - b\|$.

Given $f \in \mathrm{C}([0, 1], A)_+$ with $\|f\| < 1$, we find for each $\varepsilon > 0$ and $t \in [0, 1]$, some $\delta \in (0, 1)$ such that $\|f(t) - f(s)\| < \varepsilon$ for all $s \in [t - \delta, t + \delta] \cap [0, 1]$. There we take $\gamma \in (0, \min(\delta, \varepsilon))$ and a contractions $d_1, d_2 \in \mathrm{C}([0, 1], A)$ with

$$d_1(s)^*(f(s) - \gamma)_+ d_1(s) = (f(t) - \varepsilon)_+$$

and

$$d_2(s)^*(f(t) - 2\varepsilon)_+ d_2(s) \;=\; (f(s) - 3\varepsilon)_+\,.$$

One gets at the end-points $f(t - \delta)$ and $f(t + \delta)$ different rows D, e.g. with $D^* f(t - \delta) D \;=\; \mathrm{diag}((f(t - \delta) - 3\varepsilon)_+, (f(t - \delta) - 3\varepsilon)_+)\,.$????

For *simple* locally purely infinite A the algebra $\mathrm{C}([0, 1], A)$ is strongly purely infinite because simple l.p.i. algebras are *strongly* p.i. by Proposition 2.2.1(v). The later considered applications requires strong pure infiniteness in sense of Definition 1.2.2 for the algebras in question.

We apply permanence properties of the considered class of strongly purely infinite algebras, and sometimes additional properties of A ([44]), to obtain that a particular class of C^*-algebras A has the property that the locally or weakly purely infinite algebras in this particular class are automatically strongly purely infinite. This *unsolved verification problem* restricts the applications of the notion

[44] E.g., that $A \cong A \otimes D$ for some tensorial self-absorbing unital algebra $D \neq \mathbb{C}$.

of purely infinite algebras considerably. It is still unknown if all the definitions of pure infiniteness coincide at least in case of (non-simple) *nuclear* C^*-algebras A. In case of *non-elementary* simple C^*-algebras A, i.e., $A \ncong \mathbb{K}(\mathcal{H})$ for any Hilbert space $\mathcal{H}$, the algebra A is locally p.i. (i.e., is l.p.i. in sense of Definition 2.0.3) if and only if A is strongly p.i. in sense of Definition 1.2.2.

It could be that topological properties of the primitive ideal space $\operatorname{Prim}(A)$ of A plays a role in a final answer. It could also be that non-existence or existence of characters for the C^*-algebras $F(B, A) := (B' \cap A_\omega)/\operatorname{Ann}(B, A_\omega)$ for B any character-less sub-homogenous C^*-subalgebra of A_ω plays a role in a final answer. Unfortunately only rather partial results exist and are not obvious. Possibly related properties could be ideal system equivariant versions of the corona factorization property (CFP), but that is not clear.

In principle, all what we must require for the classification works only for "target" algebras B that are *strongly* purely infinite, e.g. the construction of suitable nuclear *-monomorphisms $A \hookrightarrow B$ of separable exact A into a C^*-algebra B needs that B is *strongly* purely infinite. One can do really nothing with the algebra B if one can only prove pure infiniteness, weak pure infiniteness or even only local pure infiniteness. But sometimes additional properties of B allow to conclude later that B or "sufficiently big" C^*-subalgebras of B are strongly purely infinite. This is the true reason for our study of the "non-strong" versions of pure infiniteness, and that this "weak" properties are easier to check.

12. Non-simple purely infinite algebras

There are several definitions of "pure infiniteness" for C^*-algebras between "locally purely infinite" and "strongly purely infinite". Their interrelations and permanence properties have been studied in [**462**], [**463**], [**92**], [**93**] and [**443**]. The properties are equivalent in the case of algebras of real rank zero or in the case of algebras with finite-dimensional Hausdorff primitive ideal spaces. It is still an open question, whether or not all this properties are equivalent in general. We get some partial results in this direction (cf. also [**443**]). Open problems will be listed in Section **??**. We generalize some methods of Section 2 for the study of pure infiniteness of non-simple algebras.

`HERE comes imported text from other places!`

`Replace citations by similarities ??? here!`

Property pi-n implies property pi(n) on A. Conversely if A has property pi(m) for some m then there exists $n \geq m$ such that A has property pi-n, but no general function $f : \mathbb{N} \to \mathbb{N}$ is known yet with the property that $n \leq f(m)$, such that A has property pi-$f(m)$ if A has property pi(m). Moreover, there exists for every factorial state ρ on A a closed ideal J of A with the properties

(i) $\rho|J \neq 0$,

(ii) J is "essential" in A, i.e., $a \in A$ and $a \cdot J = \{0\}$ implies $a = 0$, and
(iii) the ideal J has property pi-n (if A has property pi(n)).

If A has property pi(m) then there exists $n \geq m$ such that A has property pi-n. But until now no estimating function function $n(t)$ is known with the property that $n(m) \geq m$ if A has property pi(m). It seems to depend from topological properties of Prim(A).

We give an overview about the known results and open questions concerning non-simple (locally, weakly or strongly) purely infinite algebras in Section **??** – with some parts of the needed proofs postponed to later sections and chapters.

By [**463**, lem. 4.4]):

Let a be a non-zero positive element in a C^*-algebra A and let n be a natural number. The following conditions are equivalent:
(i) $a \otimes 1_n$ is properly infinite,
(ii) $a \otimes 1_m \precsim a \otimes 1_n$ for all (natural numbers) $m \in \mathbb{N}$,
(iii) $a \otimes 1_m \precsim a \otimes 1_r$ for all natural numbers r, m with $r \geq n$,
(iv) $a \otimes 1_{n+1} \precsim a \otimes 1_n$,
(v) for each $\varepsilon > 0$ and for each m in $\mathbb{N}$ there is x in $M_{m,n}(A)$ such that x^*x belongs to $M_n(\overline{aAa})$ and $xx^* = (a - \varepsilon)_+ \otimes 1_m$.

Permanence properties of property pi-n:

The property pi-n on A passes to non-zero hereditary C^*-subalgebras $D \subseteq A$, non-zero quotients A/J, and to $A_\infty := \ell_\infty(A)/c_0(A)$ and the ultrapowers A_ω and (that are special quotients of $\ell_\infty(A)$).

If A and B have property pi-n, then $A \oplus B$ has property pi-n, $\ell_\infty(A_1, A_2, \ldots)$ is pi-n for sequences $A_1, A_2, \ldots$ of C^*-algebras.

Both of pi-n and pi(n) pass from A to ultra-powers A_ω.

All n-homogenous elements of A are properly infinite in A itself, if A has property pi-n or pi(n).

The property pi(n) is equal to property pi-n on each closed ideal J of A that is generated by a hereditary C^*-subalgebra D of A with the property that D is n-homogenous in the sense that there exists a hereditary C^*-subalgebra $E \subseteq D$ such that $M_n(E) \cong D$. The maximal closed ideals J with this property have in Prim(A) and prime(A) open supports that are there dense, i.e. there is no non-zero closed ideal orthogonal to J.

Thus, all is reduced to an extension problem for the sum of two ideals ...

The Property pi-n will be preserved by inductive limits,

passes to $M_2(A)$, – and then to stabilizations of A, – ...???

If $A_+ \ni b = \sum_{k=1}^{m} d_k^* a d_k$ for $a \in A_+$, then for each $\varepsilon > 0$, there exists $e_1, \ldots, e_n \in A$ with the property $(b - \varepsilon)_+ = \sum_{j=1}^{n} e_j^* a e_j$. The algebra A has no non-zero quotient A/J of finite dimension, because property pi-n carries over to non-zero quotients, and all non-zero hereditary C^*-subalgebras of A/J. Certainly $\mathbb{C}$ is not pi-n.

More generally, all C^*-algebras with property pi(n) or pi-n are residually antiliminary.

??? Why???

Part (iv) shows only that an n-homogenous element in A is infinite in A itself if there exist something orthogonal to this element...

Needs to to show that the infiniteness in A itself is the same as infiniteness in $M_n(A)$.

$A \in a \approx a \otimes e_{11}$ in $A \otimes M_n$ and $a \otimes e_{11} \approx b \otimes 1_n$ and $(b \otimes 1_n) \oplus 0 \approx (b \otimes 1_n) \oplus c$ in $A \otimes M_{n+1}$, then there must be shown that

$$a \otimes e_{11} \approx a \oplus c = a \otimes e_{11} + c \otimes e_{22}$$

in $A \otimes M_2 \cong M_2(A)$. Here $A \oplus A$ is identified with the diagonal matrices in $M_2(A)$.

It is not difficult to see that $\ell_\infty(A)$ is pi-n if A is pi-n. Therefore it implies that $\ell_\infty(A)$ can not have a finite dimensional quotient, i.e., that property pi-n implies property pi(m) for some $m \leq n$. This unknown $m \in \mathbb{N}$ could depend from the topology of Prim(A). This could be because for T_0 (non-Hausdorff) spaces the covering dimension and the decomposition dimension can be very different. Perhaps also the lattice structure of the family of hereditary C^*-subalgebras (or closed left ideals) could play some role ...

It is easy to see that property pi(n) implies that each non-zero $(n+1)$-homogenous element is properly infinite in A. tion **??** provides the non-trivial fact that in general all n-homogenous elements in A are properly infinite if A has property pi(n).

It implies properties pi(n) and pi-n are the same for C^*-algebras A with the property that $1_{\mathcal{M}(A)}$ is properly infinite in $\mathcal{M}(A)$, e.g. in case where A is stable. Moreover, then both properties coincide with the property that all non-zero n-homogenous elements $a \in A_+$ are properly infinite, cf. Proposition 2.7.16.

The above given Definitions 2.0.4, **??** of local, weak pure infiniteness coincide for simple C^*-algebras, cf. Proposition 2.2.1.

(Was mentioned earlier)

Definition 2.12.1. We call a C^*-algebra A **hyper-antiliminary** if each non-zero quotient C^*-algebra $\ell_\infty(A)/J$ of $\ell_\infty(A)$ is antiliminary (= NGCR).

Is it equivalent to the property that no hereditary C*-subalgebra D of $\ell_\infty(A)$ has a character?

It should be equivalent to the property that $\ell_\infty(A)$ is "residual antiliminary" in the sense of Definition 2.7.2

`FIND or Give general Definition`

The in next Lemma used term "antiliminary" should be recalled "residual antiliminary" ??

LEMMA 2.12.2. *The C^*-algebra A is* hyper-antiliminary, *if and only if, there exist an universal constant $n := n(A,2) \in \mathbb{N}$ such that for each contractions $a_1, a_2, a_3 \in A_+$ with $a_1a_2 = a_1$ and $a_2a_3 = a_2$ there are n contractions $d_1, \ldots, d_n \in a_3Aa_3$ and 2-homogenous positive contractions $e_1, \ldots, e_n \in a_2Aa_2$ such that $a_1 = \sum_{j=1}^{n} d_j^* e_j d_j$.*

If A is hyper-antiliminary then there exist numbers $n(A,k) \in \mathbb{N}$, $k = 2, 3, \ldots$, $n(A, k+1) \geq n(A,k)$, such that the same holds with $n := n(A,k)$ and k-homogenous contractions $e_j \in A_+$.

The C^*-algebra A is hyper-antiliminary *if no non-zero hereditary C^*-subalgebra of $\ell_\infty(A)$ has a character.*

The latter is the case if and only if $D(\ell_\infty(A)) \cap \mathbb{K}(\mathcal{H}) = \{0\}$ for every irreducible representation $D: \ell_\infty(A) \to \mathcal{L}(\mathcal{H})$ of $\ell_\infty(A)$.

PROOF. It is not difficult to see that a C^*-algebra B is antiliminary if and only if $\overline{b\,B\,b}$ has no non-zero character for each positive contraction $b \in B$.

Indeed: If $\overline{b\,B\,b}$ has a character, then this character extends to a pure state ρ on B that defines an irreducible representation D of B that contains the compact operators in the image of B.

Conversely, if D is an irreducible representation and $D(B)$ contains the compact operators, then there exists a contraction $b \in B_+$ such that $D(b)$ is a projection with rank one. Then $\overline{b\,B\,b}$ has a non-zero character.

Moreover, if $J \lhd B$ is a closed ideal such that B/J contains a non-zero Abelian hereditary C^*-subalgebra E, then $\pi_J^{-1}(E)$ is a hereditary C^*-subalgebra of B that has a non-zero character.

Take now $B := \ell_\infty(A)$ and let $b := (b_1, b_2, \ldots)$ with contractions $b_n \in A_+$.

Consider the Abelian C^*-subalgebras $C^*(c_n) \subseteq A$ generated by $c_n := \sum_k 2^{-k} b_{n+k}$.

`to be filled in...` ??

PROPOSITION 2.12.3. *Suppose that A locally purely infinite (l.p.i.). Then A has following properties:*

1. *Every hereditary C^*-subalgebra $D \subseteq A$ is l.p.i.*
2. *Every quotient A/J is l.p.i.*
3. *$A \otimes B$ is l.p.i. for every* exact *B.*
4. *A is (2-quasi-) traceless, cf. Lemma 2.10.2.*
5. *If A is l.p.i. then A is residually antiliminary.*

Moreover:

All inductive limits of l.p.i. algebras are l.p.i.

It is not known if $\ell_\infty(A)$ is l.p.i. if A is l.p.i. It would show that "l.p.i." implies "w.p.i." (in some sense).

PROOF. **??** Where is the Def. of "residually anti-liminary"

(Is it the same as: Every hereditary □

LEMMA 2.12.4. *Suppose that A satisfies condition (i) of Definition 2.0.4 of the property* pi(n)*. Then:*

(i) *Property (i) of Definition 2.0.4 for pi(n), i.e., that each element $b \in J(a)$ can be approximated by n-term sums $\sum_{1\leq k\leq n} e_k a d_k$, passes to quotients A/J of A, hereditary C^*-subalgebras of A and to $\ell_\infty(A)$.*

(ii) *This has been improved in between (time?):*

Each non-zero n-homogenous $a \in A_+$ is properly infinite inside $D := \overline{aAa}$ if A satisfies Property (i) of Definition 2.0.4 for pi(n) and A has no irreducible representation of dimension $\leq n$. –

It carries over to n-homogenous elements of $\ell_\infty(A)$ but excludes not irreducible representations of $\ell_\infty(A)$ with dimension $\leq (n-1)$... ????

One point here is that we do not know if characters χ on $\overline{h\ell_\infty(A)h}$ with $\chi(h) = 1$ for $h = (h_1, h_2, \ldots) \in \ell_\infty(A)_+$ with $\|h\| = 1$ (can moreover take here h with $\|h_n\| = 1$ for all $n \in \mathbb{N}$). can be represented on all separable C^*-subalgebras $C \subseteq \ell_\infty(A)$ with $h \in C$ by a sequence ρ_n of pure (!) states on A such that $V : \ell_\infty(A) \to \ell_\infty(\mathbb{C})$ given by

$$V((a_1, a_2, \ldots)) := (\rho_1(a_1), \rho_2(a_2), \ldots)$$

and a character ψ on $\ell_\infty(\mathbb{C})$ have the property that for all $c \in C$ holds $\chi(c) = \psi(V(c))$.

The point is that all bigger separable C^*-sub-algebras in $\overline{h\ell_\infty(A)h}$ must have the same representation of χ.

Then still all is rather complicate: Have to show that there exists 2-homogenous elements $g_n \in A_+$ with $\|g_n\| = 1$ and $\rho_n(h_n^{1/2} g_n h_n^{1/2}) \geq 2/3\rho_n(h_n)$.

(Perhaps even a stable element g_n if in question for other topics?)

Then χ can not be a character on $\overline{h\ell_\infty(A)h}$, provided that $\chi = \psi \circ V$ holds also on the hereditary C^*-algebra generated by the element $(h_1, h_2, \ldots)$ ...

`A lot to check!`

Suppose that non-zero $a \in A_+$ is n-homogenous ([45]).

Let $J := J(a) := \overline{\mathrm{Span}(AaA)}$ denote the closed ideal of A that is generated by $\{a\}$, and let $\mathrm{Ann}(a, J) := \{b \in J\,;\, ab = 0 = ba\}$, i.e., $\mathrm{Ann}(a, J) = J \cap \mathrm{Ann}(a, A)$.

[45] i.e., there exists a C^*-morphism $\psi\colon \mathrm{C}_0(0, \|a\|] \otimes M_n \to A$ with $a = \psi(f_0 \otimes 1_n)$ for $f_0(t) := t$

If the closed two-sided ideal of A generated by $\mathrm{Ann}(a, J)$ *contains* a, *then* a *is properly infinite.*

In particular, if $c \in A_+$ *with* $\|c\| = 1$ *is an* $(n+1)$*-homogenous element of* A, *then* $(c - \delta)_+$ *is properly infinite for each* $\delta \in [0, \|c\|)$.

The dimension of $\mathcal{H}$ *is* $\leq n$, *if there exists an irreducible representation* $D \colon A \to \mathcal{L}(\mathcal{H})$ *with* $D(A) \cap \mathbb{K}(\mathcal{H}) \neq \{0\}$.

(iii) *If* A *has no non-zero quotient* A/J *of dimension* $\leq n^2$, *then* $\overline{a^*Aa}$ *is pi*(n) *for each* $a \in \mathrm{Ped}(A)$ *(*$:=$ *Pedersen ideal, the minimal dense ideal of* A*).*

(iv) *If* $\mathcal{M}(A)$ *has no non-zero quotient of dimension* $\leq n^2$, *then* A *is pi*(n).

(v) *If* A *is* σ*-unital, then, for every* $S, T \in \mathrm{Q}(A) := \mathcal{M}(A)/A$ *(respectively* $S, T \in \mathcal{M}(A)$*) with* S *in the closed ideal generated by* T, *and every* $\varepsilon > 0$, *there exist* $X_1, \ldots, X_{2n} \in \mathrm{Q}(A)$ *(respectively* $X_1, \ldots, X_{3n} \in \mathcal{M}(A)$*) with* $\|S - \sum_j X_j^* T X_j\| < \varepsilon$.

(vi) *If* A *is* σ*-unital and is pi*(n), *then* $\mathcal{M}(A)$ *has no finite-dimensional quotient and is pi*(k) *(for some* $k \leq 3n$*).*

(vii) *If* A *(itself) has no irreducible representations of dimension* $\leq n$, *then* A *is* locally purely infinite *(cf. Def. 2.0.3).*

In particular, then A *is* traceless *(in sense of Def. 2.8.1).*

Proof. (i): The passage to hereditary C^*-subalgebras and to quotients A/J is almost obvious from the definition.

The passage of property pi(n) to $\ell_\infty(A)$ requires an uniform estimate for property (i) of Definition 2.0.4:
If $b_k := S_k a_k S_k^*$, for $a_k, b_k \in A_+$, $S_k \in M_{1,m}(A)$ (for some fixed $m \in \mathbb{N}$) with $\|a_k\| \leq 1$ and $\gamma := \sup_k \|S_k\| < \infty$, then $\|b_k - S_k(a_k - \delta)_+ S_k^*\| \leq \gamma^2 \delta$. This allows to find $T_k \in M_{1,n}(A)$ with $\sup_k \|T_k\| \leq 2/\sqrt{\varepsilon}$, such that $\|b_k - T_k a_k T_k^*\| < \varepsilon$ for all $k \in \mathbb{N}$. Now use that $M_{1,n}(\ell_\infty(A)) = \ell_\infty(M_{1,n}(A))$.

(ii): Let $b := \psi(f_0 \otimes p_{1,1})$. The elements a and b generate the same closed ideal J, and $b \otimes 1_n \sim a \oplus 0_{n-1}$ in $M_n(A)$. For $x \in \mathrm{Ann}(a, J)$ holds $a + x \in J$. Thus $(a + x) \oplus 0_{n-1} \precsim b \otimes 1_n,$. Since $ax = xa = 0$, also $a \oplus x \sim (a + x) \oplus 0$. Together: $a \oplus x \oplus 0_{n-2} \precsim a \oplus 0_{n-1}$, i.e., x is in $I(a) := \{x \in A\,;\ a \oplus x \precsim a\}$ for all $x \in \mathrm{Ann}(a, J)$. By Lemma 2.5.3(i), $I(a)$ is a closed ideal of A. By assumptions, a is in the closed ideal of A that is generated by $\mathrm{Ann}(a, J)_+$. Thus, $a \oplus a \precsim a \oplus 0$ follows from $\mathrm{Ann}(a, J) \subseteq I(a)$.

If $\psi \colon \mathrm{C}_0(0, \gamma] \otimes M_m \to A$ is given with $\gamma := \|c\|$, $m > n$ and $\psi(f_0 \otimes 1_m) = c$ for $f_0(t) := t$, then, for each $0 \leq \delta < \gamma$, the element $(a - \delta)_+ = \psi((f_0 - \delta)_+ \otimes e_n)$ (where $e_n := p_{11} + p_{22} + \cdots + p_{nn}$) satisfies the above considered assumptions on a. Thus, $(a - \delta)_+$ is properly infinite. The element $(c - \delta)_+$ is in the ideal generated by $\{(a - \delta)_+\}$. We get $(c - \delta)_+ \precsim (a - \delta)_+ \leq (c - \delta)_+$.

Thus $(c - \delta)_+$ is properly infinite for all $\delta \in [0, \|c\|)$ ...????

If $D \colon A \to \mathcal{L}(\mathcal{H})$ is an irreducible representation, then the compact operators $\mathbb{K}(\mathcal{H})$ are contained in the image of D, and $\mathbb{K}(\mathcal{H})$ becomes isomorphic to a quotient of an ideal of A. $\mathbb{K}(\mathcal{H})$ satisfies property (i) of Definition 2.0.4, if and only if $\mathcal{H}$ has dimension $\leq n$, because $\mathbb{K}(\mathcal{H})$ contains no properly infinite element, but contains $n+1$-homogenous elements if the dimension of $\mathcal{H}$ is $> n$.

(iii): All finite-dimensional irreducible representations of A are of dimension $\leq n$, by our assumptions on A. But this sort of irreducible representations can not exist by our assumption that A has no non-zero quotient of dimension $\leq n^2$. It implies that $\overline{fM_n(A)f}$ has no finite-dimensional quotient if $0 \neq f \in M_n(A)_+$.

Let $a \in \mathrm{Ped}(A)$. Then $b := a^*a \in \mathrm{Ped}(A)$ and $B := \overline{a^*Aa} = \overline{bAb}$. The (minimal dense) Pedersen ideal of A is algebraically generated by the elements $\{(e-\varepsilon)_+ \,;\; e \in A_+, \varepsilon > 0\}$. Hence, there are $e \in A_+$, $\varepsilon > \delta > 0$ and $d_1, \ldots, d_n$ with $b = d_1^*(e-\delta)_+d_1 + \cdots + d_n^*(e-\delta)_+d_n$ (the n comes from property (i) of Definition 2.0.4).

There are contractions $f, x \in M_n(A)$ and $x \in M_n(A)$ such that $fxx^* = xx^*$ and $f \geq 0$ and $B \otimes p_{11} = \overline{xM_n(A)x^*}$.

It follows that $\ell_\infty(B)$ is isomorphic to a hereditary C^*-subalgebra of $M_n(\ell_\infty(A))$ that is contained in $gM_n(A_\omega)g$ for $g := (f, f, \ldots)$, where we use $\ell_\infty(M_n(A)) \cong M_n(\ell_\infty(A))$.

Since, by Part (i), B, $\ell_\infty(B)$ and $\ell_\infty(A)$ satisfy the condition (i) of Definition 2.0.4, all irreducible representation of $\ell_\infty(B)$ that contain non-zero compact operators in its image are of dimension $\leq n$, and all irreducible representation of $M_n(\ell_\infty(B))$ that contain non-zero compact operators in its image are of dimension $\leq n^2$. Therefore, each irreducible representation of $\ell_\infty(B)$ of finite dimension extends to an irreducible representation of $M_n(\ell_\infty(A))$, that contains compact operators in its image, thus is of dimension $\leq n^2$.

But $gM_n(A_\omega)g$ can not have an irreducible representation of finite dimension, because otherwise, $\overline{fM_n(A)f}$ has a non-zero quotient of finite dimension.

Thus, $\ell_\infty(B)$ has no quotient of dimension $\leq n^2$, i.e., satisfies also condition (ii) of Definition 2.0.4, i.e., B is $\mathrm{pi}(n)$.

(iv): If $\mathcal{M}(A)$ has no non-zero quotient of dimension $\leq n^2$, then $\ell_\infty(\mathcal{M}(A))$ can not have a non-zero quotient C^*-algebra of dimension $\leq n^2$, because $\mathcal{M}(A)$ is unitally contained in $\ell_\infty(\mathcal{M}(A))$.

The same happens with the (essential) ideal $\ell_\infty(A)$ of $\ell_\infty(\mathcal{M}(A))$.

(v): `like in [463] ??`

Next considers relations between separable C^*-subalgebras in $\mathrm{Q}(A)$ and in A_∞ ?

LEMMA 2.12.5. *Suppose that A is σ-unital. Then, for every separable C^*-subalgebra $D \subseteq \mathcal{M}(A)$, there exist a sequence $a_0, a_1, \ldots \in A_+$ of commuting contractions such that $\sum a_n = 1$ (strictly in $\mathcal{M}(A)$) $a_n a_m = 0$ for $|n-m| > 1$, $T - \sum_n a_n^{1/2} T a_n^{1/2} \in A$, and $MT - TM \in A$ for $M := \sum_{n \in X} a_n$, for all $T \in D$ and all $X \subseteq \mathbb{N}$.*

??????????????

to be filled in

In particular, for each separable C^*-subalgebra $C \in \mathrm{Q}(A)$, there exist hereditary C^*-subalgebras $E_1, E_2 \subseteq \ell_\infty(A)$ and mono-morphisms $\psi_j \colon E_j \to \mathcal{M}(A)$ such that $C \subseteq \pi_A(\psi_1(E_1)) + \pi_A(\psi_2(E_2))$. ??????

PROOF. **??** □

(???): If A is σ-unital, then, for each separable C^*-subalgebra $C \in \mathrm{Q}(A)$, there exist hereditary C^*-subalgebras $E_1, E_2 \subseteq \ell_\infty(A)$ and monomorphisms $\psi_j \colon E_j \to \mathcal{M}(A)$ such that $C \subseteq \pi_A(\psi_1(E_1)) + \pi_A(\psi_2(E_2))$. See 2.12.5.

If A is pi(n), then every hereditary C^*-subalgebra E of $\ell_\infty(A)$ does not have non-zero quotient algebras of finite dimension.

Suppose now that $\mathcal{M}(A)$ has an irreducible representation $D \colon \mathcal{M}(A) \to \mathcal{L}(\mathcal{H})$ of finite dimension, then necessarily $D(A) = \{0\}$, i.e., $D = d \circ \pi_A$ for an irreducible representation d of $\mathrm{Q}(A)$. Let $C \subseteq \mathrm{Q}(A)$ a separable C^*-subalgebra with $d(C) = \mathcal{L}(\mathcal{H})$, and E_1, E_2 as above.

?????????????

Then $D \circ \psi_1$ or $D \circ \psi_2$ is non-zero. Thus, there exists a hereditary C^*-subalgebra E of $\ell_\infty(A)$ that has a non-zero quotient of finite dimension. This contradicts the existence

of

???????????????????????????

a non-zero hereditary C^*-algebra E of $\ell_\infty(A)$ and a C^*-morphism $\psi \colon E \to \mathcal{M}(A)$ with $D(\psi(E)) \neq 0$.

(???): `to be filled in`

?? □

Recall that a C^*-algebra A `Check definitions!!` has *property pi-n* (or A is pi-n) if, for each $a \in A$, the n-fold sum $a \oplus a \oplus \cdots \oplus a = a \otimes 1_n$ is properly infinite in $M_n(A)$, cf. Definition **??**.

There are other places where this result is discussed and partly proven. Compare and unite them!

LEMMA 2.12.6. *The C^*-algebra A is pi-n, if and only if, $\ell_\infty(A)$ is pi-n, if and only if, A_ω is pi-n.*

If A is pi-n, then all non-zero quotients and non-zero hereditary C^*-subalgebra are pi-n.

If A is pi-n then A is traceless. (In particular, A contains no non-zero hereditary C^*-subalgebra D that has a non-zero character. In particular, A admits no irreducible representation of finite dimension.)

If A is pi-n, then A has property pi(m) for some $m \leq n$.

If A is stable *then A has property pi(n), if and only if, A is pi-n.* More general, this holds if the unit element of $\mathcal{M}(A)$ is properly infinite.

More general:
A has property pi-n if A has property pi(n) and for each element $a \in A_+$ and $\varepsilon > 0$ there exists an n-homogenous element $b \in A_+$ with the property that b is the closed ideal generated by a and $(a-\varepsilon)_+$ is contained in the closed ideal of A generated by b.

In between, question for further studies:
If a, $b \in A_+$ are *residually* properly infinite in A, is then $a+b$ infinite in A?

Give Ref. to *residually* p.i. elements in A_+ !!!

(What about counterexamples?

A can be supposed separable?

Where is the Definition of *residually properly infinite* elements in A_+ ?)

If this is the case, then all pi(n) and pi-n are are equivalent to pi-1.!!! Why that ???

If $J \subseteq A$ is a closed ideal with property pi-n and suppose that A/J has pi-n. It is then known that A has property pi-m for some $m \leq 2n$. can it be improved to $m = n$?

PROOF. `to be filled in` ??

If A is stable, then its multiplier algebra $\mathcal{M}(A)$ contains isometries S, T with $S^*T = 0$. Suppose from now on that A has the property that $\mathcal{M}(A)$ contains isometries $S, T \in \mathcal{M}(A)$ with $S^*T = 0$. The isometries $T_k := T^k S$ have mutually orthogonal ranges: $S^*(T^*)^\ell T^k S = \delta_{k,\ell} 1$.

Let $a, b \in M_n(A)$. Clearly $a \precsim b$ in $M_n(A)$ if and only if $a \precsim b$ in $M_n(\mathcal{M}(A))$.

????????? □

It is sometimes useful and easier, to consider local properties of the ultrapower A_ω of A, instead of local properties of the algebra A itself.

Let $a \in A_+$, $t \in (0, \infty)$ and $V : A \to A$ an *inner* completely positive contraction ([46]). We define $\mu(a, V, t)$ as the smallest $m \in \mathbb{N}$ of *contractions* $d_1, \ldots, d_m \in A$ such that $\sum_{j=1}^m d_j^* a d_j = (V(a) - t)_+$. Here we do not require that $\| \sum_{j=1}^m d_j^* d_j \| \leq 1$.

`Add remark/def concerning control of` $\mathrm{CP}_{\mathrm{in}}(A)$ `from notes (which one ????).` ??

LEMMA 2.12.7. *A C^*-algebra A satisfies condition* (i) *of the Definition 2.0.4 of property pi(n) for some $n \in \mathbb{N}$, if and only if, $\mu(t) := \sup_{a,V} \mu(a, V, t) < \infty$ for*

[46] A c.p. map V is *inner*, if there exist $d_1, \ldots, d_m \in \mathcal{M}(A)$ with $V(a) := \sum d_j^* a d_j$.

each $t \in (0,1)$, where (a, V) runs over all inner c.p. contractions $V \in \mathrm{CP}(A, A)$ and over all positive contractions $a \in A_+$.

PROOF. Suppose that $n := \mu(1/4) < \infty$. Let $0 \neq b \in A_+$ a contraction and $\varepsilon \in (0, 1/2)$ such that $b \in \overline{\mathrm{span}(AaA)} =: J_a$. We show that there are contractions $d_1, \ldots, d_n \in A$ and $\delta > 0$ such that

$$(2/\delta) \sum_{j=1}^{n} d_j^* a d_j \geq (b - \varepsilon)_+ \, .$$

It implies then condition (i) of Definition 2.0.4 by Lemma 2.1.9.

Let $c := b^\alpha$ for $0 < \alpha := -\log(2)/\log(\varepsilon) < 1$, i.e., for $\alpha \in (0,1)$ with $\varepsilon^\alpha = 1/2$. Then $(c - 1/2)_+ = (b^\alpha - 1/2)_+ \geq (1/2)(b - \varepsilon)_+$ and $c \in J_a$. Thus, there exists $e_1, \ldots, e_m \in A$ and $\delta > 0$ with

$$\sum_{k=1}^{m} e_k^* (a - \delta)_+ e_k = (c - 1/4)_+ \, .$$

It holds $a \geq \delta f_\delta(a)$ for the $f_\delta(t) := \min(2/\delta(t - \delta/2)_+, 1)$ for $t \in [0, \infty)$. Define $V \colon A \to A$ for $x \in A$ by

$$V(x) := \sum_{k=1}^{m} e_k^* (a - \delta)_+^{1/2} x (a - \delta)_+^{1/2} e_k \, .$$

Then $\|V\| \leq 3/4$ and $V(f_\delta(a)) = (c - 1/4)_+$. Thus $(V(f_\delta(a)) - 1/4)_+ = (c - 1/2)_+$. It follows, that there are contractions $d_1, \ldots, d_n \in A$ with $n \leq \mu(1/4)$ and

$$\sum_{j=1}^{n} d_j^* f_\delta(a) d_j = (c - 1/2)_+ \geq (1/2)(b - \varepsilon)_+ \, .$$

□

PROPOSITION 2.12.8. *Let A denote a non-zero C^*-algebra and A_ω its ultrapower with respect to some free ultrafilter $\omega \in \gamma(\mathbb{N}) := \beta(\mathbb{N}) \setminus \mathbb{N}$. Then the following properties of A are equivalent:*

(i) *A is weakly purely infinite (i.e., A has property pi(n) for some $n \in \mathbb{N}$).*
(ii) *A_ω is locally p.i.*
(iii) *Every lower semi-continuous 2-quasi-trace of $(A_\omega)_+$ is trivial, i.e., takes only the values 0 and ∞.*
(iv) *There exists $m \in \mathbb{N}$, such that $a \otimes 1_m$ is a properly infinite element of $M_m(A)$ for every non-zero $a \in A_+$, i.e., A is pi-m.*
(v) *The ultrapower A_ω has no finite-dimensional irreducible representation, and, for every sequence of approximately inner completely positive contractions $V_n \colon A \to A$, the ultrapower $V_\omega := \prod_\omega (V_n)$ of $(V_1, V_2, \ldots)$ is an ideal-system preserving c.p. map on A_ω, i.e., V_ω satisfies $V_\omega(J) \subseteq J$ for every closed ideal J of A_ω.*
(vi) *A_ω is pi-m for some $m \in \mathbb{N}$.*

Question: What happens if no closed hereditary C^*-subalgebra of A_ω has a character?

The part (v) says equivalently that ?????

(v): The ultrapower A_ω has no finite-dimensional irreducible representation, and, for every sequence of approximately inner completely positive contractions $V_n\colon A \to A$, the ultrapower $V_\omega := \prod_\omega (V_n)$ of $(V_1, V_2, \ldots)$ is an ideal-system equivariant c.p. map on A_ω, i.e., V_ω satisfies $V_\omega(J) \subseteq J$ for every closed ideal J of A_ω.

(vi): A_ω is pi-m for some $m \in \mathbb{N}$.

The new result says: If A is stable then pi(n) = pi-n and pi(n) requires only
that $\overline{\operatorname{span}(AaA)}$ can be approximated in n steps and that
A has no irreducible representations of dimension $\leq n$.

PROOF. (iv)⇒(i): By Lemma **??**, A is pi(n) for some $n \leq m$.

(i)⇒(ii): By Lemma **??**, $\ell_\infty(A)$ and its quotient A_ω are pi(n). By Lemma **??**, pi(n) implies local p.i.

(ii)⇒(iii): local p.i. implies traceless

(iii)⇒(iv): By Remark 2.8.3, A_ω is traceless, if and only if,

(*) for every $a \in (A_\omega)_+$ and $\varepsilon > 0$ there is $n(a, \varepsilon) \in \mathbb{N}$ such that $(a - \varepsilon)_+ \otimes 1_{2n} \precsim a \otimes 1_n$ for all $n \geq n(a, \varepsilon)$.

For $b, c \in M_k(A)_+$ holds $b \precsim c$ in $M_k(A)$, if and only if, $b \precsim c$ in $M_k(A_\omega) = (M_k(A))_\omega$. Thus, for every $a \in A_+$ and $\varepsilon > 0$ there is $n \in \mathbb{N}$ with $(a - \varepsilon)_+ \otimes 1_{2n} \precsim a \otimes 1_n$ in $M_{2n}(A)$. We denote from now on by $n(a, \varepsilon)$ the minimal $n \in \mathbb{N}$ with this property.

Suppose that there exists $\varepsilon > 0$ and a sequence of contractions $a_1, a_2, \ldots \in A_+$ such that $n(a_k, \varepsilon/2) \to \infty$ if $k \to \infty$. Then the positive contraction $a := \pi_\omega(a_1, a_2, \ldots) \in A_\omega$ satisfies

check: ????????????

$(a - \varepsilon/4)_+ \otimes 1_{2n} \not\precsim a \otimes 1_n$ for all $n \in \mathbb{N}$. The latter contradicts property (*) of A_ω.

Thus, there is "universal" $m \in \mathbb{N}$ with the property that $(a-1/2)_+ \otimes 1_{2n} \precsim a \otimes 1_n$ in $M_{2n}(A)$ for each contractions $a \in A_+$ for some $n = n(a, 1/2) \leq m$.

????????????????

(iv)⇒(v): Property (ii) passes to $\ell_\infty(A)$, to its quotient A_ω, and to any non-zero quotients of A_ω. In particular, A_ω cannot have any finite dimensional irreducible representation.

If A satisfies (ii) and if $a = (a_1, a_2, \ldots) \in \ell_\infty(A)_+$ is a representative of $b \in (A_\omega)_+$, then $(V_\omega(b) - 2\varepsilon)_+ = \pi_\omega(c_1, c_2, \ldots)$ with $c_n = (V_n(a_n) - 2\varepsilon)_+$.

Since $a_n \otimes 1_m$ is properly infinite for some fixed $m \in \mathbb{N}$, and since $V_n(a_n)$ is in the ideal generated by a_n, we find, as in the last step of the proof of Proposition

2.15.11, $d_{n,1}, \ldots, d_{n,m} \in A$ with $\|(d_{n,1})^* d_{n,1} + \cdots + (d_{n,m})^* d_{n,m}\| \leq \frac{2\|a_n\|}{\varepsilon}$, such that $c_n = (d_{n,1})^* a_n d_{n,1} + \cdots + (d_{n,m})^* a_n d_{n,m}$. Thus $(V_\omega(b) - 2\varepsilon)_+$ is in the ideal generated by b.

(v)⇒(iv): An indirect argument shows that (v) implies the existence of (universal) $m \in \mathbb{N}$, such that, for contractions $a, b \in A_+$ with b in the ideal generated by a, there are $d_1, \ldots, d_m \in A$ with $\sum d_j^* a d_j = (b - 1/2)_+$. Then $1/2$ can be replaced by any $\varepsilon > 0$ if we replace b by b^α with $\alpha := -2\log 2/\log \varepsilon$.

Moreover, this implies that for every $\varepsilon > 0$ and $b \in A_+$ in the closed ideal generated by $a \in A_+$ there is $\delta > 0$ such that there are

??????????

If such $m \in \mathbb{N}$ exists, then

??????????

passes to A_ω with the same number m.

It implies that a lower semi-continuous 2-quasi-trace τ on A_ω annihilates the closed ideal $J(B)$ of A_ω, which is generated by the image $B := h(\mathrm{C}_0((0,1], M_{2m}))$ of a C^*-morphism h from $\mathrm{C}_0((0,1], M_{2m})$ into A_ω, so far as $\tau|B_+$ is semi-finite. Since A_ω has no irreducible representation of finite dimension, the Pedersen ideal of every closed ideal of A_ω is contained in the union of the direct sums of ideals $J(B)$. Now we use again, that τ is lower semi-continuous, and get that τ can only take the values 0 and ∞. □

It is obvious, that (iii), equivalently, means, that all singly generated ideals of A_ω are closed unions of ultrapowers of sequences of singly generated closed ideals of A and that those ultrapowers are singly generated, and that A_ω has no finite-dimensional quotient.

Corollary 2.12.9. *Let $n \in \mathbb{N}$. Suppose that A satisfies condition (i) in the Definition 2.0.4 of the property pi(n), i.e., for each $a \in A_+$, $b \in J(a) := \overline{\mathrm{span}(AaA)}$ and $\varepsilon > 0$ there exist $d_1, \ldots, d_n \in A$ with $\|b - \sum_k d_k^* a d_k\| < \varepsilon$.*

This property passes to quotients A/J of A and to $\ell_\infty(A)$.

The following properties (i)–(v) *of A are equivalent under condition (i) of Definition 2.0.4:*

(i) *A is pi(n).*
(ii) *There exists some free ultrafilter ω such that A_ω has no irreducible representation of dimension $\leq n$.*
(iii) *$\ell_\infty(A)$ is pi(n).*
(iv) *A_ω is pi(n) for* any *free ultrafilter ω.*
(v) *$\ell_\infty(A)$ has no irreducible representation of dimension $\leq n$.*

A sufficient condition for Part (v) *is that $\mathcal{M}(A)$ has no irreducible representation of dimension $\leq n$.*

And this condition is equivalent to Part (v) *if A is σ-unital.*

PROOF. (i) $\Leftrightarrow$ (v): By Definition 2.0.4 A is pi(n) if and only if it satisfies Condition (i) of Definition 2.0.4 and its Condition (ii), which says that $\ell_\infty(A)$ has no irreducible representation of dimension $\leq n$.

(v)$\Rightarrow$(iv): Each A_ω is a quotient of $\ell_\infty(A)$.

(v)$\Rightarrow$(i): By Lemma 2.12.4(i), the quotient A_ω of $\ell_\infty(A)$ has also property (i) of Definition 2.0.4.

If $\omega \in \beta(\mathbb{N}) \setminus \mathbb{N}$ is given with the property that A_ω has no non-zero irreducible representation of dimension $\leq n$, then A_ω is pi(n) by Part (iii) of

????????????, to be filled in ??

because, for each positive $a \in A_\omega$, there is a positive contraction $e \in A_\omega$ with $ea = a$, in particular, $\mathrm{Ped}(A_\omega) = A_\omega$.

By Proposition 2.12.8, there exists $m \in \mathbb{N}$ such that A is pi-m (for some $m \geq n$).

Then $\ell_\infty(A)$ is pi-m by Lemma 2.12.6.

In particular, $\ell_\infty(A)$ can not have a finite-dimensional quotient.

□

REMARK 2.12.10. If σ-unital A satisfies condition (i) of Definition 2.0.4, then condition 2.0.4(ii) of $\ell_\infty(A)/c_0(A)$ is equivalent to:
$\mathcal{M}(A)$ has no irreducible representation of dimension $\leq n$.

This happens, because – otherwise – a suitable hereditary C^*-subalgebra D of $\ell_\infty(A)/c_0(A)$ has a C^*-morphism into $\mathrm{Q}(A) := \mathcal{M}(A)/A$ with image that is not in the kernel of that irreducible representation.

One can see:
If A_ω has no irreducible representation of dimension $\leq n$, then, for each $\delta > 0$ there is $m = m(\delta) \in \mathbb{N}$ such that, for every contraction $a \in A_+$, there are $n+1$-homogenous contractions $e_1, \ldots, e_m \in A_+$ and contractions $d_1, \ldots, d_m \in A$ with $\sum_k d_k^* e_k f_k = (a - \delta)_+$.

Question: Is each element $b \in \mathrm{Q}(A)_+$ a sum of 4 commuting positive elements that are in the closed ideal generated by the $n+1$-homogenous elements?

The closed ideal J_{n+1} of $\mathrm{Q}(A)$ generated by the $n+1$-homogenous elements of $\mathrm{Q}(A)$ is the intersection of all kernels of the C*-morphisms from $\mathrm{Q}(A)$ into M_k with $k < n+2$. The minimal requirement is therefore that $\mathrm{Q}(A)$ has no irreducible representation into M_k for $k \leq n+1$. ...

The possible differences between properties pi(n) and pi-n can be seen by the following Proposition 2.12.11 (see also Question ??). Here $\mathrm{Ped}(A)$ denotes the *minimal* dense algebraic ideal of A, the "Pedersen-ideal".

PROPOSITION 2.12.11. *Let A an inductive limit of algebras $A_1, A_2, \ldots$.*

(i) *If each A_k is pi(n), then, for every non-zero $a \in \mathrm{Ped}(A)$, the algebra $\overline{a^* A a}$ is pi(n).*

(ii) *If each A_k has property pi(n) and if $\mathcal{M}(A)$ has no non-zero finite-dimensional quotient C*-algebra, then A is pi(n).*
(iii) *If each A_k has property pi-n, then A has property pi-n.*
(iv) *If each A_k is locally p.i., then A is locally p.i.*

The next proposition lists some elementary implications of the properties Xpi of C*-algebras.

PROPOSITION 2.12.12. *If A has Property pi-n, then A is pi(n) (thus is weakly purely infinite).*

If A is pi(n) (respectively has Property pi-n), then $\ell_\infty(A)$, A_ω, every hereditary C-subalgebra D of A and every quotient of A are pi(n) (respectively have Property pi-n).*

This is somewhere below also shown?!

The C-algebra A is purely infinite (in sense of Definition 1.2.1, i.e., A is pi(1)), if and only if, A has property pi-1, i.e., each non-zero $a \in A_+$ is properly infinite.*

If A is weakly purely infinite, then A is locally purely infinite.

Locally purely infinite algebras are traceless.

PROOF. To be filled in ?? □

PROPOSITION 2.12.13. *We have the implications: $A \cong A \otimes \mathcal{O}_\infty$ implies A s.p.i. implies $C' \cap A_\omega$ p.i. for all* separable commutative *subalgebras $C \subseteq A_\omega$*

`Also from Chps. 5, 6, 12!!!  ?? The notation` K `for closed ideals of` $M(B)$ `is irritating ...`

`Important!  Check ideal characterization carefully again!!!`

LEMMA 2.13.1. *Let* B *a* σ*-unital stable* C^**-algebra, and* $b \in \mathcal{M}(B)_+$. *Then there exists a sequence* $(a_1, a_2, \ldots) \in \ell_\infty(B)_+$ *such that*

$$(1/2)\| b + B + K \| \leq \| (\sum_n s_n a_n s_n^*) + B + K \| \leq \| b + B + K \| ,$$

for every norm-closed ideal K *of* $\mathcal{M}(B)$ ([47]). *In particular,*

$$I(b) + B = I(\sum_n s_n a_n s_n^*) + B$$

for the norm-closed ideals $I(b)$ *and* $I(\sum_n s_n a_n s_n^*)$ *of* $\mathcal{M}(B)$ *generated by* b *respectively by* $\sum_n s_n a_n s_n^*$.

PROOF. Recall that $\|b + B + K\| = \|\pi_{B+K}(b)\|$ in $\mathcal{M}(B)/(B + K) \cong$ Q$(B)/\pi_B(K)$.

If we use a suitable, approximately with b commuting, commutative approximate unit $e_1, e_2, \ldots \in B_+$ with $e_n e_{n+1} = e_n$, then we can manage that for $g_0 := 0$, $g_n := (e_n - e_{n-1})^{1/2}$ and $b_0 := \sum_n g_{2n} b g_{2n}$, $b_1 = \sum_n g_{2n-1} b g_{2n-1}$, holds $\sum g_n^2 = 1$, $b_0 - (\sum_n g_{2n}^2)b \in B$, $b_1 - (\sum_n g_{2n-1}^2)b \in B$, $b_0 + b_1 - b \in B$ and $\|b_j + K + B\| \leq \|b + K + B\|$ for every closed ideal K of $\mathcal{M}(B)$. Now let $X := \sum g_{2n} b^{1/2} s_{2n}$, $Y := \sum g_{2n-1} b^{1/2} s_{2n-1}$. Then $XX^* = b_0$, $YY^* = b_1$ and $YX^* = 0$. Let $A := X^*X + Y^*Y$. It follows,

$$\|A + K\| = \max(\|X^*X + K\|, \|Y^*Y + K\|) = \max(\|b_0 + K\|, \|b_1 + K\|)$$

and $\|b_0 + b_1 + K\| \leq \|b_0 + K\| + \|b_1 + K\| \leq 2\|A + K\|$ for every closed ideal K of $\mathcal{M}(B)$. In particular, $(1/2)\|b + K + B\| = \|A + K + B\| \leq \|b + K + B\|$, because $b + B = b_0 + b_1 + B$. Thus, the sequence $a_n := b^{1/2} g_n^2 b^{1/2}$ has the desired properties. □

The following Proposition 2.13.2 has applications to ideal-equivariant extension and lifting problems. The stable corona Q(B) of (general) σ-unital and stable B has usually many ideals that are very different from the special ideals $\pi_B(\mathcal{M}(B, J))$, –

[47] Here, the $s_1, s_2, \ldots \in \mathcal{M}(B)$ are isometries with the property that $\sum_n s_n (s_n)^*$ converges strictly to 1, cf. Remark 5.1.1(8).

even if B is stable and separable. Notice that the corona algebra $\mathrm{Q}(B)$ of the stable (not w.p.i.) C^*-algebra $B := \mathrm{C}_0((0,1] \times [0,1]^\infty, \mathbb{K})$ does not have the property derived in Proposition 2.13.2 for s.p.i. algebras.

PROPOSITION 2.13.2. *Suppose that B is a σ-unital and weakly purely infinite C^*-algebra. Let $a, b \in \mathrm{Q}(B) := \mathcal{M}(B)/B$. Then*

$$\|a + \pi_B(\mathcal{M}(B,J))\| \leq \|b + \pi_B(\mathcal{M}(B,J))\|, \qquad \textit{for every } J \in \mathcal{I}(B),$$

implies that the element a is in the closed ideal $I(b)$ of $\mathrm{Q}(B)$ generated by b.

General ideals should be J, K, ..., because $I(b)$ is reserved for the by b absorbed ideal...

PROOF. We may suppose that B is stable, because $B \otimes \mathbb{K}$ is again weakly purely infinite and σ-unital, and there is an isomorphism φ from $\mathrm{Q}(B)$ onto the corner $\pi_{Q\otimes\mathbb{K}}(\mathcal{M}(B) \otimes p_{11})$ of $\mathrm{Q}(B \otimes \mathbb{K})$, that satisfies

$$\varphi(\pi_B(\mathcal{M}(B,J))) = \varphi(\mathrm{Q}(B)) \cap \pi_{Q\otimes\mathbb{K}}(\mathcal{M}(B \otimes \mathbb{K}, J \otimes \mathbb{K}))\,.$$

Now suppose that B is stable, σ-unital and is weakly p.i.

Why $B \otimes \mathbb{K}$ is again weakly purely infinite? Answer: pi-n of B implies pi-n^2 of $B \otimes \mathbb{K}$, see paper with Rørdam .
With pi(n) could be difficulties !!!.
Needs: If $X \in M_2(B)_+$ is given. Then all entries of $\mathrm{diag}(X, \ldots, X) \in M_{2n}(B)$ can be considered as properly infinite elements in $M_2(M_n(B))$, i.e., it needs some sort of “almost” strong pure infiniteness!

`Give Ref for next!:` By Definition **??** and Proposition **??** there exists $n \in \mathbb{N}$ such that B is pi-n in the sense of Definition **??**, i.e., $b \otimes 1_n$ is properly infinite (in $M_n(B)$) for each $b \in B$, cf. Proposition 2.12.8(iv).

Since B is stable, $\mathcal{M}(B)$ contains a copy of $\mathcal{O}_\mathrm{n}$, i.e., there are isometries $T_1, \ldots, T_n \in \mathcal{M}(B)$ such that $T_1T_1^* + \cdots + T_nT_n^* = 1$. Let $\delta_n(b) := T_1bT_1^* + \cdots + T_nbT_n^*$ for $b \in \mathcal{M}(B)$. Then $\delta_n(J) = J \cap \delta_n(\mathcal{M}(B))$ and $\|\delta_n(b) + J\| = \|b + J\|$ for *every* closed ideal J of $\mathcal{M}(B)$ and every $b \in \mathcal{M}(B)$. Moreover, $\delta_n(b) \otimes p_{11} = Z(b \otimes 1_n)Z^* \sim_{\mathrm{MvN}} b \otimes 1_n$ in $M_n(\mathcal{M}(B))$, by the isometry $Z = T_1 \otimes p_{11} + \cdots + T_n \otimes p_{1n} \in \mathcal{M}(B) \otimes M_n$. Thus, $\delta_n(b)$ is properly infinite for every $0 \neq b \in B$.

Let $s_1, s_2, \ldots \in \mathcal{M}(B)$ a sequence of isometries such that $\sum_n s_n(s_n)^*$ converges strictly and unconditionally to $1 \in \mathcal{M}(B)$, cf. Remark 5.1.1(8). This applies also to the sequences of isometries $t_n := T_{j(n)}s_{k(n)}$ and $t_n := s_{k(n)}T_{j(n)}$. Therefore $U := \sum_{j,k} T_js_kT_j^*s_k^*$ converges strictly and unconditionally, cf. Remark 5.1.1(2). The sum U is a unitary in $\mathcal{M}(B)$ by Lemma 5.1.2(i) and satisfies $U\sum_k s_k(\delta_n(b_k))s_k^*U^* = \delta_n(\sum_k s_kb_ks_k^*)$ for every sequence $(b_1, b_2, \ldots) \in \mathcal{M}(B)$. In summary, we get $\|J + \sum_k s_kb_ks_k^*\| = \|J + \sum_k s_k\delta_n(b_k)s_k^*\|$ for every (norm-)closed ideal J of B and every sequence $(b_1, b_2, \ldots) \in \ell_\infty(B)$.

By Lemma 2.13.1, for each $Y \in \mathcal{M}(B)_+$ there is a sequence $(y_1, y_2, \ldots) \in \ell_\infty(B)_+$ such that and

$$(1/2)\operatorname{dist}(Y, B+J) \leq \operatorname{dist}(\sum_n s_n y_n s_n^*, B+J) \leq \operatorname{dist}(Y, B+J)$$

for each closed ideal J of $\mathcal{M}(B)$.

It implies, that $I(\sum_n s_n y_n s_n^*) + B = I(Y) + B$. The new sequence, $(\delta_n(y_1), \delta_n(y_2), \ldots) \in \ell_\infty(B)$ has the same properties as $(y_1, y_2, \ldots)$, but satisfies in addition that $f(\delta_n(y_n)) = \delta_n(f(y_n))$ is properly infinite or zero for every continuous function $f \colon \mathbb{R}_+ \to \mathbb{R}_+$ with $f(0) = 0$.

We have seen above:
There are sequences $(c_1, c_2, \ldots), (d_1, d_2, \ldots) \in \ell_\infty(B)_+$ such that $f(c_n)$ and $f(d_n)$ are properly infinite or zero for each $n \in \mathbb{N}$ and every $f \in \mathrm{C}_0(0,1]$, and such that, for $c := \pi_B(\sum_n s_n c_n s_n^*)$ and $d := \pi_B(\sum_n s_n d_n s_n^*)$, holds $I(c) = I(a)$, $I(d) = I(b)$, $\|c + K\| \leq \|a + K\|$ and $\|b + K\| \leq 2\|d + K\|$ for all closed ideals K of $\mathrm{Q}(B)$.

Let $e := 2d$, $e_n := 2d_n$ and $E := \sum_n s_n e_n s_n^*$. Notice that $e = \pi(E)$ and $\pi_B(\sum_n s_n a_n s_n^*)$ generate the same ideal of $\mathrm{Q}(B)$ if there is a surjective map $\lambda \colon \mathbb{N} \to \mathbb{N}$ such that $a_n = e_{\lambda(n)}$ and $\lambda^{-1}(k)$ is finite for all $k \in \mathbb{N}$. Indeed: If σ is a permutation $\mathbb{N}$, then $\sum_n s_n a_{\sigma^{-1}(n)} s_n^* = \sum_n s_{\sigma(n)} a_n (s_{\sigma(n)})^*$ is unitarily equivalent to $\sum_n s_n a_n s_n^*$ in $\mathcal{M}(B)$ by the unitary $\sum_n s_{\sigma(n)} s_n^*$, cf. Lemma 5.1.2(i). After a suitable permutation (of indices) of the sequence $(a_1, a_2, \ldots)$ we may suppose that there is a strictly increasing sequence $1 = m_1 < m_2 < \cdots \in \mathbb{N}$ such that $e_k = a_{m_k} = a_{m_k+1} = \cdots = a_{m_{k+1}-1}$ for $k = 1, 2, \ldots$, i.e., that the sets $\lambda^{-1}(k)$ are now disjoint intervals with $j < i$ for all $j \in \lambda^{-1}(k)$ and $i \in \lambda^{-1}(\ell)$ if $k < \ell$. Let $A_k := \sum_{j=m_k}^{m_{k+1}-1} s_j e_k s_j^*$, $R := \sum_k s_{m_k} e_k (s_{m_k})^*$ and $P_k := \sum_{j=m_k}^{m_{k+1}-1} s_j s_j^*$. Then $\sum_k P_k = 1$, $A_k \in B$, $A := \sum_n s_n a_n s_n^* = \sum_k A_k \geq R$, and there is an isometry $T \in \mathcal{M}(B)$ with $TT^* = \sum_k s_{m_k} s_{m_k}^*$ and $T^*AT = T^*RT = E := \sum_n s_n e_n s_n^*$. Let $\delta > 0$. Since $(e_k - \delta)_+$ is zero or properly infinite, there is $g_k \in BP_k$ such that $\|g_k\|^2 \leq 2/\delta$ and $g_k^* e_k g_k = (A_k - \delta)_+$. The sequence $\sum_k s_k g_k$ is strictly convergent to an element $G \in \mathcal{M}(B)$ with $G^*EG = (A - \delta)_+$, cf. Remark 5.1.1(2).

Further notice, that $\|f(e) + \pi_B(\mathcal{M}(B,J))\| = f(\|e + \pi_B(\mathcal{M}(B,J))\|)$ for increasing continuous functions $f \colon \mathbb{R}_+ \to \mathbb{R}_+$ with $f(0) = 0$, because $\|f(e) + \pi_B(\mathcal{M}(B,J))\|$ is the norm of the natural image of $e \in \mathrm{Q}(B)$ in $\mathrm{Q}(B/J)$.

Now we show that, if $\|c + \pi_B(\mathcal{M}(B,J))\| \leq \|e + \pi_B(\mathcal{M}(B,J))\|$ for all $J \in \mathcal{I}(B)$, then $C := \sum_n s_n c_n s_n^*$ is contained in $I(E) + B$:
We have, for $\delta > 0$,

$$\|(c-\delta)_+ + \pi_B(\mathcal{M}(B,J))\| = (\|c + \pi_B(\mathcal{M}(B,J))\| - \delta)_+ \leq \|(e-\delta)_+ + \pi_B(\mathcal{M}(B,J))\|\,.$$

It follows, that $(C - \delta)_+ = \sum_n s_n (c_n - \delta)_+ s_n^* \in B + \mathcal{M}(B, J_k)$ for each $k \in \mathbb{N}$, where J_k denotes the closed ideal of B generated by $\{(e_n - \delta)_+\,;\ n = k, k+1, \ldots\}$.

Let $\sum_n s_n (c_n - \delta)_+ s_n^* = x + y$ with $x \in B$ and $y \in \mathcal{M}(B, J_k)$, then $\lim s_n^* x s_n = 0$ implies that there exists $m \in \mathbb{N}$ (depending on k) such that $\|(c_n - \delta)_+ - s_n^* y s_n\| <$

$\delta/2$ for all $n \geq m(k)$. Thus, there exist contractions $z_n \in B$ with $z_n^* s_n^* y s_n z_n = (c_n - 2\delta)_+$. It follows that $(c_n - 2\delta)_+ \in J_k$ for all $n \geq m$.

We define $m(k) \in \mathbb{N}$ inductively: Let $m(0) = 1$, and let $m(k)$ denote the smallest $m \geq \max(k+2, m(k-1)+2)$ with the property $(c_n - 2\delta)_+ \in J_k$ for all $n \geq m$.

For each $n \geq m(k)$, there are $\ell(n,k) \geq k$ and $h_{n,k} \in B$ such that

$$(c_n - 3\delta)_+ \,=\, h_{n,k}^* \big(\sum_{j=k}^{\ell(n,k)} s_n s_j (e_j - \delta)_+ s_j^* s_n^* \big) h_{n,k} \,.$$

This $\ell(n,k)$ and $h_{n,k}$ exists, because the sums $\sum_{j=k}^{\ell} s_j (e_j - \delta)_+ s_j^*$ are properly infinite, generate J_k, and $(c_n - 3\delta)_+$ is in the Pedersen ideal $\mathrm{Ped}(J_k)$ of J_k. Now let $Y_n := s_n(\sum_{j=k}^{\ell(n,k)} s_j e_j s_j^*) s_n^*$ for $n \geq m_1$, $\psi(t) := (\max(t-\delta, 0)/t)^{1/2}$, and $H_n := \psi(Y_n) h_{n,k} s_n^*$. The operators H_n satisfy $H_n^* Y_n H_n = s_n(c_n - 3\delta)_+ s_n^*$ and $\|H_n\|^2 \leq 2/\delta$. The sums $\sum_n Y_n = \sum_n s_n(s_n^* Y_n s_n) s_n^*$ and $\sum H_n = \sum s_n(s_n^* \psi(Y_n) h_{n,k}) s_n^*$ converge strictly to elements $Y \in \mathcal{M}(B)_+$, $H \in \mathcal{M}(B)$ and satisfy $H^* Y H = \sum_{n \geq m_1} s_n(c_n - 3\delta)_+ s_n^*$, cf. Remark 5.1.1(2). Thus, $(C - 3\delta)_+ - H^* Y H \in B_+$. The construction of Y and H depends on $\delta > 0$.

We are going to show that $Y \precsim A$ in $\mathcal{M}(B)$ for some suitable $A = \sum_m s_m a_m s_m^*$ (of the above considered type). It implies $Y \in I(A) = I(E)$ and, finally, $C \in I(E) + B$.

Consider the subsets

$$X_k := \{(n,j)\,;\; m_k \leq n < m_{k+1}, k \leq j \leq \ell(n,k)\,\} \subseteq \mathbb{N} \times \mathbb{N}\,.$$

The sets X_k are pairwise disjoint and $X := \bigcup_k X_k \subseteq \mathbb{N} \times \mathbb{N}$ has the property, that the map $p_2 \colon X \ni (n,j) \mapsto j \in \mathbb{N}$ is surjective with finite $(p_2)^{-1}(n)$ for each $n \in \mathbb{N}$. The map $p_1 \colon X \ni (n,j) \mapsto n \in \mathbb{N}$ maps X onto $\mathbb{N} \setminus \{1, \ldots, m_1 - 1\}$, and $\lambda_1^{-1}(n)$ is finite for each $n \geq m_1$. We find a bijective map $\xi \colon \mathbb{N} \to X$ from $\mathbb{N}$ onto X. Now let $\lambda := p_1 \circ \xi$ and consider the sequence $(a_1, a_2, \ldots)$ with $a_m = e_{\lambda(m)}$, and let $A := \sum_m s_m a_m s_m^*$ Furthermore, consider the map $(n,j) \mapsto T_{(n,j)} := s_n s_j$. Then

$$Y = \sum_{n \geq m_1} Y_n = \sum_{n \geq m_1} \sum_{j \in p_1^{-1}(n)} T_{(n,j)} c_j T_{(n,j)} = \sum_{m \geq 1} T_{\xi(m)} a_m T_{\xi(m)}^*\,.$$

Thus $Y = Z^* A Z$ for the isometry $Z := \sum s_n T_{\xi(m)}^*$. The latter sum converges strictly by Remark 5.1.1(2), because $T_{\xi(m)}^* T_{\xi(n)} = \delta_{m,n} 1$ and $\sum_m T_{\xi(m)} T_{\xi(m)}^* = \sum_{n,j=1}^{\infty} s_n s_j \chi_{n,j} (s_n s_j)^*$ for $(\chi_{n,j}) \in \ell_\infty(\mathbb{N} \times \mathbb{N}) \subseteq \ell_\infty(\mathcal{M}(N))$ the characteristic function $\chi := \chi(X)$ of X. □

LEMMA 2.13.3. *Suppose that $\mathcal{S}$ is a family of closed ideals of a C^*-algebra A, and that $a, b \in A_+$ are positive contractions. The following properties (i) and (ii) are equivalent.*

(i) *For every $\varepsilon > 0$ there exists $\delta = \delta(\varepsilon, \mathcal{S}) > 0$ such that $(a - \varepsilon)_+ \in J$ for every $J \in \mathcal{S}$ with $(b - \delta)_+ \in J$.*

(ii) *There exists a continuous strictly increasing function* $f\colon [0,1] \to [0,2]$ *with* $f(0) = 0$ *such that* $\|f(b) + J\| \geq \|a + J\|$ *for all* $J \in \mathcal{S}$.

The property (i) is satisfied for all closed ideals J *of* A *if the element* $a \in A_+$ *is contained in the closed ideal* $I(b)$ *of* A *that is generated by* b.

Proof. If $a \in \overline{\mathrm{span}(AbA)}$, then, for every $\varepsilon > 0$, there are $d_1, \ldots, d_n \in A$ and $\delta := \delta(\varepsilon) > 0$, depending on a, b, ε, such that $\sum_j d_j^*(b-\delta)_+ d_j = (a-\varepsilon)_+$. It implies that $(a-\varepsilon)_+ \in J$ if $(b-\delta)_+ \in J$.
Now we can proof the equivalence of (i) and (ii):

(ii)⇒(i): Let $\varepsilon > 0$ and

$$\delta := \delta(\varepsilon, \mathcal{S}) := f^{-1}(\min(\varepsilon, f(1)))\,,$$

then $(f(b)-\varepsilon)_+ \approx (b-\delta)_+$. In particular, $(b-\delta)_+ \in J$, if and only if, $(f(b)-\varepsilon)_+ \in J$, if and only if, $\varepsilon \geq \|\pi_J(f(b)\| = \|f(b) + J\|$.

Since $\|f(b) + J\| \geq \|a + J\|$, we get $\varepsilon \geq \|\pi_J(a)\|$, i.e., $(a-\varepsilon)_+ \in J$.

(i)⇒(ii): Let $\varepsilon \in (0,1]$, consider the non-empty set $X(\varepsilon) \subseteq (0,1]$ of $\delta \in (0,1]$ with the property that $J \in \mathcal{S}$ and $(b-\delta)_+ \in J$ together imply $(a-\varepsilon)_+ \in J$. Clearly, $X(\varepsilon)$ is an interval $(0, \xi(\varepsilon))$ or $(0, \xi(\varepsilon)]$, and $X(\varepsilon) \subseteq X(\varepsilon_1)$ if $\varepsilon \leq \varepsilon_1$. Define $g(\varepsilon) := \sup X(\varepsilon) = \xi(\varepsilon)$. Then $g\colon (0,1] \to (0,1]$ is a positive and increasing function with $g(1) = 1$ and with following property:
If $g(\varepsilon) > \|b + J\|$ and $J \in \mathcal{S}$, then $\varepsilon \geq \|a + J\|$. (Because $t \geq \|b + J\|$ is equivalent to $(b-t)_+ \in J$.)

Since g is increasing and positive, there exists a strictly increasing continuous function $h\colon [0,1] \to [0,1]$ with $h(0) = 0$ and $h(\varepsilon) < g(\varepsilon)$ for all $\varepsilon \in (0,1]$. If $h(1) < 1$, then we extend h to $[0, 2-h(1)]$ by letting $h(t) := h(1) + (t-1)$ for $t \in (1, 2-h(1)]$, and get $h([0, 2-h(1)]) = [0,1]$. Now define $f\colon [0,1] \to [0,2]$ by $f := h^{-1}$.

Then, $\varepsilon \geq \|f(b) + J\| = f(\|b + J\|)$, if and only if, $h(\varepsilon) \geq \|b + J\|$, which implies $g(\varepsilon) > \|b + J\|$. It follows that $\varepsilon \geq \|f(b) + J\|$ and $J \in \mathcal{S}$ together imply $\varepsilon \geq \|a + J\|$. In particular, there is no ideal $J \in \mathcal{S}$ with $\|a + J\| > \|f(b) + J\|$. □

Corollary 2.13.4. *Suppose that* B *is a* σ*-unital, stable and weakly purely infinite* C^**-algebra, and that* $b \in \mathrm{Q}(B)_+$.

Let $\delta > 0$, *and let* $\mathcal{J}(b,\delta)$ *denote the family of ideals* $\pi_B(\mathcal{M}(B,J))$ *with* $(b-\delta)_+ \in \pi_B(\mathcal{M}(B,J))$. *Define* $I(b,\delta)$ *as the intersection of all ideals in* $\mathcal{J}(b,\delta)$.

Then the closed ideal of $\mathrm{Q}(B)$ *generated by* b *is the same as the closure of the union* $\bigcup_{\delta>0} I(b,\delta)$.

Especially all countably generated ideals of $\mathrm{Q}(B)$ *are of this type.*

If, in addition, B *is simple, then* $\mathrm{Q}(B)$ *is simple and purely infinite.*

Notice that the particular final conclusion says:
$\mathrm{Q}(B)$ is simple and p.i. if B is simple stable and p.i.

The more difficult opposite direction, namely that simplicity of $\mathrm{Q}(B)$ for stable σ-unital B implies that B is simple and p.i., is shown in

reference or cite ??????

PROOF. We combine Proposition 2.13.2 and Lemma 2.13.3, where the system of all ideals $\pi_B(\mathcal{M}(B,J))$ plays the role of $\mathcal{S}$.

All countably generated ideals are singly generated.

If, in addition, B is simple (and is weakly p.i. by assumptions !), then $\mathrm{Q}(B)$ is simple, because every singly generated ideal coincides with $\mathrm{Q}(B)$, cf. ?????

By Lemma 2.12.4(vi), $\mathrm{Q}(B)$ is again weakly purely infinite. The simplicity and the weak pure infiniteness of $\mathrm{Q}(B)$ implies the strong pure infiniteness of $\mathrm{Q}(B)$ by Proposition 2.2.1. □

14. Point-wise approximately inner maps

The technicalities of our proves have to do with the different infiniteness properties of the prime quotients of the considered C^*-algebras, or the properties of their multiplier algebras and corona algebras. Only in very comfortable situations exists a sort of local triviality with the respect to prime quotients that have reasonable infiniteness, factorial or prime properties. We try to describe such problems.

DEFINITION 2.14.1. Let X a locally compact space. We call a c.p. map $V\colon \mathrm{C_b}(X,B) \to \mathrm{C_b}(X,B)$ **point-wise approximately inner**, if there is point-norm continuous map $x \in X \mapsto V_x$ from X into the approximately inner c.p. maps on C^*-algebras B such that $V(f)(x) = V_x(f(x))$ for all $x \in X$ and $f \in \mathrm{C_b}(X,B)$.

Notice here that the positive map V is defined *on all* $f \in \mathrm{C_b}(X,B)$, if and only if, there is a general bound given by $\sup_{x\in X} \|V_x\| < \infty$ on the "fibres" V_x. (We start here with some very elementary stuff!)

DEFINITION 2.14.2. A c.p. map $V\colon A \to A$ is called **ideal system preserving** (or $\mathcal{I}(A)$**-equivariant**) if $V(J) \subseteq J$ for all closed ideals J of A.

One of the critical points is: Let $a, b \in A_+$ contractions with $ab = a$ and suppose that a is infinite (in some suitable sense). Is b infinite? Is it the case if $(a-\delta)_+$ is infinite for each $\delta \in [0, \|a\|)$?

(Notice that $ab = a$ for $a, b \in A_+$ implies that $a = (c-1)_+$ for $c := (b-(b-1)_+) + a$. And then $a(c-a) = a$. But b can not been reconstructed from c and a, because $(b-1)_+$ is then lost be this construction of c.)

What means "infinite" here? One definition is: There exists non-zero $0 \leq e_\delta \in (a-\delta)_+ A_+ (a-\delta)_+$ with

$$e_\delta \oplus (a-\delta/2)_+ \precsim (a-\delta/2)_+ \,.$$

It depends here from the answer to the question if $(a-\delta/2)_+ \oplus (b-(a-\delta/2)_+) \precsim b$. This don't happen if A is commutative!

But something like $(a-\delta/2)_+ \oplus (b-(a-\delta)_+) \precsim b$ in $M_2(C_0(a,b))$??? and $(a-\delta/2)_+ + (b-(a-\delta)_+) \geq$?????

THEOREM 2.14.3. *Let X is a σ-compact l.c. space, and suppose that the C^*-algebra $\mathrm{C}_0(X,B)$ is weakly p.i.*

Then each point-wise approximately inner *c.p. map*

$$V\colon\ \mathrm{C}_\mathrm{b}(X,B) \to \mathrm{C}_\mathrm{b}(X,B)$$

in sense of Definition 2.14.1 is ideal system preserving *(in sense of Definition 2.14.2) completely positive map.*

PROOF. It is not difficult to see that positivity preserving linear maps $T\colon C \to D$ from C^*-algebras C into C^*-algebras D that are defined on all elements of C^*-algebras C are always norm-continuous.

Thus, our map V is bounded and $\sup_{x\in X} \|V_x\| \leq \|V\| < \infty$. The assumption of point-norm continuity of $x \mapsto V_x$ and the obvious estimate $\|V_x\| \leq \|V\|$ implies that the map $x \mapsto V_x(b(x)) \in B$ is continuous on X for each continuous map $b\colon X \to B$.

Since X is σ-compact, there is a function $\gamma \in \mathrm{C}_0(X)$ with $0 < \gamma(x) \leq 1$ for all $x \in X$ and $\max_{x\in X} \gamma(x) = 1$.

We define compact sets $Y_n \subseteq X$ with the properties $Y_n \subseteq Y^\circ_{n+1}$ and $X = \bigcup_n Y_n$ and functions $\alpha_n \in \mathrm{C}_0(X)$ by

$$\alpha_n := 2^{n+1}(\gamma - 2^{-(n+1)})_+ - 2^n(\gamma - 2^{-n})_+$$

and $Y_n := \alpha_n^{-1}(1)$. Notice $\alpha_{n+1}\alpha_n = \alpha_n$ and that the support of α_n is contained in Y_n.

Then $\beta_0 := 0$ and $\beta_n := \alpha_n - \alpha_{n-1}$ for $n \in \mathbb{N}$ satisfy $\beta_{n+k}\beta_n = 0$ for $k > 1$ and $\sum_n \beta_n = 1$ on X. The support of β_n is contained Y_{n+1}.

By assumption, there is $k \in \mathbb{N}$ such that $\mathrm{C}_0(X,B)$ is pi(k). This passes to the quotients $\mathrm{C}(Y,B)$ of $\mathrm{C}_0(X,B)$ for compact subsets $Y \subseteq X$. Let $a \in \mathrm{C}_\mathrm{b}(X,B)_+$, $\varepsilon > 0$ and $y \in Y \subseteq X$. There exists $n(y) \in \mathbb{N}$, $b_1,\ldots,b_n \in B$ such that

$$\|V_y(a(y)) - \sum b_j^* a(y) b_j\| < \varepsilon\,,$$

because $V_y\colon B \to B$ is approximately inner. The continuity of the function

$$x \mapsto \|V_x(a(x)) - \sum b_j^* a(x) b_j\|$$

implies that there is an open neighborhood $U(y)$ of y such that

$$\|V_x(a(x)) - \sum b_j^* a(x) b_j\| < \varepsilon \quad \forall\ x \in U(y)\,.$$

By compactness of Y, thus implies the existence of finitely many $U_1,\ldots,U_m$ and $n(i) \in \mathbb{N}$, $b_j^{(i)} \in B$, $i = 1,\ldots,m$, $j = 1,\ldots,n(m)$ such that the U_i cover Y and $\|V_x(a(x)) - \sum_j (b_j^{(i)})^* a(x) b_j^{(i)}\| < \varepsilon$ for $x \in U_i$. If we take a partition of unit

$f_1, \ldots, f_m \in \mathrm{C}(Y)_+$ with supports of f_i in U_i and $\sum_i f_i = 1$, and let $c_\ell \in \mathrm{C}(Y, B)$ for $\ell = 1, \ldots, n(1) + \cdots + n(m)$ denote one and only one of the $f_i^{1/2} \cdot b_j^{(i)}$, then

$$\|V_x(a(x)) - \sum_\ell c_\ell(x)^* a(x) c_\ell(x)\| < \varepsilon \quad \forall \ x \in Y\,.$$

This shows that the restriction of $x \mapsto V_x(a(x))$ to Y is in the closed ideal generated by $a|Y$, for each $a \in \mathrm{C_b}(X)$. It follows that for $\delta > 0$ and compact $Y \subseteq X$ there exists $d_1, \ldots, d_k$ with

$$\|V_x((a(x) - \delta)_+) - \sum_{j=1}^k d_j(x)^*(a(x) - \delta)_+ d_j(x)\| < \delta \quad \text{for} \ \ x \in Y\,.$$

We get for each of the above constructed Y_n elements $d_1^{(n)}, \ldots, d_k^{(n)} \in \mathrm{C}(Y_n, B)$ such that the last inequality holds for $x \in Y_n$ with d_j replaced by $d_j^{(n)}$. We define elements $e_j, f_j \in \mathrm{C_b}(X, B)$ for $j = 1, \ldots, k$ by

$$e_j(x) := \sum_{n=1}^\infty \beta_{2n-1}(x)^{1/2}(a(x) - \delta)_+^{1/2} d_j^{(2n)}\,,$$
$$f_j(x) := \sum_{n=1}^\infty \beta_{2n}(x)^{1/2}(a(x) - \delta)_+^{1/2} d_j^{(2n+1)}\,.$$

Then $\| \sum_{j=1}^k e_j^* e_j\| \leq \|a\|\|V\| + \delta$, $\| \sum_{j=1}^k f_j^* f_j\| \leq \|a\|\|V\| + \delta$, $g_\delta(a) e_j = e_j$, and $g_\delta(a) f_j = f_j$ for $j = 1, \ldots, k$, where $g_\delta(t) := \min(\delta^{-1} t, 1)$. Since the functions β_{2n} (respectively the β_{2n-1}) have mutually orthogonal supports and $\sum \beta_n = 1$, one can see that

$$\|V((a - \delta)_+) - \sum_{j=1}^k e_j^* g_\delta(a) e_j + f_j^* g_\delta(a) f_j\| \leq \delta\,.$$

Since $g_\delta(a) \leq \delta^{-1} a$, the element $(V((a - \delta)_+) - 2\delta)_+$ is in the closed ideal $I(a)$ of B that is generated by a. The $\delta > 0$ can be taken arbitrarily small with e_j, f_j $(j = 1, \ldots, k)$ depending on δ. Hence, $V(a) \in I(a)$. □

The Theorem 2.14.3 is needed, because even the answer to following questions are still open.

QUESTIONS 2.14.4. Is $\mathrm{C}([0,1]^\infty, A)$ weakly purely infinite if A is purely infinite?

A positive answer would follow from a positive answer of the question: *Is* $\mathrm{C}([0,1], A)$ *purely infinite if* A *is purely infinite?* (In fact a positive answer would imply that $\mathrm{C}_0(X) \otimes A$ is purely infinite if A is purely infinite and X is a locally compact Hausdorff space.)

To understand the non-triviality of this question recall here:
A is purely infinite $\Leftrightarrow$ A is pi(1) $\Leftrightarrow$ A is 1-purely infinite (i.e., A has property pi-1).

We know only that $\mathrm{C}([0,1], A)$ has property pi-2 if A is p.i. So the zoological garden of really different pi-n or pi(n) could be bigger than we hope for. What is the secret behind such possible differences?

COROLLARY 2.14.5. *Suppose that X is a σ-compact, non-compact, locally compact Hausdorff space, and B is a C^*-algebra. Let $Y \subseteq \beta(X) \setminus X$ a closed subset of the corona of X, $A \subseteq \mathrm{C_b}(X,B)|Y$ a separable C^*-subalgebra of $\mathrm{C_b}(X,B)|Y$ and let $C \subseteq A$ a commutative C^*-subalgebra of A.*

If the C^*-algebra $\mathrm{C_0}(X,B)$ is weakly p.i., then there exists a continuous map

$$V\colon X \ni x \to V_x \in \mathrm{CP}(B)$$

from X into the approximately inner c.p. contractions $\mathrm{CP_{in}}(B)$, such that the corresponding c.p. map $V_Y := V|Y\colon \mathrm{C_b}(X,B)|Y \to \mathrm{C_b}(X,B)|Y$ maps A into a commutative C^*-subalgebra $C^*((V_Y(A))$ of $\mathrm{C_b}(X,B)|Y$, fixes the elements of C, and has the property, that $V_Y(b)$ is in the closed ideal of $\mathrm{C_b}(X,B)|Y$ that is generated by b for each positive $b \in \mathrm{C_b}(X,B)\,|Y$.

PROOF. `to be filled in, use w.p.i. of ????` ?? □

Recall that $\mathcal{S}_{\mathrm{in}}(B)$ is the set of all inner c.p. maps V defined by $V(b) := \sum_{k=1}^n d_k^* b d_k$ for some $n := n(V) \in \mathbb{N}$ and some finite sequence $d_1, \ldots, d_n \in B$. The elements of $\mathcal{S}_{\mathrm{in}}(B)$ is an *algebraic* matrix operator-convex cone. Its point-norm closure will be denoted by $\mathrm{CP_{in}}(B)$.

COROLLARY 2.14.6. *Let X be a non-compact locally compact σ-compact Hausdorff space, and let $\emptyset \neq Y \subseteq (\beta X) \setminus X$ denote a (non-empty) closed subset of the corona of X.*

Suppose that, for every point-norm continuous family $x \in X \mapsto V_x \in \mathrm{CP_{in}}(B)$ with $\|\, V_x \,\| \leq 1$, the completely positive contractions

$$V\,|Y\colon\; \mathrm{C_b}(X,B)\,|Y \to \mathrm{C_b}(X,B)\,|Y$$

are ideal-system equivariant, i.e., $V\,|Y(J) \subseteq J$, for each closed ideal of J of $\mathrm{C_b}(X,B)\,|Y$.

Then B has the following property:

There exists $\omega \in \beta(\mathbb{R}_+) \setminus \mathbb{R}_+$ such that, for every continuous path $t \in \mathbb{R}_+ \mapsto a(t) \in B_+$ with $\|a(t)\| \leq 1$ and for every $\varepsilon > 0$, there exists an open subset $U = U(\varepsilon) \subseteq \mathbb{R}_+$, in the ultrafilter of $\mathbb{O}(\mathbb{R}_+)$ defined by ω, with the property that the values $\mu(t) := \mu(a(t), \mathcal{S}_{\mathrm{in}}(B), \varepsilon)$ remain bounded on U (i.e., there is $n(U) \in \mathbb{N}$ such that $\mu(t) \leq n(U)$ for all $t \in U$).

In particular, there exists a sequence $n < t_n < t_{n+1}$ such that $\sup_n \mu(t_n) < \infty$.

If, in addition, X is "disconnected at ∞", i.e., $X = \bigcup U_n$ for compact open subsets $U_1 \subseteq U_2 \subseteq \cdots \subseteq X$, then B has the stronger property (i) of Definition 2.0.4 for some $n \in \mathbb{N}$.

Is the existence of the sequence $(t_n)_n$ equivalent to Property (i) of Definition 2.0.4 for $\mathrm{pi}(n)$ in ???? for some $n \in \mathbb{N}$?

PROOF. Recall that the notation $a\,|Y$ for $a \in \mathrm{C_b}(X,B)$ refers to the fact that $\mathrm{C_b}(X,B)$ is a $\mathrm{C_b}(X)$-algebra, i.e., $\mathrm{C_b}(X)$ is unitally contained in $\mathrm{C_b}(X,\mathcal{M}(B)) \subseteq \mathcal{M}(\mathrm{C_b}(X,B))$, and that $\mathrm{C}(\beta X) \cong \mathrm{C_b}(X)$ (both in a natural way).

By Lemma **??**, it sufficed to show that the convex set $\mathcal{S}_{\mathrm{in}}(B) \subseteq \mathrm{CP_{in}}(B)$ of inner c.p. contraction is controlled in the sense of Definition **??**, because this implies the existence of $n \in \mathbb{N}$ such that B satisfies the property (i) of Definition 2.0.4.

Suppose that $\mathcal{S}_{\mathrm{in}}$ is not controlled.

Then there is $\varepsilon > 0$ and a sequence of contractions $a_1, a_2, \dots \in B_+$ such that $\mu(a_n, \mathcal{S}_{\mathrm{in}}(B), 3\varepsilon)\ > 2^n$, i.e., there are $V_n \in \mathcal{S}_{\mathrm{in}}$ such that the equation $\sum_{j=1}^m d_j^* a d_j = (V_n(a_n) - 3\varepsilon)_+$ with contraction $d_1, \dots, d_m \in B$ implies $m \geq 2^n$.

??

`Change text and proof of cor. 2.14.6 !!!`

`Reduction to case:` B `separable,` $X = \mathbb{R}_+$, $Y = \{\omega\}$, $\omega \in \gamma(\mathbb{R}_+)$.
???

?? `proof has to be revised: Consider the case` $X = [1,\infty)$.

`Need following stronger result:`

There exist $\varepsilon \in (0, 1/4)$, a continuous path $t \in [1,\infty) \mapsto a(t) \in B_+$ with $\|a(t)\| \leq 1$, and a point-norm continuous path $t \in [1,\infty) \mapsto S_t \in \mathcal{S}_{\mathrm{in}}(B)$, such that

$$S_t(a(t)) - 3\varepsilon \leq \sum_{j=1}^m d_j^* a d_j\,,$$

with *contractions* $d_1, \dots, d_m \in B$, implies $m \geq t$ (for each fixed $t \in [1,\infty)$).

Remark: If B is separable and all non-zero σ-unital hereditary ????

`Following seems NOT to work:`

We define continuous $g_n(t)$ on $[1,\infty)$ by $g_n(t) := 0$ for $t \in [1,n]$ and $t \geq n+2$, $g_n(n+1) := 1$, and g_n linear on $[n, n+1]$ and on $[n+1, n+2]$. Then we define $a(t) := \sum_{n=1}^\infty g_n(t) a_n \in B_+$ and $S_t(a) := \sum_{n=1}^\infty g_n(t) S_n(a)$ for $t \in [1,\infty)$. The function $a(t)$ defines a positive contraction $a \in \mathrm{C_b}([1,\infty), B)_+$, the map $t \in [1,\infty) \mapsto S_t(a)$ is continuous for each $a \in B$ and $\|S_t\| \leq 1$. Therefore, $S(f)(t) := S_t(f(t))$ for $f \in \mathrm{C_b}([1,\infty), B)$ defines a positive contraction $S \in \mathrm{CP}(\mathrm{C_b}([1,\infty), B))$.

`We proceed with better definition of` $a(x)$ `and` V_x,
`given further above. (or below?)`

`End: suggestion for revision.`

Since X is σ-compact and locally compact, there is a continuous function $h\colon X \to (0,1]$ such that $h^{-1}[\delta, 1]$ is compact for each $\delta \in (0,1]$. We let $V_x(a) := S_t(a)$ and $b(x) := a(t)$ for $t := h(x)^{-1}$.

By definition of $V\,|Y$, the equation $(V\,|Y)(b\,|Y) = c\,|Y$ holds for the map $x \in X \mapsto c(x) := V_x(b(x))$ in $\mathrm{C_b}(X,B)_+$ with $\|c\| \leq 1$. Notice that $((c\,|Y) - \varepsilon)_+ = (c - \varepsilon)_+ |Y$, because $a \in \mathrm{C_b}(X,B) \mapsto a\,|Y \in \mathrm{C_b}(X,B)\,|Y$ is a *-epimorphism.

By our *assumption*, $(c\,|Y)$ is in the ideal generated by $b\,|Y$.

It follows, that there are $m \in \mathbb{N}$ and contractions $e_1, \ldots, e_m \in \mathrm{C_b}(X, B)\,|Y$, such that $\sum_j e_j^*(b\,|Y)e_j = (c-\varepsilon)_+|Y$. Let $f_j \in \mathrm{C_b}(X, B)$ contractions with $f_j\ |Y = e_j$, then

$$r(x) := \left(\sum_{j=1}^{m} f_j(x)^* b(x) f_j(x)\right) - (V_x(b(x)) - \varepsilon)_+$$

defines a selfadjoint element $r \in \mathrm{C_b}(X, B)$ with $r\,|Y\ = 0$.This means for the bounded continuous non-negative function $\lambda \in \mathrm{C_b}(X) \cong \mathrm{C}(\beta X)$ with $\lambda(x) := \|r(x)\|$ for $x \in X$ that $\lambda\,|Y\ = 0$.

The subset $Z := \{x \in \beta X\,;\ \lambda(x) < \varepsilon\}$ is an open subset of βX with $Z \supset Y$. In particular, $Z \neq \emptyset$. Since X is a dense open subset of βX, it follows that $U := X \cap Z$ is a non-empty open subset of X. The set U can not be contained in a compact subset $K \subseteq X$, because, otherwise, $\lambda(x) \geq \varepsilon$ for all $x \in (\beta X) \setminus X$, which is impossible by $\emptyset \neq Y \subseteq (\beta X) \setminus X$ and $\lambda\,|Y = 0$.

Thus, $\inf\{\,h(x)\,;\ x \in U\,\} = 0$, and there exists a sequence $x_1, x_2, \ldots \in U$ with $\lim h(x_n) = 0$, such that $\lambda(x_n) = \|r(x_n)\|\ < \varepsilon$.

Let $x \in U$ with $t := h(x)^{-1} > 2m$. Then $a(t) = b(x)$ and, with $d_j := f_j(x)$,

$$S_t(a(t)) - 2\varepsilon\ =\ V_x(b(x)) - 2\varepsilon\ \leq\ \sum_{j=1}^{m} d_j^* a(t) d_j\,.$$

The latter inequality contradicts the property $m \geq t$ for $a(t)$, S_t and contractions $d_1, \ldots, d_n \in B$. □

15. More on pi(n)-algebras

Recall here for the following Lemma 2.15.1, that an element ... ????

LEMMA 2.15.1. *Let A a C^*-algebra, $D \subseteq A$ a hereditary C^*-subalgebra of A, $\lambda\colon A \to \mathcal{L}(\mathcal{H})$ an irreducible representation such that $\lambda(D) \neq \{0\}$ and such that $\lambda(A)$ does not contain a non-zero operator of finite rank.*

Let $x \in \mathcal{H}$ with $\|x\| = 1$ and $\lambda(D)x \neq 0$, and denote by Q the orthogonal projection from $\mathcal{H}$ onto $\overline{\lambda(D)x}$.

Then, for each $n \in \mathbb{N}$, there exists an n-homogenous positive contraction $a_n \in D_+$ with $2\|\lambda(a_n)x\| \geq \|Qx\| \geq \|\lambda(a_n)x\|$.

PROOF. The restriction of λ to D and to $\overline{\lambda(D)x} \subseteq \mathcal{H}$ is an irreducible representation of D that does not contain any non-zero compact operators in its image, because otherwise it would contain also non-zero operators of finite rank in its image $\lambda(D) \subseteq \mathcal{L}(\mathcal{H})$.

Since $\lambda(D)x$ is a dense vector space in $Q\mathcal{H}$, we find for each given $n \in N$ a linear subspace $L_n \subseteq L_{n+1}$ of $\lambda(D)x$ of dimension $= n$ such that $\mathrm{dist}(Qx, L_n) \leq \|Qx\|/2$.

Let P_n denote the orthogonal projection onto L_n. The variant of the Kadison transitivity theorem given in Lemma 2.1.15 gives that there is a closed projection $q_n \in D^{**}$ of rank $= n$ such that the normal surjective extension $\overline{\lambda|D}\colon D^{**} \to \mathcal{L}(Q\mathcal{H})$ of the restriction $\lambda|D\colon D \to \mathcal{L}(Q\mathcal{H})$ defines an isomorphism Ψ_n from $q_n D^{**} q_n$ onto $\mathcal{L}(P_n\mathcal{H})$ with $\Psi_n(P_n d P_n) = q_n D(d) q_n$ for $d \in D$. In particular $M_n \cong q_n D^{**} q_n$ for some isomorphism γ of M_n with $q_n D^{**} q_n$. By Lemma 2.1.15 there exists a C^*-morphism h from $M_n \otimes \mathrm{C}_0(0,1]$ into D with $q_n h(M_n \otimes \mathrm{C}_0(0,1)) q_n = 0$ and $q_n h(T \otimes f_0) q_n = \gamma(T)$ for $T \in M_n$. In particular $a := h(1_n \otimes f_0)$ is an n-homogenous element in D_+ with $\lambda(a) = \Psi_n(\gamma(1_n)) = P_n$.

`Check it again!   :`

We get $\lambda(a_n)x = \Psi_n(q_n)x = P_n x$, $L_n = P_n\mathcal{H} = P_n Q\mathcal{H}$, and $Qx = P_n x + (Q - P_n)x$ is an orthogonal decomposition for Qx. It follows $\mathrm{dist}(Qx, L_n) = \|Qx - P_n x\| \leq \|Qx\|/2$ by construction of $L_n = P_n\mathcal{H}$.

The orthogonal decomposition $Qx = P_n x + (Q - P_n)x$ leads to

$$\|Qx\|^2 \;=\; \|P_n x\|^2 + \|Qx - P_n x\|^2 \;\leq\; \|P_n x\|^2 + (\|Qx\|/2)^2$$

and gives that $\|Qx\|^2(3/4) \leq \|P_n x\|^2$. It implies that $\|Qx\| \leq 2\|P_n x\|$. □

PROPOSITION 2.15.2. *If A is a pi(n) C^*-algebra then, for each non-zero hereditary C^*-subalgebra $D \subseteq A$ and each pure state λ on A with $\lambda(D) \neq \{0\}$, there exists a hereditary C^*-subalgebra $E \subseteq D$ with $\lambda(E) \neq \{0\}$ such that all non-zero positive elements $b \in J_E$ in the closed ideal $J_E := \overline{\mathrm{span}(AEA)}$ of A generated by E have the property that $b \otimes 1_n$ is properly infinite in $J_E \otimes M_n$.*

Moreover there exist hereditary C^*-subalgebras $E \subseteq D$ with the above properties that satisfy moreover that the ideal $J_E \otimes \mathbb{K}$ of $A \otimes \mathbb{K}$ generated by E has property pi-n.

The primitive ideal space $\mathrm{Prim}(A) \cong \mathrm{Prim}(A \otimes \mathbb{K})$ has a base of its topology that is generated the open subsets that correspond to closed ideals J of A such that $J \otimes \mathbb{K}$ has property pi-n.

Maximal open subsets with this property have the property that ... ????

Idea of proof: Take a maximal family of pairwise orthogonal n^2-homogenous contraction in A_+. The ideal generated by them has this property.

Recall here that the positive integer n for pi(n)-algebras or for the C^*-algebras with property pi-n is only an upper bound. We do not know if there exists for each $n \in \mathbb{N}$ a pi(n)-algebra that is not a pi($n-1$)-algebra. And it is only for pi(1)-algebras (i.e., for the ordinary "purely infinite" C^*-algebras) known that this class of algebras remains invariant under extensions.

Where it is shown that extensions of pi(1) algebras gives pi(1) algebras. Give cite or ref !!!

But we know only that $\mathrm{C}([0,1], A)$ is pi-2 if A is p.i. (= pi-1). This, and the above Proposition 2.15.2 indicates that some sort of "decomposition dimension" of the saturated quasi-compact subsets of Prim(A) plays a role (it means not the covering dimension which is only for Hausdorff spaces the same as the decomposition dimension).

COROLLARY 2.15.3. *The following properties (i), (ii), (iii) and (iv) are equivalent for a (non-zero) C^*-algebra A.*

(i) *A is purely infinite in sense of Definition 1.2.1 – which is equal to the property pi(1) in Definition 2.0.4 –, i.e., A has no character, and, for each $a, b \in A_+$, with b in the closed ideal of A generated by a, and given $\varepsilon > 0$ there exist $d \in A$ with $d^*ad = (b-\varepsilon)_+$.*

(ii) *A has property pi-1 as defined in Definition **??**, i.e., each non-zero element of A_+ is properly infinite, i.e., for each nonzero $a \in A_+$ and $\delta > 0$ there exist $b, c \in A$ with $\|b^*ac\| < \delta$, $\|b^*ab - a\| < \varepsilon$ and $\|c^*ac - a\| < \varepsilon$.*

(iii) *For each $a \in A_+$ and $\varepsilon > 0$ there exist $d, e \in \overline{aAa}$ with $e^*d = 0$ and $d^*d = e^*e = (a-\varepsilon)_+$.*

(iv) *For each $a \in A_+$ and each closed ideal J of A with $a \notin J$ the element $\pi_J(a) \in A/J$ is infinite in A/J, i.e., there exists non-zero $b \in (A/J)_+$ with $\pi_J(a) \oplus b \precsim \pi_J(a)$.*

Refer below to general pi(n) and $\precsim$ rules, where it is possible?! The part (iv) seems to be the suitable definition of for all non-simple C*-algebras.

PROOF. Notice that the definition of $\precsim_A$ for C^*-algebras A is a *local property* in the sense that that the relation $a \precsim_A b$ holds for $a, b \in A_+$, if and only if, $a \precsim_D b$ in the hereditary C^*-subalgebra $D := \overline{(a+b)A(a+b)}$ of A.

(i)⇒(ii): If $a \in A_+$ is a non-zero 2-homogenous element then each element in the hereditary C^*-subalgebra $D := \overline{aAa}$ is properly infinite in D.

Since a is 2-homogenous there exits ????

Then $D \cong M_2(E)$, where E is a hereditary C^*-subalgebra of A that has the property that all elements ???????

Indeed, by definition of 2-homogenous elements there is C^*-morphism $\psi \colon M_2 \otimes \mathrm{C}_0(0,1] \to D$ with $\psi(1 \otimes f_0) = a$. The element $b := \psi(p_{11} \otimes f_0^{1/3})$ has the property that $b \leq a^{1/3}$ and and $d_1^*bd_1 + d_2^*bd_2 = a$ for $d_1 := \psi(p_{11} \otimes f_0^{1/3}) \in A$ and $d_2 := \psi(p_{12} \otimes f_0^{1/3}) \in A$. By Definition 1.2.1 of purely infinite algebras we get that there exists a sequence $c_n \in A$ with $a = \lim c_n^* b c_n$.

We define $E := \overline{bAb}$. If $e \in E_+$ then $e \oplus e \precsim e$, because $\|g_n e g_n - 1_2 \otimes e\| \to 0$ in $M_2 \otimes E$ for $n \to \infty$, where $g_n := \psi(p_{11} \otimes f_0^{1/n})h_{1,n} + \psi(p_{12} \otimes f_0^{1/n})h_{2,n}$ with ??????

It follows that E is a non-zero hereditary C^*-subalgebra of $D \subseteq A$ with the property that each element of E is properly infinite in A (an thus also in D).

Let $D \subseteq A$ a hereditary C^*-subalgebra such that every non-zero elements $d \in D_+$ is properly infinite in A. Then each $d \in D_+$ is also properly infinite in D by Remark **??**.

We show that each $c \in J_+ := \overline{\operatorname{span} ADA_+}$ is properly infinite. Indeed, for each $\varepsilon > 0$ there exist $d_1, \ldots, d_n \in D_+$ and $f_1, \ldots, f_n \in A$ with $(c - \varepsilon/2)_+ = \sum_{k=1}^n f_k^* d_k f_k$. It follows that there is $g \in A$ with $g^* d g = (c - \varepsilon)_+$ for $d := d_1 + \cdots + d_n$. Thus, the element $(c-\varepsilon)_+$ satisfies $d^{1/2} g g^* d^{1/2} \sim_{MvN} (c-\varepsilon)_+^2$, and, hence, is Murray–von-Neumann equivalent to a properly infinite element of D_+. It follows that c is properly infinite in A by Lemma **??**.

If $a \in A_+$ is the limit of elements $a_n \in A_+$, and there exists $\gamma > 0$ such that for each $\delta \in (0, \gamma)$ and $n \in \mathbb{N}$ the elements $(a_n - \delta)_+$ are properly infinite in A_+, then a is properly infinite in A: Given $\varepsilon \in (0, \gamma)$ then there exist $n_0 \in \mathbb{N}$ with $\|a_n - a\| < \varepsilon/3$ for all $n \geq n_0$. By Lemma 2.1.9 there exist contractions $d_n, e_n \in A$ with $d_n^* a d_n = (a_n - \varepsilon/3)_+$ and $e_n^*(a_n - 2\varepsilon/3)_+ e_n = (a - \varepsilon)_+$. Since $(a_n - 2\varepsilon/3)_+ \oplus (a_n - 2\varepsilon/3)_+ \precsim (a_n - \varepsilon/3)$ it follows that $(a-\varepsilon)_+ \oplus (a-\varepsilon)_+ \precsim a$. It implies that a is properly infinite in $\overline{aAa}$.

Thus, if J_τ is an upward directed family of closed ideals of A with the property that all non-zero positive elements of $\bigcup_\tau J_\tau$ are properly infinite, then all non-zero positive elements in the closed ideal $J := \overline{\bigcup_\tau J_\tau}$ are properly infinite.

It follows that A contains a maximal ideal J with the property that all nonzero positive elements $a \in J_+$ are properly infinite.

The maximality implies that J is closed in A.

Suppose that $J \neq A$. Since A has no characters, the quotient A/J can not have a character. Thus, there exists a 2-homogenous element $b = \varphi(1_2 \otimes f_0)$ for some non-zero C^*-morphism $\varphi \colon M_2 \otimes \mathrm{C}_0(0,1] \to A/J$. Since $M_2 \otimes \mathrm{C}_0(0,1]$ is a projective C^*-algebra, there exists a C^*-morphism $\psi \colon M_2 \otimes \mathrm{C}_0(0,1] \to A$ with $\pi_J \psi(1_2 \otimes f_0) = b$. The element $a := \psi(1_2 \otimes f_0)$ is a 2-homogenous element in A that is not in J.

Let $h \colon A \to \mathcal{L}(\mathcal{H})$ an irreducible representation of A, ?????

(ii)⇒(iii):

(iii)⇒(i):

(ii)⇒(iv): The property (ii) says $a \oplus a \precsim a$ for each $a \in A$. If J is a closed ideal of A with $a \notin J$, then this implies that $\pi_J(a) \oplus \pi_J(a) \precsim \pi_J(a)$

??????

(iv)⇒(???): The part (iv) says that for each $a \in A_+$ and closed ideal J of A with $\pi_J(a) \neq 0$ there exists non-zero $b \in (A/J)_+$ with $\pi_J(a) \oplus b \precsim \pi_J(a)$.

This implies that a is properly infinite in A, i.e., $a \oplus a \precsim a$ in A by Lemma **??** ???

Let $J := \{b \in A; a \oplus b \precsim a\}$. The set J is by an observation of J. Cuntz [**?**] a closed ideal of A with the property that $\pi_J(a)$ "finite" in A/J, i.e. the only element $c \in A/J$ with with $\pi_J(a) \oplus c \precsim \pi_J(a)$ is

□

Compare next Rem. with Def. 1.2.1 or Def. of pi-1 or pi in 1st Sect. in Chp. 2!!

REMARK 2.15.4. We recall that a (not necessarily simple) C^*-algebra A is **purely infinite** in the sense of Definition 1.2.1, that is equal to property pi(1) in Definition 2.0.4, if

(i) A is non-zero and has no character, i.e., every irreducible representation has dimension > 1, and
(ii) for every positive a in A, every positive b in the ideal generated by a, and every $\varepsilon > 0$ there exists $d \in A$ such that $\|b - d^*ad\| < \varepsilon$.

We write sometimes 'p.i.' for 'purely infinite'.

From the definition it is easy to see that *non-zero quotients of p.i. algebras are p.i.*

A hereditary C^*-subalgebra $D \subseteq A$ can not have a (non-zero) character χ. Indeed, otherwise a character χ would extend to a pure state ρ on A such that the GNS construction defines an irreducible representation $d_\rho \colon A \to \mathcal{L}(L_2(\rho))$ with the property that the algebra of compact operators $\mathbb{K}(L_2(\rho))$ is contained in $d_\rho(A)$. But this is impossible, because the quotient $A/d_\rho^{-1}(0) \cong d_\rho(A)$ is again purely infinite. But a rank-one projection can not be properly infinite.

Since every positive element in the ideal generated by a is in the norm-closure of elements $\sum_n c_n^* a c_n$, we can express (ii) equivalently:
For $a \in A_+$, $c_1, c_2 \in A$ and $\varepsilon > 0$, there is $d \in A$ with $\|c_1^*ac_1 + c_2^*ac_2 - d^*ad\| < \varepsilon$.

One can see that it suffices to consider here c_1, c_2 in a dense subset of the unit-ball of A and a in a dense subset S of A_+ with the property that $(a - 1/n)_+ \in S$ for all $a \in S$ and $n \in \mathbb{N}$.

There is no essentially better reduction to dense subsets of A_+, because e.g. for any unital A the set $A_+ + (0,1) \cdot 1_A$ is dense in A_+ and always $\sum_j c_j^* a c_j = d^*ad$ for given $c_1, \dots c_n \in A$ if $a \in A_+ + (0,1) \cdot 1_A$ and $d := a^{-1/2}(\sum c_j^* a c_j)^{1/2}$. And this is certainly not equivalent to pure infiniteness.

The reader can see from Definition 1.2.1, e.g. that the algebras of compact operators on a Hilbert space can not be purely infinite, and, more generally, that any quotient A/J of a p.i. algebra A can not contain a (non-zero) Abelian hereditary C^*-subalgebra, i.e., A is *strictly antiliminary* (equivalently expressed: no irreducible representation of A contains a non-zero compact operator in its image).

We list in Proposition 2.15.5 some elementary facts on purely infinite non-simple C^*-algebras. The proofs follow in the given order step by step almost trivially from the foregoing result. The reader can find the proofs of the propositions and corollaries 2.15.5–2.6.5 also in [**462**], [**463**] and [**93**]. The results on extensions and passage to stabilizations are not trivial.

Is it good to use ''stably p.i.'' ?

PROPOSITION 2.15.5. *Let $A \neq \{0\}$ a C^*-algebra.*

(o) *A is p.i., if and only if, $M_n(A)$ is p.i., if and only if, $A \otimes \mathbb{K}$ is p.i.*
 `Compare with other places e.g. Part (iv)`
(i) *Let J is a closed ideal of A, with $\{0\} \neq J \neq A$. Then A is p.i. if and only if, J and A/J are p.i.*
(ii) *Every p.i. algebra A has no irreducible representation that contains a (no-zero) compact operator in its image.*
 In particular, A is strictly antiliminary *(i.e., each non-zero quotient of A is NGCR).*
(iii) *Non-zero hereditary C^*-subalgebras of a p.i. algebra are p.i.*
(iv) *The inductive limit of p.i. algebras is p.i.*
(v) *The C^*-algebra $\prod_n B_n$ of bounded sequences $(a_1, a_2, \ldots)$ with $a_n \in B_n$ is p.i. if B_n is p.i. for every $n = 1, 2, \ldots$.*
 In particular, the ultrapowers B_ω of B are p.i. if $M_2(B)$ is p.i.
(vi) *$M_2(A)$ is p.i. if and only if A is p.i. and, for every $a \in A_+$ and $\varepsilon > 0$, there exist $b, c \in A$ with $b^*c = 0$ and $b^*b = c^*c = (a - \varepsilon)_+$.*
(vii) *If A is p.i. and σ-unital, and has no unital quotient, then A is stable.*
(viii) *Zero is the only semi-finite lower semi-continuous 2-quasi-trace on* $\mathrm{Ped}(A)_+$ *if A is p.i.*

Part (vii) generalizes Zhang's dichotomy for simple p.i. algebras. Its proof reduces to a special case of [**373**, prop. 5.1], cf. our Corollaries 5.5.1 and 5.5.3.

The next result shows that the class of p.i. algebras is closed under extensions.

Temporary we call A **stably p.i.** if $M_2(A)$ is p.i. This is equivalent to the property that $A \otimes \mathbb{K}$ is p.i. by Proposition 2.15.5(vi).

PROPOSITION 2.15.6. *Suppose that A is a C^*-algebra, and J is a closed ideal of A, such that J and A/J are both stably p.i. Then A is stably p.i.*

COROLLARY 2.15.7. *Every p.i. C^*-algebra is stably p.i. This means:*

(i) *$A \otimes \mathbb{K}$ is p.i. , if and only if, A is p.i.*
(ii) *A is p.i. if and only if for every $b \in A_+$ and $\varepsilon > 0$ there exists $c, d \in bAb$ with $c^*d = 0$ and $c^*c = d^*d = (b - \varepsilon)_+$.*

COROLLARY 2.15.8. *Let A a unital C^*-algebra. Every non-zero quotient A/J of A contains a non-unitary isometry, if and only if, 1_A is properly infinite, i.e., if and only if, there exists a unital C^*-morphism $\varphi \colon \mathcal{O}_\infty \to A$.*

PROOF. Easy direction: Suppose that 1_A is properly infinite, – i.e., that there is a unital C^*-morphism $\psi \colon \mathcal{E}_2 = C^*(s, t;\ s^*t = 0,\ s^*s = 1 = t^*t) \to A$ –, then the compositions $\pi_J \circ \psi$ with the C^*-epimorphisms π_J deliver non-unitary isometries in A/J for all closed ideals $J \neq A$ of A.

The less trivial opposite direction is an evident consequence of Part (iii) of Lemma 2.5.3: Let $a := 1$ and $J := I(a)$. Then $\pi_J(a)$ is finite in A/J by 2.5.3(iii).

By assumption on the quotients, it means that $A/J = \{0\}$ and $J = I(a) = A$, i.e., there exist $d \in M_2(A)$ with $d^*(1 \oplus 0)d = 1 \oplus 1$. This gives that 1 is properly infinite in A: $s^*s = 1$, $s^*t = 0$ and $t^*t = 1$ for $s := d_{1,1}$, $t := d_{1,2}$.

There is also a different looking "amazing" elementary argument for a proof of the non-trivial direction. We carry it out in any detail (!) – otherwise it would take only three lines. It goes as follows:

Since A itself contains at least one non-unitary isometry t by our assumptions, the set of the projections $p_t := 1 - tt^*$ for all isometries $t \in A$ is not empty. Consider now the well-defined non-zero closed ideal J of A that is generated by all (co-range) projections p_t, where t runs through *all* non-unitary isometries in A. All positive elements of the ideal J can be approximated by elements of the form d^*p_td, because the family of elements of this type is hereditary and $d^*p_sd + e^*p_te = f^*p_{s\cdot t}f$ for $f := p_sd + se$. (Use here that $p_{s\cdot t} = p_s + sp_ts^*$.)

If $J = A$ then we are ready, because then there exist $t, d \in A$ with $t^*t = 1$ and $\|d^*p_td - 1\| < 1/2$. The isometries $s := p_td(d^*p_td)^{-1/2}$ and t have orthogonal ranges $s^*t = 0$.

We show now that A/J does not contain a non-unitary isometry (in every generality for all unital C^*-algebras A that contain a non-unitary isometry). It implies that $J = A$, i.e., $A/J = \{0\}$ if each non-zero quotient of A contains a non-unitary isometry.

Notice for the following, that a unital C^*-algebra B does not contain any non-unitary isometry, if and only if, every left-invertible element of B is also right-invertible (and vice versa).

By definition of J, the image $\pi_J(t) \in A/J$ of each isometry $t \in A$ is a unitary element in A/J because $p_t := 1 - tt^* \in J$. It implies that also the image $\pi_J(b)$ of each right-invertible or left-invertible element $b \in A$ is invertible in A/J, because $t := b(b^*b)^{-1/2}$ (respectively $t := b^*(bb^*)^{-1/2}$) is an isometry.

We show now that – moreover – for every contraction $a \in A$ with $1 - a^*a \in J$ there exists an isometry $t \in A$ and $d \in A$ such that $b := ta - p_td$ satisfies $\|1 - b^*b\| < 1/2$. Then $p_t \in J$ and $\pi_J(t)^*\pi_J(b) = \pi_J(a)$ is invertible in A/J by above remarks.

Indeed, as shown above, there exists $d \in A$ and an isometry $t \in A$ with

$$\|(1 - a^*a) - d^*(1 - tt^*)d\| < 1/2$$

but this means for $b := ta - p_td$ that $\|1 - b^*b\| < 1/2$.

Thus, for every unital C^*-algebra A, the quotient A/J has the property that each isometry in A/J is unitary, if J denotes the closed ideal of A that is generated by $\{1 - tt^* \,;\, t \in A,\, t^*t = 1\}$. Moreover, above considerations show that this ideal J is equal to the ideal $I(1)$ for $1 \in A$ defined in Lemma 2.5.3(iii). □

DEFINITION 2.15.9. We say that A has the **Global Glimm halving property** if, for each $b \in A_+$ and $\delta > 0$, there exist $e \in A$ with $e^2 = 0$ and $e^*e + ee^* \in bAb$ such that $(b - \delta)_+$ is in the ideal generated by e.

Equivalently expressed:
For each $b \geq 0$ and $\delta > 0$, there is a C^*-morphism

$$\varphi\colon M_2(\mathrm{C}_0(0,1]) \to bAb$$

such that $(b-\delta)_+$ is contained in the *closed* ideal of A generated by the image of φ.

`Here seems to be a wrong definition?:` The original "halving property" says that, for given $X \in A_+$ and $\varepsilon > 0$, there exist $d_1, d_2 \in A$ such that $\|d_1^* X d_2\| < \varepsilon$ and $(X-\varepsilon)_+$ is in the closed ideal $J_1 \cap J_2$ of A, where $J_k := J(d_k^* X d_k)$ is the closed ideal generated by $d_k^* X d_k$.

Is it the same? CHECK!

REMARK 2.15.10. Every purely infinite C^*-algebra has the global Glimm halving property by Proposition 2.15.11.

The other sorts of infinity of C^*-algebras are in a sense of local nature that does not shows any understandable relation to "Glimm having" ...

PROPOSITION 2.15.11. *For every non-zero C^*-algebra A the following properties* (i) *and* (ii) *are equivalent:*

(i) *The algebra A has the Global Glimm halving property (Def. 2.15.9), and, for every $b \in A_+$ and every $\varepsilon > 0$, there is an $m = m(b, \varepsilon) \in \mathbb{N}$, – depending only on b and ε (and not on a) –, such that:*
If b is in the closed ideal generated by $a \in A_+$, then there are $d_1, \ldots, d_m \in A$ with

$$\|b - \sum_{1 \leq j \leq m} d_j^* a d_j\| < \varepsilon\,.$$

(ii) *The algebra A is purely infinite.*

PROOF. (ii)⇒(i): If A is purely infinite, then we can take $m(b, \varepsilon) := 1$ for all $b \in A_+$ and $\varepsilon > 0$. We use Lemma 2.5.15

Corollary 2.15.7 to check the global Glimm halving property:
There are $\tau \in (0, \delta)$ and $d_1, d_2 \in A$ with $d_1^*(a-\tau)_+ d_2 = 0$ and $(a-\delta)_+ = d_j^*(a-\tau)_+ d_j$ $(j = 1, 2)$. Let $e := (a-\tau)_+^{1/2} d_2 d_1^* (a-\tau)_+^{1/2}$, then $e^2 = 0$, $ee^* + e^*e \in aAa$, and $d_2^*(a-\tau)_+^{1/2} e (a-\tau)^{1/2} d_1 = (a-\delta)_+^2$.

(i)⇒(ii): The proof is an adaptation of the proof of Proposition 2.2.1(iv):
By induction, we see from condition (ii), that, for every $a \in A_+$, $\delta > 0$, and $m \in \mathbb{N}$, there exist $f_1, \ldots, f_m$ in the closure of $(a-2\delta)_+ A (a-2\delta)_+$, such that $f_j^* f_i = \delta_{ij} f_1^* f_1$, and $(a-3\delta)_+$ is in the closed ideal of A which is generated by $f_0 := f_1^* f_1$. In particular, A can not have a non-zero character.

Now let $a, b \in A_+$, such that b is in the closed ideal generated by a. Let $\varepsilon > 0$ be given. We define $\rho := \varepsilon/3$, and let $m := m((b-\rho)_+, \rho)$.

There exist $\delta > 0$ and $c_1, \ldots, c_n \in A$, such that

$$\sum_{1\leq k\leq n} c_k^*(a-3\delta)_+ c_k = (b-\rho)_+ \,.$$

Let $f_1, \ldots, f_m$ as above and $f_0 := (f_1)^* f_1$. Then $(b-\rho)_+$ is in the ideal generated by f_0. By definition of m, there exist $d_1, \ldots, d_m \in A$, such that

$$\| \sum_{1\leq j\leq m} d_j^* f_0 d_j - (b-\rho)_+ \| < \rho \,.$$

We define $g \in \mathrm{C}_0((0, \|a\|])$ by $g(t) := 0$ for $t \in [0, \delta]$, $g(t) := t/\delta - 1$ for $t \in [\delta, 2\delta]$, and $g(t) = 1$ for $t \in [2\delta, \|a\|]$. Let $h(t) := (g(t)/t)^{1/2}$.

Then $d := h(a) \cdot \sum_{1\leq j\leq m} f_j d_j$ satisfies $\|d^* a d - b\| < \varepsilon \,.$ □

REMARK 2.15.12. In joint works with Étienne Blanchard and Mikael Rørdam the above observation was used to show the following:

Suppose that A is a separable C^*-algebra and that the primitive ideal space Prim(A) *is Hausdorff, i.e., A is the algebra of continuous sections vanishing at ∞ of a continuous field of simple C^*-algebras in the sense of* [**471**] ([48]).

If, in addition, $\dim(\mathrm{Prim}(A)) < \infty$, *then A is p.i. if and only if every* simple *quotient of A is p.i. (i.e., if every fiber A_x of the continuous field on* Prim(A) *associated to A is p.i.)*

The criteria (i) and (ii) for p.i. algebras applies, because there is a "global" version of the "local " Glimm halving lemma, cf. Remark 2.1.16(ii).

The condition (i) comes from the finite dimension of Prim(A) if the fibers are simple and p.i. A "global" version of the "halving" in Remark 2.1.16(ii) probably does not extend to C^*-bundles with non-simple fibers.

It could be conjectured that also continuous fields of C^*-algebras over a Hausdorff space, and with strongly purely infinite fibers are strongly purely infinite, in particular if the algebra of continuous sections again has a Hausdorff space as primitive ideal space.

16. Characterizations of non-simple strongly p.i. algebras

The strongly purely infinite C^*-algebras A, as defined in Definition 1.2.2, are the C^*-algebras that are later used for our variant of the classification program. We need several equivalent characterizations that allow in special cases to verify the strong pure infiniteness of given C^*-algebras. So far it seems that the study of the zoological garden of possibly different versions of pure infiniteness becomes not easier to study in case of separable nuclear C^*-algebras. And this is obvious, because we have to work also with its ultra-powers and corona algebras that are in general not nuclear.

[48] I.e., A is the algebra of continuous sections vanishing at infinity of a continuous field of simple C^*-algebras over a Polish l.c. space.

We do not use here the later proven results of Chapters 9 or 10 right now (just to underline logical consistency), instead we work formally with the "decoy" version $\mathcal{D}_\infty := \mathcal{O}_\infty \otimes \mathcal{O}_\infty \otimes \cdots$ of $\mathcal{O}_\infty$, to emphasis that we use here only above proved material and results from Appendices A and B.

```
!!!  compare notations in the following with new names
coming from notation in extra papers (started at 2002, now 2018--2021)
```

We recall here the inequalities (2.2) for the definition of *strongly pure infinite* C^*-algebras A:

For any given $a, b \in A_+$ and $\varepsilon > 0$ there exist $d, e \in A$ that satisfy following inequalities 16.1.

$$\| a^2 - d^* a^2 d \| < \varepsilon , \quad \|b^2 - e^* b^2 e\| < \varepsilon \quad \text{and} \quad \|d^* abe\| < \varepsilon . \tag{16.1}$$

If we find for given non-zero $a, b \in A_+$, $\delta \in (0, \max(\|a\|, \|b\|))$ and $\varepsilon \in (0, \delta^2)$, some elements $d, e \in A$ that satisfy the inequality (16.1) with $(a-\delta)_+$ and $(b-\delta)_+$ in place of a and b, then we can find "solutions" d, e of the original inequality (16.1) for a, b itself – but now with the additional upper estimate of the norms $\max\{\|d\| , \|e\|\} \leq (2/\varepsilon) \cdot \max(\|a\|, \|b\|)$ for d and e.

Improvement ??:

Take in $M_2(A)$ the diagonal matrix G with diagonal entries d and e and then the matrix $F := [f_{jk}]$ with entries $f_{11} = a$, $f_{12} = b$ and $f_{21} = 0 = f_{22}$ and diagonal H in $M_2(A)$ with $h_{11} = a^2$, $h_{22} = b^2$ and $h_{12} = 0 = h_{21}$ then $\|G^*(F^*F)G - H\| < 2\varepsilon$.

One has here to find an estimate of the norm $\|G\|$ of G !!!

We need a better estimate to get the formaly stronger matrix diagonalisation property:

For each positive matrix $T = [t_{jk}] \in M_n(A)_+$ and $\varepsilon > 0$ there exists a diagonal matrix G with $\|G * TG - D\| < \varepsilon$ where D is the diagonal of T, i.e. D is the diagonal matrix with entries $d_{jk} := \delta_{jk} \cdot t_{jk}$.

To find an estimate of $\|G\|$ for G, one could use here that, for example,

$$\|d^*(a-\varepsilon)_+^2 d - (a-\varepsilon)_+^2\| < \gamma^2$$

with $\varepsilon \leq \|a\|$ and $\gamma \in (0, \varepsilon)$ implies

$$\|(a-\varepsilon)_+ d\| \leq (\gamma^2 + (\|a\| - \varepsilon)^2)^{1/2} \leq \|a\| .$$

Then notice that $\|a^{-1}(a-\varepsilon)_+ d\| \leq \varepsilon^{-1} \|(a-\varepsilon)_+ d\|$.

REMARK 2.16.1. If A is a strongly purely infinite, J a closed ideal of A and D a non-zero hereditary C^*-subalgebra of A, then A/J and D are again strongly p.i.

To see this, take for $a_1, b_1 \in (A/J)_+$ elements $a, b \in A_+$ with $\pi_J(a) = a_1$ and $\pi_J(b) = b_1$. Find $d, e \in A$ that satisfy inequality (2.2) for a and b then $d_1 := \pi_J(d)$ and $e_1 := \pi_J(e)$ fulfill the Inequality (2.2) for a_1 and b_1 (in place of a, b and d, e).

Let $a, b \in D_+$ and $d, e \in A$ that satisfy the Inequality (2.2). Let $c := a^2 + b^2$ and $\gamma := \|a\|^2 + \|b\|^2$, then, for sufficiently large $n \in \mathbb{N}$, $e_n := c^{1/n} d c^{1/n}$ and $f_n := c^{1/n} e c^{1/n}$ satisfy the Inequality (2.2) with $e_n, f_n \in D$ in place of e, f. It is clear that $\|c\| \leq \gamma$ and it is easy to see that

$$\max(\|a - c^{1/n}a\|\,,\ \|b - c^{1/n}b\|) \ \leq\ \|(1-c^{1/n})c\| \ \leq\ \max\{\,1/(n+1)\,, \gamma\cdot|1-\gamma^{1/n}|\,\}\,.$$

It follows that D is again strongly purely infinite.

`Uses:` $\lim c^{1/n}a = a$ for each $0 \leq a \leq c$: Indeed, it implies $0 \leq a^{1/n} \leq c$ $a^2 \leq \|a\| a \leq \|a\| c$, and therefore

$$\|(1-c^{1/n})a\|^2 = \|(1-c^{1/n})a^2(1-c^{1/n})\| \leq \|a\|\cdot\|(1-c^{1/n})^2 c\| \leq \sup\{(t-t^{1+1/n})^2\,,$$

and

$$\sup\{|t - t^{1+1/n}|\,;\ t \in [0,\gamma]\,\} = \max\{\,1/(n+1)\,, \gamma\cdot|1-\gamma^{1/n}|\,\}\,.$$

LEMMA 2.16.2. *Suppose that a C^*-algebra A contains a dense *-subalgebra B with the properties that $(b^*b - \varepsilon)_+ \in B$ for each $b \in B$ and $\varepsilon > 0$.*

Then A is strongly purely infinite, if and only if, for each $f, g \in B$ and $\varepsilon > 0$, there exist $d, e \in A$ with

$$\max\{\,\|\,(f^*f)^2 \ -\ d^*(f^*f)^2 d\,\|\,,\ \|(g^*g)^2 - e^*(g^*g)^2 e\|\,,\ \|d^*(g^*g)(f^*f)e\|\,\} \ <\ \varepsilon\,. \tag{16.2}$$

The elements $d, e \in A$ in the inequalities (16.2) can be chosen with norms $\leq \varepsilon^{-1}\cdot 2\max\{\,\|f\|^4, \|g\|^4\,\}$.

In particular, inductive limits of strongly purely infinite algebras are strongly purely infinite.

PROOF. If we take in Definition 1.2.2 of s.p.i. C^*-algebras A the elements $a := f^*f$ and $b := g^*g$ then we find $d, e \in A$ that satisfy inequalities (16.2).

Conversely, if $a, b \in A_+$ with $\|a\| = \|b\| = 1$ and $\varepsilon \in (0,1)$ are given, then let $\delta := ???\cdot\varepsilon???$. We find $f = f^*, g = g^* \in B$ with $\|f - a^{1/2}\| < \delta$ and $\|g - b^{1/2}\| < \delta$.

There exist $d, e \in A$ with $\|d\| \leq (2/\varepsilon)????$, ... $\|d^*f^4d - f^4\| < \varepsilon/2$, $\|e^*g^4e - g^4\| < \varepsilon/2$, ... and $\|d^*f^4g^4e - f^4\| < \varepsilon/2$, ... It follows existence of contractions $x, y \in A$ with $x^*f^2x = (a-\gamma)_+$ and $y^*g^2y = (b-\gamma)_+$ ...

By Lemma 2.1.9, there exists contractions $x, y \in A$ with $x^*f_+x = (a^{1/2} - \varepsilon^2/4)_+$

By assumption, there exist exist $d, e \in A$ that satisfy Inequalities (16.2). □

DEFINITION 2.16.3. We say that a C^*-algebra A has the (m.d.) **matrix diagonalization property** if for every matrix $M = [b_{ij}] \in M_2(A)_+$ and $\varepsilon > 0$ there exists a diagonal matrix $D := \mathrm{diag}(d_1, d_2) \in M_2(A)$ with

$$\|D^*MD - \mathrm{diag}(b_{11}, b_{22})\| < \varepsilon\,.$$

PROPOSITION 2.16.4. *The C^*-algebra A is strongly purely infinite, if and only if, A has the matrix diagonalization property (m.d.), cf. Definition 2.16.3.*

PROOF. ??

Suppose that A has the matrix diagonalization property of Definition 2.16.3.

We show that it implies that A is strongly purely infinite in sense of Definition 1.2.2, i.e., that, for every $a, b \in A_+$ and $\varepsilon > 0$, there exist $d, e \in A$ such that

$$\| a^2 - d^* a^2 d \| < \varepsilon , \quad \|b^2 - e^* b^2 e\| < \varepsilon \text{ and } \|d^* abe\| < \varepsilon . \tag{16.3}$$

Here we can apply this formula with non-zero $a, b \in A_+$ replaced by $(a-\gamma)_+$ and $(b-\gamma)_+$ for some $\gamma \in (0, \min(\|a\|, \|b\|))$ we can find a solution (d, e) of the inequalities (16.3) for $\varepsilon := \gamma^2$. Then $\|(a-\gamma)_+ d\|^2 \leq \gamma^2 + (\|a\| - \gamma)^2 \leq \|a\|^2$, and similarly $\|(b-\gamma)_+ e\| \leq \|b\|$.

If $a, b \in A_+$ satisfy $\|a\| = 1 = \|b\|$ and if $\varepsilon \in (0, 1)$, then this gives the general estimate for a solution (d, e) of the inequalities (16.3) with $\max(\|e\|, \|d\|) \leq 1/\varepsilon$, where one uses that e.g. $\|a^{-1}(a-\gamma)_+ d\| \leq \|(a-\gamma)_+ d\| / \gamma$.

Let $a, b \in A_+$ and consider the 2×2-matrix $[a_{ik}] = [a, b]^\top [a, b]$ in $M_2(A)_+$ with entries $a_{11} := a^2$, $a_{22} := b^2$, $a_{21}^* = a_{12} = ab$, and let $\varepsilon > 0$.

By assumption we find $d_1, d_2 \in A$ with

$$\| \operatorname{diag}(d_1, d_2)^* [a_{ik}] \operatorname{diag}(d_1, d_2) - \operatorname{diag}(a, b)\| < \varepsilon .$$

But this implies the Inequalities (16.3) with $d := d_1$ and $e := d_2$.

Conversely suppose that A is strongly purely infinite. Let $c \in A_+$ and take $a := b := c^{1/2}$ in (16.3) for given $\varepsilon > 0$. We observe that the there proposed $d, e \in A$ satisfy $\|d^* cd - c\| < \varepsilon$, $\|e^* ce - c\| < \varepsilon$ and $\|d^* ce\| < \varepsilon$. Which says $\|[d, e]^* \operatorname{diag}(c, 0)[d, e] - \operatorname{diag}(c, c)\| < \varepsilon$ in $M_2(A)$ with $[d, e] := d \otimes p_{11} + e \otimes p_{12}$.

This can be rewritten also as

$$\| \operatorname{diag}(d, e)^* (c \otimes E) \operatorname{diag}(d, e) - \operatorname{diag}(c, c)\| < \varepsilon ,$$

where E denotes the 2×2-matrix with all entries $= 1$.

Now let $M = [b_{ij}] \in M_2(A)_+$ a positive 2×2-matrix and $f := b_{11} + b_{22}$. Then

$$M \leq 2 \operatorname{diag}(b_{11}, b_{22}) \leq 2 \operatorname{diag}(f, f)$$

By operator monotony of the function $t^{1/2}$ this implies that

$$M^{1/2} \leq 2^{1/2} \operatorname{diag}(f^{1/2}, f^{1/2})$$

It follow that

$$M = \lim_{n \to \infty} M^{1/2} \operatorname{diag}(f^{1/n}, f^{1/n}) M^{1/2} ,$$

thus, for $\delta > 0$ there exists $n \in \mathbb{N}$ and $d, e \in A$ such that for $c := f^{1/n}$ (with suitable $n \in \mathbb{N}$) the row matrix

$$[g, h] := [c^{1/2} d, c^{1/2} e] M^{1/2}$$

satisfies

$$\|M - [g, h]^* [g, h]\| < \delta$$

That means, that a given positive matrix $M \in M_2(A)_+$ can be arbitrary well approximated by matrices that are products $[g, h]^* [g, h]$.

Let $u(g^*g)^{1/2} = g$ and $v(h^*h)^{1/2} = h$ the polar decompositions and $\alpha \in (0, 1/2)$ sufficiently small. Define $S := (g^*g)^\alpha u^* = u^*(gg^*)^\alpha$, $T := (h^*h)^\alpha v^*$, $a := (gg^*)^{1/2+\alpha}$ and $b := (hh^*)^{1/2+\alpha}$. Then

$$\operatorname{diag}(S,T)^*[g,h]^*[g,h]\operatorname{diag}(S,T) = [a,b]^*[a,b]$$

and there exist $d, e \in A$ that satisfy the Inequalities (16.3) for a, b with $\max(\|d\|, \|e\|) < 4/\varepsilon$.

Thus, if we have for fixed ε the given 2×2-matrix $M = [b_{ij}] \in M_2(A)_+$ approximated well enough by a matrix $[g,h]^*[g,h]$ and take the α in the above formula small enough then we get

$$\|\operatorname{diag}(d,e)^* M \operatorname{diag}(d,e) - \operatorname{diag}(b_{11}, b_{22})\| < \varepsilon .$$

□

REMARK 2.16.5. Property (m.d.) of a C^*-algebra A implies the (formally stronger) property of A that, for every $m, n \in \mathbb{N}$ with $n > 1$, every positive elements $a_1, \ldots, a_m \in A_+$ and arbitrary elements $x_\ell \in A$ ($\ell = 1, \ldots, n$) there exist *contractions* $d_1, \ldots, d_m \in A$ such that $\|d_j^* a_j d_j - a_j\| < \varepsilon$ for $j = 1, \ldots, m$ and $\|d_j^* x_\ell d_k\| < \varepsilon$ for $\ell = 1, \ldots, n$ and $j \neq k$, $1 \leq j, k \leq m$.

?? [the cite is KirRor2] Compare [**463**, ????], but there are misleading typos that should be read: ?????

DEFINITION 2.16.6. The following properties of C^*-algebras A are between pure infiniteness and strong pure infiniteness.

(lsp) The algebra A is purely infinite and for every non-zero contraction $a \in A$ there exist isometries s, t in the multiplier algebra $\mathcal{M}(D)$ of $D := \overline{(a\,a^* + a^*a)\,A\,(a\,a^* + a^*a)}$ with $s^*t = 0$ and $3 \cdot \|s^*at\| < 2$. (Then we call A **sq-pi**.)

Why not "(lsp)" ? Anyway, it seems to be a bit difficult to use or to compare with others ...

(labs) For every positive contraction $a \in (A_\omega)_+$, there exists a *-monomorphism $\psi\colon C^*(a) \otimes \mathcal{O}_\infty \to A_\omega$ with $\psi(a \otimes 1) = a$. (Then we say that A is **locally $\mathcal{O}_\infty$-absorbing**.)

(lcpi) $\{a\}' \cap A_\omega$ is p.i. for every positive element $a \in (A_\omega)_+$. (A is **locally commutant-p.i.**.)

(cpi) For every separable commutative C^*-subalgebra C of A_ω, there exists a *-monomorphism $\psi\colon C \otimes \mathcal{O}_\infty \to A_\omega$ with $\psi(a \otimes 1) = a$ for $a \in C$. Then A is **commutant purely infinite** or **c.p.i.**.

REMARK 2.16.7. We have following two rows of implications:

s.p.i. ⇔ m.d.p. ⇒ (lsp) ⇒ p.i.

s.p.i. ⇒ (cpi) ⇒ (lcpi) ⇒ (labs) ⇒ p.i.

Here is an equivalent formulations of (c.p.i):

There exist increasing continuous functions $f_n\colon [0,2] \to [0,3]$ with $f_n(0) = 0$ with the property that for n contractions $a_1, \ldots, a_n \in A_+$, there are contractions $d_1, d_2 \in A$ such that

$$\|d_i a_k - a_k d_i\| + \|d_i^* a_k d_j - \delta_{i,j} a_k\| \leq f_n(\gamma(a_1, \ldots, a_n))$$

for $1 \leq k \leq n$, $i, j \in \{1, 2\}$, where we let $\gamma(a_1, \ldots, a_n) := \sup_{1 \leq p,q \leq} \| a_p a_q - a_q a_p \|$.

For every separable and commutative C^*-subalgebra $C \subseteq A_\omega$, the relative commutant $C' \cap A_\omega$ is purely infinite.
(Equivalently: $F(C, A) := (C' \cap A_\omega)/\operatorname{Ann}(C, A_\omega)$ is p.i. for every separable commutative C^*-subalgebra C of A_ω.)

PROPOSITION 2.16.8. *We have the implications:*

$A \cong A \otimes \mathcal{D}_\infty$

implies that

A is s.p.i., if and only if, A_ω is s.p.i.,

and this implies that

$C' \cap A_\omega$ is p.i. for all separable commutative *subalgebras $C \subseteq A_\omega$.*

The latter implies that A is pi(1), iff A pi-1, iff A is p.i. A_ω is p.i.

REMARK 2.16.9. "Strongly" p.i. algebras in the sense of Definition 1.2.2 are p.i.

But it needs some work to see that strongly p.i. algebras in the sense of Definition 1.2.2 have the WvN-property of Definition 1.2.3.

The WvN-property is needed for our classification results. We give in Chapter 3 a proof (based on [**443**] and the joint paper with M. Rørdam [**463**]) that strongly p.i. algebras have the WvN-property.

Compare the remarks at the end of Chapter 3.

$A \otimes F$ is strongly p.i. for $F := \mathcal{O}_\infty \otimes \mathcal{O}_\infty \otimes \ldots$ and for every C^*-algebra A. Notice that $F \cong \mathcal{O}_\infty$ because $\mathcal{O}_\infty \otimes \mathcal{O}_\infty \cong \mathcal{O}_\infty$ and

Give precise citations (!!!) of the work with E. Blanchard and M. Rørdam:

In joint works with E. Blanchard and M. Rørdam about p.i. algebras there are some sufficient criteria for p.i. algebras to be strongly p.i. and the study of some cases where p.i. implies "strongly" p.i. in some cases, e.g.:

If A is p.i. and $\operatorname{Prim}(A)$ is Hausdorff, then A is strongly p.i.

If A is locally p.i. and $\operatorname{Prim}(A)$ is a Hausdorff space of finite dimension, then A is p.i. (and therefore is s.p.i.).

If A is exact and "approximately divisible", ...

Where is the definition of "approximately divisible"? Are they criteria concerning $F(A)$???

... then A is strongly purely infinite if every (additive) lower semi-continuous traces $\tau\colon A_+ \to [0,\infty]$ takes only the values $\{0,\infty\}$. The same happens if $A \cong A \otimes \mathcal{Z}$, where $\mathcal{Z}$ is the Jiang-Su algebra.

The algebras $A \otimes \mathcal{O}_\infty$ are always s.p.i. Separable *nuclear* s.p.i. algebras A are isomorphic to $A \otimes \mathcal{O}_\infty$ ([49])

Since $\mathcal{O}_\infty$ is approximately divisible, cf. Remark B.5.1, this implies that a separable nuclear C^*-algebra A is s.p.i., if and only if, A is approximately divisible and has only trivial lower semi-continuous traces.

`give Refs or Cites:`

An other equivalent to s.p.i. for separable nuclear A is that A tensorial absorbs the Jiang-Su algebra $\mathcal{Z}$ and that A has only trivial l.s.c. traces. (The proof is more engaged then the case of "approximate divisibility".)

If A has real rank zero and is *locally* p.i., then A is *strongly* p.i. (More generally, for each projection p in a locally p.i. algebra A there is $n = n(p, A) \in \mathbb{N}$ such that $p \otimes 1_n$ is infinite in $M_n(A)$. This property holds also for each projection r in each quotient A/J of A – with $n(\pi_J(a), A/J)$ possibly different from $n(p, A)$ –, because A/J is locally p.i. too. Since $p \in J$ for projection $p \in A$, or there is stable hereditary C^*-subalgebra D of pAp that is not contained in J. Then $\pi_J(D)$ is non-zero and stable and contains a non-zero projection $r \in \pi_J(D) \subseteq A/J$. Now let $n := n(r, A/J)$. The stability of $\pi(D)$ allows to define a monomorphism from $r(A/J)r \otimes M_n$ into $\pi(D)$. Thus $\pi_J(D)$ contains an infinite projection. The argument works also if each non-zero hereditary C^*-subalgebra E of each quotient A/J of A contains a non-zero projection r. This projection must be properly infinite by the above arguments (applied to r and the quotients A/I for $J \leq I \leq A$). It again follows that every non-zero $a \in A_+$ is properly infinite, i.e., that A is purely infinite, One gets that A is strongly p.i. if A has real rank zero case, because algebras of real rank zero contain sufficiently many locally central elements: namely just the projections.)

If A is weakly p.i. or if $\mathcal{M}(A)$ is (itself) *locally* p.i., then there is $n \in \mathbb{N}$ such that $M_n(\mathcal{M}(A))$ has a properly infinite unit. (The first case has an estimate $n \leq 1 + 2k$ if A is $pi(k)$.)

Remark 2.16.10. If X is any (non-empty) locally compact Hausdorff space and $\omega \in \beta(X)$.

Where is $\beta(X)$ defined?

[49] The stable and the unital case follow from Theorem M or from [**463**, thm. 8.6], this passes to the general case by the extension property of s.p.i. algebras, which implies that the unit of $\mathcal{M}(A)$ is properly infinite for s.p.i. A and that $\mathcal{E}(\mathcal{O}_\infty, \mathcal{O}_\infty)$ is s.p.i. Alternatively one can use the arguments in Chapter 10.

Let I_ω the kernel of the character χ_ω associated to ω. It is given by

$$f \in \mathrm{C_b}(X) \cong \mathrm{C}(\beta(X)) \mapsto f(\omega) := \chi_\omega(f)\,.$$

We define (similar to the case $X = \mathbb{N}$) the C^*-algebra $A_\omega := \mathrm{C_b}(X, A)/J_\omega$, where $J_\omega := I_\omega \cdot \mathrm{C_b}(X, B)$

It is not immediate but similar to the arguments used in case $\omega \in \beta(\mathbb{N}) \setminus \mathbb{N}$ that we have that A is strongly p.i. if A_ω is strongly p.i.

Clearly the case $\omega \in X$ is trivial, because s.p.i. passes to quotients, cf. Proposition **??** or Proposition 2.17.1.

The proof that strong pure infiniteness of A implies strong pure infiniteness of $\mathrm{C_b}(X, A)$ (at least for σ-compact X) and of its quotient A_ω follows from the the strong pure infiniteness of A and factorizes over the strong pure infiniteness of $\mathrm{C_0}(X, A)$ and its multiplier algebra $\mathcal{M}(\mathrm{C_0}(X, A)) = \mathrm{C_{b,st}}(X, \mathcal{M}(A))$ with σ-unital A and σ-compact X.

(Here, $\mathrm{C_{b,st}}(X, \mathcal{M}(A))$ denotes the C^*-algebra of bounded maps $f\colon X \mapsto \mathcal{M}(A)$ with the property that $x \mapsto f(x)a$ and $x \mapsto af(x)$ are in $\mathrm{C_b}(X, A)$ for all $a \in A$.)

Proof. `to be filled in` **??**

We use the norm-function $N\colon \mathrm{C_b}(X, A) \to \mathrm{C_b}(X)_+$, that is defined as $N(f)(x) := \|f(x)\|$. The norm of $\pi_\omega(f) \in A_\omega$ is then given by $\chi_\omega(N(f)) = \|\pi_\omega(f)\|$. If $\chi_\omega(N(f)) = 0$ then $N(f) \in (I_\omega)_+$. We get $\inf_{x\in X} G(x) = 0$ for all $G \in (I_\omega)_+$ if we use now that $I_\omega \cong \mathrm{C_0}(\beta(X) \setminus \{\omega\})$, and that X is dense in $\beta(X)$.

Let $a_1, a_2 \in A$ positive contractions and $\varepsilon > 0$. Since A_ω is s.p.i., there exist contractions $f_1, f_2 \in \mathrm{C_b}(X, A)$ such that the functions

$$g_{j,k} := N(f_j^* a_j^* a_k f_k - \delta_{j,k} a_j^* a_k) \in \mathrm{C_b}(X)_+$$

satisfy $\chi_\omega(g_{j,k}) < \varepsilon/2$ for $j, k \in \{1, 2\}$.

Let $G(x) := \sum_{j,k} (g_{j,k}(x) - \varepsilon/2)_+$. Then $\chi_\omega(G) = 0$, i.e., $G \in I_\omega$. Thus, $\inf_{x\in X} G(x) = 0$. This implies the existence of $x_0 \in X$ with $G(x_0) < \varepsilon/2$. But this yields $g_{j,k}(x_0) < \varepsilon$ for $j, k \in \{1, 2\}$, and $d_1 := f_1(x_0)$ and $d_2 := f_2(x_0)$ satisfy for $j, k \in \{1, 2\}$ the inequalities

$$\|d_j^* a_j^* a_k d_k - \delta_{j,k} a_j^* a_k\| < \varepsilon\,.$$

□

Question 2.16.11. Let $A := \mathrm{C_0}((1/2, 1], \mathbb{K})$ and $F \subseteq C^*((0, 1], \mathcal{M}(A))$ the C^*-subalgebra that is generated by A and $f\colon t \in (0, 1] \mapsto \psi(t) \cdot 1_{\mathcal{M}(A)}$ with $\psi(t) := \min(2t, 1)$.

Is f an infinite element in F? (certainly not properly infinite).

(It seems not to be such ???, even if one tensors again...???)

17. Permanence properties of strongly p.i. algebras

We list some permanence properties of the class of *strongly p.i.* C^*-algebras A (i.e., where A is "s.p.i.", as defined in Definition ?????):

Passage to non-zero hereditary C^*-subalgebras D of A

A is s.p.i. if A contains a full hereditary C^*-subalgebra D such that D is s.p.i.

Morita-equivalence,

Extensions,

passage to quotients

inductive limits

Each s.p.i. A is the inductive limit of the net of separable C^*-subalgebras that are s.p.i. and are relatively weakly injective in A.

Infinite direct products, $\Pi_\infty(A_1, A_2, \ldots)$, (and passage to its quotients, e.g. A_ω if $A_n := A$)

Commutator algebras of separable amenable C^*-subalgebras of A_ω if A is s.p.i.

spatial tensor product with arbitrary C^*-algebras in case that prime-ideals are cartesian. (Is exactness necessary?)

Some crossed products by quantum groups??

PROPOSITION 2.17.1. *If A is strongly p.i., then every hereditary C^*-subalgebra and every non-zero quotient A/J is strongly p.i.*

PROOF. Let $D \subseteq A$ a hereditary C^*-subalgebra, $a_1, a_2 \in D_+$ positive contractions and $\varepsilon > 0$.

Since $\|a^{4\gamma}a^2 - a^2\| \leq 2\gamma$ for positive contractions $a \in A_+$, we get, for $\gamma := \varepsilon/4$ and $k, j \in \{1, 2\}$, that

$$\delta_{j,k}\|a_j a_k - a_j^{2\gamma} a_j a_k a_k^{2\gamma}\| \leq \varepsilon/2\,.$$

There exist $e_1, e_2 \in A$ such that, for $j, k \in \{1, 2\}$,

$$\|e_j^* a_j^\gamma a_j a_k a_k^\gamma e_k - \delta_{jk} a_j^\gamma a_j a_k a_k^\gamma\| \; < \; \varepsilon/2\,.$$

Because a_1^γ and a_2^γ are positive contractions in D, we obtain that the elements $d_1 := a_1^\gamma e_1 a_1^\gamma$ and $d_2 := a_2^\gamma e_2 a_2^\gamma$ are in D and satisfy, for $j, k \in \{1, 2\}$, the inequalities

$$\|d_j^* a_j a_k d_k - \delta_{jk} a_j a_k\| \; < \; \varepsilon/2 + \varepsilon/2\,.$$

If $J \lhd A$ is a closed ideal, $b_1, b_2 \in (A/J)_+$ and $\varepsilon > 0$, then there are $a_1, a_2 \in A_+$ and $e_1, e_2 \in A$ such that $\pi_J(a_k) = b_k$ and $\|e_j^* a_j a_k e_k - \delta_{jk} a_j a_k\| < \varepsilon$ for $j, k \in \{1, 2\}$. Thus, $d_j := \pi_J(e_j)$, $j = 1, 2$ satisfy $\|d_j^* b_j b_k d_k - \delta_{jk} b_j b_k\| \; < \varepsilon$ for $j, k \in \{1, 2\}$. □

PROPOSITION 2.17.2. *If A is a purely infinite C^*-algebra and B is a simple non-elementary C^*-algebra and at least one of A or B is exact, then $A \otimes B$ is* strongly *purely infinite.*

PROOF. Where is the general definition of " non-elementary C^*-algebra " ???

Does it work well if B is UHF?

What is the bound if for every finite sequence $y_1, \ldots, y_n \in B$, $b_1, b_2 \in B_+$ and $\delta > 0$ there exist contractions $z_1, z_2, g_1, g_2, h_1, h_2 \in B$ such that $\|z_1^* z_2\| \leq \delta$, $\|[z_k, y_1]\| \leq \delta$ for $k = 1, \ldots, n$ $g_k^*(z_k^* b_k z_k) g_k + h_k^*(z_k^* b_k z_k) h_k = (b_k - \delta)_+$.

Since one of A or B is exact, we get from Lemma **??** that

$$\mathcal{F} := \{a \otimes b\,;\; 0 \neq a \in A_+, 0 \neq b \in B_+\}$$

is a "filling family" for $A \otimes B$.

Definition of "filling family" for a C^*-algebra ???

The non-zero elements $a \otimes b \in \mathcal{F}$ are properly infinite in $A \otimes B$ and $a \otimes b \sim a \otimes c$ in $A \otimes B$ for $b, c \in B_+ \setminus \{0\}$.

Moreover we find for $\delta > 0$ elements $g_1, \ldots, g_n \in B$ with $\sum g_\ell^* b g_\ell = (c - \delta)_+$. $h_1, \ldots, h_n$ with

$$\mathrm{diag}((a-\delta)_+, \ldots, (a-\delta)_+) = [h_1, \ldots, h_n]^* a [h_1, \ldots, h_n]\,.$$

Then $D := \sum_\ell h_\ell \otimes g_\ell \in$ satisfies $D^*(a \otimes b) D = (a - \delta)_+ \otimes (c - \delta)_+$.

`Give controlling bound !!`

If follows that it is enough to prove that for each $\delta > 0$, elements $a_1, a_2, c_1, \ldots, c_n \in A_+$, $b_1, b_2, d_1, \ldots, d_n \in B_+$, $y := \sum_{k=1}^n c_k \otimes d_k$ there exist non-zero contractions $x_1, x_2 \in B_+$ with $\|x_j b_j x_j\| \geq \|b_j\| - \delta$ and $x_1 b_1 d_k b_2 x_2 = 0$ for $k = 1, \ldots, n$.

Provided one has a controlling bound for the x_j and/or D depending on $\delta > 0$.

... □

THEOREM 2.17.3. *The minimal (= spatial) C^*-algebra tensor product $A \otimes B$ is strongly p.i. if A and B satisfy at least one of the following conditions:*

(1) *A is strongly p.i. and the natural map $(I, J) \mapsto A \otimes J + I \otimes B$ from $\mathrm{prime}(A) \times \mathrm{prime}(B)$ into $\mathrm{prime}(A \otimes B)$ is surjective.*
(2) *A is weakly p.i, and B is exact, simple and non-elementary.*
(??) *?????????????? If A is (quasi-)traceless, B is exact and tensorial absorbs a tensorial self-absorbing separable unital C^*-algebra $\mathcal{D} \ncong \mathbb{C}$.*

PROOF. `to be filled in` **??** □

COROLLARY 2.17.4. *Let A and B C^*-algebras. The algebra $A \otimes B$ is strongly p.i. if A is strongly p.i. and at least one of the C^*-algebras A or B is exact.*

PROOF. Recall that, by our convention, $A \otimes B$ denotes the completion of the algebraic tensor product $A \odot B$ with respect to the spatial C^*-norm. This is the minimal C^*-norm on the algebraic tensor product $A \odot B$ of C^*-algebras A and B, cf. [**766**], [**767**, thm. IV.4.19]. In particular each non-zero closed ideal of $A \otimes B$ has non-zero intersection with $A \odot B$.

More precisely, it is shown in [**766**], but is not explicitly stated there, that if a C^*-semi-norm N on $A \odot B$ has the property that $N(a \otimes b) > 0$ for each non-zero $a \in A_+$ and non-zero $b \in B_+$, then $\|x\|_{\max} \geq N(x) \geq \|x\|_*$ for each $x \in A \odot B$, where we here (temporary and only here) denote by $\|x\|_*$ the spatial norm. This shows that $\|x\|_*$ is the minimal possible C^*-norm on $A \odot B$, from now on denoted by $\|x\|_{\min} := \|x\|_*$ or simply by $\|x\|$.

But this shows even more: If K is a non-zero closed ideal of $A \otimes B$ then there exist non-zero positive contractions $a \in A_+$ and $b \in B_+$ such that $a \otimes b \in K$, because otherwise for the quotient map $A \otimes B \to (A \otimes B)/K$ would hold $\|x\|_{\min} \geq \|\pi_K(x)\| \geq \|x\|_{\min}$ for all $x \in A \odot B$, which implies $K = \{0\}$. Compare also the stronger result of Lemma A.24.1, in Section 24 of Appendix A.

Thus, every non-zero closed ideal K of the spatial tensor product $A \otimes B$ contains a tensor product $I \otimes J$ of non-zero ideals $I \triangleleft A$ and $J \triangleleft B$.

Exactness of a C^*-algebra A means that for every C^*-algebra B and each closed ideal $J \triangleleft B$ the sequence

$$0 \to A \otimes J \to A \otimes B \to A \otimes (B/J) \to 0$$

is short exact. The exactness property of A induces the exactness of I and A/I for each closed ideal $I \triangleleft A$ of A. Moreover the exactness of A yields the local lifting property for its quotients A/I. The latter yields also the short exactness of the sequences

$$0 \to I \otimes B \to A \otimes B \to (A/I) \otimes B \to 0\,,$$

and all together imply – now by the 3×3-lemma (also called “5 of 6 lemma”) of category theory – the short exactness of

$$0 \to A \otimes J + B \otimes I \to A \otimes B \to (A/I) \otimes (B/J) \to 0\,,$$

i.e., if A or B is exact then for each $I \triangleleft A$ and $J \triangleleft B$ there are natural isomorphisms

$$(A \otimes B)/(A \otimes J + B \otimes I) \cong (A/I) \otimes (B/J)\,.$$

Recall that a closed ideal $K \triangleleft C$ of a C^*-algebra is prime, $K \in \operatorname{prime}(C)$, if $K_1 \cap K_2 \subseteq K$ implies always that at least one of K_1 and K_2 is contained in K for ideals $K_1 \triangleleft C$ and $K_2 \triangleleft C$. The original definition says only that $K_1 \cap K_2 = K$ implies $K_1 = K$ or $K_1 = K$, but one can change this into the above more flexible formulation if we replace K_j by $K + K_j$ for $j = 1, 2$. Then it means that $\pi_K(K_1) \cap \pi_K(K_2) = 0$ implies that $\pi_K(K_1) = 0$ or $\pi_K(K_2) = 0$.

Note that all primitive ideals are prime [**616**, prop. 3.13.10], and in case of separable C^*-algebras all prime ideals are primitive, cf. [**616**, prop. 4.3.6.]. For non-separable A the space of prime ideals $\operatorname{prime}(A)$ is the “sobrification” or “point-wise completion” of the space $\operatorname{Prim}(A)$ of primitive ideals. It means that the lattice of open subsets of $\operatorname{Prim}(A)$ is the same as the lattice of open subsets of $\operatorname{prime}(A)$.

If one of A or B is exact, then the map $(I, J) \mapsto A \otimes J + I \otimes B$ from $\mathrm{prime}(A) \times \mathrm{prime}(B)$ into $\mathrm{prime}(A \otimes B)$ is surjective. To see this, observe that, for a prime ideal K of $A \otimes B$, the maximal possible ideals $I \in \mathcal{I}(A)$ and $J \in \mathcal{I}(B)$ with $A \otimes J + I \otimes B \subseteq K$ are prime, and that the exactness implies then that $K = A \otimes J + I \otimes B$. The maximal I and J with the properties $I \otimes B \subseteq K$ and $A \otimes J \subseteq K$ are well-defined, because, e.g. the set of all algebraic *-ideals $I \in A$ with $I \otimes B \subseteq K$ is closed under finite and infinite *algebraic* sums and under taking the closure.

Indeed, the epimorphism $A \otimes B \to A/I \otimes B/J$ has, – by exactness of A or of B –, precisely the kernel $A \otimes J + I \otimes B$, as we have seen above. If $\pi \colon A \otimes B \to A/I \otimes B/J$ denotes the quotient map, then $\pi(K)$ becomes an ideal of $A/I \otimes B/J$ that must have trivial intersection $\pi(K) \cap (A/I \odot B/J) = \{0\}$ with the algebraic tensor product $A/I \odot B/J$, because otherwise our above considerations on the minimal (= spatial) C^*-norm (here on $A/I \odot B/J$) show that there would be elements $c \in A_+$ and $d \in B_+$ with $c \otimes d \notin A \otimes J + I \otimes B$ and $c \otimes d \in K$. But the latter would imply, by primeness of K, that also the one of the ideals $A \otimes J_1 + I \otimes B$ or $A \otimes J + I_1 \otimes B$ is contained in K, where $I_1 := I + \overline{\mathrm{span}(AcA)}$ and $J_1 := J + \overline{\mathrm{span}(BdB)}$. This contradicts the maximality of the above defined ideals I and J with the property $A \otimes J + I \otimes B \subseteq K$.

In fact, the map

$$(I, J) \in \mathrm{prime}(A) \times \mathrm{prime}(B) \mapsto A \otimes J + I \otimes B \in \mathrm{prime}(A \otimes B)$$

is moreover a homeomorphism of (sober) locally quasi-compact T_0 spaces if one of A or B is exact.

Thus, Theorem 2.17.3(i) applies. □

Since $\mathrm{C}_0(X, A) \cong \mathrm{C}_0(X) \otimes A$ and $\mathrm{C}_0(X)$ is exact, we get from Theorem 2.17.3, Corollary 2.17.4 and Proposition ??:

Corollary 2.17.5. *For every locally compact Hausdorff space X, $\mathrm{C}_0(X, A)$ is strongly purely infinite, if and only if, A is strongly purely infinite.*

Theorem 2.17.6. *Suppose that A is σ-unital. Then $\mathcal{M}(A)$ is strongly p.i., if and only if, A is strongly p.i.*

Proof. By Proposition 2.17.1 the ideal A of $\mathcal{M}(A)$ is strongly p.i., if $\mathcal{M}(A)$ is strongly p.i.

`to be filled in, see extra SPI-paper` ?? □

Corollary 2.17.7. *Let X a non-empty σ-compact locally compact Hausdorff space. The algebra $\mathrm{C}_\mathrm{b}(X, A)$ is strongly p.i., if and only if, A is strongly p.i., if and only if, $\mathrm{Q}(X, A) := \mathrm{C}_\mathrm{b}(X, A)/\,\mathrm{C}_0(X, A)$ is strongly p.i., if and only if, $\mathrm{Q}(X, A)|F$ is strongly p.i. for a non-empty closed subset F of $\beta(X) \setminus X$.*

Proof. The algebra A is s.p.i. if and only if $A \otimes \mathrm{C}_0(X)$ is s.p.i., by Corollary 2.17.5.

If X is σ-compact, A is s.p.i. and $D \subseteq A$ is a σ-unital hereditary C^*-subalgebra, the algebra $\mathrm{C}_0(X, D) \cong D \otimes \mathrm{C}_0(X)$ is σ-unital and s.p.i. By Theorem 2.17.6, it follows that $\mathcal{M}(D \otimes \mathrm{C}_0(X))$ is s.p.i. if and only if $D \otimes \mathrm{C}_0(X)$ is s.p.i.

The algebra $\mathrm{C}_\mathrm{b}(X, D)$ is an ideal of the algebra $\mathcal{M}(\mathrm{C}_0(X, D))$. It implies that $\mathrm{C}_\mathrm{b}(X, D)$ is s.p.i. if $\mathrm{C}_0(X, D)$ is s.p.i. (and σ-unital).

Since X is σ-compact, the C^*-algebra $\mathrm{C}_\mathrm{b}(X, A)$ is the inductive limit of its C^*-subalgebras $\mathrm{C}_\mathrm{b}(X, D)$ with $D \subseteq A$ σ-unital hereditary C^*-subalgebras of A, we obtain that $\mathrm{C}_\mathrm{b}(X, A)$ is s.p.i. if A is s.p.i.,

Now use that $\mathrm{Q}(X, A)|F$ is a quotient of $\mathrm{C}_\mathrm{b}(X, A)$.

Thus, $\mathrm{Q}(X, A)$ (case $F = \beta(X) \setminus X$), $\mathrm{Q}(X, A)|F$ and, in particular, $\mathrm{Q}(X, A)|\{\omega\} =: A_\omega$ for a point $\omega \in F \subseteq \beta(X) \setminus X$ are strongly p.i. by Proposition 2.17.1.

If A_ω is s.p.i. for some $\omega \in \beta(X)$ then A is s.p.i. by Remark 2.16.10. □

We do not know if it is necessary to suppose that X is σ-compact in Corollary 2.17.7.

If X is not σ-compact then in general $\mathrm{C}_\mathrm{b}(X, A)$ is not anymore the inductive limit of its C^*-subalgebras $\mathrm{C}_\mathrm{b}(X, D)$ with hereditary σ-unital $D \subseteq E$, and $\mathcal{M}(D \otimes \mathrm{C}_0(X))$ is possibly not s.p.i.

The class of strongly purely infinite C^*-algebras is closed under extension by the following:

THEOREM 2.17.8. *Let $J \triangleleft A$ a closed ideal. The C^*-algebra A is strongly purely infinite if and only if J and A/J are strongly purely infinite.*

PROOF. We know that A is purely infinite by Theorem **??**.

The proof can easily reduced to the case, where A is separable and unital (thus contains a copy of $\mathcal{O}_\infty$ unitally), and where J is stable. The proof uses the K_1-injectivity of A as an important tool.

See [**443**] for a proof of Theorem 2.17.8. □

18. Strongly p.i. crossed products and generalized Toeplitz algebras

change whole section.

PROPOSITION 2.18.1. *Suppose that A is a C^*-algebra and that $\alpha \in \mathrm{Aut}(A)$ has the property that $\{0\}$ and A are the only α-invariant ideals.*

simple and p.i. crossed products appear in following cases:

If, for every $a \in A_+ \setminus \{0\}$ and $n \in \mathbb{N}$ there exist $b \in A_+ \setminus \{0\}$ such that $b \leq a$ and $\alpha^k(b)$ are pairwise orthogonal, then $A \rtimes_\alpha \mathbb{Z}$ is simple and purely infinite.

above this is wrongly stated

Full-corner endomorphisms, ...????

There is a projection $p \in Z(A^{**})$ such that $\bigvee_{n\in\mathbb{Z}} \alpha^n(p)$ is faithful for A

(or: is not contained in any α-invariant open central projection of A^{**} ????)

and $\alpha^m(p) \perp \alpha^n(p)$ for $m \neq n$.

For every non-zero α-invariant closed central projection p and every $n \in \mathbb{N}$, $a \in A_+$, $\varepsilon > 0$ there is a non-zero central projection $q \leq p$ with $\alpha^j(q)\alpha^k(q) = 0$ for $-n \leq j, k \leq n$ and $\|ra\| + \varepsilon \geq \|pa\|$. Then $A \rtimes_\alpha \mathbb{Z}$ is simple.

A simple and p.i., for every $n \in \mathbb{N}$ there is a unitary $U_n \in F(A)$ such that $\alpha(U_n) = e^{2\pi i/n}U_n$. Then $A \rtimes_\alpha \mathbb{Z}$ is simple.

The action $F(\alpha)$ on $F(A)$ has full spectrum.

PROOF. ??

(Reduction to separable case?) □

COROLLARY 2.18.2. *Suppose that A is purely infinite and simple, and $\alpha \in \mathrm{Aut}(A)$ is such that α_* has infinite order in $\mathrm{Aut}(K_*(A))$. Then $A \rtimes_\alpha \mathbb{Z}$ is purely infinite and simple.*

PROOF. `to be filled in` ?? □

COROLLARY 2.18.3. *Suppose that B is a simple C^*-algebra and $\psi \colon B \to B$ is an endomorphism from B into B, such that for each $a, b \in B_+$ with $\|b\| = 1 \geq \|a\|$ and for each $\varepsilon > 0$ there are $k \in \mathbb{N}$ and $d \in B$ with $\|\psi^k(a) - d^*bd\| < \varepsilon$ (respectively $\|a - d^*\psi^k(b)d\| < \varepsilon$).*

Then the semi-crossed product $B \rtimes_\psi \mathbb{N}$ is purely infinite.

PROOF. Consider the natural circle action on $B \rtimes_\psi \mathbb{N}$ ...

`to be filled in` ??

If $d(A) \cap \mathbb{K}(\mathcal{H}) = \{0\}$ and d is injective then $\mathcal{T}(\mathcal{H}) = \mathcal{O}_{\mathcal{H}}$

$\mathcal{O}_{\mathcal{H}}$ is simple if ??????.

$\mathcal{T}(\mathcal{H})$ is simple, separable, stable and nuclear if A is separable, stable and nuclear, $d(A) \cap \mathbb{K}(\mathcal{H}) = \{0\}$ and there are no-invariant ideals (modular quotients).

PROOF. Use Lemma **??**

(ref. is:: " lem:App.A.fix-algebra.of.compact.group")

and the gauge circle action on $\mathcal{T}(\mathcal{H})$ for nuclearity, exactness and WEP (= weak injectivity).

(here WEP means "weak expectation property" ??) □

DEFINITION 2.18.8. An automorphism α of a C^*-algebra A is **properly outer**, if for every $a \in \widetilde{A} = A + \mathbb{C}1$ and every non-zero hereditary C^*-subalgebra B of A holds that

$$\inf\{\, \|xa\alpha(x)\|\,;\ 0 \leq x\ \in B,\ \|x\| = 1\,\} = 0\,.$$

REMARK 2.18.9. Suppose that A is separable.

(1) By [**578**, thm. 6.6], the automorphism α is properly outer, if and only if, for every non-zero α-invariant closed ideal $I \triangleleft A$ and every unitary u in the multiplier algebra $\mathcal{M}(I)$ holds $\|\alpha|I - \mathrm{Ad}_u\| = 2$.

This is also equivalent to:
There is no non-zero α-invariant $I \triangleleft A$ such that there is a *-derivation δ of I and a unitary $u \in \mathcal{M}(I)$, with $\alpha|I = \mathrm{Ad}_u \circ \exp\delta$.

`Check next again`

(2) Proper outer-ness of α is implied by the property that for each primitive ideal J of $A \rtimes_\alpha \mathbb{Z}$ the group $\widetilde{\mathbb{T}}(\alpha, J)$ of $\lambda \in \mathbb{T}$ $(= S^1)$ with $\widehat{\alpha}_\lambda(J) = J$ is non-trivial, where $\widehat{\alpha}\colon \mathbb{T} \to \mathrm{Aut}(A \rtimes_\alpha \mathbb{Z})$ means the dual action of the $\mathbb{Z}$-action $n \in \mathbb{Z} \mapsto \alpha^n$. (See *proof* of [**478**, lem.1.1].)

(3) If A is separable and simple, then

$$\{1\} \neq \widetilde{\mathbb{T}}(\alpha) := \bigcap_J \widetilde{\mathbb{T}}(\alpha, J)$$

implies that α is inner, cf. [**577**].

(4) The subgroup $\widetilde{\mathbb{T}}(\alpha) \subseteq \mathbb{T}$ is called the *strong Connes spectrum* of α, cf. [**477**].

THEOREM 2.18.10. *Suppose that $G \neq \{e\}$ is a countable discrete group, that A is a separable C^*-algebra A of infinite dimension, and that $\alpha\colon G \to \mathrm{Aut}(A)$ is an action of G on A such that the automorphism $\alpha(g)$ of A is a properly outer for each $g \in G \setminus \{e\}$ (cf. Definition 2.18.8).*

If there is (fixed) $n \in \mathbb{N}$ such that, for each $a, b \in A_+$ with $\|a\| \leq 1 = \|b\|$ and $\varepsilon > 0$, there are $g_1, \ldots, g_n \in G$ and $d_1, \ldots, d_n \in A$ with $\|a - \sum_k d_k^* \alpha(g_k)(b) d_k\| < \varepsilon$, then the reduced crossed product $A \rtimes_{\alpha,r} G$ is simple and purely infinite.

PROOF. Let $\{0\} \neq I \triangleleft A$ invariant under $\alpha(G)$, and let $b \in I_+$ with $\|b\| = 1$. Furthermore, let $a \in A_+$ with $\|a\| = 1$ and $\varepsilon > 0$. By assumption, we find $g_1, \ldots, g_n \in G$ and $d_1, \ldots, d_n \in A$ with $\|a + I\| \leq \|a - \sum_k d_k^* \alpha(g_n)(b) d_k\| < \varepsilon$. Thus $a \in I$ and $I = A$. It follows now from the proof of [**478**, thm. 3.1] or by [**578**, thm. 7.2] that $C := A \rtimes_{\alpha,r} G$ is simple. It can not be (linearly) one-dimensional, because A is (isomorphic to) a C^*-subalgebra of C. We can consider A as a subalgebra of C. Suppose that C is of finite dimension, then A is unital and the reduced group C^*-algebra of G is contained in C

...??? further?

We show that the simple C^*-algebra $A \rtimes_{\alpha,r} G$ is locally purely infinite.

`To be filled in` ?? □

DEFINITION 2.18.11. Let $\alpha\colon G \to \mathrm{Aut}(A)$ an action of a discrete group G on a C^*-algebra A. We write also $\alpha(g)$ for the natural extension $\alpha(g)^{**}$ to the second conjugate A^{**} of A.

The action α has the **weak Rokhlin property** if the center of A^{**} contains a projection p with the properties

(i) $p\alpha(g)(p) = 0$ for all $g \in G \setminus \{e\}$, and
(ii) $\sup_{g\in G} \|p \cdot \alpha(g)(a)\| > 0$ for all nonzero $a \in A$.

The action α has the **residual weak Rokhlin property** if the projection $p \in \mathcal{Z}(A^{**})$ satisfies (i) and the following stronger property (ii*) instead of (ii):

(ii*) For each $a \in A$ and every $\alpha(G)$-invariant closed ideal $J \lhd A$ (with central support q_J in A^{**}) $\|a + J\| = \sup_{g\in G} \|(1 - q_J)p \cdot \alpha(g)(a)\|$.

The action α of a locally compact group G on A is **exact** if $J \rtimes_{\alpha|,r} G$ is the kernel of the natural epimorphism $A \rtimes_{\alpha,r} G \to (A/J) \rtimes_{[\alpha],r} G$ for every $\alpha(G)$-invariant ideal $J \lhd A$.

An l.c. group G is **exact** if every action of G on C^*-algebras is exact.

LEMMA 2.18.12. *The weak Rokhlin property passes to subgroups H of G.*

The weak Rokhlin property for $G = \mathbb{Z}$ or $G = \mathbb{Z}_n$ implies that $\alpha(g)$ is properly outer for each $g \in G \setminus \{e\}$.

The residual Rokhlin property passes to quotients.

PROOF. `to be filled in` ?? □

THEOREM 2.18.13. *Suppose that A is a separable C^*-algebra, G a countable discrete* exact *group, and $\alpha\colon G \to \mathrm{Aut}(A)$ is an action that satisfies (I) and (II):*

(I) *α satisfies the residual Rokhlin* property, i.e., the center $\mathcal{Z}(A^{**})$ of the second conjugate of A contains a projection P with the following properties*
  (a) *$P\alpha(g)(P) = 0$ for all $g \in G \setminus \{e_G\}$*
  (b) *If $R \leq S$ are $\alpha(G)$-invariant A-open central projections with $R \neq S$, then there is $g \in G$ with $(S - R)\alpha(g)(P) \neq 0$.*

(II) *For any $a, b \in A_+$, $c \in A$ and $\varepsilon > 0$ there are$d_1, d_2 \in A$ and $g_1, g_2 \in G$ with $\|d_1^* a d_1 - \alpha(g_1)(a)\| < \varepsilon$, $\|d_2^* b d_2 - \alpha(g_2)(b)\| < \varepsilon$, and $\|d_1^* c d_2\| < \varepsilon$.*

Then $A \rtimes_{\alpha,r} G$ is strongly purely infinite.

`compare the following with the new observations on HarKir and KirSira`

COROLLARY 2.18.14. *Suppose that A is stable and separable, that $h\colon A \to \mathcal{M}(A)$ is non-degenerate, faithful, and satisfies*

(i) *h and its infinite repeat $\delta_\infty \circ h$ are approximately unitarily equivalent in $\mathcal{M}(A)$. (In particular, $h(A) \cap A = \{0\}$.)*
(iii) *$a \in \mathrm{span}(Ah(a)A)$ for all $a \in A_+$.*

(ii) *if* $J \in \mathcal{I}(A)$ *and* $h(J)A \subseteq J$*, then* $h(J) = h(A) \cap \mathcal{M}(A, J)$.

(iv) $\mathcal{M}(h) \circ h$ *is approximately unitarily equivalent to* h *in* $\mathcal{M}(A)$. Check!!!

Then $\mathcal{T}(\mathcal{H}) = \mathcal{O}_{\mathcal{H}}$ *for the Hilbert* A–A *bi-module* $\mathcal{H} := A$ *defined by* $h\colon A \to \mathcal{M}(A)$*, and* $\mathcal{T}(\mathcal{H})$ *is strongly purely infinite.*

check: *Moreover,* $h\colon A \to \mathcal{M}(A)$ *defines a* $\mathrm{KK}(\mathcal{C}\,;\; A, \mathcal{M}(A))$ *equivalence of* A *and* $\mathcal{T}(\mathcal{H}) = \mathcal{O}_{\mathcal{H}}$ *with respect to the matrix operator convex cone* $\mathcal{C}$ *generated by* h*.* This seems strange? Because $\mathcal{M}(A)$ is often KK-trivial?

CHAPTER 3

Nuclear c.p. maps and operator-convex cones

We have seen in Chapter 2, among others, that simple purely infinite algebras in the sense of J. Cuntz are purely infinite in the sense of Definition 1.2.1. Moreover we have shown that *locally* purely infinite (i.e., l..p.i.) simple C^*-algebras are *strongly* purely infinite in the sense of Definition 1.2.2. Now we study the effect of the property of strong pure infiniteness for C^*-algebras on residual nuclear c.p. maps between them. (Notice that strong pure infiniteness of C^*-algebras and residual nuclearity of C^*-morphisms are in general completely unrelated properties.)

We prove in this Chapter 3, among others, that the ultrapower D_ω and asymptotic corona $\mathrm{Q}(\mathbb{R}_+, D)$ of strongly purely infinite algebras D (cf. Definition 1.2.2) satisfy a local version of *Weyl–von-Neumann property* (WvN-property of Definition 1.2.3), cf. Proposition 3.2.15. It implies that the algebras $\mathrm{Q}(\mathbb{R}_+, D)$ are *strongly purely infinite* in the sense of Definition 1.2.2, because they are rich of approximately inner completely positive maps from separable C^*-subalgebras A into commutative C^*-subalgebras C that fix given elements of $A \cap C$. It is a basic observation for the later applications with help of our cone-related KK-theory and to the proof of its equivalence with cone-related un-suspended $\mathcal{E}$-theory.

The WvN-property allows to prove in Chapter 5 variants of generalized Weyl-von Neumann theorems. We use the results of Chapters 3 and 5 in Chapter 6 for the proof of Theorem A and for the proof of Theorem 6.3.1 that is a special case of the, in the last Chapter 12 finally proven, Theorem K.

Remark 3.0.1. We get later results of the following form, that one can consider as an approximate factorization over the cones of sums of matrix algebras.

Let A and B C^*-algebras, $U\colon A \to B$ a nuclear map, $X \subset A_+$ a finite subset of the positive contractions in A and $\varepsilon > 0$.

Then there exist following

(a) a finite dimensional C^*-algebra F,
(b) a c.p. map $V\colon F \to B$ with $\|V\| = \|U\|$,
(c) a C^*-morphism $\phi\colon \mathrm{C}_0((0,1], F) \to A$
(d) a contraction $d \in A_+$ (almost commuting with $\phi(\mathrm{C}_0((0,1], F))$?)

such that $\|U(dad) - U(a)\| < \varepsilon$ for all $a \in X$, and $\mathrm{dist}(dad, \phi(\mathrm{C}_0((0,1], F))) < \varepsilon$ for all $a \in X$, and $\|V(g(1)) - U(d^n\phi(g)d^n)\| < \varepsilon$ for all $g \in \mathrm{C}_0((0,1], F)$.

This means: We can locally "compress" $X \subset A$ – by some approximately inner c.p. map – into a suitable C^*-subalgebra $\phi(\mathrm{C}_0((0,1], F))$ of A and then apply the given nuclear map U to this compressed subset of $\phi(\mathrm{C}_0((0,1], F))$.

This is then in a sense "almost" the restriction U to X.

HERE IS NEEDED a list of "corona" type algebras:

$\mathrm{Q}(\mathbb{R}_+, B)$ (!!!), $\mathrm{Q}(X, B)$ (X with finite dimension??), $\mathrm{Q}^{\mathrm{s}}(B)$ (!!!), some quotients of those, e.g. ultrapowers ...

FIND list of defining properties! Certainly more than sub-Stonean!?

(At present state, in the terminology of Ilijas Farah ...).

B_∞ and B_ω among them?,

Desire: Should be σ-sub-Stonean.

Moreover, should satisfy Kasparov's Technical Lemma (KTL).

It should also require that they all have a property that there are sufficiently many "good" Abelian C^*-subalgebras that allows to get approximate factorization of separable C^*-subalgebras through algebras with regular abelian C^*-algebras.

Would be interesting to see how is the interplay... σ-sub-Stonean versus (KTL).

Where is the Definition "def:res.nuc.cp.map" **??** ???: of residual nuclear (or "residually nuclear") c.p. maps $V : A \to B$ that are "ideal system preserving", i.e., $V(A \cap J) \subseteq J$ for all $J \in \mathcal{I}(B)$ (in case $A \subseteq B$).

Or that (more generally) an map $\lambda : J \in \mathcal{I}(B) \to \lambda(J) \in \mathcal{I}(A)$ from the system of ideals $J \in \mathcal{I}(B)$ of B to the system of ideals $\mathcal{I}(A)$ is given and we require that $V(\lambda(J)) \subseteq J$. ????

The proof of next Theorem needs:

LEMMA 3.0.2. *Let $A \subseteq B$ C^*-algebras, and suppose that A or B strongly p.i.*

Then each residually nuclear *c.p. contraction $V : A \to B$* ([1]) *is approximately 1-step inner, i.e., for each finite subset $F \subset A$ and $\varepsilon > 0$ there exists a contraction $d \in B$ with $\|V(a) - d^*ad\| < \varepsilon$ for all $a \in F$.*

PROOF. WHERE is the Def. of `to be filled in` **??** □

```
Need for later applications the following 1-step inner-ness
(in blue, to be moved to suitable place).
But perhaps we must suppose that φ is itself nuclear?
Define the notion of ``corona type C*-algebra''
```

THEOREM 3.0.3. *Let A an exact C^*-algebra and $\varphi : A \otimes \mathcal{O}_\infty \to B$ a C^*-morphism, and suppose that $V : A \to B$ is a nuclear c.p. map that has the following Property (*):*

[1] The Definition **??** of residual nuclear c.p. maps includes that V is "ideal system preserving", i.e., $V(A \cap J) \subseteq J$ for all $J \in \mathcal{I}(B)$.

(*) *For every* $a \in A_+$*, its image* $V(a)$ *is contained in the closure of the algebraic ideal* $\mathrm{span}(B\varphi(a \otimes 1)B)$ *of* B *that is generated by* $\varphi(a \otimes 1)$.

Then there exist for every finite subset $X \subseteq A$ *and* $\varepsilon > 0$ *an element* $b \in B$ *with* $\|b\|^2 \leq \|V\|$ *and*

$$\|b^*\varphi(a \otimes 1)b - V(a)\| < \varepsilon \quad \textit{for all } a \in X\,.$$

If, in addition, A *is separable and* B *is a "corona" type algebra, then* V *is one-step "inner", i.e.,* $V(a) = b^*\varphi(a \otimes 1)b$ *for all* $a \in A$ *for some* $b \in B$ *with* $\|b\|^2 \leq \|V\|$.

Proposition 3.0.4. *If* A *is separable and exact,* B *is strongly purely infinite (or if* B *is not necessarily s.p.i., but* A *is strongly p.i.) and* $\varphi\colon A \to B$ *is a nuclear* C^**-morphism, then* φ *"extends" to a* C^**-morphism*

$$\varphi_e\colon\, A \otimes \mathcal{O}_\infty \,\to B_\omega \,:=\, \ell_\infty(B)/c_\omega(B)$$

with $\varphi_e(a \otimes 1) = \iota(\varphi(a))$ *for* $a \in A$ *and* $\iota(b) = (b, b, \ldots) + J_\omega$ *for* $b \in B$.

If B *is a strongly purely infinite "corona" algebra*

? Precise Def. of ''corona C*-algebra'' C?
Perhaps in Chp. 5, or extra section in Appendices?
There should be σ-unital D such that C is a non-zero hereditary subalgebra of $\mathcal{M}(D)/D$,
Characterize coronas by ''better than sub-Stonean''? ,

then φ *itself extends to a* C^**-morphism* $\psi\colon A \otimes \mathcal{O}_\infty \to B$ *with* $\psi(a \otimes 1) = \varphi(a)$ *for* $a \in A$.

`Transfer Remark 3.0.5 to suitable place?!`

Remark 3.0.5. Operator-matrix calculations appear in most chapters. We identify often the ternary rings $M_{p,q}(A) \subseteq M_n(A)$ with $\max(p, q) \leq n$ with the tensor products $M_{p,q} \otimes A$. The results of calculations in both of them look sometimes different if we do not care about different interpretations of this calculations.

This difference between this two conventions appears because the correct multiplication $r \cdot c \in e_{11} \otimes A$ of $r \in M_{1,n} \otimes A$ and $c \in M_{n,1} \otimes A$ comes from the identification of columns in $M_{n,1}(A)$ with tensors in $M_{n,1} \otimes A$ and of rows in $M_{1,n}(A)$ with tensors in $M_{1,n} \otimes A$.

Then $M_{1,n}(A) \cdot M_{n,1}(A) = M_{1,1}(A) = A$ but $(M_{1,n} \otimes A) \cdot (M_{n,1} \otimes A) = e_{1,1} \otimes A$ considered in $M_n \otimes A$. If we use in applications both of them, then we have in some cases to observe that we must identify $a \in A$ with $e_{11} \otimes a \in e_{11} \otimes A$.

In other calculation we have to identify $a \in A$ with $1_n \otimes a$ in $M_n \otimes A$. and M_n with $M_n(\mathbb{C} \cdot 1_{\mathcal{M}(A)}) \subseteq \mathcal{M}(M_n(A))$.

If the multiplier algebra $\mathcal{M}(A)$ contains a copy of $\mathcal{O}_2$ with $1_{\mathcal{M}(A)} \in \mathcal{O}_2$, and all elements have to be considered only up to MvN-equivalence, then such differences are usually not important.

1. Exact C^*-algebras and nuclear maps

We recall some definitions and basic facts concerning nuclear maps, exact C^*-algebras and nuclear C^*-algebras. A C^*-algebra B is called **nuclear** if its algebraic tensor $B \odot C$ product with any other C^*-algebra C admits only one C^*-algebra norm ([2]).

U. Haagerup showed in [**340**] with help of results of A. Connes in [**159**] that a C^*-algebra is nuclear if and only if it is *amenable* ([3]). We don't use the (co-homological) *amenability* here, because we work here with special classes of *nuclear maps*, and therefore, we use characterizations of nuclear maps and nuclear C^*-algebras that we recall in Remark 3.1.2(i).

A C^*-algebra B is called **exact** if, for every short exact sequence of C^*-algebras,

$$0 \to J \to A \to A/J \to 0\,,$$

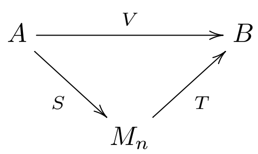
the spatial (or "minimal") tensor products with B of this sequence,

$$0 \to J \otimes B \to A \otimes B \to (A/J) \otimes B \to 0$$

is again exact, i.e., if the closure $J \otimes B$ of the algebraic tensor product $J \odot B$ in $A \otimes B$ is the same as the kernel of the natural C^*-algebra epimorphism $A \otimes B \to (A/J) \otimes B$. With other words: *The algebra B is exact if the functor $A \mapsto A \otimes B$ is a* **short exact functor** *in the category of C^*-algebras.*

Every nuclear C^*-algebra B is exact, because the functor $A \mapsto A \otimes^{\max} B$ is *short-exact* for *every* C^*-algebra B by the "universality" of the maximal C^*-tensor product $A \otimes^{\max} B$ ([4]).

Definition 3.1.1. Let A and B be C^*-algebras and let $V : A \to B$ be a completely positive map. The map V will be called **factorable** if it factorizes through M_n for some n, i.e., if there exist completely positive maps $S : A \to M_n$ and $T : M_n \to B$ such that the diagram



commutes.

By definition, a map $V : A \to B$ is **nuclear** if V can be approximated in point-norm topology by factorable maps (i.e., is the point-wise limit of a net of factorable maps).

---

[2] It was called property (T) by Takesaki [**766**].

[3] The C^*-algebra B is **amenable** if every derivation of an dual Banach B-bi-module X^* is inner, i.e., if X is a Banach B-bi-module and if $\partial : B \to X^*$ satisfies $\partial(ab)(x) = \partial(b)(xa) + \partial(a)(bx)$ for all $a, b \in B$ and $x \in X$, then there is $\rho \in X^*$ with $\partial(a)(x) = \rho(ax - xa)$ for all $a \in B$, $x \in X$.

[4] The algebraic sequence $0 \to J \odot B \to A \odot B \to (A/J) \odot B \to 0$ of algebraic tensor products is always exact, and the same holds then automatic for the maximal C^*-algebra tensor product $\otimes^{\max}$ – in place of $\odot$ – by universality and uniqueness of bi-functor $\odot$.

We say that a completely positive map $V\colon A \to M$ from a C^*-algebra into a von-Neumann algebra M is **weakly nuclear** if it can be approximated in point-$\sigma(M, M_*)$ topology by factorable maps.

The next remark collects a few key observations concerning nuclearity and exactness.

REMARK 3.1.2. In the following denotes $\mathrm{CP}(A, B)$ the (point-norm) closed convex cone of completely positive maps from A into B. The algebraic tensor product and the minimal (respectively maximal) C^*-algebra tensor product of C^*-algebras will be denoted respectively by $A \odot B$ and $A \otimes B$ (respectively by $A \otimes^{\max} B$), corresponding to the minimal C^*-norm $\|\cdot\|_{\min}$ (respectively to the maximal C^*-norm $\|\cdot\|_{\max}$ on $A \odot B$).

(o) The set $\mathrm{CP}_f(A, B)$ of factorable c.p. maps $V\colon A \to B$ is a *convex* cone in the space $\mathcal{L}(A, B)$, – the bounded *linear* maps from A to B with finite-dimensional image in B –, but with the important additional property that the map $a \mapsto c^*\big(V \otimes \mathrm{id}_k(r^*(a)r)\big)c$ is in $\mathrm{CP}_f(A, B)$ for every $k \in \mathbb{N}$, every row matrix $r \in M_{1,k}(\mathcal{M}(A))$ and every column matrix $c \in M_{k,1}(\mathcal{M}(B))$:
Indeed: Let $k = 1, 2$, $V_k = T_k S_k$ with c.p. maps $S_k\colon A \to M_{n_k}$ and $T_k\colon M_{n_k} \to B$. Then $V_1 + V_2 = T_3 S_3$ with

$$S_3\colon A \ni a \mapsto S_1(a) \oplus S_2(a) \in M_{n_1} \oplus M_{n_2} \subseteq M_{n_3}\,,$$

and suitable c.p. maps $T_3\colon M_{n_3} \to B$ for $n_3 := n_1 + n_2$, e.g. for $T_3 := R \circ P$ where P denotes the conditional expectation from M_{n_3} onto $M_{n_1} \oplus M_{n_2} \subset M_{n_3}$, and $R(c \oplus d) := V_1(c) + V_2(d)$ for $c \oplus d \in M_{n_1} \oplus M_{n_2}$).

The set $\mathrm{CP}_f(A, B)$ is a matrix operator-convex cone in sense of Definition 3.2.2 and can be described as follows:
If $V = TS$, then $V \otimes \mathrm{id}_m = (T \otimes \mathrm{id}_m)(S \otimes \mathrm{id}_m)$ is in $\mathrm{CP}_f(A \otimes M_m, B \otimes M_m)$, $(S \otimes \mathrm{id}_m)(r^*(\cdot)r)$ is in $\mathrm{CP}(A, M_{nm})$ for $r \in A \otimes M_n$ and $c(T \otimes \mathrm{id}_m)(\cdot)c^*$ is in $\mathrm{CP}(M_{nm}, B)$ for $c \in B$.

Notice that $\mathrm{CP}_f(A, B)$ is contained in the set $\mathrm{CP}_{f.r.}(A, B) \subseteq \mathrm{CP}(A, B)$ of c.p. maps of finite rank inside $\mathrm{CP}(A, B)$. (But it is still not clear if all c.p. maps $V\colon A \to B$ of finite vector space dimension $\dim(V(A)) < \infty$ are contained in $\mathrm{CP}_f(A, B)$).

The operator-norm closure of $\mathrm{CP}_f(A, B)$ in the Banach space of general bounded linear maps $\mathcal{L}(A, B)$ ([5]) contains all c.p. maps $V\colon A \mapsto B$ of finite rank cf. Lemma 3.1.11(iv).

The finite rank self-adjoint linear maps from A to B are differences of c.p. maps of finite rank (using Lemma 3.1.4).

(i) Simple Hahn-Banach separation arguments (cf. proof of [**426**, lem. 2] or similar arguments in Section 7) show, that a completely positive map $V\colon A \to B$ is nuclear,

[5] This "uniform" closure of $\mathrm{CP}_f(A, B)$ is usually smaller than the point-norm closure, and therefore does not contain all nuclear maps in general.

if and only if, for every C^*-algebra D,

$$V \otimes^{\max} \mathrm{id}_D : \; A \otimes^{\max} D \to B \otimes^{\max} D$$

annihilates the kernel of the natural epimorphism $A \otimes^{\max} D \to A \otimes^{\min} D$, (cf. [**140**], [**726**, prop. 1.2]). I.e., $V \in \mathrm{CP}(A, B)$ *is nuclear, if and only if,* $V \otimes^{\max} \mathrm{id}_D$ *naturally factorizes over the spatial (= minmal) C^*-algebra tensor product* $A \otimes D$.

It suffices to consider unital singly generated D (e.g. by taking stabilization and unitization). If we let $G := C^*(F_2)$, the full group C^*-algebra of the free group F_2 on two generators. Then $D \cong G/J$ for a suitable closed ideal $J \triangleleft G$.

Every C^*-semi-norm μ on the algebraic tensor product $A \odot G$ with $\mu(a \otimes 1) > 0$ for $a \neq 0$ is given on $c \in A \odot G$ by $\mu(c) = \|(\mathrm{id} \otimes \pi_J)(c)\|_\beta$ for suitable $J \triangleleft G$ and some C^*-*norm* $\| \cdot \|_\beta$ on $A \odot (G/J)$ with $\| \cdot \|_{\min} \leq \| \cdot \|_\beta \leq \| \cdot \|_{\max}$, i.e., the kernel of $A \otimes^{\max} D \to A \otimes^{\beta} D$ is contained in the kernel of $A \otimes^{\max} D \to A \otimes^{\min} D$ for $D = G/J$ ([6]). Now notice that $B \otimes^{\max} (\cdot)$ is always a short exact functor, i.e., that $B \otimes^{\max} (J)$ is the kernel of $B \otimes^{\max} G \to B \otimes^{\max} (G/J)$. If we combine the above observations using a diagram check, then we can reformulate the tensorial nuclearity criterion equivalently by the following more flexible criterion:

A map $V \in \mathrm{CP}(A, B)$ *is nuclear, if and only if,* $(V \otimes^{\max} \mathrm{id})(I)$ *is contained in* $B \otimes^{\max} J$ *for every closed ideal* I *of* $A \otimes^{\max} C^*(F_2)$ *with* $I \cap (A \otimes 1) = \{0\}$ *and the largest ideal* J *of* $C^*(F_2)$ *with* $A \otimes^{\max} J \subseteq I$. ([7]).

In particular, *the identity map* id_A *on a C^*-algebra A is nuclear if and only if A is nuclear* ([**140**], [**426**], [**145**]).

(ii) A C^*-algebra $A \subseteq \mathcal{L}(H)$ is exact, if and only if, the inclusion map $A \hookrightarrow \mathcal{L}(H)$ is nuclear. We gave two different proofs in [**432**] and in [**438**]. The proof in [**432**] uses part(i), a simple intersection result (less general than the "distance" lemma [**438**, lem. 3.6]), an inspection of kernels in certain commutative diagrams, and the fact that on the algebraic tensor product $\mathcal{L}(H) \odot C^*(F)$ of $\mathcal{L}(H)$ with the full group C^*-algebra $C^*(F)$ of the free groups F on countably many generators there is only one C^*-norm. The authors proof in [**432**] of the uniqueness of the C^*-norm on $\mathcal{L}(H) \odot C^*(F)$ has been simplified considerably by G. Pisier [**640**].

(iii) The composition of a nuclear map with any other completely positive map is again nuclear. In particular:

(a) $W = b^* V(\cdot) b$ is nuclear if V is nuclear.
(b) The restriction $V|D \colon D \to C$ is nuclear if $D \subseteq A$ is a C^*-subalgebra and $V \colon A \to C$ is nuclear.

Therefore from (i) and (ii) we see, that *nuclear C^*-algebras are exact and that C^*-subalgebras of exact C^*-algebras are again exact.*

---

[6] It follows from [**766**]: A C^*-*semi*norm ν on $A \odot D$ satisfies $\nu(c) \geq \|c\|_{\min}$ for all $c \in A \odot D$, if and only if, $\nu(a \otimes d) > 0$ for each non-zero $a \in A_+$ and $d \in D_+$. See also [**767**, thm. IV.4.19].

[7] It is a special case of a characterization of point-norm closed m.o.c. cones $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ by its associated action $\Psi_{\mathcal{C}} \colon A \otimes^{\max} C^*(F_2) \mapsto A \otimes^{\max} C^*(F_2)$ cf. Section 7.

(c) Every completely positive map from A to B is nuclear if A or B is nuclear, cf. Part (i).

(d) *Every* completely positive map from A to B is nuclear if A is *exact* and B has the *weak expectation property* (i.e., equivalently, B is *weakly injective* in the sense: $\psi\otimes^{\max}\mathrm{id}_C\colon B\otimes^{\max}C \to D\otimes^{\max}C$ for every *-monomorphism $\psi\colon B \to D$ and every C^*-algebra C).
Indeed, let $A \subseteq \mathcal{L}(H)$ and $B \subseteq \mathcal{L}(H)$ (for sufficiently large H and with embedding maps η_A and η_B), then a c.p. contractions $V\colon A \to B$ extends to a c.p. contraction $T\colon \mathcal{L}(H) \to \mathcal{L}(H)$ by the Arveson extension theorem (complete injectivity of $\mathcal{L}(H)$, cf. [**42**]), i.e., $T \circ \eta_A = \eta_B \circ V$ for the inclusion maps η_A and η_B. Then $T \circ \eta_A$ is nuclear by (ii). The nuclearity criteria in part (i) and the above given criteria for the weak injectivity of B show that $V\colon A \to B$ is nuclear.

(e) In general a completely positive map $V\colon A \to B \subseteq C$ is not nuclear as a map from A to B if $V \in \mathrm{CP}_{\mathrm{nuc}}(A, C)$, i.e., where V becomes nuclear if considered as a map from A to C.
(Use part (ii) and the existence of non-nuclear exact C^*-algebras A, as e.g. $V := \mathrm{id}_A$, $A = B = C^*_{\mathrm{red}}(G) \subseteq \mathcal{L}(\ell_2(G)) =: C$ for $G := \mathrm{SL}_2(\mathbb{Z})$.)

(f) Every c.p. map $V\colon A \to B$ of *finite rank*, i.e., with $\mathrm{Dim}(V(A)) < \infty$, is the limit in operator-norm of factorable maps, i.e., there exists a sequence of factorable maps $T_n\colon A \to B$ with $\lim_n \|T_n - V\| = 0$ in the norm of $\mathcal{L}(A, B)$, cf. [**426**], see also Lemma 3.1.11(iv).

(g) It follows from part (f) that the definition of nuclear c.p. maps given in [**426**] and that of M.D. Choi and E.G. Effros in [**140**] define the same class of maps.

(iv) There exist c.p. maps $W\colon A/J \to B$ such that $V := W\circ\pi_J\colon A \to B$ is nuclear, but the map W itself is *not* nuclear.
This follows from the existence of W*-algebras that are not weakly exact (compare Remark B.7.4, [**436**], [**597**]).

It is a *problem to find non-trivial sufficient criteria* on $(A, J \lhd A, B)$ that allow to conclude the nuclearity of $W\colon A/J \to B$ from the nuclearity of $W \circ \pi_J\colon A \to B$. We use non-exact subalgebras of the asymptotic corona $B = \mathrm{Q}(\mathbb{R}_+, D)$, – e.g. in our proofs on the classification of nuclear algebras. Those algebras are often *not locally reflexive*, because $\mathrm{Q}(\mathbb{R}_+, D)$ is locally reflexive, if and only if, D is sub-homogenous.

Local reflexivity is formally weaker than exactness of a C^*-algebra A, i.e., exactness implies that A is locally reflexive. But it was still unknown (June 2019) if local reflexivity implies exactness.

Therefore, we must *bypass* the problem concerning the nuclearity of $[V]_J = W\colon A/J \to B$ for nuclear $V\colon A \to B$ with $V(J) = \{0\}$, and have introduced the notion of Ψ-*residually nuclear* maps, cf. Definition 1.2.8, and recognize that it is of interest for us (!) to know when Ψ-equivariant *and* nuclear c.p. maps are automatically Ψ-*residually nuclear* maps.

(v) Here is a very special case, where one has a positive answer to the problem discussed in Part(iv):
Let $J \lhd A$ a closed ideal and suppose that $J \otimes D \to A \otimes D \to (A/J) \otimes D$ is exact for every unital separable C^*-algebra D ([8]), then it holds:

> (∗) *If* $W \in \mathrm{CP}(A/J, B)$ *and* $W \circ \pi_J$ *is nuclear – i.e.,* $W \circ \pi_J \in \mathrm{CP}_{\mathrm{nuc}}(A, B)$*, then* W *is nuclear.*

Local lifting results of [**238**] for locally reflexive C^*-algebras A show that the sequence

$$J \otimes D \to A \otimes D \to (A/J) \otimes D$$

is exact for every locally reflexive C^*-algebra A, every ideal $J \rhd A$ and every C^*-algebra D. Hence:

$W \in \mathrm{CP}(A/J, B)$ is nuclear if A is locally reflexive and $W \circ \pi_J : A \to B$ is nuclear.

One can see that exact C^*-algebras are locally reflexive, because the separable exact C^*-algebras are quotients of subalgebras of the nuclear CAR-algebra M_{2^∞} by [**438**, cor. 1.4(v)], and sub-quotients of locally reflexive C^*-algebras are locally reflexive by [**238**].

In the mean time the author has obtained the following ?????

Proof of (∗). If $W \circ \pi_J$ is nuclear, then, by Part(i),

$$(W \circ \pi_J) \otimes^{\max} \mathrm{id} \colon A \otimes^{\max} D \to B \otimes^{\max} D$$

(naturally) factorizes over $A \otimes D$, in the sense that $(W \circ \pi_J) \otimes^{\max} \mathrm{id}$ maps the kernel ideal of $A \otimes^{\max} D \to A \otimes D$ to zero. Thus, there is a c.p. map $V \colon A \otimes D \to B \otimes^{\max} D$ with $V \circ \lambda_{A,D} = (W \circ \pi_J) \otimes^{\max} \mathrm{id}$ for the natural *-epimorphism $\lambda_{A,D} \colon A \otimes^{\max} D \to A \otimes D$. It follows that $V(a \otimes d) = W(a + J) \otimes d$ for $a \in A$ and $d \in D$. It yields $V(J \otimes D) = \{0\}$. The exactness of $J \otimes D \to A \otimes D \to (A/J) \otimes D$ implies that there is a C^*-morphism $\beta \colon (A/J) \otimes D \to B \otimes^{\max} D$ with $\beta \circ (\pi_J \otimes \mathrm{id}_D) = \alpha$, i.e., $\beta((a + J) \otimes d) = W(a + J) \otimes d$ for $a \in A$, $d \in D$. Thus, the natural c.p. map $W \otimes^{\max} \mathrm{id} \colon (A/J) \otimes^{\max} D \to B \otimes^{\max} D$ factorizes over $(A/J) \otimes D$.

It implies that $W \colon A/J \to B$ is nuclear by Part(i). □

(vi) Quotients A/J of exact C^*-algebras A are exact.
Indeed: If $A/J \subseteq \mathcal{L}(K)$ and $A \subseteq \mathcal{L}(H)$, then, by the Arveson extension theorem, cf. [**42**], there is a complete contraction $T \colon \mathcal{L}(H) \to \mathcal{L}(K)$ with $T(a) = \pi_J(a)$, i.e., $T \circ \eta_A = \eta_{A/J} \circ \pi_J$, where η indicates the inclusion map. The map $\eta_A \colon A \hookrightarrow \mathcal{L}(H)$ is nuclear by (ii), the maps $\eta_{A/J} \circ \pi_J$ and $\eta_{A/J} \colon A/J \hookrightarrow \mathcal{L}(K)$ are nuclear by Remark (v). See [**436**] for a different proof of exactness for quotients of exact C^*-algebras.

(vii) A C^*-algebra B is nuclear, if and only if, A is exact and the natural *-epimorphism $A \otimes^{\max} C^*(F_2) \to A \otimes^{\min} C^*(F_2)$ is an isomorphism.

[8] The sequence $J \otimes D \to A \otimes D \to (A/J) \otimes D$ is *exact* for $D := \mathcal{L}(\ell_2)$ if and only if $\mathrm{id}_{A/J}$ is locally completely contractive liftable, cf. [**238**].

Indeed: It induces that $A \otimes^{\max} D \to A \otimes^{\min} D$ is an isomorphism for for every hereditary C^*-subalgebra D of $C^*(F_2)$. The exactness of $A \otimes^{\min} (\cdot)$ and the general exactness of $(\cdot) \otimes^{\max} (\cdot)$ imply that the natural C^*-morphisms $A \otimes^{\min} D/J \to A \otimes^{\max} D/J$ are isomorphisms for each closed ideal of D. It is not difficult to see that each separable C^*-algebra is isomorphic to a quotient of a hereditary C^*-subalgebra $C^*(F_2)$. Thus, $A \otimes^{\max} B \to A \otimes^{\min} B$ is an isomorphism for every separable C^*-algebra B. This carries over to all C^*-algebras B, i.e., A is nuclear.

REMARK 3.1.3. In in late 2015 the author has obtained the following characterization of *locally reflexive* separable C^*-algebras B by the following "co-exactness criterium" (unpublished but presented in talks of the author):

A separable C^*-algebra B is locally reflexive, if and only if, for every closed left ideal $L \subseteq \mathbb{K} \otimes B$ and every separable C^*-algebra C the sequence

$$L \otimes^{\min} C \to (\mathbb{K} \otimes B) \otimes^{\min} C \to ((\mathbb{K} \otimes B)/L) \otimes^{\min} C$$

is exact. That means equivalently that the natural linear contraction

$$((\mathbb{K} \otimes B) \otimes^{\min} C)/(L \otimes^{\min} C) \mapsto ((\mathbb{K} \otimes B)/L) \otimes^{\min} C$$

is an isomorphism of Banach spaces.

So far no example of a non-exact separable locally reflexive C^*-algebra has been found. But it is important to check this.

For completeness we give the almost obvious separation on finite sets of linear functionals on C^*-algebras.

LEMMA 3.1.4 (Separation lemma). *If $\rho_1, \ldots, \rho_n$ are continuous linear functionals on a C^*-algebra A, then there is a cyclic *-representation $d \colon A \to \mathcal{L}(\mathcal{H})$ with cyclic vector $\xi \in \mathcal{H}$ of norm $\|\xi\| = 1$, and operators $t_1, \ldots, t_n \in d(A)'$, such that $\rho_k(a) = \langle d(a)\xi, t_k\xi\rangle$ for $a \in A$ and $k = 1, \ldots, n$.*
The operators $t_k \in d(A)'$ are uniquely determined by (d, ξ, ρ_k).

If A is a W^*-algebra and if $\rho_1, \ldots, \rho_n$ are normal, then $d \colon A \to \mathcal{L}(H)$ and can be taken normal, i.e., such that the functionals $\langle d(\cdot)x, y\rangle$ are in the predual A_* of A.

PROOF. Since A^* is the linear span of the positive linear functionals on A, we may suppose that the ρ_k are positive and $\rho_k \neq 0$. Let $\lambda := \sum_k \rho_k$. The cyclic GNS-representation $d \colon A \to \mathcal{L}(\mathcal{H})$ of A with respect to λ has cyclic vector $y \in \mathcal{H}$ with $\|y\|^2 = \|\lambda\|$ and satisfies $\lambda(a) = \langle d(a)y, y\rangle$ for $a \in A$. In particular, $\rho_k(a^*a) \leq \|d(a)y\|^2$. It follows, that there are unique positive contractions $C_k \in \mathcal{L}(\mathcal{H})$ with $\rho_k(c^*b) = \langle d(b)y, C_k d(c)y\rangle$, and the uniqueness of the C_k implies that $C_k d(a) = d(a) C_k$ for $a \in A$, (cf. [**217**, prop. 2.5.1]). Now let $\xi := \|\lambda\|^{-1/2} y$ and $t_k := \|\lambda\| C_k$.

If A is a W*-algebra and the ρ_j are normal, then we can apply the same arguments to the $\rho_1, \ldots, \rho_n$ inside the predual A_* of A. □

The next lemma contains a useful criteria for the nuclearity of a c.p. map $V: A \to B$, that will be used later (e.g. in Chapter 6).

Say precisely where is it used and cited ? in chp.6 ? Give, or cite, or define here what means "*essential*" here.

LEMMA 3.1.5. *Suppose that $D \subseteq B$ is an* essential *hereditary C^*-subalgebra of B with (open) support projection $p_D \in B^{**}$, and that $V: A \to B$ is a completely positive map.*

If $(1-p_D)B^{**}(1-p_D)$ is an injective *W^*-algebra* and *if $a \in A \mapsto V_d(a) := dV(a)d \in D$ is a nuclear map for all $d \in D_+$, then $V: A \to B$ is nuclear.*

PROOF. We use that every c.p. map $W: A \to M$ from a C^*-algebra A to an injective W*-algebra M is weakly nuclear, because

??? the identity map id_M is weakly nuclear for all injective W*-algebras M, ??? only for all ???

and that a c.p. map $V: A \to B$ is nuclear if $V: A \to B^{**}$ is weakly nuclear.

The inclusion map for $A \subseteq L(H)$ is always weakly nuclear ??? Here is some misunderstanding ...

A better argument should be: If $(1-p_D)B^{**}(1-p_D)$ is injective (as vN-algebra), then there exists a central projection $Q \geq (1-p_D)$ in B^{**} such that $B^{**}Q$ is injective. Then the kernel of $b \mapsto bQ$ in a closed ideal J of B with $J \subseteq D$.

But it is not clear if ?????

Indeed, by Definition 3.1.1, each weakly nuclear map is in the point-$\sigma(B^{**}, B^*)$ topology the point-wise limit of factorable maps from A to B^{**} and those can be again point-wise approximated in $\sigma(B^{**}, B^*)$ topology by factorable maps from A to B. Thus, we can then use a Hahn-Banach separation argument to see that $V: A \to B$ can be approximated in point-norm by factorable maps from A to B.

We show the weak nuclearity of $V: A \to B^{**}$:
Let Q denote the smallest central projection of B^{**} with $(1-p_D) \leq Q$. Then $(1-Q) \leq p_D$ and $B^{**}Q$ is an injective W*-algebra.

Thus, $V(a) = (1-Q)V(a) + QV(a)$ is the sum of the weakly nuclear maps $a \mapsto QV(a)$ (by injectivity of $B^{**}Q$) and of $(1-Q)V(a) = (1-Q)p_D V(a) p_D$ (that is an weak limit of $a \mapsto (1-Q)dV(a)d$ with contractions $d \in D_+$).

Hence, V is weakly nuclear – if considered as a c.p. map from A to B^{**}. □

REMARK 3.1.6. Any positive linear map V from a unital complex C^*-algebra B into a C^*-algebra $C \subseteq \mathcal{L}(\mathcal{H})$ has norm $\|V\| = \|V(1_B)\|$, cf. [**402**, exercise 10.5.10] (using [**402**, exercise 10.5.4]), or use the original Russo-Dye theorem [**222**] for complex C^*-algebras to reduce the calculation of the norm $\|V\|$ to the case of the special complex C^*-algebra $B := \mathrm{C}(S^1)$, where all positive V are automatically completely positive. The proof of [**207**, thm. I.8.4] shows the stronger result that set of all convex combinations of finitely many unitaries in a unital C^*-algebra A contains all $a \in A$ with $\|a\| < 1$. This is also shown in [**402**, exercise 10.5.92].

In the case of real C^*-algebras C acting on real Hilbert spaces one has at least $\|V\| \leq \|V_2(1_B \otimes 1_2)\|$ in the case that $V_2 := V \otimes \mathrm{id}_{M_2(\mathbb{R})}$ is positive, because V is "real" 2-positive, and it suffices for real C^*-algebras B to consider the case $C := M_2(\mathbb{R})$.

If a map V is moreover completely positive then this implies that $\|V(1)\| = \|V\| = \|\mathrm{id}_n \otimes V\| = \|V\|_{cb} := \sup_n \|\mathrm{id}_n \otimes V\|$. Here id_n denotes the identity map on M_n and the norm on $M_n \otimes C \subseteq M_n \otimes \mathcal{L}(\mathcal{H}) \cong \mathcal{L}(\ell_2(n) \otimes \mathcal{H})$ is the operator norm.

The complete positivity of a map $V \in \mathrm{CP}(M_n, A)$ implies that $(\mathrm{id}_n \otimes V)(X) \geq 0$ for all $X \in (M_n \otimes A)_+$, where we naturally identify $M_n(A)$ with $M_n \otimes A$.

The *generalized Schwarz inequality* (of R.V. Kadison [**399**]) says that, if a linear map $\eta\colon A \to B$ is positive (i.e., if $\eta(A_+) \subseteq B_+$) and $\|\eta^{**}(1_A)\| \leq 1$, then $\eta(a)^2 \leq \eta(a^2)$ for all $a \in A_{s.a.}$.

`!!  Compare with other remarks above/below !!  e.g next.`

REMARK 3.1.7. We have often to do with positive maps $T\colon C \to A$ between C^*-algebras. This maps T are bounded:
Indeed, otherwise for each $n \in \mathbb{N}$ there would exist $c_n \in C_+$ with $\|c_n\| = 1$ and $\|T(c_n)\| \geq 4^n$, and the well-defined element $S := \sum_n 2^{-n} c_n \in C_+$ must have the – impossible – property $\|T(S)\| \geq 2^{-n}\|T(c_n)\| \geq 2^n$ for all $n \in \mathbb{N}$.

Another often used elementary fact for approximations of positive maps $T\colon C \to A$ used special case is the following property:

Let $C \subseteq \mathcal{M}(A)$ a C^*-subalgebra, $\mathcal{S}$ a set of positive maps from C into A with the property that $S(e(\cdot)e) \in \mathcal{S}$ for all $S \in \mathcal{S}$ and $e \in C_+$. If $T\colon C \to A$ can be approximated in point-norm topology by $S \in \mathcal{S}$, then T is positive and one finds also a point-norm approximation of T by $S \in \mathcal{S}$ with the additional property $\|S\| \leq \|T\|$, cf. Lemma 3.1.8.

The following Lemma 3.1.8 applies to to the particular case of the family of n-step approximately inner c.p. maps $V\colon C \to A$ and to the approximation of nuclear maps by more special factorable maps.

See also Lemma B.16.5(i) in Appendix B.

LEMMA 3.1.8. *Suppose that C is a C^*-algebra and B is a C^*-algebra (respectively that B is a von-Neumann algebra). Denote by $\mathcal{S}$ a* set *of positive linear maps from a C^*-algebra C into B.*

If $V\colon C \to B$ is a contraction *in the closure of $\mathcal{S}$ with respect to the point-norm topology (respectively with respect to the point-strong topology), then V is in the closure of the set of positive maps*

$$\mathcal{S}_1 := \{S(e(\cdot)e)\,;\ S \in \mathcal{S},\, e \in C_+\,,\ \|e\| < 1\,,\ \|S(e^2)\| \leq 1\}$$

with respect to the point-norm topology
(respectively then V is in the closure of the set of positive maps

$$\mathcal{S}_2 := \{fS(e(\cdot)e)f\,;\ S \in \mathcal{S},\ e \in C_+,\ \|e\| < 1,\ f \in B_+, \|f\| \leq 1\, \|fS(e^2)f\| \leq 1\,\}$$

*with respect to the point-*strong topology).*

Notice for later applications of Lemma 3.1.8 that the maps in $\mathcal{S}_1$ and $\mathcal{S}_2$ are *contractions*, but that we do not assume any sort *convexity* for the given set $\mathcal{S}$.

But in cases where we can consider convex sets $\mathcal{S}$, the following general fact in Functional analysis applies and improves Lemma 3.1.8 a bit:
If the point-norm closure of $\mathcal{S} \subseteq \mathcal{L}(C, B)$ is *convex*, then the point-$\sigma(B, B^*)$ closure of $\mathcal{S}$ coincides with its point-norm closure, (respectively the point-$\sigma(M, M_*)$ closure of bounded convex $\mathcal{S} \subseteq \mathcal{L}(C, M)$ coincides with its point-*strong closure of $\mathcal{S}$).

Proof. Case, where B is a C^*-algebra and $V \colon C \to B$ is in the point-norm closure of $\mathcal{S}$:
Let $c_1, \ldots, c_n \in C$ and $\varepsilon > 0$, $M := \max(\|c_1\|, \ldots, \|c_n\|)$, and $\eta := \varepsilon/(2 + M)$. There exists $d \in C_+$ with $\|d\| < 1$ such that $\|dc_jd - c_j\| < \eta$ for $j = 1, \ldots, n$. There is $S \in \mathcal{S}$ with $\|S(d^2)\| \leq \|V(d^2)\| + \eta$ and $\|S(dc_jd) - V(dc_jd)\| < \eta$. Let $t := (1 + \eta)^{-1/2}$, $e := td$ and $T(b) := S(ebe)$ for $b \in C + \mathbb{C} \cdot 1$. Then $\|T\| = \|T(1)\| = t^2\|S(e^2)\| \leq 1$, because T is positive. The map $T|C$ is in $\mathcal{S}_1$ and

$$\|T(c_j) - V(c_j)\| \leq 2t^2\eta + (1 - t^2)M \leq \varepsilon \qquad \text{for} \quad j = 1, \ldots, n\,.$$

Case, where $B \subseteq \mathcal{L}(\mathcal{H})$ is a von-Neumann algebra and $V \colon C \to B$ is in the point-strong closure of $\mathcal{S}$:
Suppose that $B \subseteq \mathcal{L}(\mathcal{H})$, $x_1, \ldots, x_m \in \mathcal{H}$, $c_1, \ldots, c_n \in C$, and $\varepsilon > 0$. Let $\mu := 2\max(1, \|x_1\|, \ldots, \|x_m\|)$, and $c_0 := 1 \in B$. There are $e \in C_+$ with $\|e\| < 1$ and $\|c_k - ec_ke\| < \varepsilon/\mu$. By assumption, there is a directed net (S_γ) of elements of $\mathcal{S}$ such that $S_\gamma(ec_ke)$ converges strongly to $V(ec_ke)$ for $k = 0, 1, \ldots, n$.

The function $h \colon t \in \mathbb{R} \to (0, \infty)$ with $h(0) := 1$ and $h(t) := \min(|t|^{-1/2}, 1)$ for $t \neq 0$ is in $\mathrm{C}_0(\mathbb{R})_+$. Thus, $f_\gamma := h(S_\gamma(e^2)) \leq 1$ converges strongly to $h(V_\gamma(e^2)) = 1$ by [**400**, thm. 5.3.4]. Moreover, $f_\gamma S_\gamma(e^2) f_\gamma \leq 1$. It follows that the map $T_\gamma(c) := f_\gamma S_\gamma(ece) f_\gamma$ (for $c \in C + \mathbb{C} \cdot 1$) is in the set $\mathcal{S}_2$, and has the property that $T_\gamma(c_k)$ converges strongly to $V(ec_ke)$ for $k = 1, \ldots, m$. Thus there is $T \in \mathcal{S}_2$ with $\|T(c_k)x_j - V(c_k)x_j\| \leq \varepsilon/2 + \|c_k - ec_ke\|\|x_j\| < \varepsilon$ for $j = 1, \ldots, m$ and $k = 1, \ldots, n$. □

Proposition 3.1.9. *Let $e_{jk} \in M_n$ denote the matrix units of M_n for $n \in \mathbb{N}$ and let A denote a C^*-algebra.*

There is a bijective and additive relation between the cone of positive matrices $[a_{jk}] \in M_n(A)_+$ and the matrix operator-convex cone of all completely positive maps $V \colon M_n \to A$:

If $[a_{jk}] \in M_n(A)_+$ is given then a completely positive map $V \in \mathrm{CP}(M_n\,,\,A)$ is defined by

$$V(\beta) := \sum_{j,k=1}^{n} \beta_{jk} a_{jk} \quad \text{for all } \beta \in M_n\,.$$

If a completely positive map $V \in \mathrm{CP}(M_n\,,\,A)$ is given, then a positive matrix $[a_{j,k}] \in M_n(A)_+$ is defined by its entries $a_{jk} := V(e_{jk})$. Their norms estimate each other by

$$\|V\|_{cb} = \|V\| = \|a_{11} + a_{22} + \cdots + a_{nn}\| \quad \text{and} \quad \|[a_{jk}]\| \leq n\|V\|\,.$$

Following Parts (o)-(iv) show more details:

(o) *If $e_{jk} \in M_n$ denote the n^2 canonical matrix-units and if $V \colon M_n \to A$ is a completely positive map from M_n into a C^*-algebra A, then the linear map $\mathrm{id}_n \otimes V \in \mathcal{L}(M_n \otimes M_n, M_n \otimes A)$ is a positive map from $M_n \otimes M_n$ to $M_n \otimes A$. In particular, the matrix $[V(e_{jk})] = (\mathrm{id}_n \otimes V)([e_{jk}]) =: [a_{jk}]$ is positive in the C^*-algebra $M_n(A)$.*

(i) *If $[a_{jk}] \in M_n(A)$ is a positive element in the C^*-algebra $M_n(A)$, then there exists column matrices $c_1, \ldots, c_n \in M_{n,1}(A)$ such that the completely positive map $V \in \mathrm{CP}(M_n, A)$ defined by*

$$V(\beta) := \sum_{k=1}^{n} c_k^* \beta c_k \quad \text{for all } \beta \in M_n$$

satisfies $V(e_{jk}) = a_{jk}$ for $j,k \in \{1,\ldots,n\}$. Thus, $V(\beta) = \sum_{j,k} \beta_{j,k} a_{jk}$ and $\|V\| = \|V\|_{cb} = \|a_{11} + \cdots + a_{nn}\|$.

It implies that $\| \sum_{k=1}^{n} c_k^* c_k \| = \|V\|$ ([9]).

(ii) *Suppose that A has the property that for every positive contraction $a \in A_+$ and $\varepsilon > 0$ there exist elements $b_1, b_2 \in A$ with $\|b_j^* b_k - \delta_{jk} a\| < \varepsilon$ for $j,k \in \{1,2\}$ ([10]).*

Then each $V \in \mathrm{CP}(M_n\,, A)$ can be "orthogonal and elementary approximated in norm" – in the sense that for each $\gamma \in (0,1)$ there exist columns $d_0, d_1 \in M_{n,1}(A)$ with $d_0^* \beta d_1 = 0$ and $d_0^* \beta d_0 = d_1^* \beta d_1$ for all $\beta \in M_n$, and with the property that the completely positive map $U(\beta) := d_0^* \beta d_0$ ($\beta \in M_n$) satisfies that $V - U$ is a completely positive map with $\|V - U\| < \gamma$. In particular, $U(1_n) \leq V(1_n)$ and $\|d_0\| = \|d_1\| \leq \|V\|^{1/2}$.

(iii) *If $A = D/J$ for a C^*-algebra D and a closed ideal J of D, then there exists a c.p. map $T \colon M_n \to D$ with $\pi_J \circ T = V$ and $\|T\| = \|V\|$.*

(iv) *Let $A \subseteq N$ a C^*-subalgebra of a W^*-algebra N that is weakly dense in N and let $T \colon M_n \to N$ a c.p. contraction.*

*Then there exists a net $\{V_\rho\}$ of c.p. contractions $V_\rho \colon M_n \to A$ that converges in point-*ultrastrong topology to T.*

Part (ii) applies e.g. if the unit element of $\mathcal{M}(A)$ is properly infinite or if A is purely infinite, cf. Lemma 2.1.7(ii). Equivalent formulations of the additional

[9] Here we identify M_n naturally with $M_n(\mathbb{C} \cdot 1) \subseteq M_n(\mathcal{M}(A))$.

[10] We don't require here that $b_j b_j^* \in \overline{aAa}$.

assumption in Part (ii) can be found in Parts (b, i) and (b,iii) of Lemma 2.1.12. We use in our proof also the equivalence of Parts (a, i) and (a,ii) of Lemma 2.1.12.

PROOF. Let $\mathcal{M}(A)$ denote the C^*-algebra of two-sided multipliers of A. We identify naturally $M_n(A) \subseteq M_n(\mathcal{M}(A))$ with $M_n \otimes A \subseteq M_n \otimes \mathcal{M}(A)$ and $M_n = M_n(\mathbb{C})$ with $M_n \otimes 1 \subseteq M_n \otimes \mathcal{M}(A)$. ([11]).

(o): We identify sometimes $M_n(A)$ with $M_n \otimes A$ naturally. By Remark 3.1.6, the complete positivity of $V \in \mathrm{CP}(M_n, A)$ implies that $\|V(1_n)\| = \|V\| = \|\mathrm{id}_n \otimes V\|$ and $(\mathrm{id}_n \otimes V)(X) \geq 0$ for all $X \in (M_n \otimes A)_+$.

Recall that the matrix units $e_{ij} := e_i^* e_j \in M_n$, for $i, j = 1, \ldots, n$, are build from row-matrices

$$e_1 := [1, 0, 0, \ldots, 0]\,, \;\; e_2 := [0, 1, 0, \ldots, 0]\,, \;\ldots,\;\; e_n := [0, 0, \ldots, 0, 1]$$

that are the elements of the canonical basis of $M_{1,n}(\mathbb{C}) \cong \mathbb{C}^n$.

The $n^2 \times n^2$ matrix $E \in M_n(M_n)$ with the $n \times n$ matrices $e_{ij} \in M_n$ as its entries is given by $E := [e_{ij}] \in M_n(M_n)$ and can be expressed as $E = \sum_{ij} e_{ij} \otimes e_{ij} \in M_n \otimes M_n \cong M_n(M_n)$. It is positive in $M_{n^2} \cong M_n \otimes M_n$ because $E = R^* R$ for the row-matrix $R := [e_1, e_2, \ldots, e_n] \in M_{1,n^2}$, the norm of E is $\|E\| = n$ because $P := n^{-1}E$ is an orthogonal projection.

We define a matrix $F = [f_{jk}] \in M_n(A) \cong M_n \otimes A$ by taking its entries $f_{ij} := V(e_{ij})$, i.e., define

$$F := (\mathrm{id}_n \otimes V)(E) \;=\; \sum_{i,j} e_{ij} \otimes V(e_{ij}) \in M_n \otimes A\,.$$

Then $F \in M_n(A)_+$ is a positive matrix by the assumption of complete positivity of V, and $V(\beta) \;= \sum_{j,k=1}^n \beta_{jk} f_{j,k}$ for $\beta \in M_n$, because $P := n^{-1}E$ is an orthogonal projection in $M_n \otimes M_n$. The norm of F can be estimated roughly by

$$\|F\| \leq n\|\mathrm{id}_n \otimes V\| = n\|V(1_n)\| = n\|f_{11} + \cdots + f_{nn}\|\,.$$

(i): Let F any positive matrix in $M_n(A)_+$ with entries $f_{jk} \in A$, and let $G := F^{1/2} \in M_n(A)_+$ with entries $g_{ij} \in A$. We define a map $V \colon M_n \to A$ by $V(e_{jk}) := f_{j,k}$, i.e., $V(\beta) := \sum_{j,k=1}^n \beta_{j,k} f_{j,k}$. The complete positivity of the below shown alternative expression for the above defined map $V \colon M_n \to A$, – as sum of elementary c.p. maps $\beta \mapsto c^* \beta c$ with some $c \in M_{n,1}(A)$ –, implies then that V must be completely positive.

In conjunction with Part (i), this shows moreover:
Each completely positive map $V \in \mathrm{CP}(M_n, A)$ can be expressed as sum of n maps of the form $\beta \mapsto c^* \beta c$ with columns $c \in M_{n,1}(A)$.
(The $c_k \in M_{n,1}(A)$ are *not* uniquely determined by this property.)

We can rewrite the matrix $G \in M_n(A)_+$ in the notation for elements of $M_n \otimes A$ as $G = \sum_{i,j} e_{ij} \otimes g_{ij} \in M_n \otimes A$. The equations $G^* = G$ and $G^2 = F$ imply that

[11]Matrices $b = [b_{jk}] \in M_n(\mathcal{M}(A))$ with entries $b_{jk} \in \mathbb{C} \cdot 1$ can be written as $b = \beta \otimes 1$ with unique $\beta \in M_n$.

$g_{ij}^* = g_{ji}$ and $\sum_{k=1}^n e_{ij} \otimes g_{ik}g_{kj} = e_{ij} \otimes V(e_{ij})$, i.e.,

$$f_{ij} = V(e_{ij}) = \sum_{k=1}^{n} g_{ki}^* g_{kj} .$$

We define columns $c_1, c_2, \ldots, c_n \in M_{n,1}(A) \cong M_{n,1} \otimes A \subseteq M_n \otimes A$ by

$$c_k := [g_{k,1}, g_{k,2}, \ldots, g_{k,n}]^\top \in M_{n,1}(A) ,$$

i.e., take here the *transposes* of the rows $r_k = [g_{k,1}, g_{k,2}, \ldots, g_{k,n}]$ in $M_{1,n}(A)$ of the $n \times n$-matrix $G \in M_n(A)$ ([12]).

In the tensorial terminology with $a \in A$ identified with $e_{11} \otimes a$ it can be rewritten as $c_k = \sum_j e_{j1} \otimes g_{k,j}$.

It gives that $c_k^*(e_{ij} \otimes 1)c_k = e_{11} \otimes (g_{k,i}^* g_{k,j}) = e_{11} \otimes g_{ik}g_{k,j}$ for $k \in \{1, \ldots, n\}$, and implies $e_{11} \otimes V(e_{ij}) = \sum_{k=1}^n c_k^*(e_{ij} \otimes 1)c_k$ for $i, j \in \{1, \ldots, n\}$.

Notice that the products $c_j^* X c_k$ are in $e_{11} \otimes A$ for all $X \in M_n(A) \cong M_n \otimes A$ if we consider columns c_j as element of $M_{n,1} \otimes A$, i.e., as the element $\sum_j e_{j1} \otimes g_{k,j} \in M_n$. Then $c_k^*\big(e_{ij} \otimes 1_{\mathcal{M}(A)}\big)c_k = e_{11} \otimes g_{i,k}g_{k,j}$ and, therefore,

$$\sum_k c_k^*\big(\beta \otimes 1_{\mathcal{M}(A)}\big)c_k = e_{11} \otimes V(\beta) .$$

Hence $e_{11} \otimes V(\beta) = \sum_{k=1}^n c_k^*(\beta \otimes 1_{\mathcal{M}(A)})c_k$ for $\beta \in M_n$.

If we identify M_n with $M_n(\mathbb{C}1) \subseteq M_n(\mathcal{M}(A)) = \mathcal{M}(M_n(A))$, then $c_k^* e_{ij} c_k = g_{k,i}^* g_{k,j} = g_{i,k} g_{k,j}$. Thus, $\sum_k c_k^* e_{ij} c_k = \sum_k g_{i,k} g_{k,j} = V(e_{ij})$, which implies that $\sum_k c_k^* \beta c_k = V(\beta)$ for all $\beta \in M_n$, i.e., the conventional interpretation says that there are columns $c_1, \ldots, c_n \in M_{n,1}(A)$ that satisfy:

$$V(\beta) = \sum_{k=1}^{n} c_k^* \beta c_k \qquad \text{for all } \beta \in M_n .$$

(ii): We identify M_n with $M_n(\mathbb{C}1) = M_n \otimes 1 \subseteq M_n(\mathcal{M}(A))$, where $1 := 1_{\mathcal{M}(A)}$. By Part (i) there exists columns $c_1, \ldots, c_n \in M_{n,1}(A) \cong M_{n,1} \otimes A$ that satisfy $V(\beta) = \sum_k c_k^* \beta c_k$. The entries of c_k are given by $c_{\ell,1}^{(k)} := g_{k,\ell}$ i.e.,

$$c_k := [g_{k,1}, g_{k,2}, \ldots, g_{k,n}]^\top ,$$

and the $g_{j,k}$ are entries of a positive matrix $G = [g_{j,k}]^2 = [V(e_{jk})]$. It suffices to consider the case where $\|V\| = \|V(1_n)\| = 1$, because in case $V = 0$ nothing is to prove and non-zero V can be replaced by $\|V\|^{-1}V$ if necessary.

We get norm estimates for the $g_{k,\ell}$ ($k, \ell \in \{1, \ldots, n\}$) by

$$\|g_{k,\ell} g_{k,\ell}^*\| = \|g_{k,\ell}^* g_{k,\ell}\| \leq \|c_k^* c_k\| \leq \|V(1_n)\| \leq 1 .$$

Let $h := n^{-2} \sum_{k,\ell} g_{k,\ell} g_{k,\ell}^* \in A_+$. Then $\|h\| \leq 1$, and $g_{k,\ell} g_{k,\ell}^* \leq n^2 \cdot h$ implies that $g_{k,\ell} \in \overline{hA}$ for $k, \ell \in \{1, \ldots, n\}$.

[12] This are not the columns of the adjoint matrix. Even for positive complex 2×2-matrices, e.g. $[\alpha_{j,k}]$ with $\alpha_{j,k} := i^{j-k}$. Only for matrices with self-adjoint entries is this the same as the columns of the adjoint matrix.

Consider the functions $\psi_m(t) := \min\big(1, \max((m+1)t - 1/m, 0)\big)$ for $m \in \mathbb{N}$ and $t \in [0,\infty]$. Then $\psi_m(t) = 0$ for $t \in [0, 1/(m^2+m)]$, $\psi_m(t) = 1$ for all $t \geq 1/m$ and ψ_m is linear in between. Thus, $\lim_{m\to\infty} \|x^*(1-\psi_m(h))x\| = 0$ for all $x \in \overline{hA}$.

In particular, there exists $m \in \mathbb{N}$ with

$$\|(1-\psi_m(h))^{1/2} g_{k,\ell}\|^2 \,<\, \gamma/(1+n^2) \quad \text{for all } \ k,\ell \in \{1,\ldots,n\}\,.$$

Let $\varphi := \psi_m$ and $Q := 1 - \varphi(h) \geq 0$ from now on.

We write $1_n \otimes Q$ for the diagonal matrix in $M_n(\mathcal{M}(A))$ with entries Q in the main diagonal.

The function φ is an increasing non-negative function $\varphi \in \mathrm{C}_0(0,1]$ with $\varphi|[0,\delta] = 0$ for $\delta = (m^2+m)^{-1}$ and φ has the properties that $\|\varphi\| \leq 1$ and

$$\|Q^{1/2} g_{k,\ell}\|^2 = \|(1-\varphi(h))^{1/2} g_{k,\ell}\|^2 \,<\, \gamma/(1+n^2) \qquad \text{for all } \ k,\ell \in \{1,\ldots,n\}\,.$$

Since $\|c_k^*(1_n \otimes Q)c_k\| \leq \sum_\ell \|g_{k,\ell}^* Q g_{k,\ell}\|$ it implies that

$$\|\sum_{k=1}^n c_k^*(1_n \otimes Q)c_k\,\| \,<\, \gamma\,. \tag{1.1}$$

By assumptions in Part (ii), the C^*-algebra A has the property that for every positive contraction $h \in A_+$ and $\varepsilon > 0$ there exist contractions $b_1, b_2 \in A$ with $\|b_j^* b_k - \delta_{j,k} h\| < \varepsilon$ for $j,k \in \{1,2\}$. It causes that Lemma 2.1.12 applies to $h \in A_+$. The equivalences (b,i) $\iff$ (b,ii) and (a,i) $\iff$ (a,ii) in Lemma 2.1.12 imply together immediately that there exist $b_1, b_2, \ldots, b_{2n-1}, b_{2n} \in A$ with

$$b_i^* b_j = \delta_{i,j}\varphi(h) \qquad \text{for all} \quad i,j \in \{1,\ldots,2n\}\,.$$

The diagonal matrices $1_n \otimes b_j \in M_n(A)$ ($j \in \{1,\ldots,2n\}$) and all $\beta \in M_n$ satisfy $(1_n \otimes b_j)^*\beta(1_n \otimes b_k) = \delta_{jk} \cdot \beta \otimes \varphi(h)$ and

$$(1_n \otimes Q)^{1/2}\beta(1_n \otimes Q)^{1/2} = \beta \otimes Q = \beta \otimes (1 - \varphi(h))\,.$$

Thus, $\beta = (1_n \otimes b_j)^*\beta(1_n \otimes b_j) + (1_n \otimes Q)^{1/2}\beta(1_n \otimes Q)^{1/2}$ for $\beta \in M_n$ and $j \in \{1,\ldots,2n\}$. If we conjugate this with the columns $c_k \in M_{n,1}(A)$ then this shows that the completely positive maps $V_{k,j}$ and W_k defined by

$$V_{k,j}\colon\, M_n \ni \beta \mapsto ((1_n \otimes b_j)c_k)^*\beta((1_n \otimes b_j)c_k) \in A$$

and

$$W_k\colon\, M_n \ni \beta \mapsto ((1_n \otimes Q)^{1/2}c_k)^*\beta((1_n \otimes Q)^{1/2}c_k) \in A$$

have the property that $V_{k,j}(\beta) + W_k(\beta) \,=\, c_k^*\beta c_k$ for all $\beta \in M_n$ and $j \in \{1,\ldots,2n\}$

It implies $V_{k,i}(\beta) = V_{k,j}(\beta)$ for all $i,j \in \{1,2,\ldots,2n-1,2n\}$, and the estimate (1.1) implies for the completely positive map $W := \sum_{k=1}^n W_k$ the estimate

$$\|W\| = \|W(1_n)\| = \|\sum_{k=1}^n c_k^*(1_n \otimes Q)c_k\| \,<\, \gamma\,.$$

Calculation shows for $\mu,\nu \in \{1,\ldots,2n\}$ and $i,j,k,\ell \in \{1,\ldots,n\}$ that

$$((1_n \otimes b_\mu)c_k)^*(e_{i,j} \otimes 1)((1_n \otimes b_\nu)c_\ell) \,=\, \delta_{\mu,\nu} \cdot c_k^*(e_{i,j} \otimes \varphi(h))c_\ell\,.$$

We define for $\ell \in \{0, 1\}$ the columns

$$d_\ell := \sum_{k=1}^{n} (1_n \otimes b_{k+n\ell}) c_k = \sum_{k,j}^{n} e_{j,1} \otimes (b_{k+n\ell} g_{k,j}) \in M_{n,1}(A).$$

Above considerations show that the columns d_j, $j \in \{0, 1\}$ satisfy $(\sum_{k=1}^n c_k^* \beta c_k) - d_j^* \beta d_j = \sum_{k=1}^n c_k^* (1_n \otimes Q)^{1/2} \beta (1_n \otimes Q)^{1/2} c_k$, and that the c.b.-norm on the right side is $\leq \gamma \cdot \|\beta\|$.

The orthogonality $(1 \otimes b_j)^* \beta (1 \otimes b_k) = \delta_{jk} \beta \otimes \varphi(h)$ causes that $d_1^* \beta d_0 = 0$ for $\beta \in M_n$.

It follows that d_j $(j \in \{0, 1\})$ are column matrices in $M_{n,1}(A)$ with $d_0^* \beta d_1 = 0$ and $d_0^* \beta d_0 = d_1^* \beta d_1$ such that the c.p. map $U(\alpha) := d_0^* \alpha d_0$ satisfies that $W := V - U$ is c.p. and $\|W\| < \gamma$ and $U(1_n) \leq V(1_n)$.

(iii): It suffices to consider the case where $\|V\| = 1$. Let $[a_{jk}] \in M_n(A)_+$ associated to $V \in \mathrm{CP}(M_n, A)$ by $a_{jk} = V(e_{j,k})$. Denote by $\pi_J \colon D \to A = D/J$ the quotient map. By Parts (o) and (i) it suffices to find in $M_n(D)_+$ a matrix $[d_{jk}]$ with $\pi_J(d_{j,k}) = a_{j,k}$ and $\|d_{1,1} + d_{2,2} + \cdots + d_{n,n}\| \leq 1$.

It is possible to find $[c_{j,k}] \in M_n(D)_+$ with $\pi_J(c_{j,k}) = a_{j,k}$ because the map $M_n(D) \ni [d_{j,k}] \mapsto [\pi_J(d_{j,k})] \in M_n(A)$ is an C^*-algebra epimorphism onto $M_n(A)$.

Then let $e := c_{1,1} + \cdots + c_{n,n}$ and define $f := (1 + (e-1)_+)^{-1/2} \in \mathcal{M}(D)$ and the desired matrix $[d_{j,k}] \in M_n(D)$ by $d_{j,k} := f c_{j,k} f$. The corresponding map $T \colon M_n \to D$ has norm $\|T\| = \|fef\| \leq 1$ and satisfies $\pi_J \circ T = V$.

(iv): It suffices to consider the case where $\|V\| = \|\sum_k b_{k,k}\| = 1$ for completely positive $V \colon M_n \to N$ and the corresponding matrix $B := [b_{jk}] \in M_n(N)_+$ with $b_{j,k} := V(e_{j,k})$. Then $\|B\| = \|[b_{j,k}]\| \leq n$. Let $C = [c_{j,k}] \in M_n(N)_+$ the square root of B. Then $\|C\| \leq n^{1/2}$.

Since $A \subseteq N$ is weakly dense in N, the C^*-subalgebra $M_n(A)$ is weakly dense in the W*-algebra $M_n(N)$. By the Kaplansky density theorem [**616**, thm. 2.3.3], (or [**704**, thm. 1.9.1], [**400**, thm. 5.3.5]) the unit-ball of the C^*-algebra $M_n(A)$ is dense in the unit-ball of $M_n(N)$ with respect to the *-ultra-strong topology (i.e., is $\tau(M_n(N), M_n(N)_*)$-dense in the unit-ball of $M_n(N)$), because $M_n(A)$ is weakly dense (i.e., is $\sigma(M_n(N), M_n(N)_*)$-dense) in $M_n(N)$ if A is weakly dense in N. It follows that there exists a net of elements $\{C_\rho\} \subseteq M_n(A)$ with $\|C_\rho\| \leq n^{1/2}$ that converges to C with respect to the *-ultra-strong topology on $M_n(N)$.

Let $e_\rho := \sum_{j,k} c_{k,j}^* c_{k,j}$ and let $f^{(\rho)} \in M_n(\mathcal{M}(A))_+$ the positive diagonal matrix with entries $(f^{(\rho)})_{j,k} := \delta_{j,k}(1 + (e_\rho - 1)_+)^{-1/2} \in \mathcal{M}(D)$.

The obvious *-ultra-strong continuity of addition, multiplication and involution on bounded parts of $M_n(N)$, cf. [**616**, sec. 2], shows that the directed net $\{D_\rho\}$ defined by

$$D^{(\rho)} := f^{(\rho)} C_\rho^* C_\rho f^{(\rho)} \in M_n(A)_+$$

satisfies that $\|\sum_{k=1}^n D_{k,k}^{(\rho)}\| \leq 1$ and converges to $[b_{jk}]$ in $M_n(N)$ with respect to the *-ultra-strong topology. It implies for the related c.p. maps $V_\rho \in \mathrm{CP}(M_n, A)$

that $\|V_\rho\| \leq 1$ and that the net $\{V_\rho\}$ converges to $V\colon M_n \to N$ with respect to the point–*-ultra-strong topology. □

REMARKS 3.1.10. `The last here mentioned criteria seems to be the relevant issue! But check it again!`

The arguments in the proof of Part(ii) of Proposition 3.1.9 show that we could find moreover elements $b_1, b_2, \ldots, b_{2n-1}, b_{kn} \in A$ with $b_i^* b_j = \delta_{i,j}\varphi(h)$ and the other properties of the $b_j \in A$. Then we obtain from them columns $d_0, d_1, \ldots, d_k \in M_{n,1}$ with $d_j^* \beta d_k = \delta_{j,k} U(\beta)$ with U and $V - U$ c.p. with norm $\|V - U\| < \gamma$.

But the proof of Proposition 3.1.9 shows a bit more:

If A is a C^*-subalgebra of a C^*-algebra B such that for each element $a \in A_+$ and $\varepsilon > 0$ there exists $d_1, d_2 \in B$ with $\|d_i^* d_j - \delta_{i,j} a\| < \varepsilon$, then the columns $d_0, d_1, \ldots, d_k \in B$ can be found with above properties and such that the c.p. contraction $U \in \mathrm{CP}(M_n, B)$ – defined by the d_j via $\delta_{i,j} \cdot U(\beta) = d_i^* \beta d_j$ – is also contained in $\mathrm{CP}(M_n, A)$. It does not require that $\mathcal{M}(A)$ contains any properly infinite elements, and it does not require that all elements in B are properly infinite.

One could suppose that the elements of A are "large" in B in the sense that the multiplier algebra of the hereditary C^*-subalgebra $\overline{AB_\omega A}$ of B_ω has a properly infinite unit.

But the weakened condition on A and B simply is equivalent to the property that A is contained in a stably generated ideal of B_ω or likewise of B_∞.

LEMMA 3.1.11. *Let $V\colon A \to B$ a completely positive map, and $A \subseteq D$ where D is a unital C^*-algebra.*

(i) *If V is factorable, then there is always a factorization $V = T \circ S$ through some matrix algebra M_n such that $S^{**}\colon A^{**} \to M_n$ is unital, and (therefore) $\|T\| = \|T(1)\| = \|V\|$. There exists a u.c.p. map $S_e\colon D \to M_n$ with $S_e|A = S$* [13]*.*

(ii) *If V is nuclear, then V can be approximated in point norm by factorable maps TS where $S\colon A \to M_n$ and $T\colon M_n \to B$ are completely positive maps such that $S^{**}\colon A^{**} \to M_n$ is unital and $\|T\| \leq \|V\|$.*

If A, B and V are unital then S is unital and T can be chosen with $T(1) = 1$.

(iii) *The map $V\colon A \to B$ is nuclear, if and only if, $V\colon A \to B^{**}$ is weakly nuclear – considered as a map into the W^*-algebra B^{**}.*

(iv) *Every completely positive map $V\colon A \to B$ of finite rank can be approximated in operator-norm on $\mathrm{CP}(A, B)$ by factorable maps.*

PROOF. (i): This is evident if $x = S^{**}(1)$ is invertible, because we can replace S with $x^{-1/2} S(\cdot) x^{-1/2}$ and T with $T(x^{1/2}(\cdot)x^{1/2})$. If $S^{**}(1)$ is not invertible then,

[13] The extension S_e is an special case of the Arveson extension theorem [**42**]. Since the identity map of $\mathcal{L}(\ell_2)$ factorizes over $\ell_\infty(M_2, M_3, \ldots)$ this special cases imply conversely the general Arveson extension.

since $0 \leq a \leq 1$ implies $0 \leq S^{**}(a) \leq S^{**}(1)$, S^{**} must take its values in a corner of M_n. Replacing M_n with this corner and adjusting S, T accordingly, we may assume that $S^{**}(1)$ is invertible, and use the above transformations.

Since $T(S^{**})\colon A^{**} \to B \subseteq B^{**}$ is normal, $(TS)^{**} = T(S^{**})$, and thus $\|T(1)\| = \|(TS)^{**}(1)\|$. But $\|TS\| = \|(TS)^{**}\| = \|(TS)^{**}(1)\|$ and $\|T\| = \|T(1)\|$, because T and TS are positive.

It is easy to verify that a map $R\colon D \to M_n$ is completely positive, if and only if, the linear functional $\rho_e\colon D \otimes M_n \to \mathbb{C}$ with $\rho_e(d \otimes \alpha) = (1/n)\mathrm{Tr}(\alpha^\top R(d))$ is positive (Consider R as a map from D into $M_n \subseteq \mathcal{L}(L_2(M_n, (1/n)\mathrm{Tr})) \cong \mathcal{L}(\mathbb{C}^{n^2})$). Since $A \subseteq D$, we have $A^{**} \subseteq D^{**}$ and D is a unital C^*-subalgebra of D^{**}. Let $p \in D^{**}$ denote the unit element of A^{**}. We extend $S\colon A^{**} \to M_n$ to a unital c.p. map S_0 from $C := A^{**} + (1-p)D^{**}(1-p)$ into M_n by $S_0(c) := S^{**}(pcp)$ for $c \in C$.

The n^2-positivity of S_0 implies that the (well-defined) unital linear functional ρ on $C \otimes M_n$ with $\rho(c \otimes \alpha) = (1/n)\mathrm{Tr}(\alpha^\top S_0(c))$ is positive, i.e., is a state on $C \otimes M_n$. By Hahn–Banach extension theorem, it extends to a state ρ_e on $D^{**} \otimes M_n$ with $\rho_e(1 \otimes \alpha) = (1/n)\mathrm{Tr}(\alpha)$. Thus, the unique linear map $S_e\colon D \to M_n$ with $\rho_e(d \otimes \alpha) = (1/n)\mathrm{Tr}(\alpha^\top S_e(d))$ for all $d \in D$ and $\alpha \in M_n$ must be unital and extends S_0.

(ii): Let $\widetilde{A}$ the unitization of A. V is the point norm limit of completely positive maps $V_e|A$ where $V_e\colon \widetilde{A} \to B$ is defined by $V_e(a + \gamma 1) := V(eae + \gamma e^2)$ for $e \in A_+$, $\|e\| \leq 1$ (Take an approximate unit $\{e\}$ of A). V_e is completely positive and $\|V_e\| \leq \|V\|$. Every point-norm approximation of V by a net of factorable maps $W_\lambda = T_\lambda S_\lambda$ defines a point-norm approximation of V_e by the factorable maps $(W_\lambda)_e$. Thus it suffices to consider the case where A is unital. But then the approximation satisfies $\|V(1) - W_\lambda(1)\| \to 0$. Thus, eventually we find a small perturbation of the T_λ with the desired properties.

(iii): By Remark 3.1.2(o), the set $\mathrm{CP}_f(A, B)$ of factorable c.p. maps $W\colon A \to B$ is an operator-convex cone in $\mathrm{CP}(A, B)$. It follows that $V\colon A \to B$ is in the point-norm closure of $\mathrm{CP}_f(A, B)$ if and only if V is in the point-$\sigma(B, B^*)$ closure of $\mathrm{CP}_f(A, B)$.

Every factorable c.p. map $U = T \circ S\colon A \to B^{**}$, $T\colon M_n \to B^{**}$, $S\colon A \to M_n$ with $S^{**}(1) = 1$ and $\|T\| = \|T(1)\| = \|U\|$ is the point–*-strong limit of a net of maps $U_\mu = T_\mu \circ S$ by part (i) and Proposition 3.1.9(iv), where $T_\mu\colon M_n \to B$ is a contraction with $\|T_\mu\| \leq \|T\|$.

Thus, $V\colon A \to B$ is in the point-$\sigma(B, B^*)$ closure of $\mathrm{CP}_f(A, B)$, if and only if, V is in the point-$\sigma(B^{**}, B^*)$ closure of $\mathrm{CP}_f(A, B^{**})$.

The latter means that $V\colon A \to B \subseteq B^{**}$ is a weakly nuclear map from A into B^{**}.
(An alternative proof can be given by means of Remark 3.1.2(i) and its counterpart for weakly nuclear maps.)

(iv): We consider B as a C^*-subalgebra of $\mathcal{L}(\mathcal{H}_1)$ for some Hilbert space $\mathcal{H}_1$. Since $V\colon A \to B$ has finite rank, there are functionals $\rho_1, \ldots, \rho_n \in A^*$ and operators $b_1, \ldots, b_n \in B$ with $V(a) = \sum_k \rho_k(a) b_k$. By Lemma 3.1.4 there exists a cyclic representation $d\colon A \to \mathcal{L}(\mathcal{H}_0)$, with cyclic vector $\xi \in \mathcal{H}_0$ of norm $\|\xi\| = 1$, and operators $t_k \in d(A)'$ with $\rho_k(a) = \langle d(a)\xi, t_k\xi\rangle$ for $a \in A$.

Let $C := d(A)'$, $T := \sum_k t_k^* \otimes b_k \in C \odot B \subseteq C \otimes B$ and let λ_a denote the linear functional on C given by $\lambda_a(c) := \langle c d(a)\xi, \xi\rangle$ for $a \in A$ and $c \in C$. It has norm $\|\lambda_a\| \leq \|a\|$. Then $V(a) = (\lambda_a \otimes \mathrm{id})(T)$ for $a \in A$. Since the algebraic tensor product $d(A)\xi \odot \mathcal{H}_1$ is dense in the Hilbert-space tensor product $\mathcal{H}_0 \otimes \mathcal{H}_1$, a straight calculation shows that the complete positivity of V implies that T is positive in $\mathcal{L}(\mathcal{H}_0 \otimes \mathcal{H}_1)$. It follows that T is also positive in $C \otimes B$ (by spectral permanence on the class of C^*-algebras).

Let $\varepsilon > 0$, then there is $S \in C \odot B$ with $\|T - S^*S\| < \varepsilon$ in $C \otimes B$. Let $W(a) := (\lambda_a \otimes \mathrm{id})(S^*S)$ then, for all $a \in A$,

$$\|W(a) - V(a)\| = \|(\lambda_a \otimes \mathrm{id})(T - S^*S)\| \leq \|\lambda_a\| \|T - S^*S\| < \varepsilon \|a\| \,,$$

i.e., $\|W - V\| < \varepsilon$ in $\mathcal{L}(A, B)$. Since $d\colon A \to \mathcal{L}(\mathcal{H}_0)$ has a cyclic vector ξ, the map $\gamma\colon C = d(A)' \to \mathcal{H}_0$ given by $\gamma\colon c \mapsto c\xi$ is injective, and we can write $S = \sum_j c_j \otimes d_j$ ($j = 1, \ldots, m$) with $\langle \gamma(c_i), \gamma(c_j)\rangle = \delta_{i,j}$. Let $u_n\colon \mathbb{C}^m \to \mathcal{H}_0$ the isometry with $u_n(e_j) = \gamma(c_j)$, $W_1\colon A \to M_m$ the c.p. contraction $W_1(a) := u_n^* d(a) u_n \in \mathcal{L}(\mathbb{C}^m)$, and $D \in M_{1,m}(B)$ the row matrix $D = [d_1, \ldots, d_m]$. We define $W_2\colon M_m \to B$ by $W_2(\alpha) := D\alpha D^*$, where M_m is considered as subalgebra of $M_m(\mathcal{M}(B)) \cong \mathcal{M}(M_m(B))$. Straight calculation shows that $W = W_2 \circ W_1$. Thus, V can be approximated in operator-norm by factorable maps. □

`Compare below Proof with that of Part(iv) above! Take the better one!  Notations have then to be adapted/changed.`

Details to Part (iii,f) of Remarks 3.1.2, see also Lemma 3.1.11(iv): Consider $V(a) := \sum_j f_j(a) b_j \in B \subseteq \mathcal{L}(\mathcal{H})$ and find $\varphi \in A_+^*$, $T_j \in D_\varphi(A)'$, such that $f_j(a) = \langle D_\varphi(a) x_0, T_j x_0\rangle$, cf. Lemma 3.1.4. Then $S := \sum T_j \otimes b_j \geq 0$ in the C^*-algebra $D_\varphi(A)' \otimes B$. Thus, $S^{1/2}$ can be approximated in operator norm by elements d_n in the algebraic tensor product $D_\varphi(A)' \odot B$. The maps

$$a \mapsto (\varphi \otimes \mathrm{id}_B)\big(d_n^*(D_\varphi(a) \otimes 1) d_n\big)$$

are factorable c.p. maps from A into B that approximate V with respect to the operator norm of $\mathcal{L}(A, B)$. □

We denote by $\mathrm{socle}(A)$ the algebraic ideal of A generated by the projections $p \in A$ with $pAp = \mathbb{C}p$. See [**210**], [**388**, p. 64] and [**661**, pp. 46,261–267] for notation and properties.

LEMMA 3.1.12. *Suppose that* $W : A \to M_m$ *is a completely positive map with* $W^{**}(1) = 1_m$, *and that* Γ *is a set of pure states on* A, *such that the irreducible representations* $\rho_j : A \to L_2(A, \mu_j)$ *corresponding to* $\mu_j \in \Gamma$ *are pairwise inequivalent and build a separating family for* A. *Then:*

(i) *For every compact subset* Ω *of* A *and every* $\varepsilon > 0$, *there exist pure states* $\mu_1, \dots \mu_k \in \Gamma$, $k, m_1, \dots, m_k \in \mathbb{N}$, *isometries* $I_j : \mathbb{C}^{m_j} \to L_2(A, \mu_j)$, *and a unital completely positive map* $T : F := M_{m_1} \oplus \cdots \oplus M_{m_k} \to M_m$, *such that*

$$\|T \circ S(a) - W(a)\| \le \varepsilon \qquad \forall \;\; a \in \Omega\,,$$

where $S : A \to M_{m_1} \oplus \cdots \oplus M_{m_k}$ *denotes the completely positive contraction* $S(a) := I_1^* \rho_1(a) I_1 \oplus \cdots \oplus I_k^* \rho_k(a) I_k$ *for* $a \in A$.

(ii) *If, in addition,* $W(\mathrm{socle}(A)) = 0$, *then one can manage that* $m_1, \dots, m_k \le m$, *and that* $T(f) = \sum_j d_j^* f_j d_j$ *for* $f = f_1 \oplus \cdots \oplus f_k \in F$, *for suitable* $d_j \in M_{m_j, m}$, *with* $\sum d_j^* d_j = 1_m$.

(iii) *If, in addition,* $W(\mathrm{socle}(A)) = 0$ *and the irreducible representations* d_μ *with* $\mu \in \Gamma$ *and* $d_\mu(\mathrm{socle}(A)) = 0$ *build a separating family for* $A/\overline{\mathrm{socle}(A)}$, *then in Part(i) the* $\mu_1, \dots, \mu_k \in \Gamma$ *can be taken such that* $\mu_j(\mathrm{socle}(A)) = 0$ *and* $S(\mathrm{socle}(A)) = 0$.

Note that S satisfies $S^{**}(1) = 1$. Part (iii) does *not* say that F, T and S can be found such that the properties of μ_j, I_j and T in (i), (ii) and (iii) hold at the same time (but this can be managed if $\mathrm{socle}(A) = 0$ or, at least, if $\mathrm{socle}(A/\overline{\mathrm{socle}(A)}) = 0$ and $W(\mathrm{socle}(A)) = 0$).

PROOF. (i): Let $H := \bigoplus_{\mu \in \Gamma} L_2(A, \mu)$ and $\rho : A \to \mathcal{L}(H)$ be the direct sum of irreducible representations which are defined by pure states in Γ. Then ρ is faithful. We denote by $R : A \to \mathcal{L}(\ell_2(H))$ the infinite repeat of ρ (i.e., $R(a) := \rho(a) \oplus \rho(a) \oplus \cdots$). Then $R(A) \cap \mathbb{K}(H) = 0$, and, by Lemma 2.1.22, there exists an isometry $v : \mathbb{C}^m \to H$ with $\|W(a) - v^* R(a) v\| < \varepsilon/3$ for $a \in \Omega$.

By definition of R, a small perturbation of v yields $q \in \mathbb{N}$, $\mu_1, \dots, \mu_q \in \Gamma$ (not necessarily different) and an isometry $t : \mathbb{C}^m \to L_2(A, \mu_1) \oplus \cdots \oplus L_2(A, \mu_q)$ with $\| v^* R(a) v - t^*(\rho_1(a) \oplus \cdots \oplus \rho_q(a)) t \| < \varepsilon/3$ for $a \in \Omega$, where $\rho_j : A \to L_2(A, \mu_j)$ are the representations corresponding to μ_j. We can arrange that $\mu_1, \dots, \mu_k$ are different and $\{\mu_{k+1}, \dots, \mu_q\} \subseteq \{\mu_1, \dots, \mu_k\}$ if $k \in \mathbb{N}$ denotes the maximal number of different elements of $\{\mu_1, \dots, \mu_q\}$. There are contractions $s_j : \mathbb{C}^m \to L_2(A, \mu_j)$ $(j = 1, \dots, q)$ such that $t(x) = s_1(x) \oplus \cdots \oplus s_q(x)$ for $x \in \mathbb{C}^n$, $\sum s_j^* s_j = 1_m$, and

$$\| v^* R(a) v - \sum_{j=1}^{q} s_j^* \rho_j(a) s_j \| < \varepsilon/3 \qquad \forall \;\; a \in \Omega\,.$$

For $1 \le j \le k$, we denote by L_j the linear subspace of $L_2(A, \mu_j)$ generated by the image of s_j and the images $s_i(\mathbb{C}^m)$ for $i \in \{k+1, \dots, q\}$ with $\mu_i = \mu_j$. Let $m_j := \mathrm{Dim}(L_j)$ and $I_j : \mathbb{C}^{m_j} \to L_j \subseteq L_2(A, \mu_j)$ an isometry $(j = 1, \dots, 0)$. Let $1 \le j \le k$ and $X(j) := \{1 \le i \le q\,;\; \mu_i = \mu_j\}$. We define $T_j : M_{m_j} \to M_m$ by

$T_j(g) := \sum_{i\in X(j)} s_i^* I_j g I_j^* s_i$ for $g \in M_{m_j}$ and $1 \leq j \leq k$, and then define $S\colon A \to F := M_{m_1} \oplus \cdots \oplus M_{m_k}$ and $T\colon F \to M_m$ by $S(a) := I_1^*\rho_1(a)I_1 \oplus \cdots \oplus I_k^*\rho_k(a)I_k$ respectively $T(f_1,\ldots,f_k) := T_1(f_1) + \cdots + T_k(f_k)$ for $a \in A$ and $f_j \in M_{m_j}$. Straight calculation shows that $\sum_{j=1}^q s_j^*\rho_j(a)s_j = T(S(a))$ for all $a \in A$.

(ii): Let H and $\rho\colon A \to \mathcal{L}(H)$ as above. Then $J := \rho^{-1}(\rho(A) \cap \mathbb{K}(H))$ is the closed ideal generated by the projections $p \in A$ with pAp of finite dimension, i.e., J is the closure of socle(A). Since $W(\text{socle}(A)) = 0$ by assumption, we get $W(J) = 0$. Now we can repeat the arguments for part (i) with ρ in place of R. Then, $k = q$ and $\text{Dim}(L_j) \leq m$ for $1 \leq j \leq k$. It follows that the map $t(x) := s_1(x) \oplus \cdots \oplus s_k(x)$ is an isometry from $\mathbb{C}^m$ into $I(\mathbb{C}^{m_1} \oplus \ldots \oplus \mathbb{C}^{m_k})$ and that $T_j(g) = s_j^* I_j g I_j^* s_j$ for all $g \in M_{m_j}$. Let $d_j := I_j^* s_j \in \mathcal{L}(\mathbb{C}^m, \mathbb{C}^{m_j}) \cong M_{m_j,m}$. Let $p_j\colon \mathbb{C}^n \to \mathbb{C}^{m_j}$ denote the orthogonal projection onto $\mathbb{C}^{m_j} \subseteq \mathbb{C}^n$. Then $T(f) = \sum d_j^* f_j d_j$ for $f := f_1 \oplus \cdots \oplus f_k \in F$, in particular, $\sum d_j^* d_j = 1_m$.

(iii): Apply part (i) to $A/\overline{\text{socle}(A)}$ and $[W]\colon A/\overline{\text{socle}(A)} \to M_m$. □

Lemma 3.1.13. *Let A a C^*-algebra and $W\colon A \to M_m$ a completely positive contraction with $W^{**}(1) = 1$, $\Omega \subseteq A_+$ a norm-compact subset, $f_0(t) := t$ ($t \in [0,1]$) and let $\varepsilon > 0$.*

- (I) *There exist*
  - (i) *a finite-dimensional C^*-algebra $F := M_{n_1} \oplus \cdots \oplus M_{n_k}$*
  - (ii) *a C^*-morphism $\psi\colon \mathrm{C}_0((0,1], F) \to A$,*
  - (iii) *a completely positive contraction $S\colon A \to F$ with $S(\psi(f)) = f(1)$ for all $f \in \mathrm{C}_0((0,1], F)$, and*
  - (iv) *a unital completely positive map $T\colon F \to M_m$,*

  such, that for $g := \psi(f_0 \otimes 1)$ and each $a \in \Omega$,

$$\|T \circ S(a) - W(a)\| < \varepsilon \quad \text{and} \quad \limsup_n \|g^{n+1} a g^{n+1} - g^n \psi\big(f_0^2 \otimes S(a)\big) g^n\| < \varepsilon .$$

- (II) *If $W(\text{socle}(A)) = \{0\}$ then F, ψ, S and T can be found such that, moreover, for every $\eta \in (0,1)$ the hereditary algebras*

$$(f_j - (1-\eta))_+ \cdot A \cdot (f_j - (1-\eta))_+$$

  contain n_j^2 non-zero pairwise orthogonal positive elements for $j = 1,\ldots,k$ (where $f_j := \psi(f_0 \otimes p_{11}^{(j)})$).
- (III) *If $W(\text{socle}(A)) = \{0\}$ then one can find F, ψ, S and T such that $n_j \leq m$ and that $S\colon F \to M_n$ is given by $S(f_1,\ldots,f_n) = \sum_j s_j^* f_j s_j$ for suitable $s_j \in M_{m_j,m}$.*

Proof. Apply Lemma 2.1.15. `To be filled in ??` □

Question 3.1.14.

Let $A \subseteq B$ a separable C^*-subalgebra of a unital C^*-algebra B.

Under what conditions is every nuclear c.p. map $T\colon A \to B$ approximately 1-step inner inside B?

I.e., when does there exists for each c.p. contractions $T \in \mathrm{CP}(M_n, B)$ and $S \in \mathrm{CP}(A, M_n)$ a sequence $s_1, s_2, \ldots$ of contractions in B such that $T \circ S(a) = \lim_{k\to\infty} s_k^* a s_k$ for all $a \in A$?

A *necessary* condition (for the case $n = 1$) is that for each nonzero $a \in A_+$ with $\|a\| = 1$ and every $c \in B_+$ there exists $d \in B$ – depending on c – with $d^*ad = (c - 1/2)_+$.

This implies that A is "relatively to B simple" (or $A = \{0\}$) and that the right ideal $R := AB$ satisfies $R^*R = B$.

Is this also sufficient?

Compare the result of Elliott and Kucerovsky [**264**] and its improvements in [**309**] in the case where B is a corona algebra $\mathcal{M}(C)/C$.

Following proposition is a non-commutative version of the Tietze extension theorem.

PROPOSITION 3.1.15. *Let A a σ-unital C^*-algebra and $J \subseteq A$ a closed ideal. Then the natural unital C^*-morphism $\mathcal{M}(\pi_J)\colon \mathcal{M}(A) \to \mathcal{M}(A/J)$ has kernel $\mathcal{M}(A, J) := \{T \in \mathcal{M}(A)\, ;\; AT \cup TA \subseteq J\}$.*

This natural C^*-morphism is surjective if J is σ-unital.

PROOF. Let $h\colon A \to \mathcal{M}(B)$, – e.g. for $B := A/J$ –, a C^*-morphism with the property that the hereditary C^*-subalgebra $h(A)Bh(A)$ of B contains an approximate unit of B.

This is equivalent to $B = \overline{h(A)B}$. Thus, there is a *unique unital* W*-morphism $H\colon A^{**} \to B^{**}$ that maps $\mathcal{M}(A) \subseteq A^{**}$ into $\mathcal{M}(B) \subseteq B^{**}$ and satisfies $H(a)b = h(a)b$ for all $a \in A$ and $b \in B$. The kernel of $H|\mathcal{M}(A)$ is easily seen as the operators $T \in \mathcal{M}(A)$ with $TA \cup T^*A \subseteq J$, where J is here the kernel of $h\colon A \to \mathcal{M}(B)$.

This covers the special case $B := A/J$ and $h := \pi_J$, where here simply $H = h^{**}$.

To get surjectivity for $\mathcal{M}(h) = h^{**}|\mathcal{M}(A)$ one can reduce the situation to suitable separable C^*-subalgebras if J and $B = A/J$ are σ-unital: We can find for given positive $T \in \mathcal{M}(B)$ a separable C^*-subalgebra $C \subseteq B$ that contains a strictly positive element f of B and $1_{\mathcal{M}(B)}, T \in \mathcal{M}(C) \subseteq \mathcal{M}(B)$. Then we can find a separable C^*-subalgebra D of A that contains a strictly positive element of J and satisfies $\pi_J(D) = C$. Thus, D contains a strictly positive element of A, satisfies $\mathcal{M}(D) \subseteq \mathcal{M}(A)$, and $\mathcal{M}(D)$ contains the unit element of $\mathcal{M}(A)$. Notice that under this conditions on D and C we get that

$$\mathcal{M}(\pi_J)|\mathcal{M}(D) = \mathcal{M}(\pi_{J\cap D})\colon \mathcal{M}(D) \to \mathcal{M}(C) \subseteq \mathcal{M}(B)\,.$$

This reduces in the case where J and $B = A/J$ are σ-unital the question on the surjectivity of $\mathcal{M}(\pi_J)$ to the case where B is separable. There the answer is affirmative, cf. [**616**, prop. 3.12.10]. □

Proposition 3.1.15 could be used to prove the following proposition:

PROPOSITION 3.1.16. *If A is a σ-unital C^*-algebra, then* $\mathrm{Q}(A) := \mathcal{M}(A)/A$ *is* σ-sub-Stonean, *i.e., for each separable C^*-subalgebra $B \subset \mathrm{Q}(A)$ and each $c, d \in (B' \cap \mathrm{Q}(A))_+$ with $cd = 0$ there exist contractions $e, f \in (B' \cap \mathrm{Q}(A))_+$ with $ef = 0$, $ec = c$ and $fd = d$.*

I.e., $\mathrm{Q}(A)$ *is σ-sub-Stonean in the sense of* [**448**, def. 1.4].

```
Compare Chapter 5 for more general study
and compare with the -- possibly stronger -- Kasparov's technical
theorem:
```

$\mathcal{M}(A\otimes\mathbb{K})/(A\otimes\mathbb{K}) = \mathrm{Q}^{\mathrm{s}}(A)$ satisfies Kasparov's technical theorem. It implies that $\mathrm{Q}^{\mathrm{s}}(A)$ and $\mathrm{Q}(A) \cong P\,\mathrm{Q}^{\mathrm{s}}(A)P$ are sub-Stonean. Here $P := \pi_{A\otimes\mathbb{K}}(1_{\mathcal{M}(A)}\otimes p_{11})$.

Check below proof again. Compare this with Chapter 5.

PROOF. We can suppose that $1 \in B$ and $\|c-d\| = 1$ without loss of generality.

Let $g^* = g \in \mathcal{M}(A)$ with $\pi_A(g) = c-d$ and $\|g\| = 1$, and let $a_0 \in A_+$ a strictly positive contraction in A. We find a separable unital C^*-subalgebra $D \subset \mathcal{M}(A)$ with $\pi_A(D) = B$. Consider the separable unital C^*-subalgebra $E := C^*(a_0, g, D)$ of $\mathcal{M}(A)$ that is generated by $a_0, g \in A$ and the C^*-subalgebra $D \subseteq E$.

Take dense sequence $e_1, e_2, \ldots$ in the unit ball of E containing $e_1 := g_+$ and $e_2 := g_-$ in the first places.

Build from a_0 via functional calculus with increasing functions $f_1, f_2, \ldots$ in $\mathrm{C}_0(0,1]_+$ (with properties $\|f_n\| = 1$, $f_{n+1}f_n = f_n$ and $f_n([0,\alpha_n]) = \{0\}$ for some suitable zero sequence $\alpha_n > \alpha_{n+1} > 0$) a sequence of positive contractions $a_n = f_n(a_0) \in A_+$ that have the property

$$\|a_ne_k - e_ka_n\| + \|a_n^{1/2}e_k - e_ka_n^{1/2}\| \le 8^{-n}\,.$$

Parallel selection of $\|[g_+^{1/k_n}, e_k]\|$ and its commutator norms is needed:

We know that $[g_+^{1/k_n}, e_k] \in A$. The next k_{n+1} can be found after the $[(a_{n+1} - a_n)^{1/2}, e_k]$ and ??? becomes small enough and ????

Then we define a map V on $T \in \mathcal{M}(A)$ by

$$V(T) := a_1^{1/2}Ta_1^{1/2} + \sum_{n=1}^{\infty}(a_{n+1}-a_n)^{1/2}T(a_{n+1}-a_n)^{1/2}\,.$$

The right side is convergent with respect to the strict convergence in $\mathcal{M}(A)$. Then V is a unital completely positive unital map from $\mathcal{M}(A)$ into $\mathcal{M}(A)$.

It has the property that $V(e_n) - e_n \in A$ for all $n \in \mathbb{N}$. Thus $V(x) - x \in A$ for all $x \in E \subseteq \mathcal{M}(A)$.

We define a positive contraction $Y \in \mathcal{M}(A)_+$ by

$$Y := \sum_{n=1}^{\infty} := a_1^{1/2} g_+ a_1^{1/2} + \sum_{n=1}^{\infty} (a_{n+1} - a_n)^{1/2} g_+^{1/n} (a_{n+1} - a_n)^{1/2} .$$

`Here could be a problem with` $Yx - xY \in A$

`It could be that one has to select some of the` a_{k_n} `and` g_+^{1/ℓ_n} `more careful !!  :`

`We have` $[g_+^{1/n}, e_k] \in A$ `for all` $n, k \in \mathbb{N}$`, but need further control of the selection!!`

`The` n `has to go slowly enough to` ∞`??`

The positive contraction Y has the properties $Yg_+ - Y \in A$, $Yg_- \in A$ and $Yx - xY \in A$ for all $x \in E = C^*(a_0, g, D)$.

Thus, $e := \pi_A(Y) \in \mathrm{Q}(A)$ is a positive contraction with $ec = e$, $ed = 0$ and $e \in B' \cap \mathrm{Q}(A)$.

Now we can repeat the arguments, but starting now with e in place of former d and with d in place of former c and get a positive contraction $f \in B' \cap \mathrm{Q}(A)$ with $fe = 0$ and $fd = d$.

□

`Remarks/Conjectures:`

It is known that A_ω is σ-sub-Stonean for every non-zero C^*-algebra A.

Is A_∞ σ-sub-Stonean for non-zero A?

Suppose we could prove the following (1) and (2) then $\mathrm{Q}^s(A)$ is σ-sub-Stonean for each non-zero σ-unital C^*-algebra :

(1) A_∞ is σ-sub-Stonean.

(2) If A is σ-unital and stable, then, for every separable C^*-subalgebra B of $\mathrm{Q}(A)$ there exist a c.p. contraction $V \colon \mathrm{Q}(A) \to A_\infty$ that is orthogonality preserving on B and a c.p. contraction $W \colon A_\infty \to \mathrm{Q}(A)$ that is multiplicative on $C^*(V(B))$ such that $W \circ V(b) = b$ for all $b \in B$.

Indeed: Suppose that A is σ-unital and stable, $C \subset \mathrm{Q}(A)$ separable, and that $e, f \in C' \cap \mathrm{Q}(A)$ are positive contractions with $ef = 0$.

Suppose (2) is valid:

Let $B := C^*(C \cup \{e, f\})$, $V \colon \mathrm{Q}(A) \to A_\infty$ a c.p. contraction that is orthogonality preserving on B, and let $W \colon A_\infty \to \mathrm{Q}(A)$ that is multiplicative on $C^*(V(B))$ such that $W \circ V(b) = b$ for all $b \in B$.

Since V is orthogonality preserving, we get that $V(e) \cdot V(f) = 0$.

Perhaps V preserves commutativity? Leads to question (Let $T \colon \mathrm{C}_0(X) \to D$ an orthogonality preserving c.p. contraction with D a C^*-algebra, X a closed subset of $\mathbb{R}^2$, and T is "completely" isometric. Is $C^*(T(\mathrm{C}_0(X)))$ a commutative

C^*-algebra? We can not expect that T is multiplicative because $f \mapsto f \otimes g$ is c.i. and c.p. if $\|g\| = 1$ and $g \geq 0$.)

Now suppose that (2) implies that V respects commutativity and is orthogonality preserving.

Then $V(e)V(f) = 0$ and $V(e), V(f)$ commute with all elements from $C^*(V(B))$. (If comm. is respected!)

Now, if (1) is valid, then there exist $g, h \in C^*(V(B))' \cap A_\infty$ with $g \cdot h = 0$, $gV(f) = 0$ $gV(e) = V(e)$ and $hV(f) = V(f)$.

If we apply $W\colon A_\infty \to \mathrm{Q}(A)$, then we get that $W(g)e = e$, $W(g)f = 0$ $W(g)b = bW(g)$ for all $b \in C$, and $W(g)f = 0$. This implies then finally that $\mathrm{Q}(A)$ is σ-sub-Stonean.

2. On approximate inner nuclear maps

The following Lemma 3.2.1 gives a necessary and sufficient criteria for the containment $\mathrm{CP}_{\mathrm{nuc}}(A, B) \subseteq \mathcal{C}$ for point-norm closed subsets $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ of the c.p. maps from a C^*-algebra A into a C^*-algebra B.

Lemma 3.2.1. *Let $\mathcal{C}$ a point-norm closed* subset *of* $\mathrm{CP}(A, B)$ *with the property that $S(a^*(\cdot)a) \in \mathcal{C}$ for $S \in \mathcal{C}$ and $a \in A$, and denote by $f_0 \in \mathrm{C}_0(0, 1]$ the generator $f_0(t) := t$.*

Then the following are equivalent:

(i) *The set $\mathcal{C}$ contains all nuclear c.p. maps $U\colon A \to B$.*
(ii) *For every C^*-morphism $\psi\colon \mathrm{C}_0((0, 1], F) \to A$ of the cone $\mathrm{C}_0((0, 1], F)$ over a finite-dimensional C^*-algebra F with the property $\|\psi(f_0 \otimes p)\| = 1$ for all non-zero projections $p \in F$ and for every completely positive map $V\colon F \to B$, there exists a sequence $S_n \in \mathcal{C}$ with $\lim_n S_n(\psi(f)) = V(f(1))$ for all $f \in \mathrm{C}_0((0, 1], F)$.*

Proof. The condition on $\mathcal{C}$ implies that $t\mathcal{C} \subseteq \mathcal{C}$ for $t \in \mathbb{R}_+$ (use an approximate unit of A). Thus, it suffices to show that every factorable contraction U from A into B can be approximated in point-norm topology by elements of $\mathcal{C}$. Suppose that $U = V \circ W$ with c.p. contractions $W\colon A \to M_m$ and $V\colon M_m \to B$ with $W^{**}(1) = 1$, cf. Lemma 3.1.11(i).

Let $\varepsilon > 0$ and $\Omega \subseteq A$ a compact subset. We find F, $\psi\colon \mathrm{C}_0((0, 1], F) \to A$, $T\colon F \to M_m$, and $S\colon A \to F$ as in Lemma 3.1.13(I). Then $1 \geq \|\psi(f_0 \otimes p)\| \geq \|p\|$, because $p = T(\psi(f_0 \otimes p))$. Thus, by assumptions, there is a sequence $S_n \in \mathcal{C}$ with $\lim_n S_n(\psi(f)) = V \circ T(f(1))$ for all $f \in \mathrm{C}_0((0, 1], F)$. Let $G := \psi(\mathrm{C}_0((0, 1], F)) \subseteq A$ and let D denote the hereditary C^*-subalgebra of A that is generated by G. Lemma 3.1.8 applies to the set $\mathcal{C}|G$, because ψ is a C^*-morphism and $V(a^*(\cdot)a) \in \mathcal{C}$ for $V \in \mathcal{C}$ and $a \in A$. Hence, we can select the sequence $S_n \in \mathcal{C}$ such that, in addition, $\|S_n|G\| \leq \|V \circ T\| \leq 1$. But this implies that $\|S_n|D\| \leq 1$, because G contains an approximate unit of D. It follows $\lim_n S_n(g^k\psi(f_0\otimes S(a))g^k) = V(T(S(a)))$ and

$$\inf_{n,k} \|S_n(g^{k+1}ag^{k+1}) - V\circ W(a)\| < 3\varepsilon \qquad \forall\ \ a\in\Omega\,.$$

Conversely, suppose that $\mathrm{CP}_{\mathrm{nuc}}(A,B)\subseteq\mathcal{C}$. Let F a finite-dimensional algebra and $\psi\colon \mathrm{C}_0((0,1],F)\to A$ a *-morphism with $\|\psi(f_0\otimes p)\| = 1$ for all non-zero projections $p\in F$. The image $\psi\big(\mathrm{C}_0((0,1],F)\big)$ is contained in the normalizer algebra $\mathcal{N}(D)\subseteq A$ of the hereditary C^*-subalgebra $D\subseteq A$ that is generated by $\psi(f_0(1-f_0)\otimes 1)$. The condition $\|\psi(f_0\otimes p)\| = 1$ for non-zero projections $p\in F$ is equivalent to the injectivity of $[\pi_D\circ\psi]\colon F\to\mathcal{N}(D)/D$ where $\pi_D\colon\mathcal{N}(D)\to\mathcal{N}(D)/D$ is the quotient map. Since F is an injective algebra, we can use the Arveson extension to obtain completely positive contractions $W_1\colon\mathcal{N}(D)\to F$ with

???????

and then $W\colon A\to F$ with $W(\psi(f)) = W_1(\psi(f)) = f(1)$ for all $f\in\mathrm{C}_0((0,1],F)$. If $V\colon F\to B$ is completely positive, then $S_n := V\circ W$ is nuclear and is contained in $\mathcal{C}$ by assumption. □

Definition 3.2.2. Let A and B C^*-algebras and $\mathrm{CP}(A,B)$ the cone of completely positive maps from A into B.

A subset $\mathcal{C}$ of $\mathrm{CP}(A,B)$ is a **matrix operator-convex cone** of c.p. maps, if $\mathcal{C}$ has the following properties (i) and (ii):

(OC1) $d_1^*V_1(.)d_1 + d_2^*V_2(.)d_2\in\mathcal{C}$ for $V_1,V_2\in\mathcal{C}$, $d_1,d_2\in B$ ([14])

(OC2) The map $a\in A\mapsto c^*\big(V\otimes\mathrm{id}_n(r^*ar)\big)c$ is in $\mathcal{C}$ for every $V\in\mathcal{C}$, every row-matrix $r\in M_{1,n}(A)$ and every column-matrix $c\in M_{n,1}(B)$.
(I.e., for every $V\in\mathcal{C}$, $n\in\mathbb{N}$, $r_1,\ldots,r_n\in A$ and $c_1,\ldots,c_n\in B$, the completely positive map $W(a) := \sum_{ij}c_i^*V(r_i^*ar_j)c_j$ is again in $\mathcal{C}$.)

We abridge "matrix operator convex cone" as "**m.o.c. cone**" .

The m.o.c. cone $\mathcal{C}$ **closed** if $\mathcal{C}\subseteq\mathrm{CP}(A,B)\subseteq\mathcal{L}(A,B)$ is closed with respect to topology of point-norm convergence on $\mathcal{L}(A,B)$ (= strong operator topology on $\mathcal{L}(A,B)$).

An m.o.c. cone $\mathcal{C}$ is **non-degenerate** if, for every $b\in B_+$ and $\varepsilon>0$, there are $V\in\mathcal{C}$ and $a\in A_+$ with $\|V(a)-b\| < \varepsilon$.

The cone $\mathcal{C}$ is **faithful** if $a\in A_+$ and $V(a)=0$ for all $V\in\mathcal{C}$ implies $a=0$.

Let $\mathcal{S}$ be a subset of $\mathrm{CP}(A,B)$. We denote by $\mathcal{C}_{\mathrm{alg}}(\mathcal{S})$ the smallest subset of $\mathrm{CP}(A,B)$ that is invariant under the operationsin (OC1) and (OC2), and by $\mathcal{C}(\mathcal{S})$ the point-norm closure of $\mathcal{C}_{\mathrm{alg}}(\mathcal{S})$ (i.e., the closure of $\mathcal{C}_{\mathrm{alg}}(\mathcal{S})$ in $\mathcal{L}(A,B)$ w.r.t. the strong operator topology). Then $\mathcal{C}_{\mathrm{alg}}(\mathcal{S})$ and $\mathcal{C}(\mathcal{S})$ are operator-convex cones of completely positive maps.

We say that $\mathcal{S}$ **generates** a *closed* m.o.c. cone $\mathcal{C}$ if $\mathcal{C}=\mathcal{C}(\mathcal{S})$.

[14] Thus $\sum b_i^*V_i(.)b_i\in\mathcal{C}$ if $V_1,\ldots,V_n\in\mathcal{C}$ and $b_1,\ldots,b_n\in B$.

One can see, with help of approximate units in A or B, that every point-norm closed subset $\mathcal{V}$ of of $\mathrm{CP}(A,B)$ is a convex cone in the usual sense if it satisfies (OC1), and that $\mathcal{V}$ satisfies $t\mathcal{V} \subseteq \mathcal{V}$ for $t \in [0,\infty)$ if $\mathcal{V}$ satisfies (OC2).

REMARK 3.2.3. Let $\mathcal{S} \subseteq \mathrm{CP}(A,B)$ any set of c.p. maps. We define the **(OC2)–hull** $\langle \mathcal{S} \rangle_2$ of $\mathcal{S}$ as smallest set $\langle \mathcal{S} \rangle_2 \subset \mathrm{CP}(A,B)$ of c.p. maps containing $\mathcal{S}$ and being invariant under the operations in (OC2) of Definition 3.2.2.

The point norm-closure $\mathcal{C}_2 := \overline{\langle \mathcal{S} \rangle_2}$ in $\mathrm{CP}(A,B)$ of the (OC2)-hull of $\mathcal{S}$ is in general *not convex*.

In particular such $\mathcal{C}_2$ does not satisfy the (operator convexity) property (OC1) of Definition 3.2.2 in general, and this even if $\mathcal{S}$ itself is *convex*:
Consider e.g. $\mathcal{S} := \mathbb{R}_+ \cdot \eta$ for $\eta \colon A := C^*(p_{11} - p_{22}) \hookrightarrow B := M_2$. Then $\langle \mathcal{S} \rangle_2 = \{X^* \eta(\cdot) X\,;\; X \in M_2\}$ has non-convex closure in $\mathrm{CP}(A,B)$, because the set $\{X^* p_{11} X\,;\; X \in M_2\}$ is the closed set that contains 0_2 and all positive matrices in M_2 of rank one. It is certainly not convex.

DEFINITION 3.2.4. A Hilbert (A,B)-module $(E, \phi \colon A \to \mathcal{L}(E))$, with right Hilbert B-module E, **generates** the *closed* m.o.c. cone $\mathcal{C}$, if $\mathcal{C} := \mathcal{C}(\mathcal{S})$ for the set $\mathcal{S}$ of completely positive maps $V_x \colon a \in A \mapsto \langle \phi(a)x, x \rangle \in B$.

We say that $(E, \phi \colon A \to \mathcal{L}(E))$ **defines** a closed m.o.c. cone $\mathcal{C}$ if (E,ϕ) generates $\mathcal{C}$ and, moreover, (E,ϕ) is unitarily equivalent to $(E \oplus_B E, \phi \oplus \phi)$.

(Does the latter mean that $\phi(A)' \cap \mathcal{L}(E)$ contains a copy of $\mathcal{O}_2$ unitally?)

`Need but have not the following:`

Let $V, W \in \mathrm{CP}(A,B)$ with separable C^*-algebra A.

To be shown: Then V and W are in the m.o.c. cone generated by $V + W$. (Could work with the tensor $V \otimes^{\max} \mathrm{id}_{C^*(F_\infty)}$ criterium ?)

Direct way ??

Question: Are V and W "coefficients" of the Hilbert A-B–module generated by $V + W$? Need an absorption theorem for Hilbert A-B-bi-module, like for Hilbert B-modules [**73**, thm. 13.6.2].

Suppose that E is a Hilbert B-module and that $\phi \colon A \to \mathcal{L}(E)$ a C^*-morphism.

Let $\mathcal{C} \subseteq \mathrm{CP}(A,B)$ denote the point-norm closed m.o.c. cone generated by the "coefficients" $V_x \colon a \in A \mapsto \langle \phi(a)x, x \rangle \in B$ for $x \in E$.

Let E^∞ the Hilbert-B-module given by the sequences $(x_1, x_2, \ldots)$ with $x_k \in E$ and $\sum_{k=1}^{\infty} \langle x_k, x_k \rangle \in B$.

Define $\phi^\infty \colon A \to \mathcal{L}(E^\infty)$ by $\phi^\infty(a)(x_1, x_2, \ldots) := (\phi(a)x_1, \phi(a)x_2, \ldots)$

Then the set of "coefficient" maps $A \ni a \mapsto \langle \phi^\infty(a)y, y \rangle \in B$ for $y \in E^\infty$ is an m.o.c. cone $\mathcal{C}(\phi^\infty) \subseteq \mathrm{CP}(A,B)$.

This cone is in particular σ-additively and "homogenous ??" closed.

(not so likely) CONJECTURE (1):
The family of "coefficients" is *hereditary* in the following sense:

If $V: A \to B$ is a c.p. map and has the property that there exists a c.p. map $W: A \to B$ such that $V+W$ is a "coefficient" of a representation $\varphi: A \to \mathcal{L}(\mathcal{H}_B) \cong \mathcal{M}(B \otimes \mathbb{K})$, then V and W are "coefficients" of φ.

(very likely) CONJECTURE (2):

Suppose that A and B are stable C^*-algebras, where A is separable and B is σ-unital. $\phi_1, \phi_2: A \to \mathcal{M}(B)$ C^*-morphisms such that there exists a unitary $u \in \mathcal{M}(B)$ such that $\delta_\infty(\phi_1(a))u - u\delta_\infty(\phi_1(a)) \in B$ for all $a \in A$.

Then the "coefficients" $b^*\phi_1(\cdot)b$ and $b^*\phi_2(\cdot)b$ (for all $b \in B$ together!) generate the same point norm closed m.o.c. cone $\mathcal{C} \subseteq \mathrm{CP}(A, B)$.

(By a result in Chp. 5 one gets – conversely ??? – that $\delta_\infty \circ \phi_1$ and $\delta_\infty \circ \phi_2$ are unitarily homotopic in $\mathcal{M}(B)$.)

`Urgently needed / speculative Conjectures:`

If A is σ-unital then $\mathcal{C}(\phi^\infty)$ is closed with respect to the point-norm topology.

`This is not true?` Counterexample: Let $A := \mathrm{C}([0,1])$, $B := \mathbb{C}$ and $\phi: A \to \mathcal{L}(\ell_2) = \mathcal{M}(B \otimes \mathbb{K})$ the representation generated by $\phi(f) = \sum_n f(\rho(n))e_n$ for some map ρ from $\mathbb{N}$ onto the rational numbers in $[0,1]$. Then the point-norm closure of of the algebraic $\mathcal{C}(\phi^\infty)$ defined by the set of "coefficients" does not contain the c.p. map $f \in A \mapsto \int_0^1 f(t)\mathrm{d}t \in \mathbb{C}$. But this map is in the point norm closure of $\mathcal{C}(\phi^\infty) \subseteq \mathrm{CP}(A, \mathbb{C})$.

`Need here more precise definitions !!`

Perhaps use the following 3 lemmata (if true !):

1. Let K a convex cone in $\mathrm{C}(\mathbb{C}^n, B)_+$ that satisfies that $b^*Kb \subseteq K$ for all $b \in B$ and that K is σ-additive in the sense that if $V_1, V_2, \ldots \in K$ and $W(a) := \sum_n V_n(a) \in B$ for all $a \in \mathbb{C}^n$ then $W \in K$. Then K is point-norm closed.

2. Let A a separable C^*-algebra, $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ an m.o.c. cone with the additional property that $\mathcal{C}$ is σ-additive – in the sense that if $V_1, V_2, \ldots \in \mathcal{C}$ and

$$W \otimes \mathrm{id}_2(a) := \sum_n V_n \otimes \mathrm{id}_2(a) \in B \otimes M_2 \quad \text{for all } a \in A \otimes M_2\,,$$

then $W \in \mathcal{C}$.

Then $\mathcal{C}$ is point-norm closed.

(Unfortunately it is not true in case $A = \mathrm{C}([0,1])$, $B := \mathbb{C}$???)

3. Something like this being "almost hereditary":

Let $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ a point-norm closed m.o.c. cone, $W \in \mathrm{CP}(A, B)$ and $V \in \mathcal{C}$ such that for each $T \in (A \otimes M_n)_+$ there exists $\gamma_{T,n} \in (0, \infty)$ with $(W \otimes \mathrm{id}_n)(T) \leq \gamma_{T,n} V(T)$

and ???? then $W \in \mathcal{C}$???? or?

REMARK 3.2.5. Suppose that A is separable and stable, B is σ-unital and stable and that $\mathcal{S} \subseteq \mathrm{CP}(A,B) \subseteq \mathcal{L}(A,B)$ is

a separable subset of $\mathcal{L}(A,B)$ with respect to point-norm topology ????, ???? or is "countably generated as m.o.c. cone"

in $\mathrm{CP}(A,B)$????

in the strong operator topology on $\mathcal{L}(A,B)$ ([15]).

Then, by Corollary 5.4.4, there is a C^*-morphism $H_0\colon A \to \mathcal{M}(B)$ such that

(i) H_0 is unitarily equivalent to its infinite repeat $\delta_\infty \circ H_0$,
(ii) the "coefficients" $A \ni a \mapsto b^* H_0(a) b \in B$ are all in the point-norm closed m.o.c. cone $\mathcal{C}(\mathcal{S}) \subseteq \mathrm{CP}(A,B)$ generated by $\mathcal{S}$, and
(iii) for each $V \in \mathcal{S}$ there exists $x \in B$ with $V(a) = \langle H_0(a)x, x\rangle$ for all $a \in A$.
more ????:
Need: (But have only weaker results !)
All $V \in \mathcal{C}(\mathcal{S})$ have this property !
Means:
The set of "coefficients" is closed in the topology of point-norm convergence.
(But this is not satisfied in general ... e.g. in case $\mathcal{S} \subseteq \mathrm{CP}(A,\mathbb{C})$ is generated by algebraical by a $\sigma(A^*, A)$ dense subset of the pure states of A.)

In particular, $H_0(A) \cap B = \{0\}$, and $V \in \mathcal{C}(\mathcal{S})$ if and only if there is a sequence $b_1, b_2, \ldots$ in B with $\|b_n\|^2 \le \|V\|$ such that $V(a) = \lim_n b_n^* H_0(a) b_n$ for all $a \in A$.

(This is a better property !!! But it does not say that V is itself a coefficient of of $\delta_\infty \circ H_0$. (The infinite repeat δ_∞ on $\mathcal{M}(B)$ is given by $\delta_\infty(a) := \sum_n s_n a (s_n)^*$ where $s_1, s_2, \ldots$ is a sequence of isometries in $\mathcal{M}(B)$ with $\sum_n s_n (s_n)^*$ strictly convergent to $1_{\mathcal{M}(B)}$, cf. Remark 5.1.1(8).)

H_0 is determined up to *unitary homotopy* in the sense of Definition 5.0.1, cf. Corollary 5.4.4.

(One has $H_0 = 0$ if $\mathcal{S} = \{0\}$.)

If A and B are separable then every m.o.c. cone $\mathcal{C} \subseteq \mathrm{CP}(A,B) \subset \mathcal{L}(A,B)$ is separable with respect to the point-norm operator topology (– given by the semi-norms $V \mapsto \|V(a)b\|$ on $\mathcal{L}(A,B)$ –), because $\mathcal{L}(A,B)$ is separable in the point-norm operator topology.

Question: Is the point-norm closure identical with the cone defined by the related kernel ideal of $A \otimes^{\max} C^*(F_\infty) \to B \otimes^{\max} C^*(F_\infty)$?

LEMMA 3.2.6. *Suppose that* $m_1, \ldots, m_s \in \mathbb{N}$ *and* $X_1, \ldots, X_s$ *are closed subsets of* $(0,1]$ *with* $1 \in X_j$, $j = 1, \ldots, s$.

[15] It is equal to the topology of point-norm convergence of $\mathcal{L}(A,B)$.

Let $A := \mathrm{C}_0(X_1, M_{m_1}) \oplus \cdots \oplus \mathrm{C}_0(X_n, M_{m_s})$, $F := M_{m_1} \oplus \cdots \oplus M_{m_s}$, *let* $\lambda \colon \mathrm{C}_0((0,1] \otimes F) \to A$ *the natural epimorphism given by*

$$\lambda(f \otimes (\alpha_1 \oplus \cdots \oplus \alpha_s)) := ((f|X_1) \otimes \alpha_1) \oplus \cdots \oplus ((f|X_n) \otimes \alpha_s)\,,$$

let $\pi_1 \colon A \to F$ *the epimorphism given by* $\pi_1(g_1 \oplus \cdots \oplus g_s) := g_1(1) \oplus \cdots \oplus g_s(1)$, *and let* $\mathcal{S} \subseteq \mathrm{CP}(A, B)$ *a subset with the property that*
for mutually orthogonal $a_1, \ldots, a_k \in A_+$ *with* $\|a_i\| = 1$, $b \in B_+$ *with* $\|b\| = 1$ *and* $\varepsilon > 0$, *there are* $d_1, \ldots, d_k \in B$ *and* $S \in \mathcal{S}$ *with*

$$\|d_i^* S(a_j) d_i - b\| < \varepsilon \qquad \text{for} \quad i = 1, \ldots, k\,.$$

Let $\mathcal{C}$ *denote the point-norm closure of the set of c.p. maps* $T \colon A \to B$ *such that there are* $S \in \mathcal{S}$, $n \in \mathbb{N}$, *a row* $r \in M_{1,n}(A)$ *and a column* $c \in M_{n,1}(B)$ *with* $T(\cdot) = c^* S(r^*(\cdot) r) c$.

- (o) $\mathcal{C}$ *contains the c.p. map* $T = V \circ \pi_1$ *if* $V \colon F \to B$ *is of* elementary *type, i.e.,* $V \circ \eta_j \colon M_j \to B$ *is given by a column* $b \in M_{n,1}(B)$ *in the sense* $V \circ \eta_j(\alpha) = b^* \alpha b$, *where* $\eta_j(\alpha) := 0 \oplus \cdots \oplus \alpha \oplus \cdots \oplus 0$ *with* α *at position* j.
- (i) *If, for every positive contraction* $b \in B_+$ *and* $\varepsilon > 0$, *there are contractions* $b_1, b_2 \in B$ *with* $b_2^* b_1 = 0$ *and* $\|b_j^* b_j b - b\| < \varepsilon$, *then* $\mathrm{CP}(F, B) \circ \pi_1 \subseteq \mathcal{C}$, *i.e.,* $\mathcal{C}$ *contains* all *c.p. maps* $T \colon A \to B$ *with* $T(\lambda(f_0(1 - f_0))) = 0$, *i.e.,* $V \circ \pi_1 \in \mathcal{C}$ *for all* $V \in \mathrm{CP}(F, B)$.
- (ii) *If* $\mathcal{C}$ *is convex, then* $\mathrm{CP}(F, B) \circ \pi_1 \subseteq \mathcal{C}$.
- (iii) *If* 1 *is* not *isolated in* X_j *for every* $j = 1, \ldots, k$, *then* $\mathrm{CP}(F, B) \circ \pi_1 \subseteq \mathcal{C}$.

For the parts (o)–(ii) one needs only the assumption on $\mathcal{S}$ with $k = 1$. The assumption with $k = \max(m_1, \ldots, m_s)$ is needed for the proof of part (iii).

PROOF. We consider the point-norm closed subset $\mathcal{C}_1$ of $\mathrm{CP}(F, B)$, consisting of the maps $V \in \mathrm{CP}(F, B)$ with the property that there is a sequence $T_n \in \mathcal{C}$ such that $\lim_n T_n(f) = V(f(1))$ for all $f \in \mathrm{C}_0((0,1], F)$.

The set $\mathcal{C}_1$ is invariant under the operations (OC2) of Definition 3.2.2, because $\mathcal{C}$ is invariant under the operations (OC2) and $\pi_1 \colon f \mapsto f(1)$ is an epimorphism. With other words, $V = c^* W(r^*(\cdot) r) c \in \mathcal{C}_1$ if $W \in \mathcal{C}_1$ and $c \in M_{n,1}(B)$ and $r \in M_{1,n}(F)$.

In particular, we have that $V(p(\cdot)) \in \mathcal{C}_1$ and $V_1(p_1(\cdot)) + V_2(p_2(\cdot)) \in \mathcal{C}_1$ for central projections $p, p_1, p_2 \in F$ with $p_1 p_2 = 0$, and for $V, V_1; V_2 \in \mathcal{C}_1$. (This reduces also the proof to the case where F is a full matrix algebra, i.e., to the case $s = 1$.)

(o): We denote the (upper left corner) minimal projection of $\eta_j(M_{m_j}) \cong M_{m_j}$ by $q_j \in F$, and let $\rho_j \colon F \to \mathbb{C}$ denote the (unique) pure state with $\rho_j(q_j) = 1$. Recall that $\rho_j(g) q_j = q_j g q_j$ for $g \in F$. Let $\rho = \rho_1 + \ldots + \rho_s$. (The q_j have pairwise orthogonal central supports p_j.)

If $V \colon F \to B$ is an

Def. of ''elementary'' in Part(o):
" $V \circ \eta_j \colon M_j \to B$ is given by a column $b \in M_{n,1}(B)$ in the sense $V \circ \eta_j(\alpha) = b^* \alpha b$, where $\eta_j(\alpha) := 0 \oplus \cdots \oplus \alpha \oplus \cdots \oplus 0$ with α at position j."

elementary c.p. map and $\delta > 0$, then there exists a contraction $e \in B_+$, such that $V = c^* W(r^*(\cdot)r)c$ for $W = \rho(\cdot)e$ some $c \in M_{t,1}(B)$ and $r \in M_{1,t}(F)$

Why? More precise? Part? (cf. Prop. 3.1.9).

Prop. 3.1.9 has been changed!!!

Thus, it suffices to show that, for $b \in B_+$ with $\|b\| = 1$, $\varepsilon > 0$ and $j \in \{1, \ldots, s\}$, there exists $V_j \in \mathcal{C}_1$ and $c_j \in B$ with $\|c_j^* V_j(p_j)c_j - e\| < \varepsilon$. Indeed, this implies that the point-norm closed $\mathcal{C}_1$ actually "contains" $\rho_j(\cdot)b$, and then $W, V \in \mathcal{C}_1$, because the central supports p_j of the q_j are orthogonal.

Define a c.p. map $W \colon F \to \mathrm{C}_0((0,1], F)$ by $W(g) := f_0 \otimes g$ for $g \in F$, where $f_0(t) = t$ for $t \in [0,1]$. Let $q := q_j$ and define

$$h_\delta := \delta^{-1}((f_0 - (1-\delta))_+) \otimes 1 \in \mathrm{C}_0((0,1], F)_+ \,.$$

Then $a_\delta := W(q)h_\delta$ is positive and $\|a_\delta\| = 1$, thus, there is $S_\delta \in \mathcal{S}$ and $d_\delta \in B$ with $\|d_\delta^* S_\delta(a_\delta^2)d_\delta - b\| < \delta$. Note that

$$T_\delta(g) := (d_\delta)^* S_\delta(a_\delta g a_\delta)d_\delta \qquad \text{for} \quad g \in \mathrm{C}_0((0,1], F)$$

defines a map in $\mathcal{C}$ and that $\lim_{\delta \to 0} \|T_\delta(g) - \rho_j(g(1))b\| = 0$ for all $g \in \mathrm{C}_0((0,1], F)$. Hence $\rho_j(\cdot)b \in \mathcal{C}_1$.

(i): By part (o), all

Why the Lemma applies? ??? Definition? of :

"elementary"

c.p. maps $V \colon F \to B$ are contained in $\mathcal{C}_1$. The supposed property of B implies that the elementary c.p. maps are dense in $\mathrm{CP}(F, B)$ by Proposition 3.1.9(ii). ???

Prop. 3.1.9(ii) = Old lem:3.3(ii) has been changed

(ii): This follows from part (o), because the set of $V \in \mathrm{CP}(F, B)$ with $V \circ \pi_1 \in \mathcal{C}$ contains all elementary maps V and is convex by the proposed convexity of $\mathcal{C}$.

(iii): If 1 is not isolated in X_j (for $j \in \{1, \ldots, s\}$), then we can find a strictly increasing sequence $0 =: t_0 < t_1 < t_2 < \cdots$ in X_j such that $\lim t_n = 1$. Let $q := q_j \in F$, $m := m_j$ and $p := p_j$ the central support of q.

Revise proof!
Prop. 3.1.9(i) has been changed!!

We show that our general assumptions (with $k \geq m$) implies that $\mathcal{C}_1$ contains $V(p(\cdot)) = V \circ \pi_j$ for every $V \in \mathrm{CP}(M_m, B)$:

By Proposition 3.1.9(i) there are columns $c_1 = [c_{11}, c_{12}, \ldots, c_{1n}]^\top, \ldots, c_n \in M_{n,1}(B)$ such that $V(\alpha) = \sum_{i=1}^n c_i^* \beta c_i$. There are contractions $e_n \in B_+$ with $\|c_i - (e_n \otimes 1_n)c_i\| < 1/n$.

We identify $C_0(0,1]$ naturally with the center $C_0(0,1] \otimes 1$ of $C_0((0,1], M_m) \subseteq C_0((0,1], F)$. We find (pice-wise linear) non-negative functions $f_n \in C_0(0,1]_+$ with support in $[(t_{n-1}+t_n)/2, (t_n+t_{n+1})/2]$ such that $\|f_n\| \leq 1$ and $f(t_n) = 1$.

Further there are functions $b_n \in C_0(0,1]_+$ with support in $[t_{n-1}, 1]$ such that $0 \leq b_n \leq 1$ and $b_n|[(t_{n-1}+t_n)/2, 1] = 1$. Then $b_n b_{n+1} = b_{n+1}$ and $b_n f_{n+j} = f_{n+j}$ for all $j \geq 0$.

Let $W(g) := f_0 \otimes g$

`Where/ What was Part (o) ???`

(as in proof of (o))

and $a_n := W(q) f_n \in C_0(0,1] \otimes q$. Then $\|a_n\| = t_n$ and the a_n are mutually orthogonal. Therefore (and by assumptions on $\mathcal{S}$), there exist $S_n \in \mathcal{S}$ and $d_{n,0}, \ldots, d_{n,m-1} \in B$ with

$$\|(d_{n,j})^* S_n\big((a_{n+j})^2\big) d_{n,j} - (t_{n+j})^2 e_n\| < 1/n \qquad \forall\ j \in \{0, \ldots, n-1\}.$$

Consider the c.p. maps $T_n(g) := Z_n^* S_n(R_n^* g R_n) Z_n$ with column $Z_n \in M_{m^2,1}(B)$ with transposed row $(Z_n)^\top$ given by

$$(Z_n)^\top := [d_{n,0} \cdot (c_1)^\top, \ldots, d_{n,m-1} \cdot (c_m)^\top] = [d_{n,0} c_{11}, d_{n,0} c_{21}, \ldots, d_{n,m-1} c_{mm}]$$

and row $R_n \in M_{1,m^2}(C_0((0,1], M_m))$ given by

$$R_n := [r_1^{(n)}, \ldots, r_m^{(n)}],$$

where $r_j^{(n)} := [(1 \otimes e_{1,1}) \cdot a_{n+j-1}, \ldots, (1 \otimes e_{m,1}) \cdot a_{n+j-1}]$ which is equal to

$f_{n+j-1} \cdot [(f_0 \otimes e_{1,1}), \ldots, f_0 \otimes e_{n,1}]$.

Here $e_{i,k}$ denote the matrix units of M_m. Note that $q = e_{1,1}$ and $[\alpha_{ij} q] = x^* \alpha x \in M_m(M_m)$ for $\alpha \in M_m$ and $x := [e_{1,1}, \ldots, e_{m,1}] \in M_{1,m}(M_m)$. It follows

$$T_n(f \otimes \alpha) = \sum_j \Big(\sum_{i,k} \alpha_{ik} c_{ij}^* d_{n+j-1}^* S_n(a_{n+j-1}(f \otimes q) a_{n+j-1}) d_{n+j-1} c_{kj}\Big)$$

for $f \in C_0(0,1]$ and $\alpha \in M_m$. `check? to be filled in`

??

The c.p. maps $d_n^* S_n(a_n(\cdot) a_n) d_n$ have norms $\leq 1 + 1/n \leq 2$. Since $0 \leq g \leq f \otimes 1_m \leq \|g\|$ for $f(t) = \|g(t)\|$ if $g \in C_0((0,1], F)_+$, we can see that $\|T_n\| \leq 2m\|V\|$. For $\varepsilon > 0$ there is n_0 with $\|f b_n - f(1) b_n\| < \varepsilon/(2m)^3$ for $n \geq n_0$. Since $T_n((f b_n) \otimes \alpha) = T_n(f \otimes \alpha)$ and $S_n(a_{n+j-1}(b_n \otimes q) a_{n+j-1}) = S_n(a_{n+j-1}^2)$, it follows that, for $n \geq n_0$,

$$\|T_n(f \otimes \alpha) - f(1) \sum_j \sum_{ik} \alpha_{ik} c_{ij}^* e_{n+j-1} c_{kj}\| \leq \max(|\alpha_{ik}|) \cdot m^3 (1/n + 2\varepsilon/(2m)^3)$$

Thus $\lim_n \|T_n(f \otimes \alpha) - f(1) V(\alpha)\| = 0$ for all $f \in C_0(0,1]$ and $\alpha \in M_m$. Since $\sup \|T_n\| < \infty$, it follows $\lim_n \|T_n(g) - V(g(1))\| = 0$ *for every* $g \in C_0((0,1], F)$. By our construction, $T_n \in \mathcal{C}$. Hence $V \in \mathcal{C}_1$. □

LEMMA 3.2.7. *Suppose that* $\mathcal{S} \subseteq \mathrm{CP}(A, B)$ *is a set of completely positive maps such that, for every* $k \in \mathbb{N}$, $a_1, \ldots, a_k \in A_+$ *with* $\|a_j\| = 1$ *and* $a_i a_j = 0$ *for* $i \neq j$, *every* $b \in B_+$ *with* $\|b\| \leq 1$ *and every* $\varepsilon > 0$, *there exist* $d_1, \ldots, d_k \in B$ *and* $S \in \mathcal{S}$ *with* $\|d_j^* S(a_j) d_j - b\| < \varepsilon$ *for* $j = 1, \ldots k$.

Let $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ *denote the point-norm closure of the* (OC2)*-hull* $\langle \mathcal{S} \rangle_2$ *of* $\mathcal{S}$, *i.e., let* $\mathcal{C}$ *denote the point-norm closure of the set of c.p. maps* $T \colon A \to B$ *such that there are* $S \in \mathcal{S}$, $n \in \mathbb{N}$, *a row* $r \in M_{1,n}(A)$ *and a column* $c \in M_{n,1}(B)$ *with* $T(\cdot) = c^* S(r^*(\cdot) r) c$.

Then we get that ????

$\mathrm{CP}_{\mathrm{nuc}}(A, B) \subseteq \mathcal{C}$, *i.e., each nuclear c.p. map* $V : A \to B$ *can be approximated in point-norm by maps* $T := c^* S(r^*(\cdot) r) c$ *with* $S \in \mathcal{S}$.

in each of the following cases (i), (ii) *or* (iii)*:*

(i) *If, for every* $b \in B$ *and* $\varepsilon > 0$, *there exist* $e_1, e_2 \in B$ *with* $e_1^* e_2 = 0$ *and* $\|b - e_j^* e_j\| < \varepsilon$ *for* $j = 1, 2$.
(ii) *If* $\mathcal{C}$ *is convex.*
(iii) *If* $\mathrm{socle}(A) = \{0\}$.

The condition (i) is e.g. satisfied if B stable, or if B contains an approximate unit $\{e_\alpha\}$ of properly infinite contractions.

The proofs of the cases (i), (ii), and (iii) are rather different, e.g. in the proof of (i) and (ii), we use only the case $k = 1$. In a sense the assumption on $\mathcal{S}$ is almost necessary, because if $b \in B_+$ and orthogonal $a_1, \ldots, a_k \in A_+$ of norm one are given, then there are pure states $\rho_1, \ldots, \rho_k$ on A with $\rho_j(a_j) = 1$. Then $S(a) := (\sum_j \rho_j(a)) b^{1/3}$ and $d_j := b^{1/3}$ satisfy the assumptions on $\mathcal{S}$, e.g. in case $\mathcal{S} := \{ f(\cdot) b \,;\, f \in A_+^* \,, b \in B_+ \}$.

PROOF. (i, ii): We check the criteria for $\mathrm{CP}_{\mathrm{nuc}}(A, B) \subseteq \mathcal{C}$ of Lemma 3.2.1. Let F finite-dimensional and $\psi \colon \mathrm{C}_0((0, 1], F) \to A$ a *-morphism such that $\|\psi(f_0 \otimes p)\| = 1$ for all non-zero projections $p \in F$. Then the quotient $\psi(\mathrm{C}_0((0, 1], F))$ of $\mathrm{C}_0((0, 1], F)$ and the restrictions of $V \in \mathcal{S}$ satisfy the assumptions of Lemma 3.2.6, because (OC2)-hull of $\mathcal{S} \circ \psi$ is point-norm dense in $\mathcal{C} \circ \psi$ for the (OC2)-hull of $\mathcal{S} \subseteq \mathrm{CP}(A, B)$.

Thus the criteria is satisfied in the cases (i) and (ii) by Lemma 3.2.6(i,ii). Hence, $\mathrm{CP}_{\mathrm{nuc}}(A, B) \subseteq \mathcal{C}$ under the additional assumptions of parts (i) and (ii) by This proves (i) and (ii).

(iii): We use Lemma 3.2.6(iii) to show that the criteria of Lemma 3.2.1 is satisfied. Again let F finite-dimensional and $\psi \colon \mathrm{C}_0((0, 1], F) \to A$ a *-morphism such that $\|\psi(f_0 \otimes p)\| = 1$ for all non-zero projections $p \in F$. Unfortunately, 1 could be isolated in the spectrum of $\psi(f_0 \otimes p)$ for some minimal non-zero projection $p \in F$.

Let $F \cong M_{m_1} \oplus \cdots \oplus M_{m_k}$ and let $\psi_j \colon \mathrm{C}_0((0,1], M_{m_j}) \to A$ the *-morphisms with $\psi(g) = \psi_j \circ \pi_j(g)$ for $j = 1, \ldots, k$, where π_j denotes the natural epimorphism $\pi_j \colon F \to M_{m_j}$.

The hereditary C^*-subalgebras D_j of A generated by $\psi_j(\mathrm{C}_0((0,1], M_{m_j}))$ are mutually orthogonal. Since $\mathrm{socle}(A) = 0$ (by assumption), $\mathrm{socle}(D_j) = 0$ and Lemma A.10.3 says that there exist increasing continuous maps $\lambda_j \colon [0,1] \to [0,1]$ with $\lambda_j(0) = 0$ and $\lambda_j(1) = 1$, *-morphisms $\varphi_j \colon \mathrm{C}_0((0,1], M_{m_j}) \to D_j$ with $\varphi_j(f \circ \lambda_j) = \psi_j(f)$ for $f \in \mathrm{C}_0((0,1], M_{m_j})$, such that 1 is not isolated in the spectrum of $\varphi_j(f_0 \otimes 1)$ and $\varphi_j(f_0 \otimes 1)\varphi_i(f_0 \otimes 1) = 0$ for $i \neq j$. Then the image of $\varphi(g) := \sum \varphi_j(\pi_j(g))$ satisfies the assumptions of Lemma 3.2.6(iii), i.e., 1 is not isolated in $X_1, \ldots, X_n \subseteq (0,1]$ with $\varphi(\mathrm{C}_0((0,1] \otimes F)) \cong \mathrm{C}_0(X_1, M_{m_1}) \oplus \cdots \oplus \mathrm{C}_0(X_k, M_{m_k})$. Thus Lemma 3.2.6(iii) applies to φ, and for every $V \in \mathrm{CP}(F, B)$ there is a sequence $S_n \in \mathcal{C}$ with $\lim_n S_n(\varphi(g)) = V(g(1))$ for all $g \in \mathrm{C}_0((0,1], F)$. By Lemma 3.1.8, it follows from the (OC2)-invariance of $\mathcal{C}$ that sequence S_n can be chosen with $\|S_n\| \leq \|V\|$. Thus $S_n|D$ has norm $\leq \|V\|$, where D denotes the hereditary C^*-algebra generated by $\varphi(f_0 \otimes 1)$. In particular, $\lim_n S_n(\varphi((f_0(1 - f_0) \otimes 1)) = 0$. Since S_n is positive, it follows $\lim_n S_n(a) = 0$ for all $a \in E$, where E denote the hereditary C^*-subalgebra of A generated by $\varphi((f_0(1 - f_0) \otimes 1)$. By Lemma A.10.3, $\psi(g) - \varphi(g) = \sum_j \varphi_j(\pi_j(g \circ \lambda_j) - \pi_j(g)) \in E$ for $g \in \mathrm{C}_0((0,1], F)$. It follows $\lim_n S_n(\psi(g)) = \lim_n S_n(\varphi(g) + e) = V(g(1))$. Thus, the criteria of Lemma 3.2.1 is satisfied. □

Corollary 3.2.8. *The set* $\mathrm{CP}_{\mathrm{nuc}}(A, B)$ *of nuclear c.p. maps is a point-norm closed m.o.c. cone in the sense of Definition 3.2.2.*

It is the point-norm closure of the smallest subset $\mathcal{S} \subseteq \mathrm{CP}(A, B)$*, that*

(a) *contains all maps* $a \mapsto \sum_{j=1}^{n} \rho_j(a) b_j$ *with pure sates* ρ_j *on* A ($j = 1, \ldots, n$) *and* $b_j \in B_+$*, and*
(b) *is closed under the operation* (OC2) *in Definition 3.2.2.*

If $\mathrm{socle}(A) = \{0\}$*, then it suffices to consider only pure states* ρ_j *on* A *that have pairwise non-equivalent irreducible representations* $D_j \colon A \to L_2(A, \rho_j)$.

Proof. The set of the maps $a \mapsto \sum_{j=1}^{n} \rho_j(a) b_j$ is convex and satisfies the assumptions of Lemma 3.2.7(ii). □

Remark 3.2.9. A first application of Lemma 3.2.7(ii) is the following observation:
Suppose that $C, D \subseteq \mathcal{M}(B)$ *are* C^**-subalgebras of the multiplier algebra* $\mathcal{M}(B)$ *of* B*, such that* DB *is dense in* B *and* $CD \subseteq D$*, and that* D *is simple. Then every nuclear map* $V \colon C \to B$ *is approximately inner*, i.e., can be approximated in point-norm topology by inner c.p. maps $c \in C \mapsto \sum_j b_j^* c b_j \in B$ (with $b_1, \ldots, b_n \in B$).

(Indeed, the cone $\mathrm{CP}_{\mathrm{in}}(C, B)$ of inner c.p. maps $c \mapsto \sum_j b_j^* c b_j$ satisfies (OC1) and (OC2). The assumptions of Lemma 3.2.7(ii) are satisfied, because D is a simple non-degenerate C^*-subalgebra of $\mathcal{M}(B)$ and $C \subseteq \mathcal{M}(D) \subseteq \mathcal{M}(B)$:

Indeed, if $a_1, \ldots, a_k \in C_+$ are non-zero, pair-wise orthogonal and have norms $\|a_j\| = 1$, $b \in B_+$, then, for $\varepsilon > 0$, there are $e_0, e_1, \ldots, e_k \in D$ with $e_i^* a_j e_i = \delta_{ij} e_0$, $\|e_0\| = 1$ and $f_1, \ldots, f_m \in C$ with $\|b - \sum b^{1/2} f_j^* e_0 f_j b^{1/2}\| < \varepsilon$ (because $C \subseteq \mathcal{M}(D) \subseteq \mathcal{M}(B)$, D is simple and DB is dense in B). Thus, $T(c) := \sum_{i,j} (e_i f_j b^{1/4})^* c (e_i f_j b^{1/2})$ and $d_i = b^{1/4}$ satisfy the assumptions of Lemma 3.2.7.)

Next related to WvN-Thm. form Elliott and Kucerovsky.
Give precise reference to it!!!

LEMMA 3.2.10. *Suppose that $C \subseteq \mathcal{M}(B)$ is a C^*-subalgebra, $J \lhd C$ is a closed ideal and that for every $c \in C_+$ with $\|c + J\| = 1$, every $b \in B_+$ and $\varepsilon > 0$ there exists $d = d(c, b, \varepsilon) \in B$ with $d^* c d \geq (b - \varepsilon)_+$.*

Let $V : C \to B$ a c.p. map with $V(J) = 0$ such that $[V]_J : C/J \to B$ is nuclear.

Then V is approximately one-step inner in $\mathcal{M}(B)$.

?...in the sense that there exists a net of elements $\{d_\tau\} \subseteq B$ with $V(c) = \lim_\tau d_\tau^* c d_\tau$ for each $c \in C$. In particular, $\lim_\tau d_\tau^* c d_\tau = 0$ for all $c \in J$....?

PROOF. We let $A := C/J$ and let $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ denote the *set* of c.p. maps $V : A \to B$ with the property that $V \circ \pi_J : C \to B$ is one-step approximately inner, i.e., that for $c_1, \ldots, c_k \in C_+$ and $\varepsilon > 0$ there is $d \in B$ with $\|d\|^2 \leq \|V\|$ and $\|V(\pi_J(c_j)) - d^* c_j d\| < \varepsilon$ for $j = 1, \ldots, k$. Clearly, $\mathcal{C}$ is closed under the operations (OC2) of Definition 3.2.2.

If $A := C/J \cong \mathbb{C}$ then $A = \mathbb{C} \cdot q$. Let $V : A \to B$ completely positive, $W := V \circ \pi_J$, $b := V(q)$, and $f \in C_+$ a contraction with $\pi_J(f) = q$. For $c_1, \ldots, c_n \in C_+$ and $\delta > 0$ there is a contraction $e \in J_+$ with $\|(1 - e)(f c_k f - \alpha_k f^2)(1 - e)\| < \delta$ if $\alpha_k p = \pi_J(c_k)$, because $f c_k f - \alpha_k f^2$ is in J. Let $d \in B$ with $\|b - d^*(1-e) f^2 (1-e) d\| < \delta$, then $\|W(c_k) - g^* c_k g\| < 2\delta$ for $k = 1, \ldots, n$.

Suppose now that $A := C/J$ has (linear) dimension ≥ 2, then a maximal commutative C^*-subalgebra F of A has dimension ≥ 2. Thus there are $a_1, a_2 \in A_+$ with $a_1 a_2 = 0$ and $\|a_i\| = 1$ for $i = 1, 2$. There is $c \in C$ with $c^* = c$, $\|c\| = 1$ and $\pi(c) = a_1 - a_2$. Let $c_1 := c_+$ and $c_2 := c_-$. Then $\pi_J(c_i) = a_i$ for $i = 1, 2$.

Let $b \in B$ and $\varepsilon > 0$, then there are (by assumptions) $d_i \in B$ with $d_i^*(c_i)^2 d_i \geq (b - \delta)_+$ for $\delta := \varepsilon/3$. By Lemma 2.1.9 there are contractions $f_i \in B$ such that $e_i^* e_i = (b - 2\delta)_+$ for $e_i = c_i d_i f_i \in B$ $(i = 1, 2)$, and $e_1^* e_2 = 0$.

Thus suffices to show, that A, B and $\mathcal{S}$ satisfy the assumptions of Lemma 3.2.7(i) (where the case $k = 1$ is sufficient as the proof of Lemmas 3.2.6(i) and 3.2.7(i) shows), i.e., it suffices to show that, for (given) $a_0 \in A_+$ with $\|a_0\| = 1$, $b \in B_+$ with $\|b\| \leq 1$ and $\varepsilon > 0$, there is $S \in \mathcal{C}$ with $\|S(a_0) - b\| < \varepsilon$.

Let $c_0 \in C_+$ a contraction with $\pi_J(c_0) = a_0$, and let $\varphi \in A^*$ a pure state on A with $\varphi(a_0) = 1$. Then $\psi := \varphi \circ \pi_J$ is a pure state on C with $\psi(J) = 0$. Let $V(a) := \psi(a) b$. It suffices to show that $W := V \circ \pi_J$ is approximately inner. Note that $W(c) = \psi(c) b$.

By Lemma **??**, there exists a directed net $\mathcal{G} \subseteq C$ of positive contractions $g \in \mathcal{G}$ with $\psi(g) = 1$ such that $\lim_{g\to\mathcal{G}} \|gcg - \psi(c)g^2\| = 0$ for all $c \in C$. Thus, for $c_1, c_2, \ldots, c_n \in C$ and $\varepsilon > 0$ (and $\delta := \varepsilon/M$ for $M := (2+2\max_j \|c_j\|)$) there exists a contraction $g \in C_+$ with $\psi(g) = 1$ and $\|gc_jg - \psi(c_j)g^2\| < \delta$ for $j = 1, \ldots, n$. Since $\|\pi_J(g)\| \geq \psi(g) = 1$, there is $d \in B$ with $\delta^{-1}d^*(g^2 - (1-\delta))_+ d = (b-\delta)_+$ (by assumption and by Lemma 2.1.9). Let $f := \delta^{-1/2}(g^2 - (1-\delta))_+ d$. Then $\|f\| \leq 1$, and for $j = 1, \ldots, n$,

$$\|(gf)^* c_j (gf) - \psi(c_j)b\| \leq \delta(1 + 2\max_j \|c_j\|) < \varepsilon\,.$$

□

HERE in next lem.: ''compact'' and ''nuclear'' in what sense?
The point is the question what kind of approximation by factorable maps is required,
i.e., what kind of topology in the set of c.p. contractions has to be taken,
and what kind of c.p. maps S into M_n are accepted?
Strictly continuous S?,
uniformly continuous on which kind of subsets?
all compact subsets, ... norm-continuous anyway ...
Minimal: approx on finite subsets ...,
but ''uniformly'' continuous on the base sets of the topology.
Classic: point-wise uniform on finite sets.

LEMMA 3.2.11. *Let C be a separable C^*-subalgebra of the multiplier algebra $\mathcal{M}(D)$ of a C^*-algebra D (respectively of a von-Neumann algebra M) and $V\colon C \to B$ a nuclear completely positive contraction into a C^*-algebra B.*

Then for every compact subset $\Omega \subseteq C$, every $\varepsilon > 0$ there exist $n \in \mathbb{N}$ and completely positive contractions $S\colon \mathcal{M}(D) \to M_n$ (respectively $S\colon M \to M_n$), $T\colon M_n \to B$, such that

$$\|V(c) - TS(c)\| < \varepsilon \qquad \text{for} \quad c \in \Omega\,,$$

and S is unital and continuous w.r.t. the strict topology on $\mathcal{M}(D)$ (respectively S is unital and $\sigma(M, M_*)$-norm continuous).

PROOF. The multiplier algebra $\mathcal{M}(D)$ is unitally contained in the W*-algebra D^{**} with pre-dual $D^* = (D^{**})_*$. The natural embedding is continuous w.r.t. to the strict topology on $\mathcal{M}(D)$ on bounded parts and w.r.t. the $\sigma(D^{**}, D^*)$-topology on D^{**}. In particular, $S|\mathcal{M}(D)$ is unital and strictly continuous for every ultra-weakly continuous u.c.p. map $S\colon D^{**} \to M_n$. Thus, we can restrict to the case of $C \subseteq M$, where M is a von-Neumann subalgebra of $\mathcal{L}(\mathcal{H})$ for some Hilbert space $\mathcal{H}$. Notice that $S_u(a) := u^*(a \otimes 1)u \in \mathcal{L}(\mathbb{C}^n) \cong M_n$ defines an ultra-weakly continuous u.c.p. map $S_u\colon M \to M_n$ if $u\colon \mathbb{C}^n \to \mathcal{H} \otimes \ell_2(\mathbb{N})$ is an isometry.

Let $\{c_1, \ldots, c_m\} \subseteq \Omega$ a δ-dense subset of Ω for $\delta := \varepsilon/4$. By Definition 3.1.1, Lemma 3.1.8 and Lemma 3.1.11(ii), there are $m \in \mathbb{N}$ and completely positive contractions $S_0 \colon C \to M_m$ and $T_0 \colon M_m \to B$, such that $\|V(c_j) - T_0(S_0(c_j))\| < \delta$ for $j = 1, \ldots, m$.

Since $C \subseteq M \subseteq \mathcal{L}(H)$ we can extend S_0 to a c.p. contraction $W \colon \mathcal{L}(H) \to M_n$ (e.g. by the Arveson extension theorem [**42**]).

The natural extensions of the irreducible representations of D to irreducible representations of $\mathcal{M}(D)$ are strictly continuous if one considers them with the *strong operator topology. The family of this particular irreducible representations of $\mathcal{M}(D)$ is separating for $\mathcal{M}(D)$. If we apply Lemma 3.1.12(i) to this class of irreducible representations of $\mathcal{M}(D)$, then we get a strictly continuous unital c.p. map $S_1 \colon \mathcal{M}(D) \to M_{m_1} \oplus \cdots \oplus M_{m_k} =: F$ and a c.p. contraction $T_1 \colon F \to M_n$ with $\|W(c_j) - T_1(S_1(c_j))\| < \delta$ for $j = 1, \ldots, n$. Thus $\|V(c) - T(S(c))\| < \varepsilon$ for $c \in \Omega$ and $S := T_1 \circ S_1$. □

`The following Lemma 3.2.12 is only` $1\times$ `really cited and used in the proof of Lemma ??. Formulations and proofs have to be improved in both cases.`

In the next proofs we use the property of non-elementary simple C^*-algebras stated in the following Lemma 3.2.12. Here $[\,\cdot\,]$ denotes matrices of operators, and $\|\cdot\|$ means their norms. In part (iv) we put two consecutive rows $[f_{ik}]_i$ ($i = 1, \ldots, k_n$, $k = n, n+1$) together to a row $[h_{in}]_i$ of length $k_n + k_{n+1}$.

Recall that a simple C^*-algebra A is "non-elementary" if A is not isomorphic to the algebra of compact operators on a Hilbert space (and is non-zero). The point of the following Lemma 3.2.12 is that the irreducible representation $D_\varphi \colon A \to \mathcal{L}(A/L_\varphi)$ is faithful on A but has the property that $A \cap \mathbb{K}(A/L_\varphi) = \{0\}$.

LEMMA 3.2.12. *Let A be a non-elementary simple C^*-algebra, φ be a pure state on A and $Y_1 \subseteq Y_2 \subseteq \ldots$ a sequence of subsets of the contractions in the multiplier algebra $\mathcal{M}(A)$ such that each Y_n is* compact *with respect to the* strict *topology on $\mathcal{M}(A)$.*

(This topology on $\mathcal{M}(A)$ is given by the semi-norms $T \in \mathcal{M}(A) \mapsto \|Ta\|$ for $a \in A$?

Check by Def.'s given in Chp. 5.

If A s unital then we could take $X_n = \{1\}$??? What is here X_n? Is it Y_n?)

Where the simplicity plays a role?

`Are ‘‘strictly’’ compact subsets of the unit ball of` $\mathcal{M}(A)$
(i.e., `compact with respect to the strict topology)`
`separable subsets of` $\mathcal{M}(A)$ `in norm topology?`
`It seems that this is supposed implicit below.`
`Have only that this sets are separable w.r.t. strict topology on` $\mathcal{M}(D)$ `if` D `is`σ`-unital.`

Is the unit ball of $\mathcal{L}(\ell_2)$ in the strong operator topology compact? It is at least weakly compact ...*

Let $S_n \colon \mathcal{M}(A) \to M_{k_n}$ a sequence of strictly continuous unital completely positive maps from $\mathcal{M}(A)$ into M_{k_n}.

Does it say that the S_n are ''supported'' in A?
And that the S_n are the unique strictly continuous extensions of $S_n|A$?
If ''yes'' then we find positive contractions $e_{m,n} \in A_+$ with
$\|1_{k_n} - S_n(e_{m,n})\| < 2^{-(m+n)}$,
This could the lead to the a reduction to the case
where A is σ-unital?

Then there exist contractions $f_{in} \in A$ ($n = 1, 2, \ldots$, $i = 1, \ldots, k_n$), $b \in A_+$ and a sequence $m_1 < m_2 < \ldots$ of positive integers such that

(i) $\|[\varphi(f_{in}^* a f_{jn})]_{ij} - S_n(a)\| < 4^{-n}$ *for* $a \in Y_n$,
(ii) $\|[\varphi(f_{im}^* a f_{jn})]_{ij}\| < 4^{-m}$ *for* $a \in Y_n$ *and* $m < n$, $i = 1, \ldots, k_m$, $j = 1, \ldots, k_n$,
(iii) $\|b\| = 1$ *and* $\varphi(b) = 1$,
(iv) $\|[b^\ell h_{in}^* a h_{jn} b^\ell]_{ij} - [b^{2\ell} \varphi(h_{in}^* a h_{jn})]_{ij}\| < 4^{-n}$ *for* $a \in Y_n$ *and* $m_n \leq \ell$ *where* $h_{jn} = f_{im}$ *with* $i = j$, $m = n$ *if* $j \leq k_n$, *and with* $i = j - k_n$, $m = n + 1$ *if* $k_n < j \leq k_{n+1}$.

Proof. (i) and (ii): We can suppose that $1 \in Y_n$.

Since the unital completely positive maps S_n are strictly continuous, there are sequences $d_{\ell,n} \in A_+$ such that $\|d_{\ell,n}\| = 1$ and $\lim_{\ell\to\infty} S_n(d_{\ell,n}) = 1_{k_n}$.

This implies that all S_n are supported on a σ-unital C^*-subalgebra $\overline{eAe}$ of A with $\{d_{\ell,n}\,;\ \ell, n \in \mathbb{N}\} \subseteq \overline{eAe}$.

Moreover, the S_n are restrictions to $\mathcal{M}(A) \subseteq A^{**}$ of its unique normalizations (i.e., weakly continuous extensions to A^{**}) of its restrictions $S_n|A$ to A.

The compactness of the sets Y_n with respect to the strict topology on $\mathcal{M}(A)$ implies that the set $Z := \{e\} \cup \{d_{\ell,n}\,;\ n, \ell \in \mathbb{N}\}$ and the union $\bigcup_{n,m\in\mathbb{N}} Y_n Z Y_m$ generates a separable C^*-subalgebra E of A, such that $Y_n E + E Y_n \subseteq E$ for $n = 1, 2, \ldots$.

Above we claimed that there is and invariant separable C^*-subalgebra E of A, such that $\bigcup_n Y_n$ contained in the two-sided normalizer $\mathcal{N}(E, \mathcal{M}(A)) \subseteq \mathcal{M}(A)$ of E in $\mathcal{M}(A)$.

At least we could find a σ-unital C^*-subalgebra E of A such that the S_n are supported on E, i.e., $\lim_\ell \|S_n(e^{1/\ell}) - 1_{k_n}\| = 0$ for each $n \in \mathbb{N}$ if $e \in E_+$ is a strictly positive contraction in E.

(That would be sufficiant for the rest of the proof.)

If $e \in E_+$ is a strictly positive contraction, then necessarily $\lim_{\ell\to\infty} S_n(e^{1/\ell}) = 1_{k_n}$ for $n = 1, 2, \ldots$ by strict continuity of the $S_n\colon A \to M_{k_n}$, i.e., $\lim_\ell \|S_n(e^{1/\ell}) - 1_{k_n})\| = 0$ in M_{k_n} for each $n \in \mathbb{N}$.

It follows that $\lim_{k\to\infty} S_n(e^{1/k}ae^{1/k}) = S_n(a)$ for $a \in \mathcal{M}(A)$ and $n = 1, 2, \ldots,$ because

$$\|S(fbf) - S(b)\|^2 \leq 8\|b\|^2\|1_C - S(f)\|$$

for every unital completely positive map $S\colon B \to C$ and $f \in B_+$ with $\|f\| \leq 1$.

The verification of the latter inequality can be reduced to the case $C := \mathbb{C}$:

For every state ρ on (general unital) C and contraction $c \in C_+$, holds $|1 - \rho(c)| \leq \|1 - c\|$ and there exists a pure state ρ on C with $|\rho(S(fbf) - S(b))| = \|S(fbf) - S(b)\|$ and such that the restriction of ρ to the Abelian C^*-subalgebra generated by $S(fbf) - S(b)$ is a character.

But if λ (e.g. $\lambda := \rho \circ S$) is a positive functional on B with norm $\|\lambda\| \leq 1$ and $b, f \in B_+$ with $\|f\| \leq 1$ then

$$|\lambda(fbf) - \lambda(b)|^2 \leq 8\|b\|^2|1 - \lambda(f)|\,.$$

Proof of latter inequality:

We can suppose that $B \subseteq \mathcal{L}(\mathcal{H})$ and λ is defined by $x \in \mathcal{H}$ as $\lambda(b) :=< bx, x >$. We let $y := f^{1/2}x$ and $z := fx = f^{1/2}y$. Have $\|x\| \leq 1$ and $\|z\| \leq 1$. $\lambda(f) =< y, y >$, $x - z = (1 - f)x$

$| < bx, x > - < bz, z > | \; = \; |\lambda(fbf) - \lambda(b)|$

$|(< bx, x > - < bx, z >) + (< x, bz > - < z, bz >)| \leq \|b\|\|x\|\|x - z\| + \|b\|\|z\|\|x - z\|$

$\leq 2\|b\|(\|(1 - f)x\|)\,.$

$\|x - fx\|^2 =< x, x > + < fx, fx > -2 < fx, x > = \|(1 - f)x\|^2 =< (1 - f)^2x, x >=< x, x > -2 < fx, x > + < f^2x, x >\leq 2(\|x\|^2 - < fx, x >)$.

$\leq 2(1- < fx, x >)$ if $0 \leq f \leq 1$ and $\|x\| \leq 1$.

Obtain estimate:

$$|\lambda(fbf) - \lambda(b)| \leq 2\|b\|(2(1 - \lambda(f)))^{1/2}$$

From the Banach-Steinhaus (uniform boundedness) theorem we get the existence of constants $C_n < \infty$ with $\|a\| \leq C_n$ for all $a \in Y_n$. Thus we find $g_n \in \mathbb{N}$ such that $\|S_n(e_nae_n) - S_n(a)\| \leq 8^{-n}$ for $e_n = e^{1/g_n}$, $a \in Y_n$.

`It seems that here a quasi-central approximate unit` e_n
`would do on all places a much better job!`

$\Omega_n := e_1Y_1e_1 \cup \cdots \cup e_nY_ne_n$ is a compact subset of $E \subseteq A$.

We consider M_{k_n} as naturally realized on $\mathbb{C}^{k_n}$. The irreducible representation R_φ defined by φ on $H := L_2(A, \varphi)$ (with canonical cyclic vector x) is faithful and

$R_\varphi(A) \cap \mathbb{K} = 0$, because A is simple. By Lemma 2.1.22, there is a sequence of isometries $v_n\colon \mathbb{C}^n \to H$ such that $\|S_n(a) - v_n^* a v_n\| \le 8^{-n}$ and $\|v_n^* a v_m\| < 8^{-n}$ for $a \in \Omega_n$, $m < n$. By the Kadison transitivity theorem, we get contractions $p_{in} \in A$ such that $R_\varphi(p_{in})x = v_n(e_{i,k_n})$. Thus $[\varphi(p_{jn}^* a p_{in})]_{ij} = v_n^* a v_n$ in M_{k_n} and $[\varphi(p_{jm}^* a p_{in})]_{ij} = v_n^* a v_m$ in $M_{k_n,k_m} = \mathcal{L}(\mathbb{C}^{k_m}, \mathbb{C}^{k_n})$ for $a \in \mathcal{M}(A)$ and $m < n$, where $i = 1, \ldots, k_n$, $j = 1, \ldots, k_m$. The elements $f_{in} := e_n p_{in}$ are as desired.

(iii) and (iv): The existence of $b \in A_+$ with (iii) and (iv) follows from Lemma **??**, because the union of the sets $f_{im}^* Y_k f_{jn}$ generate a separable C^*-subalgebra of A by compactness of the sets Y_k with respect to the strict topology. □

`next Prop. and others overlap with chp. 5?`

PROPOSITION 3.2.13. *Suppose that B is a C^*-algebra, and that $D \subseteq \mathcal{M}(B)$ is a simple,* purely infinite, *and non-degenerate C^*-subalgebra of the multiplier algebra $\mathcal{M}(B)$ of B, (i.e., $\overline{DB} = B$).*

Let C a separable C^*-subalgebra of $\mathcal{M}(B)$ that satisfies $CD \subseteq D$.

If $V : C \to B$ is a nuclear *completely positive contraction, then V can be approximated by 1-step inner c.p. maps in the sense of following property (i), respectively properties (i,ii) if B is unital:*

(i) *There exist sequences of contractions $d_n^{(i)} \in B$ ($i = 1, 2$, $n = 1, 2, \ldots$) with $\lim_{n\to\infty} (d_n^{(i)})^* a d_n^{(i)} = V(a)$ for $i = 1, 2$, $a \in C$, and $\lim_{n\to\infty} (d_n^{(i)})^* a d_n^{(j)} = 0$, for $i \neq j$, $a \in C + \mathbb{C}1$.*
(ii) *If, moreover, B is unital, $1_B \in C$ and $V(1) = 1$, then the sequences $(d_n^{(i)})$ ($i = 1, 2$) in (i) can be chosen as isometries with orthogonal ranges: $(d_n^{(i)})^* d_n^{(j)} = \delta_{ij} 1$.*

PROOF. The crucial role plays here that we have the intermediate simple purely infinite C^*-subalgebra $D \subseteq \mathcal{M}(B)$.

(i): We prove a more precise and general result: Let $C \subseteq \mathcal{M}(D)$, $D \subseteq \mathcal{M}(B)$ with $\overline{DB} = B$ (i.e., $1_{\mathcal{M}(B)} \in \mathcal{M}(D) \subseteq \mathcal{M}(B)$), D simple and purely infinite, and let $\Omega_1 \subseteq \Omega_2 \subseteq \ldots \subseteq C$ be a sequence of norm compact subsets of C and $W_n\colon C \to B$ nuclear completely positive contractions, then there exist contractions $d_1, d_2, \ldots \in B$ such that $\|d_n^* d_{n+1}\| \le 2^{-n}$ and $\|d_n^* b d_n - W_n(b)\| < 2^{-n}$ for $b \in \Omega_n$ and $\|d_n^* b d_{n+1}\| < 2^{-n}$ for $b \in \Omega_n$, $n = 1, 2, \ldots$.

Let $V_1 = \ldots = V_8 := W_1$, $V_{n+8} := W_n$. At first we find by Lemma 3.2.11 completely positive contractions $S_n\colon \mathcal{M}(D) \to M_{k_n}$ and $T_n\colon M_{k_n} \to B$ such that S_n is unital and strictly continuous, and $\|T_n(S_n(b)) - V_n(b)\| < 8^{-n}$ for $b \in \Omega_n$.

`Prop. 3.1.9(i) (was old a Lemma) has been changed!!`

Moreover we can assume that T_n is of the form described in Proposition 3.1.9(i) (by passing, if necessary, to $M_{k_n} \otimes M_{k_n}$ and $S_n(.) \otimes 1$). That is, there exist

$e_1^{(n)} \ldots e_{k_n}^{(n)} \in B$ with $T_n(\alpha) = E_n \alpha E_n^*$ for $\alpha \in M_{k_n}$ where E_n is the row matrix $[(e_1^{(n)})^*, \ldots, (e_{k_n}^{(n)})^*]$ and $E_n E_n^* = \sum_{j=1}^{k_n} (e_j^{(n)})^* e_j^{(n)}$ is a contraction.

The Lemma 3.2.12 is imprecise formulated and is used only here!! Find a better source or an other proof here or there?

By Lemma 3.2.12 there exist row matrices $F_n = [f_1^{(n)}, \ldots, f_{k_n}^{(n)}]$ with elements in D, $b \in D_+$ and a sequence $m_1 < m_2 < \ldots$ of positive integers such that (with $b_n := b^{m_n}$)

$$\|(1_{k_n} \otimes b_n) F_n^* a F_n (1_{k_n} \otimes b_n) - S_n(a) \otimes b_n^2\| < 4^{-n} 2$$

and

$$\|(1_{k_n} \otimes b_n) F_n^* a F_{n+1} (1_{k_{n+1}} \otimes b_{n+1})\| < 4^{-n} 2 \qquad \forall \quad a \in \Omega_n \cup \{1\}.$$

Let $\delta_n := (\sup\{\|S_n(a)\| \colon a \in \Omega_n \cup \{1\}\})^{-1}$ and $\gamma_n := \delta_n/(5k_n)$. Consider the separable C^*-subalgebra B_1 of B which is generated by the $e_j^{(n)}$, $n = 1, 2, \ldots$, $j = 1, \ldots, k_n$. B_1 contains a strictly positive element $e \geq 0$ with $\|e\| = 1$. We find a sequence of positive integers $p_n < p_{n+1} < \ldots$ such that, with $e_n := e^{1/p_n}$, we get $\|e_n e_j^{(n)} - e_j^{(n)}\| < 16^{-n} \gamma_n$ for $j = 1, \ldots, k_n$, $n = 1, 2, \ldots$. Then from $B = \overline{DB}$ we get contractions $g_n \in D$ with $\|g_n e_n - e_n\| < 16^{-n} \gamma_n$.

The separable C^*-subalgebra D_1 of D generated by g_n contains a strictly positive element $h \in D_+$ with $\|h\| = 1$, and we find positive integers $r_n < r_{n+1} < \ldots$ such that (with $h_n := h^{1/r_n}$) $\|h_n g_n - g_n\| < 16^{-n} \gamma_n$.

It follows
$\|h_n e_j^{(n)} - e_j^{(n)}\| < 16^{-n} 5 \gamma_n = 16^{-n} \delta_n / k_n$ and $\|E_n^* - (1_{k_n} \otimes h_n) E_n^*\| < 16^{-n} \delta_n$.

Since D is purely infinite and simple, $b_n, h_n \in D_+$ and $\|b_n\| = \|h_n\| = 1$, we find (by Proposition 2.2.1(ii)) $c_n \in D$ with $\|c_n\| = 1$ and $\|c_n^* b_n^2 c_n - h_n\| < 16^{-n} \delta_n$. Then

$$\|E_n(\alpha \otimes c_n^* b_n^2 c_n) E_n^* - E_n \alpha E_n^*\| < 4^{-n} \|\alpha\| \delta_n$$

for $\alpha \in M_{k_n}$, because E_n is a contraction.

Here M_{k_n} is embedded in $M_{k_n}(\mathcal{M}(D)) \cong M_{k_n} \otimes \mathcal{M}(D)$ by $\alpha \mapsto \alpha \otimes 1$.

Now let $z_n := F_n(1_{k_n} \otimes (b_n c_n)) E_n^* \in B$, i.e. $z_n := \sum_{j=1}^{k_n} f_j^{(n)} b_n c_n e_j^{(n)}$. Then

$$\|z_n^* a z_n - T_n S_n(a)\| < 4^{-n} 2 + \|E_n(S_n(a) \otimes c_n^* b_n^2 c_n) E_n^* - E_n S_n(a) E_n^*\|.$$

$$\|z_n^* a z_{n+1}\| \leq \|(1_{k_n} \otimes b_n) F_n^* a F_{n+1} (1_{k_{n+1}} \otimes b_{n+1})\|,$$

because $\|(1 \otimes c_n) E_n^*\| = \|c_n\| \cdot \|E_n\| \leq 1$. It follows that

$$\|z_n^* a z_{n+1}\| < 4^{-n} 2 \qquad \text{and} \qquad \|z_n^* a z_n - T_n S_n(a)\| < 4^{-n} 3 \qquad \forall \quad a \in \Omega_n \cup \{1\}.$$

In particular $\|z_n\|^2 \leq 1 + 4^{-n} 3$.

Let $d_n := (\max(1, \|z_n\|))^{-1} z_n$, then d_n is as desired.

(ii): We have $\lim_{n\to\infty} (d_n^{(i)})^* d_n^{(j)} = 0$ and $\lim_{n\to\infty} (d_n^{(i)})^* d_n^{(i)} = 1$ ($i \neq j$ and $i, j = 1, 2$) from part (i). Thus, eventually small perturbations of the $d_n^{(i)}$'s (i=1,2) are as desired. □

Next remark sort of pre-version of the WvN-theorem in chp.5?

REMARK 3.2.14. There is a more delicate counterpart of Proposition 3.2.13 for the case $D \cong \mathbb{K}$ (which is implicitly contained in [**?**]):

Suppose that B is a C^*-algebra, and that $C, D \subseteq \mathcal{M}(B)$ are C^*-subalgebras of the multiplier algebra $\mathcal{M}(B)$ of B, such that D is non-degenerate, i.e., $D \cdot B = B$, and $D \cong \mathbb{K}$. Let C be a separable C^*-subalgebra of $\mathcal{M}(B)$ such that $CD \subseteq D$, and let $V \colon C \to B$ a completely positive map such that $V(C \cap D) = \{0\}$ and suppose that the c.p. map $[V] \colon C/(D \cap C) \to B$ on the "classes"

$$[c] := c \mod (D \cap C) = c + D \cap C$$

is a *nuclear* completely positive map.

Then V is approximately 1-step inner. More precisely, there exists a sequences of contractions $d_n \in B$ with $\lim_{n\to\infty} d_n^* a d_{n+k} = \delta_{0,k} V(a)$ for $a \in C$.

The *proof* uses Lemma 2.2.3 and modifications of arguments from the proof of Proposition 3.2.13.

In the following proposition $\mathrm{C_b}(X, B)$ means the C^*-algebra of continuous functions on a locally compact space X with values in B, and $\mathrm{C_0}(X, B)$ is the closed ideal in $\mathrm{C_b}(X, B)$ formed by the functions $f \in \mathrm{C_b}(X, B)$ with $x \in X \mapsto \|f(x)\|$ vanishing at infinity.

PROPOSITION 3.2.15. *Let $D \subseteq B$ be C^*-algebras, where D is simple and purely infinite and $\overline{DB} = B$. Let X be a locally compact and σ-compact space, C a separable C^*-subalgebra of $\mathrm{C_b}(X, D)$, and $x \in X \mapsto (V_x \colon D \to B) \in \mathrm{CP}(D, B)$ a point-norm continuous map from X into the* nuclear *completely positive contractions from D to B, i.e., $V_x \in \mathrm{CP_{nuc}}(D, B)$ for all $x \in X$.*

Consider the c.p. contraction $V\colon \mathrm{C_b}(X, D) \to \mathrm{C_b}(X, B)$ defined by $V(d)(x) := V_x(d(x))$ for $x \in X$ and $d \in \mathrm{C_b}(X, D)$.

(i) *There exists a contraction $d \in \mathrm{C_b}(X, B)$ such that $d^*cd - V(c) \in \mathrm{C_0}(X, B)$ for $c \in C$.*
(ii) *If moreover B and D are unital, then $1_D = 1_B$. If then $1_D \in C$, i.e., if C contains the unit element of the C^*-algebra $\mathrm{C_b}(X, D)$, and nuclear c.p. map $V_x \colon D \to B$ is unital for every $x \in X$, then the element d in Part(i) can be chosen such that d is moreover an isometry in $\mathrm{C_b}(X, B)$.*

Notice that the $\mathrm{C_b}(X)$-modular c.p. map $c \in \mathrm{C_b}(X, D) \to V(c) \in \mathrm{C_b}(X, B)$ is in general not nuclear, but it is easy to see with help of the "tensor product criterium" that the c.p. maps $c \mapsto f^*V(c)f \in \mathrm{C_0}(X, B)$ with $f \in \mathrm{C_0}(X, B)$ are all nuclear.

PROOF. We reduce the proof essentially to the proof of Part(i) by adding to C a special constant positive contraction $e \in D_+ \subseteq \mathrm{C_b}(X, D)_+$ that makes the larger $C^*(C, e) \supseteq C$ a separable σ-unital C^*-subalgebra of $\mathrm{C_b}(X, D)$, and then select the proposed contraction $d \in \mathrm{C_b}(X, B)$ such that it satisfies in addition the inequality $\|d^*ed - V(e)\| < 1/3$.

(i): By local compactness and σ-compactness of X, there exist an increasing sequence $X_1 \subseteq X_2 \ldots \subseteq X$ of open subsets of X with compact closures $\overline{X_n} \subseteq X_{n+1}$ such that $X = \bigcup X_n$.

If we use the Tietze-Urysohn extension theorem then we find continuous functions $f_n \colon X \to [0,1]$ with $f_n(x) = 1$ for $x \in \overline{X_n}$ and $f_n(x) = 0$ for $x \in X \setminus X_{n+1}$. Let $g_1 := f_1^{1/2}$, $g_n := (f_n - f_{n-1})^{1/2}$ for $n > 1$. Then $f_n f_{n+1} = f_n$, and therefore $g_n g_m = 0$ if $|n - m| > 1$.

Since C is separable by our assumptions, we find separable C^*-subalgebras $D_n \subseteq D$ such that the evaluation epimorphisms $\pi_x \colon \mathrm{C_b}(X_n, D) \to D$ for $x \in \overline{X_n}$ map the separable C^*-algebra $C|\overline{X_n}$ into the separable C^*-subalgebra D_n, i.e., $\pi_x(C) \subseteq D_n$. Thus, the separable C^*-subalgebra $D_\infty := \overline{\bigcup_n D_n}$ has the property that $C \subseteq \mathrm{C_b}(X, D_\infty)$. Let $e \in D_\infty$ a strictly positive contraction in D_∞. Consider it as constant element of $\mathrm{C_b}(X, D)$ and replace C by $C^*(e, C) \subseteq \mathrm{C_b}(X, D)$. Then $e \in C^*(e, C)$ is a strictly positive element of $C^*(e, C)$. If D is unital then we can likewise also take here 1_D in place of e. From now on we suppose that C contains a "distinguished" strictly positive contraction e. Likewise this is the unit of $\mathrm{C_b}(X, D)$ if D is unital.

Now let $Y_1 \subseteq Y_2 \subseteq \ldots \subseteq C$ be finite-dimensional linear subspaces of C, such that C is the closure of the union of the Y_n. Since $C \subseteq \mathrm{C_b}(X, D)$, we find compact subsets $\Omega_1 \subseteq \Omega_2 \subseteq \ldots \subseteq D$ such that $y(x) \in \Omega_n$ for points $x \in X_{n+1}$ and elements $y \in Y_n$ with $\|y\| \leq n + 1$. Consider the nuclear completely positive contractions $V_n \colon D \to \mathrm{C_0}(X, B)$ given by $V_n(b)(x) := (f_{n+1} V(b) f_{n+1})(x)$ for $x \in X$ and $b \in D$, where the $f_n \in \mathrm{C_0}(X)_+$ are as above defined.

Recall that $D \subseteq B \subseteq \mathrm{C_b}(X, B)$ and $\mathrm{C_b}(X, B) \subseteq \mathcal{M}(\mathrm{C_0}(X, B))$ naturally.

$\mathrm{C_0}(X, B)$ is the closure of $D\,\mathrm{C_0}(X, B)$, because is the closure of $B\,\mathrm{C_0}(X, B)$ and B is the closure of DB by the assumptions.

We have shown – under this assumptions of non-degeneracy – in the proof of Proposition 3.2.13 that there exist contractions $d_1, d_2, \dots \in \mathrm{C_0}(X, B)$ with $\|d_n^* b d_n - V_n(b)\| < 2^{-n-1}$, $\|d_n^* b d_{n+1}\| < 2^{-n-1}$ for $b \in \Omega_n$ and $\|d_n^* d_{n+1}\| < 2^{-n-1}$.

Let $h := \sum_{n=1}^{\infty} g_{n+1} d_n$. Now use the above listed properties of g_n, d_n, and the definitions of Ω_n and Y_n.

Then a simple calculation shows, that $h \in \mathrm{C_b}(X, B)$, $\|h(x)\| \leq 1 + 2^{-n}$ for $x \in X \setminus X_n$, $\|h(x)^* b(x) h(x) - V_x(b(x))\| \leq 2^{-n}\|b\|$ for $b \in Y_n$ and $x \in X \setminus X_n$ and $n > 1$, or $n = 1$ and $y \in X$.

Need that $\|d(x)^* e d(x) - e\| < 1/4$ ... ????

Thus $d(x) := (\max(1, \|h(x)\|))^{-1} h(x)$ is a contraction d in $\mathrm{C_b}(X, B)$ with the desired properties.

(ii): If B is unital, then $\overline{DB} = B$ implies $1_B \in D$.

If then $1_B \in C$ and the $V_x(\cdot)$ are unital, then the element we can assume that

$1 \in Y_1$ and have $d(x)^*d(x) \le 1$ and $1 - d^*d \in \mathrm{C}_0(X, B)$. Thus we can replace $d(x) := h(x)(h(x)^*h(x))^{-1/2}$ is an isometry in $\mathrm{C_b}(X, B)$ with the desired properties. □

COROLLARY 3.2.16. *Suppose that B is purely infinite and simple.*

(i) *Let C be a C^*-subalgebra of $\mathcal{M}(B)$. Then every nuclear completely positive contraction V from C to B can be approximated point-wise by maps of the form $c \in C \mapsto d^*cd \in B$, where $d \in B$ and $\|d\| \le 1$.*

(ii) *If C is a separable C^*-subalgebra of $\ell_\infty(B)$ and if $V_n : B \to B$ ($n = 1, 2, \ldots$) is a sequence of nuclear completely positive contractions, then there exist sequences $d_1, d_2, \ldots$ and $e_1, e_2, \ldots$ of contractions in B such that $\lim e_n^* d_n = 0$ for $n = 1, 2, \ldots$, $\lim \|d_n^* \pi_n(c) d_n - V_n(\pi_n(c))\| = 0$ and $\lim \|e_n^* \pi_n(c) e_n - V_n(\pi_n(c))\| = 0$.*

PROOF. (i): Let $Y \subseteq C$ a finite subset and $\varepsilon > 0$. By Proposition 3.2.13 (with $B = D$) there exists a contraction $d \in B$ with $\|d^*ad - V_n(a)\| < \varepsilon$ for $a \in Z$.

(ii): Let $Y_1 \subseteq Y_2 \subseteq \ldots \subseteq C$ be a linear filtration of C. By Proposition 3.2.13 (with $B = D$) there exist contractions $d_n, e_n \in B$ with $\|e_n^* d_n\| \le 1/n$, $\|d_n^* a d_n - V_n(a)\| < 1/n$ and $\|e_n^* a e_n - V_n(a)\| < 1/n$ for every a in the compact set $\{\pi_n(c) : c \in Y_n, \|c\| \le n\}$. □

REMARK 3.2.17. Corollary 3.2.16(ii) has a converse, which is easily established (using Proposition 2.2.1(ii) and the nuclear contractions $a \mapsto \psi(a)b$ for suitable states ψ):
If every nuclear contraction from an arbitrary subalgebra B of $A \neq \{0\}$ into A can be approximated by maps $b \mapsto d^*bd$, $d \in A$ and $\|d\| \le 1$, then either A is simple and purely infinite or $A \cong \mathbb{C}$.

REMARK 3.2.18. As noted in Remark 3.2.17, the assumption that A is purely infinite is quite essential to approximate nuclear maps on subalgebras by maps $b \mapsto d^*bd$.

However, Haagerup and Zsido [**351**] published a proof of the Dixmier conjecture that every simple unital C^*-algebra A with a unique trace state ρ has the so-called "Dixmier property": There exists a net $\{V_\tau\}$ in the convex combination of the inner automorphisms on A that converges point-wise to the map $\rho(\cdot)1$.

REMARK 3.2.19. For contractions a and b in a C^*-algebra B and $\varepsilon \in [0, 1)$ with $\|a^*b\| < \varepsilon^2$ there exist contractions $c, d \in B$ such that $c^*d = 0$, $\|a - c\| < \varepsilon^{1/2}$ and $\|b - d\| < \varepsilon^{1/2}$.

In the case of positive contractions $a, b \in \mathrm{C}_0(X, M_2)_+$ with $\|ab\| < \varepsilon^2$ one can find contractions $c, d \in \mathrm{C}_0(X, M_2)_+$ with $c^*d = 0$ and $\|c - a\| < 2\varepsilon$ and $\|d - b\| < 2\varepsilon$. This is also the general conjecture for contractions $a, b \in C^*(a, b) \subseteq \mathcal{L}(\ell_2)$.

It is easy to see that in case of any functions $a, b \in \mathrm{C}_0(X)$ with $\|ab\| \le \varepsilon$ there exists functions $c, d \in \mathrm{C}_0(X)$ with $cd = 0$, $\|c - a\| \le \varepsilon$ and $\|d - b\| \le \varepsilon$.

In case of projections $a = p$ and $b = q$ we can take $c := p$ and $d := (1-p)q$ with $\|a-c\| = 0$ and $\|b-d\| = \|ab\|$.

The estimates allow us to show that the proofs of Proposition 3.2.13(i) and Corollary 3.2.16(i) can be arranged such that, moreover, $(d_n^{(i)})^* d_n^{(j)} = 0$ for $i \neq j$ (respectively that $e_n^* d_n = 0$).

More details for Remark 3.2.19 : We can replace the contractions a and b by the positive contractions $e := (aa^*)^{1/2}$ and $f := (bb^*)^{1/2}$. Then $a = ev = v(a^*a)^{1/2}$ and $b = fw = w(b^*b)^{1/2}$ for the polar decompositions. They satisfy $\|ef\| = \|a^*b\|$. Let $\gamma := \|ef\|$.

An estimate of the infimum of the distances $\max(\|e - ge^{1/2}\|, \|f - hf^{1/2}\|)$ to all contractions $g, h \in A$ with $g^*h = 0$ then we get also the desired estimate, because $c := ge^{1/2}v$ and $d := hf^{1/2}w$ satisfy $\|c-a\| = \|e - ge^{1/2}\|$ and $\|d-b\| = \|f - hf^{1/2}\|$.

Thus it suffices to consider the special case where $\|e - ge^{1/2}\|$ and $\|f - hf^{1/2}\|$ with $g := (e-f)_+^{1/2}$ and $h := (f-e)_+^{1/2} = (e-f)_-^{1/2}$. Then $(f-e)_+ = (e-f)_-$ implies $g^*h = 0$.

Recall $2(f-e)_+ = |f-e| + (f-e)$ and $2(e-f)_+ = |f-e| - (f-e) = 2(f-e)_-$.

It implies $e - (e-f)_+ = 2^{-1}(e + f - |e-f|) = f - (f-e)_+$.

Since $\|e\| \leq 1$ and the square root is operator convex, we get

$$\|e - ge^{1/2}\| \leq \|e^{1/2} - g\| \leq \|e - g^2\|^{1/2} = \|e - (e-f)_+\|^{1/2} = 2^{-1/2} \cdot \|e + f - |e-f|\|^{1/2} .$$

Now we use again that square root is operator convex and and that $|e-f|^2 = (e-f)^2$ to obtain $\|e + f - |e-f|\| \leq \|(e+f)^2 - (e-f)^2\|^{1/2}$. Using $(e+f)^2 - (e-f)^2 = 2(ef + fe)$ and $\|ef\| = \|fe\|$ we obtain $\|e + f - |e-f|\| \leq 2^{1/2}\|ef\|^{1/2}$ and finally that

$$\|e - ge^{1/2}\| \leq \|ef\|^{1/4} .$$

Similar calculation shows that

$$\|f - hf^{1/2}\| \leq \|ef\|^{1/4} .$$

COROLLARY 3.2.20. *Suppose that B is a simple C^*-algebra and A is a C^*-subalgebra of $\mathcal{M}(B)$.*

Then for every nuclear contraction $V : A \to B$, every compact subset Ω of A and every $\varepsilon > 0$ there are $b_1, \ldots, b_n$ in B such that $\|\sum b_i^* b_i\| \leq 1$ and

$$\Big\| V(a) - \sum b_i^* a b_i \Big\| < \varepsilon \qquad \text{for all } \ a \in \Omega .$$

It is an idea from ''3rd draft''.
It is true for all ideal-system preserving residually nuclear maps $V : A \to B$ from $A \subseteq \mathcal{M}(B)$ to B, i.e., if $V(A \cap \mathcal{M}(B,J)) \subseteq J$ and $[V]_J : A/(A \cap \mathcal{M}(B,J)) \to B/J$ is nuclear for all closed ideals $J \subseteq B$.
Thus, residually nuclear maps are approximately sums of inner c.p. maps ...

It comes from the generalized separation theorem for m.o.c. cones.

Derive it as a Corollary from the general result for those C^*-algebras where every ideal-respecting nuclear map is automatic residual nuclear??
E.g. where all ideals are ''locally semi-split''.
???Are all exact C^*-algebras locally semi-split ???

PROOF. Consider the nuclear map $V \otimes \mathrm{id}$ from $A \otimes \mathcal{O}_\infty \subseteq \mathcal{M}(B \otimes \mathcal{O}_\infty)$ into $B \otimes \mathcal{O}_\infty$ (that is again nuclear because $\mathcal{O}_\infty$ is a nuclear C^*-algebra; i.e., $V \otimes \mathrm{id}$ is nuclear). By Theorem E, the C^*-algebra $B \otimes \mathcal{O}_\infty$ is simple and purely infinite, because B is simple and $\mathcal{O}_\infty$ is simple and purely infinite, cf. [**169, 172**]. By Corollary 3.2.16, $V \otimes \mathrm{id}$ can be approximated by maps of the form $a \otimes \xi \mapsto x^*(a \otimes \xi)x$ for a suitable contraction $x \in B \otimes \mathcal{O}_\infty$. In particular, for a given $\varepsilon > 0$, we can find $x \in B \otimes \mathcal{O}_\infty$, $\|x\| \leq 1$ such that $\|V(b) \otimes 1 - x^*(b \otimes 1)x\| < \varepsilon/2$ for $b \in \Omega$. Approximating x by elementary tensors, we can achieve

$$\|V(b) \otimes 1 - (\sum a_i \otimes d_i)^*(b \otimes 1)(\sum a_i \otimes d_i)\| < \varepsilon$$

and

$$\|\sum a_i \otimes d_i\| \leq 1$$

for suitable elements $a_i \in B$ and $d_i \in \mathcal{O}_\infty$. Now let ρ be a pure state on $\mathcal{O}_\infty$. Applying the Gram-Schmidt orthogonalization procedure we may suppose that $\rho(d_i^* d_j) = \delta_{ij}$ for all i, j, and obtain suitable new $\sum a_i \otimes d_i$. But then (applying $\mathrm{id} \otimes \rho$) we get

$$\|V(b) - \sum a_i^* b a_i\| < \varepsilon$$

for $b \in \Omega$. Now $\|\sum a_i^* a_i\| \leq 1$ because $\|\sum a_i \otimes d_i\| \leq 1$. □

Next follows from s.p.i. permanences:
A s.p.i. and B exact
(e.g. B nuclear, $B = \mathrm{C}_0(X)$ for l.c. space X)
then $A \otimes B$ s.p.i.
Result and Proof should be given somewhere in Chp. 2.

COROLLARY 3.2.21. *If D is simple and purely infinite, Y a* compact *space, $\varepsilon > 0$ and $a, b \in \mathrm{C}(Y, D)_+$ such that $\|b\| \leq 1$ and $\|a(y)\| = 1$ for every $y \in Y$ then there exists a contraction $d \in \mathrm{C}(Y, D)$ such that $\|b - d^* a d\| < \varepsilon$.*

PROOF. For every $y \in Y$ we find a state λ_y on D such that $\lambda_y(a(y)) = 1$. In an open neighborhood $U(y)$ of y we have $|1 - \lambda_y(a(x))| < \varepsilon/2$ for $x \in U(y)$. Since Y is compact, we find a finite sequence $y_1, \ldots, y_n \in Y$ such that the union of the $U(y_k)$ equals Y. We may assume that the system is minimal with this property. Let $e_k \colon Y \to [0, 1]$ $(k = 1, \ldots, n)$ a finite decomposition of 1 such that the support of e_k is contained in $U(y_k)$.

Let $\lambda_k := \lambda_{y_k}$ and $T_y(c) := (\sum e_k(y)\lambda_k(c))b(y)$.

Then $\|T_y(a(y)) - b(y)\| \leq \varepsilon/2$ for every $y \in Y$ and $y \mapsto T_y$ is a strongly continuous map from Y into the nuclear completely positive contractions from D into D. Since $\{a(y) \colon y \in Y\}$ is norm compact, there exists a contraction $d \in \mathrm{C}(Y, D)$ with $\|T_y(a(x)) - d(y)^* a(x) d(y)\| < \varepsilon/2$ for all $x, y \in Y$, by Proposition 3.2.15. To obtain this estimate from Proposition 3.2.15, let $B := D$, $X := Y \times \mathbb{N}$, i.e. X is the countable disjoint union of copies of Y, define V by $V(a)(y, n) := T_y(a)$, and let C be the separable C^*-subalgebra of $D \subseteq \mathrm{C_b}(X, B) = \ell_\infty(\mathrm{C}(Y, D))$ which is generated by $\{a(x) \colon x \in Y\}$.

Thus $\|b - d^* a d\| < \varepsilon$. □

Lemma 3.2.22. *Let $A := \mathrm{C}(X_1, D_1) \oplus \ldots \oplus \mathrm{C}(X_n, D_n)$, where the X_k ($k = 1, \ldots, n$) are compact metric spaces and D_k ($k = 1, \ldots, n$) are simple purely infinite C^*-algebras and $\varepsilon > 0$.*

If $a, b \in A$, $b^* = b$, $0 \leq a$, $\|a\| \leq 1$ and there are contractions $c_1, \ldots, c_m \in A$ such that $\|b - \sum c_j^* a c_j\| < \varepsilon$ and $\|\sum c_j^* c_j\| \leq 1$, then there is a contraction $d \in A$ with $\|b - d^* a d\| < 3\varepsilon$.

Better use here:
Direct sums of s.p.i. algebras A_k are s.p.i.
and $\mathrm{C}(X, D) = \mathrm{C}(X) \otimes D$ is s.p.i. if D is s.p.i.
$\Leftarrow$ follows from s.p.i. permanences in Chapter 2.
Find -- give -- references!

In other words: A is a non-simple strongly purely infinite C^*-algebra in the sense of Definition 1.2.2.

Proof. We have $b = b_1 \oplus \ldots \oplus b_n$, $a = a_1 \oplus \ldots \oplus a_n$. Thus, it suffices to consider the case $A = \mathrm{C}(X, D)$ for simple purely infinite D and compact X. But then

$$\|b - \sum c_j^* a c_j\| < \varepsilon$$

implies $\|b - b_+\| < \varepsilon$ and

$$\|b(y)\| < \varepsilon + \|a(y)\|$$

for $y \in X$, because $a \to \sum c_j^* a c_j$ is a completely positive contraction.

Let $Y := \{y \in X \colon 2\varepsilon \leq \|b(y)\|\}$. By functional calculus, for $y \in Y$, we have $\|b(y)\| = \|b(y)_+\|$, $\varepsilon \leq \|(b(y) - \varepsilon)_+\| = \|b(y)\| - \varepsilon$ and $\|(b(y) - \varepsilon)_-\| \leq 2\varepsilon$, i.e., $\|b(y) - (b(y) - \varepsilon)_+\| \leq 2\varepsilon$.

On the other hand $\varepsilon < \|a(y)\|$ and $0 < \|a(y)\|^{-1}(\|b(y)\| - \varepsilon) < 1$ for $y \in Y$.

Let $c(y) := (\|b(y)\| - \varepsilon)^{-1}(b(y) - \varepsilon)_+$

By Corollary 3.2.21, there exists a contraction $d_1 \in \mathrm{C}(Y, D)$ such that

$$\|c(y) - d_1(y)^*(\|a(y)\|^{-1} a(y)) d_1(y)\| < \varepsilon \qquad \forall\, y \in Y\,.$$

$g(y) := ((\|b(y)\| - \varepsilon)/\|a(y)\|)^{1/2}$ has norm ≤ 1 on Y. The contraction $d_2(y) = g(y) d_1(y)$ in $\mathrm{C}(Y, D)$ satisfies $\|((b|Y) - \varepsilon)_+ - d_2^*(a|Y) d_2\| < \varepsilon$ and therefore $\|(b|Y) - d_2^*(a|Y) d_2\| < 3\varepsilon$.

Now let $d_3 \in \mathrm{C}(X, D)$ a contraction with $d_3(y) = d_2(y)$ for $y \in Y$. Then there is an open neighborhood U of Y with $\|b(x) - d_3(x)^* a(x) d_3(x)\| < 3\varepsilon$ for $x \in U$. We find $h \colon X \to [0,1]$ continuous with $h(y) = 1$ for $y \in Y$ and $h(x) = 0$ for $x \in X \setminus U$.

The map $d(x) := h(x)^{1/2} d_2(x)$ defines a contraction $d \in \mathrm{C}(X, D)$ such that

$$\|b(x) - d(x)^* a(x) d(x)\| \leq (1 - h(x))\|b(x)\| + h(x)\|b(x) - d_3(x)^* a(x) d_3(x)\| < 3\varepsilon .$$

□

B in next Corollary is s.p.i. because the A_n are s.p.i. and inductive limits of s.p.i. C^*-algebras are s.p.i.

Corollary 3.2.23. *Let $h_n \colon A_n \to A_{n+1}$ a sequence of C^*-algebra morphisms. Suppose that*

(i) *$B := \mathrm{indlim}(h_n \colon A_n \to A_{n+1})$ is non-zero, and*
(ii) *each A_n is a finite direct sum of algebras $\mathrm{C}(X_j, D_j)$ of continuous functions from compact spaces X_j into a simple purely infinite C^*-algebra D_j $(j = 1, \dots, k_n)$.*

Then B is strongly purely infinite.

Proof. By Lemma 3.2.22, the algebras A_n are strongly purely infinite in the sense of Definition 1.2.2. Therefore, B is strongly purely infinite by Proposition **??**(??) (See Proposition 2.15.5(iv) for the p.i. case.) □

3. From m.o.c. cones to morphisms in general position

We need a good metric on m.o.c. cones, that gives the point-norm convergence topology in case of separable A and countably generated $\mathcal{C} \subseteq \mathrm{CP}(A, B)$. And have to describe the natural transformations and extensions with respect to Morita equivalence.

Need

$$\mathrm{KK}(\mathcal{C};\, A, B) \cong \mathrm{KK}(\mathcal{C} \otimes \mathrm{CP}(\mathbb{K}, \mathbb{K});\, A \otimes \mathbb{K}, B \otimes \mathbb{K}) .$$

Need

$$\mathrm{Ext}(\mathcal{C};\, A, B) \cong \mathrm{Ext}(\mathcal{C} \otimes \mathrm{CP}(\mathbb{K}, \mathbb{K});\, A \otimes \mathbb{K}, B \otimes \mathbb{K}) .$$

Compare with related sections on m.o.c.c's versus bi-modules !!

Definition 3.3.1. Let B a stable σ-unital C^*-algebra and A a σ-unital C^*-algebra. A C^*-morphism $H \colon A \to \mathcal{M}(B)$ is **in general position** if H is *unitarily homotopic to its infinite repeat $\delta_\infty \circ H$*

By Definition 5.0.1 and Remark 5.1.1(8) this means that there exists a *norm-continuous* path of unitaries $t \in [0, \infty) \to U(t) \in \mathcal{M}(B)$ such that $U(t)^* H(a) U(t) - \delta_\infty(H(a)) \in B$ and, for all $a \in A$,

$$\lim_{t \to \infty} \|U(t)^* H(a) U(t) \,-\, \delta_\infty(H(a))\| \,=\, 0\,.$$

It is not clear if the condition $U(t)^* H(a) U(t) - \delta_\infty(H(a)) \in B$ (for all $a \in A$) in Definition 3.3.1 implies that for the norm-continuous map $t \in [0, \infty) \to X(t)$ given by $X(t) := U(t)^* H(a) U(t) - \delta_\infty(H(a)) \in B$ holds that $X(t)$ converges strictly to 0 if and only if $t \to \|X(t)\|$ converges to 0 for $t \to \infty$. If it is true, then it does not matter if we require that $\lim_{t \to \infty} X(t) = 0$ in the strict topology on $\mathcal{M}(B)$ or in norm topology on $\mathcal{M}(B)$. Here "strictly" says that $\lim_t \|X(t)b\| = 0$ for each $b \in B$, and "in norm-topology" means that $\lim_t \|X(t)\|^2 = 0$ for the bounded norm-continuous path $t \mapsto X(t) \in B$.

But it is not clear if one can here replace the strictly continuous path $t \in \mathbb{R}_+ \to U(t) \in \mathcal{U}(\mathcal{M}(B))$ by a norm-continuous path.

It is known ???? by definition ???? that each C^*-morphism $H \colon A \to \mathcal{M}(B)$ " in sufficiently general position", i.e., where H is unitary equivalent modulo B to $\delta_\infty \circ H$, is unitarily homotopic to its infinite repeat – in the sense of Definition 5.0.1, cf. Remark 5.1.1(8).

4. M.o.c. cones and Hilbert bi-modules

Remark 3.4.1. For every point-norm closed m.o.c. cone $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ there is a (right) Hilbert B-module $\mathcal{H}$ and a *-representation $d \colon A \to \mathcal{L}(\mathcal{H})$ such that for every $x \in \mathcal{H}$ the map $a \in A \mapsto \langle d(a)x, x\rangle \in B$ is in $\mathcal{C}$ and *for every* $V \in \mathcal{C}$ there exists $x \in \mathcal{H}$ such that $V(a) = \langle d(a)x, x\rangle$ for $a \in A$.

But even for separable A and B the needed "multiplicity" of $\mathcal{H}$ over B can be much bigger than the cardinality of a subset of $\mathcal{C}$ that is dense in $\mathcal{C}$ with respect to the matricial point-norm topology on $\mathrm{CP}(A, B)$. This can be seen even in the – for us not important – easy case where $A := \mathrm{C}([0,1])$, $B := \mathbb{C}$ and $\mathcal{C} := \mathrm{CP}(A, B) \cong \mathrm{C}([0,1])^*_+$.

Suppose, in addition, that A is separable, B is σ-unital and stable and that $\mathcal{C} \subseteq \mathrm{CP}(A, B) \subseteq \mathcal{L}(A, B)$ is countably generated, faithful and non-degenerate. Then an other module is given by a C^*-morphism $H_\mathcal{C} \colon A \to \mathcal{M}(B)$ such that $H_\mathcal{C}$ is unitarily equivalent to its infinite repeat $\delta_\infty \circ H_\mathcal{C}$, that $b^* H_\mathcal{C}(\cdot) b \in \mathcal{C}$ for each $b \in B$, and that for each $V \in \mathcal{C}$ with $\|V\| \leq 1$ there exist a sequence of contractions $b_1, b_2, \ldots \in B$ such that $V(a) := \lim_n b_n^* H_\mathcal{C}(a) b_n$ for all $a \in A$.

The $H_\mathcal{C}$ with this properties is uniquely determined by $\mathcal{C}$ up to unitary homotopy.

(Uses general W-vN-theorem: Sums of two of them will be asymptotic unitarily absorbed by each of them ...?).

(See Corollary 5.4.4 and Remark 5.4.5.)

Compare next with Parts (xvi) of Proposition 2.2.1 in Chp. 2 !
There it is the non-unital case.

LEMMA 3.4.2. *Suppose that $1_E \in A \subseteq E$ are C^*-algebras, where A is separable and for every $a \in A_+$ with $\|a\| = 1$ there exists a sequence of contractions $T_1, T_2, \ldots \in E$ with $\lim_n T_n^* a T_n = 1_E$. (In particular, each nonzero $a \in A_+$ is properly infinite inside E and generates E as closed ideal.)*

Then every factorable c.p. contraction $U \circ V$ with $V : A \to M_n$ and $U : M_n \to E$ is approximately 1-step inner in E, i.e., there exists a sequence of contractions $S_1, S_2, \ldots \in E$ such that $\lim_n S_n^* a S_n = U(V(a))$ for all $a \in A$.

PROOF. Should be part of Chapter 2 **??** □

More general alternative formulation for non-unital and not necessarily simple E:

LEMMA 3.4.3. *Suppose that $A \subseteq E$ are C^*-algebras, where A is separable and for every $a \in A_+$ with $\|a\| = 1$ and every contraction $b \in E_+$ in the closed ideal of E generated by a there exists a sequence of contractions $T_1, T_2, \ldots \in E$ with $\lim_n T_n^* a T_n = b$.*

Then every c.p. contraction $U \circ V$ given by c.p. contractions $V : A \to M_n$ and $U : M_n \to E$ such that $U \circ V$ is ideal-system preserving

Should work only for E with finitely many ideals???
We need case of simple A or simple E!

is approximately 1-step inner in E, i.e., there exists a sequence of contractions $S_1, S_2, \ldots \in E$ such that $\lim_n S_n^* a S_n = U(V(a))$ for all $a \in A$.

PROOF. **??** □

REMARKS 3.4.4. Let A a separable C^*-algebra and B a σ-unital stable C^*-algebra. Take any faithful non-degenerate *-representation $\varphi : A \to \mathcal{M}(\mathbb{K}) \cong \mathcal{L}(\ell_2(\mathbb{N}))$ and any non-degenerate *-representation $\lambda : \mathbb{K} \to \mathcal{M}(B)$.

Then the H_0 for $\mathrm{CP}_{\mathrm{nuc}}(A, B)$ is up to unitary homotopy given by $H_0 := \delta_\infty \circ \mathcal{M}(\lambda) \circ \mathcal{M}(\varphi)$.

If D is non-unital, then $\pi_B \circ H_0$ dominates zero.

If a C^*-morphism $\psi : A \to \mathrm{Q}(B) := \mathcal{M}(B)/B$ has the property that for every $a \in A_+$ and $\varepsilon > 0$ there exists a contraction $T_a \in \mathrm{Q}(B)$ with $T_a^* \psi(a) T_a = \|a\|(1 - \varepsilon)1$, then ψ and $\psi \oplus \pi_B \circ H_0$ are unitarily equivalent by a unitary in $\mathcal{U}_0(\mathrm{Q}(B))$ if B is non-unital. If A and ψ are both unital then ψ and $\psi \oplus \pi_B \circ H_0$ are equivalent by unitary in $\mathcal{U}(\mathrm{Q}(B))$.

The existence of the T_a is equivalent to the property that for each $a \in A_+$, $\delta \in (0, \|a\|)$ and $c \in \mathcal{M}(B)$ with $\pi_B(c^* c) = \psi((a - \delta)_+)$ the hereditary *-subalgebra cBc^* of B contains a full stable C^*-subalgebra of B.

(Compare also [**264**] and [**310**].)

DEFINITION 3.4.5. Let $\mathcal{C} \subseteq \mathrm{CP}(A,B)$ a matrix o.c. cone. A Hilbert A-B-module $(\mathcal{H},\phi)$ is **$\mathcal{C}$-compatible** if the c.p. maps

$$A \ni a \mapsto \langle x, \phi(a)x\rangle \in B$$

are in $\mathcal{C}$ for all $x \in \mathcal{H}$.

DEFINITION 3.4.6. A point-norm closed matrix o.c. cone $\mathcal{C} \subseteq \mathrm{CP}(A,B)$ is **countably generated** if $\mathcal{C} = \mathcal{C}(\mathcal{S})$ for some countable subset $\mathcal{S} \subseteq \mathcal{C}$. We say that $\mathcal{C}$ is **singly generated** if $\mathcal{C} = \mathcal{C}(\{V\})$ for some $V \in \mathcal{C}$.

REMARK 3.4.7. If a point-norm closed m.o.c.c. $\mathcal{C} \subseteq \mathrm{CP}(A,B)$ is countably generated, say by c.p. contractions $\{V_1, V_2, \ldots\} \subseteq \mathcal{C}$, then $\mathcal{C}$ is also singly generated, e.g. by $V := \sum_n 2^{-n} V_n$, because $\mathcal{C}$ is hereditary in $\mathrm{CP}(A,B)$ by Corollary **??**.

If B is σ-unital (with strictly positive element $b_0 \in B_+$) and if A admits a faithful positive functional $f_0 \in A^*_+$, then $\mathrm{CP}_{\mathrm{nuc}}(A,B)$ is singly generated by $V = f_0(\cdot)b_0$.

If A and B are separable, then each point-norm closed m.o.c. cone $\mathcal{C} \subseteq \mathrm{CP}(A,B)$ is singly generated.

PROPOSITION 3.4.8. *Suppose that a compact metric group G acts on A and B (by α and β), where A is separable and B is σ-unital. Let $\mathcal{C} \subseteq \mathrm{CP}(A,B)$ a countably generated m.o.c. cone with $\beta(g) \circ \mathcal{C} \circ \alpha(g^{-1}) = \mathcal{C}$ for all $g \in G$.*

Then there is a "universal" $\mathcal{C}$-compatible Hilbert A-B-module $(\mathcal{H},\phi)$ with a G-action $\gamma\colon G \to \mathrm{Iso}(\mathcal{H})$, such that $\gamma(g)(\phi(a)xb) = \phi(\alpha(g)(a))\gamma(x)\beta(g)(b)$ for $a \in A$, $b \in B$, $x \in \mathcal{H}$, and that $G \ni g \mapsto \langle y, \gamma(g)(x)\rangle \in B$ is continuous for all $x, y \in \mathcal{H}$.

PROOF. Use G-invariant $V \in \mathcal{C}$ for construction. Then use that m.o.c. cones are hereditary in $\mathrm{CP}(A,B)$.

`to be filled in` **??** □

QUESTION 3.4.9. Remains Proposition 3.4.8 true if G is a second countable l.c. group?

5. Operator-convex cones of c.p. maps (2)

This section explains the reason for our study of commutative subalgebras in ultrapowers of w.p.i. and s.p.i. C^*-algebras, i.e., it shows that asymptotic and approximate versions of generalized Weyl–von-Neumann theorems for "residually nuclear" maps can be obtained from the corresponding results on c.p. maps from separable C^*-subalgebras of ultrapowers (or, more generally, corona algebras) into commutative C^*-subalgebras of the ultrapower or corona algebra in question. One has to apply the below outlined theory of (matrix) operator-convex cones of c.p. maps (in conjunction with Property (3) in Remark 3.11.3).

We introduce a useful duality between point-norm closed operator-convex cones $\mathcal{C}$ of completely positive maps in $\mathrm{CP}(A,B)$ and intersection-preserving maps ("actions") of the Hausdorff lattice $\mathcal{I}(B\otimes C^*(F_\infty))$ of closed ideals of $B\otimes C^*(F_\infty)$ on $A\otimes C^*(F_\infty)$.

This in an operator theoretic version of the Hahn-Banach separation theorem for m.o.c. cones.

It implies a duality between m.o.c. cones $\mathcal{C}$ of "residually nuclear" maps and actions Ψ of $\mathrm{Prim}(B)$ on A. Global operations with residually nuclear maps are functorial in a natural manner.

Definition 3.5.1. Suppose that A and B are C^*-algebras. Let $\mathrm{CP}(A,B)$ denote the cone of completely positive maps from A into B. A subset $\mathcal{C}$ of $\mathrm{CP}(A,B)$ is an *operator-convex cone* of c.p. maps if $\mathcal{C}$ has the following properties (i) and (ii):

(i) $d_1^*V_1(.)d_1+d_2^*V_2(.)d_2\in\mathcal{C}$ for $V_1,V_2\in\mathcal{C}$, $d_1,d_2\in B$.
(ii) $a\in A\mapsto c^*(V\otimes \mathrm{id}_n)(r^*ar)c$ is in $\mathcal{C}$ for every $V\in\mathcal{C}$, every row-matrix $r\in M_{1,n}(A)$ and every column-matrix $c\in M_{n,1}(B)$.

Let $\mathcal{S}$ be a subset of $\mathrm{CP}(A,B)$. We denote by $\mathcal{C}_{\mathrm{alg}}(\mathcal{S})$ the smallest subset of $\mathrm{CP}(A,B)$ which is invariant under the operations in (i) and (ii), and by $\mathcal{C}(\mathcal{S})$ the point-norm closure of $\mathcal{C}_{\mathrm{alg}}(\mathcal{S})$ (i.e., the closure of $\mathcal{C}_{\mathrm{alg}}(\mathcal{S})$ in $\mathcal{L}(A,B)$ w.r.t. the strong operator topology). Then $\mathcal{C}_{\mathrm{alg}}(\mathcal{S})$ and $\mathcal{C}(\mathcal{S})$ are operator-convex cones of completely positive maps.

We call $\mathcal{S}$ the *generating set* for the operator convex cone $\mathcal{C}$ if $\mathcal{C}=\mathcal{C}(\mathcal{S})$.

One can see with help of approximate units in A and B that every point-norm closed subset $\mathcal{C}$ of $\mathrm{CP}(A,B)$ is a convex cone in the usual sense if it satisfies Part(i) of Definition 3.5.1, and that $\mathcal{C}$ satisfies $t\mathcal{C}\subseteq\mathcal{C}$ for $t\in[0,\infty)$ if $\mathcal{C}$ satisfies Definition 3.5.1(ii).

We introduce a useful duality between closed m.o.c. cones $\mathcal{C}$ of completely positive maps in $\mathrm{CP}(A,B)$ and intersection-preserving maps ("actions") of the Hausdorff lattice $\mathcal{I}(B\otimes C^*(F_\infty))$ of closed ideals of $B\otimes C^*(F_\infty)$ on $A\otimes C^*(F_\infty)$. It leads to a duality of m.o.c. cones of "residually nuclear" maps and actions of $\mathrm{Prim}(B)$ on A. Operations with residually nuclear maps are functorial in a natural manner.

First we characterize the c.p. maps V in $\mathcal{C}(\mathcal{S})$ by the values $V\otimes^{\max}\mathrm{id}(c)$ of elements $c\in A\otimes^{\max}C^*(F_\infty)$. Here $C^*(F_\infty)$ denotes the full group C^*-algebra of the free group F_∞ on infinitely many generators, and $\otimes^{\max}$ denotes the maximal C^*-algebra tensor product. In the following theorem the *ideal-kernel* of a positive functional λ on $D:=B\otimes^{\max}C^*(F_\infty)$ means the maximal ideal of D in the kernel of λ, i.e., the set of elements $d\in D$ with $\lambda(edf)=0$ for all $e,f\in D$. This is also the kernel of the cyclic representation $\rho\colon D\to\mathcal{L}(L_2(D,\lambda))$ defined by λ on D.

Here is some relation between Part(v) of Theorem 3.5.2 to and the later considered *Separation* Theorem.

THEOREM 3.5.2. *Suppose that $\mathcal{S}$ is a subset of* $\mathrm{CP}(A,B)$ *and that* $V\colon A \to B$ *is completely positive. Then the following properties* (i)–(v) *of* V *are equivalent.*

(i) $V \in \mathcal{C}(\mathcal{S}) :=$ *the point-norm closed m.o.c. cone generated by* $\mathcal{S}$.

(ii) *For every* $c \in A \otimes^{\max} C^*(F_\infty)$, *the element* $V \otimes^{\max} \mathrm{id}(c)$ *is in the closed ideal of* $B \otimes^{\max} C^*(F_\infty)$ *that is generated by the c.p. maps*

$$\{\, W \otimes^{\max} \mathrm{id}((a^* \otimes 1)c(a \otimes 1))\,;\; W \in \mathcal{S}, a \in A\,\}\,.$$

(iii) *For every factorial representation* $\rho\colon B \to \mathcal{L}(\mathcal{H})$ *of* B, $\rho \circ V$ *is in the point-weak closure of* $\mathcal{C}(\{\,\rho \circ W\,;\; W \in \mathcal{S}\,\})$.

(iv) *For every pure state* λ *of* $B \otimes^{\max} C^*(F_\infty)$, *the kernel of* $\lambda \circ (V \otimes^{\max} \mathrm{id})$ *contains the intersection of all ideal-kernels of* $\lambda \circ (b^*Wb \otimes^{\max} \mathrm{id})$ *for* $W \in \mathcal{S}$, $b \in B$.

(v) *For every factorial cyclic representation* $\rho\colon B \to \mathcal{L}(\mathcal{H})$ *(with cyclic vector* $\eta \in \mathcal{H}$*) and every unital* C^**-morphism* $h\colon C^*(F_\infty) \to \rho(B)'$, *the kernel of the positive linear functional* $\lambda \circ (V \otimes^{\max} \mathrm{id})$ *contains the intersection of all ideal-kernels of* $\lambda \circ ((b^*W(\cdot)b) \otimes^{\max} \mathrm{id})$ *for* $W \in \mathcal{S}$, $b \in B$.
(Here λ *is the positive functional on* $B \otimes^{\max} C^*(F_\infty)$ *with* $\lambda(b \otimes f) = \langle \rho(b)h(f)\eta, \eta\rangle$*.)*

If one wants to apply the result easier for some sort of cone-related KK-theory, then one could replace $C^*(F_\infty) \subseteq C^*(F_2) = \mathrm{C}(S^1) * \mathrm{C}(S^1)$ by the unital free product C^*-algebra $\mathrm{C}([0,1]) * \mathrm{C}([0,1]) \supset C^*(F_2)$. The proofs are almost verbatim the same as the below given, but with $C^*(F_\infty)$ replaced by $\mathrm{C}([0,1]) * \mathrm{C}([0,1])$. The point is that this shows that no extra homotopy invariant is involved by this reduction to the study of ideals of tensor products.

Alternatively we can formulate the for applications important equivalence between Parts (i) and (ii) as follows:

Let $\mathcal{T} \subseteq \mathrm{CP}\big(A \otimes^{\max} C^*(F_2), B \otimes^{\max} C^*(F_2)\big)$ denote the set of c.p. maps

$$\mathcal{T} := \{\, W \otimes^{\max} \mathrm{id}\,;\; W \in \mathcal{S}\,\}\,.$$

And define a lower semi-continuous action

$$\Psi := \Psi[\mathcal{T}]\colon \mathcal{I}\big(B \otimes^{\max} C^*(F_2)\big) \to \mathcal{I}\big(A \otimes^{\max} C^*(F_2)\big)$$

by

$$\Psi(J) := \text{ biggest } I \in \mathcal{I}(A \otimes^{\max} C^*(F_2)) \text{ with } W \otimes^{\max} \mathrm{id}(I) \subseteq J \;\; \forall\, W \in \mathcal{S}\,.$$

I.e., Ψ is the lower semi-continuous action of $\mathrm{Prim}\big(B \otimes^{\max} C^*(F_2)\big)$ on $A \otimes^{\max} C^*(F_2)$ that attaches to a closed ideal $J \triangleleft B \otimes^{\max} C^*(F_2)$ the largest ideal $I \triangleleft A \otimes^{\max} C^*(F_2)$ with the property that $(W \otimes \mathrm{id})(I) \subseteq J$ for all $W \in \mathcal{S}$.

This is just the natural l.s.c. action $\Psi_{\mathcal{C}(\mathcal{T})}$ defined by the point-norm closed m.o.c. cone $\mathcal{C}(\mathcal{T})$ that is generated by $\mathcal{T} := \mathcal{S} \otimes^{\max} \mathrm{id}$.

The property of V in part (ii) is equivalent to:

$$V \otimes^{\max} \mathrm{id}(\Psi_{\mathcal{C}(\mathcal{T})}(J)) \subseteq J \quad \text{for all } J \in \mathcal{I}(B \otimes^{\max} C^*(F_2))\,.$$

Thus the equivalence of (i) and (ii) can be expressed as

$$V \in \mathcal{C}(\mathcal{S}) \iff V \otimes^{\max} \mathrm{id}(\Psi_{\mathcal{C}(\mathcal{S}\otimes^{\max}\mathrm{id})}(J)) \subseteq J \ \forall\, J \in \mathcal{I}(B \otimes^{\max} C^*(F_2)) .$$

If we let $\Psi := \Psi_{\mathcal{C}(\mathcal{S}\otimes^{\max}\mathrm{id})}$, where "id" means the identity automorphism of $C^*(F_\infty)$, and if we define, more generally, for C^*-algebras E, F and actions $\Psi\colon \mathcal{I}(F) \to \mathcal{I}(E)$ the point-norm closed m.o.c. cone $\mathcal{C}_\Psi \subseteq \mathrm{CP}(E,F)$ by

$$\mathcal{C}_\Psi := \{V \in \mathrm{CP}(E,F)\, ;\ V(\Psi(J)) \subseteq J \ \forall\, J \in \mathcal{I}(F)\} ,$$

then we can express the equivalence of (i) and (ii) by

$$\mathcal{C}(\mathcal{S}) \otimes^{\max} \mathrm{id} \ = \ (\mathrm{CP}(A,B) \otimes^{\max} \mathrm{id}) \cap \mathcal{C}_\Psi . \tag{5.1}$$

Proof. (i)⇒(ii): Let $c \in B \otimes^{\max} C^*(F_\infty)$ positive and let $I(\mathcal{S}, c)$ denote the closed ideal of $B \otimes^{\max} C^*(F_\infty)$ which is *generated* by

$$I(\mathcal{S}, c) := \{\, W \otimes^{\max} \mathrm{id}((a^* \otimes 1)c(a \otimes 1))\, ;\ W \in \mathcal{S}, a \in A \,\} .$$

If $T\colon A \to B$ is a completely positive map such that $T \otimes^{\max} \mathrm{id}((a^* \otimes 1)c(a \otimes 1))$ is in $I(\mathcal{S}, c)$ for all $a \in A$, then $T \otimes^{\max} \mathrm{id}((b^* \otimes 1)c(a \otimes 1))$ is in $I(\mathcal{S}, c)$ for all $a, b \in A$, as polar-decomposition of Hermitian forms shows. It follows that the set of all c.p. maps $T\colon A \to B$ with $T \otimes^{\max} \mathrm{id}((a^* \otimes 1)c(a \otimes 1)) \in I(\mathcal{S}, c)$ for all $a \in A$ contains $\mathcal{S}$ and is closed under the operations (OC1) and (OC2) of Definition 3.2.2, and is point-norm closed. Thus it contains $\mathcal{C}(\mathcal{S})$.

(ii)⇒(i): Suppose that V is not in $\mathcal{C}(\mathcal{S})$. Then there are

- (α) a cyclic representation $\rho\colon B \to \mathcal{L}(\mathcal{H})$ with cyclic vector $\eta \in \mathcal{H}$,
- (β) elements $e_1, \ldots, e_n \in \rho(B)'$,
- (γ) elements $a_1, \ldots, a_n \in A$, and
- (δ) a *-epimorphism h from $C^*(F_\infty)$ onto $C^*(1, e_1, \ldots, e_n) \in \rho(B)'$ and elements $f_1, \ldots, f_n \in C^*(F_\infty)$ with $h(f_k) = e_k$,

such that the complex number $\lambda((V \otimes^{\max} \mathrm{id})(c))$ is not in the closure of the set of complex numbers $\{\, \lambda((W \otimes^{\max} \mathrm{id})(c))\, ;\ W \in \mathcal{C}(\mathcal{S}) \,\}$, where

$$c \ := \ a_1 \otimes f_1 + \ldots + a_n \otimes f_n \ \in A \otimes^{\max} C^*(F_\infty)$$

and λ is the positive functional on $B \otimes^{\max} C^*(F_\infty)$ with $\lambda(b \otimes f) := \langle \rho(b)h(f)\eta, \eta\rangle$. (See proof of [**463**, lem. 7.18], and notice that the Part (δ) is obvious.)

Thus, the positive functional $\lambda_V := \lambda \circ (V \otimes^{\max} \mathrm{id})$ is not in the weak closure of the convex cone κ of positive functionals $\lambda_W := \lambda \circ (W \otimes^{\max} \mathrm{id})$ for $W \in \mathcal{C}(\mathcal{S})$.

Since η is cyclic for ρ, one can see (as in the proof of [**463**, lem. 7.18]) that the functionals $d^*(\lambda_W)d$ is in the weak closure of κ for $W \in \mathcal{C}(\mathcal{S})$ and $d \in A \otimes^{\max} C^*(F_\infty)$.

Let J denote the closed ideal of $d \in A \otimes^{\max} C^*(F_\infty)$ with $\lambda_W(d^*d) = 0$ for all $W \in \mathcal{C}(\mathcal{S})$.

It follows from [**463**, lem. 7.17(ii)] that there is $d_0 \in J$ with $\lambda_V(d_0^* d_0) > 0$. On the other hand, $I(\mathcal{S}, d_0^* d_0)$ is contained in the kernel of λ by definition of J. Hence $V \otimes^{\max} \mathrm{id}(d_0^* d_0)$ is not in $I(\mathcal{S}, d_0^* d_0)$.

(i)⇒(v): Let $J(\mathcal{S}) \subseteq A \otimes^{\max} C^*(F_\infty)$ denote the intersection of all ideal-kernels of all functionals $\lambda \circ ((b^* W b) \otimes^{\max} \mathrm{id})$ on $A \otimes^{\max} C^*(F_\infty)$ with $W \in \mathcal{S}$, $b \in B$. We show that $J(\mathcal{S})$ is the intersection of all ideal-kernels of all functionals $\lambda \circ (V \otimes^{\max} \mathrm{id})$ with $V \in \mathcal{C}(\mathcal{S})$:
Let $T \in \mathrm{CP}(A, B)$ with $J(\mathcal{S})$ in the kernel of $\lambda \circ ((b^* T b) \otimes^{\max} \mathrm{id})$ for all $b \in B$, then, using the polar-formula for Hermitian forms,

$$\lambda((b_2^* \otimes 1)T \otimes^{\max} \mathrm{id}((a_2^* \otimes 1)c(a_1 \otimes 1))(b_1 \otimes 1)) = 0$$

for $c \in J$, $a_1, a_2 \in A$ and $b_1, b_2 \in B$. It follows that the set of c.p. maps $V : A \to B$ with $J(\mathcal{S})$ in the kernel of $\lambda \circ ((b^* T b) \otimes^{\max} \mathrm{id})$ for all $b \in B$ is closed under the operations (OC1) and (OC2) of Definition 3.2.2 and under pont-norm convergence, i.e., is a closed operator-convex cone, which contains the set $\mathcal{S}$. Note that $b^* V(.) b$ is in $\mathcal{C}(\mathcal{S})$ for $V \in \mathcal{C}(\mathcal{S})$ and $b \in B$.

(v)⇒(iii): Suppose that $\rho \circ V : A \to \mathcal{L}(\mathcal{H})$ is not in the point-weak closure of the operator-convex cone $\mathcal{C}(\{\rho \circ W;\, W \in \mathcal{S}\})$.
Then there is $n \in \mathbb{N}$ and $\eta \in \mathcal{H}^n$, such that $\rho_1 \circ V : A \to \mathcal{L}(\mathcal{H}_1)$ is not in the point-weak closure of $\mathcal{C}(\{\rho_1 \circ W;\, W \in \mathcal{S}\})$ for the (again factorial) cyclic sub-representation ρ_1 of

$$\rho \otimes 1_n \colon\, b \in B \mapsto \rho(b) \otimes 1_n \,\in \mathcal{L}(\mathcal{H}^n) \cong \mathcal{L}(\mathcal{H}) \otimes M_n$$

obtained by restriction of $\rho \otimes 1_n$ to $\mathcal{H}_1 := \overline{(\rho(B) \otimes 1_n)\eta}$. The rest of the proof is similar to the proof of the implication (ii)⇒(i).

(iii)⇒(iv): Let $\iota \colon B \otimes^{\max} C^*(F_\infty) \to \mathcal{L}(\mathcal{H})$ the irreducible representation with cyclic state η corresponding to λ. Let $\rho(b) := \iota(b \otimes 1)$. Then $\rho \colon B \to \mathcal{L}(\mathcal{H})$ is factorial, and there is a representation $h \colon C^*(F_\infty) \to \rho(B)'$ such that $\iota(b \otimes f) = \rho(b) h(f)$.

The elements c in the intersection J of the ideal-kernels of $\lambda \circ \big((b^* W b) \otimes^{\max} \mathrm{id}\big)$ with $W \in \mathcal{S}$, $b \in B$ satisfy $\iota\big(W \otimes^{\max} \mathrm{id}(dce)\big) = 0$ for all $d, e \in A \otimes^{\max} C^*(F_\infty)$ and $W \in \mathcal{S}$.

If $c \in A \otimes^{\max} C^*(F_\infty)$ satisfies $\iota\big(W \otimes^{\max} \mathrm{id}(dce)\big) = 0$ for all $d, e \in A \otimes^{\max} C^*(F_\infty)$ and $W \in \mathcal{S}$, then $\iota\big(T \otimes^{\max} \mathrm{id}(c)\big) = 0$ for all $T \in \mathcal{C}(\mathcal{S})$. Since $\rho \circ V$ is in the point-weak closure of the maps $\{\, \rho \circ W \,;\; W \in \mathcal{C}(\mathcal{S}) \,\}$, we get that $\iota \circ (T \otimes^{\max} \mathrm{id})$ is in the point weak closure of the cone of maps $\iota \circ (W \otimes^{\max} \mathrm{id})$. Thus $\lambda\big(W \otimes^{\max} \mathrm{id}(c)\big) = 0$.

(iv)⇒(ii): Suppose that there is $c \in A \otimes^{\max} C^*(F_\infty)$, such that $V \otimes^{\max} \mathrm{id}(c)$ is not in $I(\mathcal{S}, c)$. Then there is a pure state λ on $B \otimes^{\max} C^*(F_\infty)$ with $\lambda(I(\mathcal{S}, c)) = 0$ and $\lambda(V \otimes^{\max} \mathrm{id}(c)) \neq 0$.

$(b^* \otimes 1)W \otimes^{\max} \mathrm{id}(gch)(b \otimes 1) \,\in I(\mathcal{S}, c)$ for $W \in \mathcal{S}$, $g, h \in A \otimes^{\max} C^*(F_\infty)$ and $b \in B$, because $W \otimes^{\max} \mathrm{id}\big((a^* \otimes 1)c(a \otimes 1)\big)$ is in the ideal $I(\mathcal{S}, c)$ for $a \in A$.

Thus, the closed ideal J of $A \otimes^{\max} C^*(F_\infty)$ generated by c is contained in all kernels of $\lambda \circ ((b^*Wb) \otimes^{\max} \mathrm{id})$ for $W \in \mathcal{S}$, $b \in B$. But c is not in the kernel of $\lambda \circ (V \otimes^{\max} \mathrm{id})$. □

We derive in good cases 1-step approximately inner approximation for the members of $\mathcal{C}(\mathcal{S})$ if the elements of $\mathcal{S}$ are 1-step-approximately inner.

PROPOSITION 3.5.3. *Suppose that A and B are C^*-algebras and that $\mathcal{S}$ is a set of c.p. maps $V: A \to B$.*

(i) *Suppose that, for $V_1, V_2 \in \mathcal{S}$, the multiplier algebra $\mathcal{M}(B)$ contains contractions e_1, e_2 with $e_1^* e_2 = 0$ such that $e_1 V_1(.) e_1^* + e_2 V_2(.) e_2^* \in \mathcal{S}$, $e_k^* e_k V_k(a) = V_k(a)$ for all $a \in A$ and $k = 1, 2$.*
(a local property of J.Cuntz)??
Then $\mathcal{C}(\mathcal{S})$ is the point-norm closure of the set of all maps

$$V: a \in A \mapsto c^*\big((W \otimes \mathrm{id}_n)(r^* a r)\big)c \in B$$

with $W \in \mathcal{S}$, rows $r \in M_{1,n}(A)$ and columns $c \in M_{n,1}(B)$, $n \in \mathbb{N}$.

(ii) *If, in addition to part (i), $A \subseteq \mathcal{M}(B)$ and there is (fixed) $m \in \mathbb{N}$ such that every $W \in \mathcal{S}$ is approximately m-step-inner, then every c.p. contraction $V \in \mathcal{C}(\mathcal{S})$ can be approximated in point-norm by maps*

$$T: a \in A \mapsto d_1^* a d_1 + d_2^* a d_2 + \ldots + d_m^* a d_m \in B$$

with $d_1, \ldots, d_m \in B$ and $\|d_1^* d_1 + \ldots + d_m^* d_m\| \leq 1$.

(iii) *If, in addition to (ii), A is separable and for every $W \in \mathcal{S}$ there exists a bounded sequence of elements $d_1, d_2, \dots \in B$ such that $\lim_{k\to\infty} d_k^* a d_{k+n} = \delta_{0,n} W(a)$ for $n = 0, 1, \ldots$, $a \in A$, then, for every $V \in \mathcal{C}(\mathcal{S})$, there exists a sequence $e_1, e_2, \ldots \in B$ with $\|e_k^* e_k\| \leq \|V\|$, $\lim_{k\to\infty} e_k^* a e_{k+n} = \delta_{0,n} V(a)$ for $n = 0, 1, \ldots$, $a \in A$, and $\lim_{k\to\infty} \|e_k^* e_{k+n}\| = 0$ for $n > 0$.*

PROOF. (i): For $V_1, V_2 \in \mathcal{S}$, $r_1 \in M_{1,n}(A)$, $r_2 \in M_{1,m}(A)$, $c_1 \in M_{n,1}(B)$, $c_2 \in M_{m,1}(B)$ and $d_1, d_2 \in B$, let $V(a) := e_1 V_1(a) e_1^* + e_2 V_2(a) e_2^*$ $(a \in A)$, $r := (r_1, r_2) \in M_{1,n+m}(A)$, and $d := (d_1^* c_1^* (e_1 \otimes 1_n), d_2^* c_2^* (e_2 \otimes 1_m))^* \in M_{n+m,1}(A)$, where $e_1, e_2 \in \mathcal{M}(B)$ are the elements as descibed in (i).

Then $d_1^*(c_1^* V_1 \otimes \mathrm{id}_n(r_1^* a r_1) c_1) d_1 + d_2^*(c_2^* V_2 \otimes \mathrm{id}_m(r_2^* a r_2) c_2) d_2 = c^* V \otimes \mathrm{id}_{n+m}(r^* a r) c$. Thus the minimal matrix operator-convex hull $\mathcal{C}_{\mathrm{alg}}(\mathcal{S})$ of $\mathcal{S}$ is identical with the set of maps $c^* V \otimes \mathrm{id}_n(r^*(.) r) c$ with $V \in \mathcal{S}$, $r \in M_{1,n}(A)$, $c \in M_{n,1}(A)$, $n = 1, 2, \ldots$. $\mathcal{C}(\mathcal{S})$ is then the point-norm closure of $\mathcal{C}_{\mathrm{alg}}(\mathcal{S})$.

(ii): By [**463**, lem. 7.2], a suitable modification of the maps T (with help of an approximate unit of A) leads to a net of m-step inner c.p. maps T with $\|d_1^* d_1 + \ldots + d_m^* d_m\| \leq 1$ (in addition) such that the net converges in point-norm to V, if $V \in CB(A, B)$ can be approximated in point-norm by m-step inner c.p. maps T.

If $V \in \mathcal{S}$ can be approximated in point-norm by a net of m-step inner c.p. maps $T = d_1^*(.)d_1 + \ldots + d_m^*(.)d_m$, then $c^*V \otimes \mathrm{id}_n(r^*(.)r)c$ can be approximated in point-norm by the net with elements $T' = c^*T \otimes \mathrm{id}_n(r^*(.)r)c = e_1^*(.)e_1 + \ldots + e_m^*(.)e_m$ where $e_j = r(d_j \otimes 1_n)c$ for $j = 1, \ldots, m$.

(iii): If $V = c^*W \otimes \mathrm{id}_n(r^*ar)c$ and $d_1, d_2, \ldots$ satisfies $\lim_{k\to\infty} d_k^*ad_{k+n} = \delta_{0,n}W(a)$ for $n = 0, 1, \ldots$, then $f_k := r(d_k \otimes 1_n)c$ satisfies $\lim_{k\to\infty} f_k^*af_{k+n} = \delta_{0,n}V(a)$ for $n = 0, 1, \ldots$.

If we multiply the sequence f_k from the left by the elements in a suitable countable approximate unit $a_1, a_2, \ldots$ of A then $e_k := a_kf_k$ satisfies $\|e_k^*e_k\| < \|V\|$, $\lim_{k\to\infty} e_k^*ae_{k+n} = \delta_{0,n}V(a)$ for $n = 0, 1, \ldots$, and $\lim_{k\to\infty} \|e_k^*e_{k+n}\| = 0$ for $n > 0$. □

REMARK 3.5.4. Suppose that A is separable and $A \subseteq B$, and that $D \subseteq \mathcal{M}(B)$ is a unital C^*-subalgebra of $\mathcal{M}(B)$ with $B \subseteq D$ such that for every $b \in B$ there is an isometry $t \in D$ with $bt = 0$, and that D contains two isometries with orthogonal ranges.

Then one gets for (ii) and (iii) of Proposition 3.5.3:

(α) for T in (i) holds $T(a) = f_1^*af_1 + \ldots + f_m^*af_m$ for all $a \in A$ with $f_1, \ldots, f_m \in D$ such that $f_1^*f_1 + \ldots + f_m^*f_m = \|V\| \cdot 1$ (in particular, f_1 is an isometry in case $m = 1$ and V contractive),

(β) the elements $e_1, e_2, \ldots$ in (iii) can be replaced by isometries $t_1, t_2, \ldots \in D$ with $t_j^*t_k = \delta_{j,k}1$ and $\lim_k \|V\|t_k^*at_{n+k} = \delta_{0,n}V(a)$ for $a \in A$.

PROOF. (α): Let $a_0 \in A_+$ a strictly positive element of A, $g := a_0 + d_1d_1^* + \ldots d_md_m^*$, $h := (\|V\| \cdot 1 - (d_1^*d_1 + \ldots + d_m^*d_m))^{1/2} \in D$, t an isometry in D with $gt = 0$. Then $f_k := d_k + (1/m)th \in D$ satisfies $d_k^*ad_k = f_k^*af_k$ for $a \in A$ and $f_1^*f_1 + \ldots + f_m^*f_m = \|V\|.1$.

(β): Let $g := a_0 + \sum_k 2^{-k}e_ke_k^*$ and $t \in D$ an isometry with $gt = 0$. If D contains two isometries with orthogonal ranges, then D contains a countable sequence $s_1, s_2, \ldots \in D$ of isometries with pair-wise orthogonal ranges: $s_j^*s_k = \delta_{j,k}$. If $V = 0$ then $t_k = ts_k$ is as desired. If $V \neq 0$, let $r_k := e_k + ts_k(\|V\| - e_k^*e_k)^{1/2}$, then $r_k \in D$, $r_j^*r_k = e_j^*e_k + \delta_{j,k}(\|V\| - e_k^*e_k)$ and $r_j^*ar_k = e_j^*ae_k$ for $a \in A$, $j, k = 1, 2, \ldots$. It follows that there is a sequence $u_1, u_2, \ldots$ of unitaries in D such that $\lim_k \|u_k - 1\| = 0$ and $s_k := \|V\|^{-1/2}u_kr_k$ is a sequence of isometries in D with $s_j^*s_k = \delta_{i,k}1$. It must satisfy $\lim_k \|V\|s_k^*as_{k+n} = \delta_{0,n}V(a)$ for $a \in A$. □

DEFINITION 3.5.5. Let Y a T_0 space (e.g. $Y \cong \mathrm{Prim}(D)$ for some algebra D), and $\mathbb{O}(Y)$ its lattice of closed ideals (e.g. $\mathbb{O}(Y) \cong \mathcal{I}(D)$).

We call a map $\Psi\colon \mathbb{O}(Y) \to \mathbb{O}(\mathrm{Prim}(A)) \cong \mathcal{I}(A)$ an *action* or Ψ-*action* of Y on a C^*-algebra A, if $\Psi(U) \subseteq \Psi(V)$ for $U \subseteq V$. (More generally, one can consider increasing maps from down-ward directed partially ordered sets in place of $\mathbb{O}(Y)$ into the set $\mathcal{I}(A)$ of closed ideals of A.)

Ψ is by definition *lower semi-continuous* if $\Psi((\bigcap U_\tau)^\circ) = (\bigcap_\tau \Psi(U_\tau))^\circ$ for every family of open subsets of Y. (We use this name because the intersection property implies that Ψ transforms l.s.c. functions on $\mathrm{Prim}(A)$ into l.s.c. functions on Y in a natural manner.)

If $\Psi_A \colon \mathbb{O}(Y) \to \mathcal{I}(A)$ and $\Psi_B \colon \mathbb{O}(Y) \to \mathcal{I}(B)$ are two actions, then a c.p. map $V \colon A \to B$ is Ψ-equivariant if $V(\Psi_A(U)) \subseteq \Psi_B(U)$ for all $U \in \mathbb{O}(Y)$. The set of Ψ-equivariant maps will be denoted by $\mathcal{C}(\Psi_A, \Psi_B)$. Clearly, $\mathcal{C}(\Psi_A, \Psi_B)$ is a point-norm closed operator-convex cone of c.p. maps, i.e., $\mathcal{C}(\Psi_A, \Psi_B)) = \mathcal{C}_{\mathrm{alg}}(\Psi_A, \Psi_B)$.

If $Y = \mathrm{Prim}(B)$ and Ψ_B is the identity map $\mathrm{id}_{\mathcal{I}(B)}$ of $\mathbb{O}(Y)$, then we write $\mathcal{C}(\Psi_A)$ for $\mathcal{C}(\Psi_A, \Psi_B)$. Clearly $V \in \mathcal{C}(\Psi_A)$ if and only if $V(a) \in J$ for $J \in \mathcal{I}(B)$ and $a \in \Psi_A(U_J)$.

If $\mathcal{S}$ is a subset of $\mathrm{CP}(A, B)$ let

$$\Psi^{\mathcal{S}}(J) := \{a \in A\,;\ V(b^*ab) \in J \ \ \forall V \in \mathcal{S},\ \ \forall b \in A\,\}$$

It is a lower semi-continuous action of $\mathrm{Prim}(B)$ on A, because $\mathbb{O}(\mathrm{Prim}(B)) \cong \mathcal{I}(B)$ naturally, and, obviously,

$$\Psi^{\mathcal{S}}(\bigcap_\tau J_\tau) = \bigcap_\tau \Psi^{\mathcal{S}}(J_\tau)$$

for every family $\{J_\tau\}_\tau$ of closed ideals of B. The action $\Psi^{\mathcal{S}}$ is possibly degenerate, e.g. if $\mathcal{S} = \{0\}$.

Obviously, $\Psi^{\mathcal{S}} = \Psi^{\mathcal{C}(\mathcal{S})}$ and $\mathcal{C}(\mathcal{S}) \subseteq \mathcal{C}(\Psi^{\mathcal{S}})$. Clearly $V \in \mathcal{C}(\Psi^{\mathcal{S}})$ if and only if, for every $a \in A$, $V(a)$ is contained in the closed ideal of B generated by $W(a)$ for all $W \in \mathcal{S}$.

Example 3.5.6. If $B, C \subseteq A_\omega$, then $Y := \mathrm{Prim}(A_\omega)$ acts on B and C by the maps from Ψ_B and Ψ_C from $\mathbb{O}(Y) \cong \mathcal{I}(A_\omega)$ into $\mathcal{I}(B)$ (respectively $\mathcal{I}(C)$) by $\Psi_B(J) := B \cap J$ (respectively $\Psi_C(J) := C \cap J$). The corresponding action of $\mathrm{Prim}(C)$ on B is in general not l.s.c.

The equivalence of (i) and (ii) of Theorem 3.5.2 gives the following characterization of m.o.c. cones by actions:

Corollary 3.5.7. *Let $\mathcal{S} \subseteq \mathrm{CP}(A, B)$, $V \colon A \to B$ completely positive, and consider the set $\mathcal{T}$ of completely positive maps $W \otimes^{\max} \mathrm{id}$ from $A \otimes^{\max} C^*(F_\infty)$ into $B \otimes^{\max} C^*(F_\infty)$ for $W \in \mathcal{S}$.*

Then $V \in \mathcal{C}(\mathcal{S})$ if and only if $V \otimes^{\max} \mathrm{id} \in \mathcal{C}(\Psi^{\mathcal{S}})$.

`there is a similar result later on`

`compare results and notations ??`

Remark 3.5.8. An action Ψ_B naturally extends to stabilizations or to tensor-products: $\Psi_{B \otimes E}(Z) = \Psi_B(Z) \otimes E$.

If E is simple and nuclear then this extension is unique (as e.g. in the often considered cases where E is one of $\mathcal{O}_\infty$, $\mathcal{O}_2$, $\mathbb{K}$, M_n or the Jiang-Su algebra $\mathcal{Z}$).

A natural extension of Ψ_B to $C_0(X,B)$, e.g. for $X=[0,1]$ or $X=(0,1]$, is given by $\Psi_{C_0(X,B)}(Z) := C_0(X,\Psi_B(Z))$.

Also it extends naturally to Hilbert–B-modules $\mathcal{H}$ and to $\mathcal{L}(\mathcal{H})$ by $\Psi_{\mathcal{H}}(Z) := \overline{\mathcal{H}\Psi_B(Z)}$,

Next Def. o.k.? $\Psi_{\mathcal{L}(\mathcal{H})}(Z) := \{\, T\in\mathcal{L}(\mathcal{H})\,;\; T\mathcal{H}\subseteq \Psi_{\mathcal{H}}(Z)\,\}$ and so on ...

In particular, $\Psi_{M(B)}(Z) = M(B,\Psi_B(Z)) =$ strict closure of $\Psi_B(Z)$, that is $T\in\Psi_{M(B)}(Z)$ if and only if $d^*Td\in\Psi_B(Z)$. (Note that $\Psi_B(Z)$ is an ideal of B.)

Definition 3.5.9. If Ψ_A and Ψ_B are actions of Y on A and B, then a c.p. map $V\in \mathrm{CP}(A,B)$ is called **Ψ-residually nuclear** if

(i) V is Ψ-equivariant, i.e., $V(\Psi_A(U))\subseteq\Psi_B(U)$ for every $U\in\mathbb{O}(Y)$, and
(ii) the completely positive class map

$$[V]\colon A/\Psi_A(U)\to B/\Psi_B(U)$$

is nuclear for every $U\in\mathbb{O}(Y)$.

$\mathcal{C}_{rn}(\Psi_A,\Psi_B)$ denotes the **cone of Ψ-residually nuclear maps** . It is a point-norm closed (matrix) operator-convex cone of completely positive maps.

If $A\subseteq\mathcal{M}(B)$, then $Y=\mathrm{Prim}(B)$ acts naturally on A by

Same notation Ψ for Ψ_A and Ψ_B ???

$\Psi_A(J) := A\cap\mathcal{M}(B,J)$ and $\Psi_B(J)=J$

(????)

for $J\in\mathcal{I}(B)\cong\mathbb{O}(\mathrm{Prim}(B))$, then we write "residually nuclear" instead of "Ψ-residually nuclear".

We use the notation $\mathcal{C}_{rn}(A\subseteq\mathcal{M}(B))$ or $\mathcal{C}_{rn}(\Psi)$ for the operator-convex cone of residually nuclear maps $V\colon A\to B$.

That means $V(\Psi(J)\cap A)\subset J$ and $[V]_J\colon A/\Psi(J)\to B/J$ is nuclear for each $J\lhd B$.

Note, that, for the natural action of $\mathrm{Prim}(B)$ on $A\subseteq\mathcal{M}(B)$, a c.p. map $V\colon A\to B$ is equivariant if and only if $V(a)$ is contained in the closed ideal of B generated by BaB for every $a\in A_+$.

Remark 3.5.10. A Ψ-equivariant map $V\colon A\to B$ is Ψ-residually nuclear, if and only if, for every $U\in\mathbb{O}(Y)$ and every separable C^*-algebra F, the completely positive map

$$[V]\otimes^{\max}\mathrm{id}\colon (A/\Psi_A(U))\otimes^{\max}F\to(B/\Psi_B(U))\otimes^{\max}F$$

factorizes over $A/\Psi_A(U)\otimes^{\min}F$, i.e., the kernel of

$$(A/\Psi_A(U))\otimes^{\max}F\to(A/\Psi_A(U))\otimes^{\min}F$$

is contained in the kernel of $[V]\otimes^{\max}\mathrm{id}$.

The reason is that a c.p. map $T\colon D \to E$ is nuclear if and only if

$$T \otimes^{\max} \mathrm{id}\colon D \otimes^{\max} F \to E \otimes^{\max} F$$

factorizes over $D \otimes^{\min} F$ for every separable C^*-algebra F. The latter can be seen by a simple Hahn-Banach separation argument using [**463**, lem. 7.17(i)], the proof is implicitly contained in the proof of a less general result in [**426**].

Since the containment of ideals can be checked with help of primitive ideals and since the maximal tensor product on C^*-algebras is short-exact, we get the following equivalent characterizations of Ψ-residually nuclear maps:

$V \in CB(A, B)$ is Ψ-residually nuclear if and only if for every irreducible representation

$$\rho\colon B \otimes^{\max} C^*(F_\infty) \to \mathcal{L}(\mathcal{H})\,,$$

every $U \in \mathbb{O}(Y)$ with $\rho(\Psi_B(U) \otimes^{\max} C^*(F_\infty)) = 0$ and every closed ideal J of $C^*(F_\infty)$ with $\rho(B \otimes^{\max} J) = 0$, the completely positive map

$$\rho \circ (V \otimes^{\max} \mathrm{id})\colon A \otimes^{\max} C^*(F_\infty) \to \mathcal{L}(\mathcal{H})$$

factorizes over $(A/\Psi_A(U)) \otimes^{\min} (C^*(F_\infty)/J)$.

By the above cited separation arguments this can be easily seen to be equivalent to the following:

$V \in \mathrm{CP}(A, B)$ is Ψ-residually nuclear, if and only if, for every C^*-morphism h from B into a von-Neumann factor N with $h(B)'' = N$ and every $U \in \mathbb{O}(Y)$ with $h(\Psi_B(U)) = 0$, holds $h(V(\Psi_A(U))) = (h \circ V)(\Psi_A(U)) = 0$ and that the c.p. map $[h \circ V]\colon A/\Psi_A(U) \to N$ is weakly nuclear.

Question 3.5.11. Suppose that A is separable. Is $\mathcal{C}_{rn}(\Psi^{\mathcal{S}}) = \mathcal{C}(\mathcal{S})_{rn}$ for $\mathcal{S} = \mathcal{C}(\Psi_A, \Psi_B)$? I.e., $\mathcal{C}_{rn}(\Psi^{\mathcal{C}(\Psi_A,\Psi_B)}) = \mathcal{C}_{rn}(\Psi_A, \Psi_B)$? This would show that all operator-convex cones of Ψ-residually nuclear maps from A to B are cones of residually nuclear maps for suitable lower semi-continuous actions Ψ of $\mathrm{Prim}(B)$ on A.

Question has now (since 2015, unpublished) a positive answer for separable A and B,
because each stable separable $C*$-algebra B has
''Abelian'' factorization.

Lemma 3.5.12. *Suppose that A is a C^*-algebra, N a von-Neumann factor and $\mathcal{C} \subseteq \mathrm{CP}(A, N)$ an operator-convex cone of completely positive maps.*

If $\mathcal{C}$ is separating for A, i.e., if $W(a) = 0$ for all $W \in \mathcal{C}$ implies $a = 0$, then every nuclear c.p. map $V\colon A \to N$ is contained in the point-weak closure of $\mathcal{C}$.

Proof. One can reduce all to the particular case where N is a von-Neumann subalgebra of $\mathcal{L}(\mathcal{H})$, and $\mathcal{H}$ contains a cyclic vector η for N, in a way that it suffices to show that the positive linear functional $\lambda \circ (V \otimes^{\max} \mathrm{id})$ on $A \otimes^{\max} M$ is in the point-weak closure of the convex cone κ of linear functionals $\lambda \circ (W \otimes^{\max} \mathrm{id})$ with $W \in \mathcal{C}$ (compare the arguments in proofs of [**463**, lem. 7.17, 7.18]).

Here $M := N' \subseteq \mathcal{L}(\mathcal{H})$ is the commutant of N, and let λ the partially normal positive functional on $N \otimes^{\max} M$ given by $\lambda(n \otimes m) = \langle mn\eta, \eta \rangle$.

The functional $\lambda \circ (V \otimes^{\max} \mathrm{id})$ factorizes over $A \otimes^{min} M$, i.e., annihilates the elements in the kernel of the epimorphism $A \otimes^{\max} M \to A \otimes^{min} M$, because $V : A \to N$ is weakly nuclear.

Since η is an cyclic vector for N, one gets (as in the proof of the implication (ii)⇒(i) for Theorem 3.5.2) that [**463**, lem. 7.17(ii)] applies to weak closure of κ, i.e., every positive linear functional φ on $A \otimes^{\max} M$ which annihilates the intersection J of the ideal-kernels of the functionals in κ is in the point-weak closure of κ. J does not contain a non-zero elementary element $a \otimes m$, because M and N are factors and $\mathcal{C}$ is separating for A.

It follows that J is contained in in the kernel of $A \otimes^{\max} M \to A \otimes^{min} M$. Hence $\lambda \circ (V \otimes^{\max} \mathrm{id})$ is in the point-weak closure of κ. □

REMARK 3.5.13. Let $A \subseteq M(D) \subseteq D^{**}$ such that $A \hookrightarrow D^{**}$ is weakly nuclear. Then $V : A \to D$ is residually nuclear if and only if V is approximately inner.

In particular, the identity map of every nuclear C^*-subalgebra $A \subseteq \mathcal{M}(D)$ is residually nuclear for the natural action of $\mathrm{Prim}(D)$ on A.

The following corollaries are combinations of special cases of the above results combined with some of the results of Sections 4–8.

COROLLARY 3.5.14. *Suppose that A and B are C^*-algebras and that $\mathcal{S}$ is a set of c.p. maps $V : A \to B$.*

(i) *For every $J \in \mathcal{I}(B)$ holds*

$$\Psi^{\mathcal{S}}(J) = \bigcap_{V \in \mathcal{C}(\mathcal{S})} V^{-1}(J)$$

where $\Psi^{\mathcal{S}}$ is the lower semi-continuous action of $\mathrm{Prim}(B)$ on A as defined in Definition 3.5.5.

(ii) *Every $\Psi^{\mathcal{S}}$-residually nuclear map $W : A \to B$ is in $\mathcal{C}(\mathcal{S})$.*

PROOF. (i) follows from $b^* V(a^*(.)a)b \in \mathcal{C}(\mathcal{S})$ for $V \in \mathcal{C}(\mathcal{S})$.

(ii): Combine Theorem 3.5.2(iii), Remark 3.5.10 and Lemma 3.5.12. □

COROLLARY 3.5.15. *Suppose that $B, C \subseteq A$ are C^*-subalgebras of a C^*-algebra A and that $V : B \to A$ is a c.p. map with $V(B) \subseteq C$.*

(i) *V is a.i. in A, – i.e., V can be approximated inside $\mathrm{CP}(B, A)$ in point norm by restrictions to B of inside A inner completely positive maps $b \in A \mapsto \sum_j (a_j)^* b a_j$ –, if and only if, $V(B \cap J) \subseteq J$ for every closed ideal J of A and $[h \circ V] : B/(B \cap J) \cong h(B) \to h(C) \subseteq N$ is weakly a.i. in N for every von-Neumann factor representation $h : A \to N \subseteq \mathcal{L}(H)$ of A.*

(ii) *If B or C is nuclear then V is a.i. in A, if and only if, for every $b \in B_+$, $V(b)$ is in the closed ideal $\overline{\mathrm{span}(AbA)}$ of A generated by b.*

COROLLARY 3.5.16. *Suppose that A is an exact C^*-subalgebra of a C^*-algebra B, and that $V\colon A \to B$ is a c.p. map. We consider the natural action Ψ of $\mathrm{Prim}(B)$ on A given by*

$$\Psi\colon J \in \mathcal{I}(B) \cong \mathbb{O}(\mathrm{Prim}(B)) \mapsto J \cap A \in \mathcal{I}(A)\,.$$

(i) *V is residually nuclear, if and only if, V is nuclear and Ψ-equivariant with respect to the natural action of $\mathrm{Prim}(B)$ on A, if and only if, V is nuclear and (finite-step-) a.i. in B.*
(ii) *Moreover, if B is s.p.i. and , V is 1-step-approximately inner, if V is residually nuclear.*
(iii) *Suppose that $\mathcal{S} \subseteq \mathrm{CP}(A, B)$ satisfies that, for every $a \in A$ and $\varepsilon > 0$, there exists $W \in \mathcal{S}$, $u \in A$ and $v \in B$ such that $\|v^*W(u^*au)v - a\| < \varepsilon$. Then every Ψ-residually nuclear map is in $\mathcal{C}(\mathcal{S})$. In particular, every nuclear Ψ-equivariant map $V\colon A \to B$ is approximately one-step inner if the elements of $\mathcal{S}$ are approximately one-step inner.*
(iv) *If $B = D_\omega$ for some s.p.i. algebra D, V is a residually nuclear contraction and A is separable, then there is a contraction d in B with $V(b) = d^*bd$ for all $b \in A$.*
(v) *If, in addition to (iv), D is stable, then there is an isometry $S \in (M(D))_\omega \subseteq M(B)$ such that $V(b) = S^*bS$ for $b \in A$.*

PROOF. `To be filled in` ?? □

6. Approximate decomposition of residually nuclear maps

We derive now an important later used sufficient condition for approximate decompositions and for one-step innerness of residually nuclear maps inside ultra-powers B_ω. Recall that $D \subseteq \mathcal{M}(B)$ is "non-degenerate" if $\overline{D \cdot B} = B$.

PROPOSITION 3.6.1. *Suppose that D is a strongly purely infinite non-degenerate C^*-subalgebra of $\mathcal{M}(B)$ and that $C \subseteq \mathcal{M}(D) \subseteq \mathcal{M}(B)$ is a separable C^*-subalgebra. Let $X := \mathrm{Prim}(D)$, and define actions of X on C and B by*

$$\begin{aligned}\Psi_C &:= \Psi^{\mathrm{up}}_{D,C}\colon\ \mathcal{I}(D) \cong \mathbb{O}(X) \to \mathcal{I}(C)\\ &\textit{and}\\ \Psi_B &:= \Psi^{D,B}_{\mathrm{down}}\colon\ \mathcal{I}(D) \cong \mathbb{O}(X) \to \mathcal{I}(B)\,,\end{aligned}$$

as in Definition 1.2.7. Then:

(i) *A map $V\colon C \to B$ is $\Psi^{\mathrm{up}}_{B,C}$- $\mathrm{id}_{\mathcal{I}(B)}$–residually nuclear, if and only if, V is Ψ_C-Ψ_B–residually nuclear, if and only if, V is $\mathrm{id}_{\mathcal{I}(C)}$- $\Psi^{C,B}_{\mathrm{down}}$–residually nuclear.*

(ii) *Every* Ψ_C-Ψ_B*–residually nuclear contraction* $V: C \to B \subseteq B_\omega$ *can be approximated in point-norm topology by compositions* $T \circ S$*, where* $T: D_\omega \to B_\omega$ *is a one-step-approximately inner completely positive contraction, and* $S: C \to D_\omega$ *is a residually nuclear contraction with respect to the action* $\Psi^{\mathrm{up}}_{D_\omega, C}$ *of* $\mathrm{Prim}(D_\omega)$ *on* C*, where we consider the embeddings*

$$C \subseteq \mathcal{M}(D) \subseteq \mathcal{M}(D)_\omega \subseteq \mathcal{M}(D_\omega)\,.$$

(iii) *The maps* $S \circ T$ *of Part* (ii) *can be approximated by* 1*-step-inner completely positive contractions.*

In particular, $V: C \to B$ *is approximately inner in* $\mathcal{M}(B)$ *if* V *is* Ψ_C-Ψ_B*–residually nuclear.*

We use the following Lemma 3.6.2 for the proof of Proposition 3.6.1.

LEMMA 3.6.2. *Let* $A \subseteq \mathcal{M}(D)$ *and* $D \subseteq \mathcal{M}(B)$ *non-degenerate. Then:*

(i) $\mathcal{M}(B, J)$ *is the strict closure of* $J \lhd B$*, and, for every strictly closed ideal* I *of* $\mathcal{M}(B)$ *holds* $I = \mathcal{M}(B, J)$ *for* $J := I \cap B \lhd B$.
(ii) $\Psi^{\mathrm{up}}_{D,A}(\Psi^{\mathrm{up}}_{B,D}(J)) = \Psi^{\mathrm{up}}_{B,A}(J)$ *for all* $J \in \mathcal{I}(B)$.
(iii) $\Psi^{A,B}_{\mathrm{down}}(\Psi^{\mathrm{up}}_{D,A}(K)) \subseteq \Psi^{D,B}_{\mathrm{down}}(K)$ *for all* $K \in \mathcal{I}(D)$.
(iv) $\Psi^{A,B}_{\mathrm{down}}(\Psi^{\mathrm{up}}_{B,A}(J)) \subseteq \Psi^{D,B}_{\mathrm{down}}(\Psi^{\mathrm{up}}_{B,D}(J)) \subseteq J$ *for all* $J \in \mathcal{I}(B)$.
(v) $L \subseteq \Psi^{\mathrm{up}}_{B,A}(\Psi^{A,B}_{\mathrm{down}}(L))$ *for all* $L \in \mathcal{I}(A)$.

PROOF. (i): If $s \in \mathcal{M}(B)$ and $sB \subseteq J$, then $bs \in B$ and $bse \in J$ for all $e \in B_+$, which implies that $Bs \subseteq J$, i.e., $s \in \mathcal{M}(B, J)$. For $t \in \mathcal{M}(B)$, $s \in \mathcal{M}(B, J)$ holds $tsB \subseteq tJ = tBJ \subseteq J$ and $stB \subseteq sB \subseteq J$. Thus $\mathcal{M}(B, J)$ an ideal of $\mathcal{M}(B)$.

If $(t_\alpha) \subseteq \mathcal{M}(B, J)$ converges strictly to $s \in \mathcal{M}(B)$ then $sb = \lim t_\alpha b \in J$ for all $b \in B$, i.e., $s \in \mathcal{M}(B, J)$. Thus $\mathcal{M}(B, J)$ is a strictly closed ideal of $\mathcal{M}(B)$. In particular, $\mathcal{M}(B, J)$ is norm-closed in $\mathcal{M}(B)$. Therefore it is a *-ideal of $\mathcal{M}(B)$. For $s \in \mathcal{M}(B, J)$ and a bounded approximate unit $\{e_\alpha\}$ of B holds that $se_\alpha \in J$ converges strictly to s in $\mathcal{M}(B)$.

It holds $IB \subseteq B \cap I$ and $J := B \cap I$ is a closed ideal of B, thus $I \subseteq \mathcal{M}(B, J)$ and $J \subseteq I$. It follows $\mathcal{M}(B, J) = I$ because $\mathcal{M}(B, J)$ is the strict closure of J in $\mathcal{M}(B)$.

(ii): Since $D \subseteq \mathcal{M}(B)$ is non-degenerate, there is a unique strictly continuous and unital embedding $\iota: \mathcal{M}(D) \hookrightarrow \mathcal{M}(B)$ with $\iota(d) = d$ for all $d \in D$ ([16]), and we can identify $\mathcal{M}(D)$ with $\iota(\mathcal{M}(D))$.

Let $K := \Psi^{\mathrm{up}}_{B,D}(J) = D \cap \mathcal{M}(B, J)$. Then $\mathcal{M}(D, K) \subseteq \mathcal{M}(D) \cap \mathcal{M}(B, J)$, because $\mathcal{M}(D, K)$ is the strict closure of K in $\mathcal{M}(D)$ by (i), $\mathcal{M}(D) \hookrightarrow \mathcal{M}(B)$ is strictly continuous and $\mathcal{M}(D) \cap \mathcal{M}(B, J)$ is strictly closed in $\mathcal{M}(D)$. The same arguments show that $\mathcal{M}(D) \cap \mathcal{M}(B, J)$ is a strictly closed ideal of $\mathcal{M}(D)$. By (i), there is a closed ideal L of D with $\mathcal{M}(D, L) = \mathcal{M}(D) \cap \mathcal{M}(B, J)$. It follows

[16]In general, $\iota(\mathcal{M}(D))$ is not strictly closed in $\mathcal{M}(B)$, even if $D \hookrightarrow \mathcal{M}(B)$ is non-degenerate.

$L \subseteq K$ and $\mathcal{M}(D,K) \subseteq \mathcal{M}(D,L)$, ie $K = KD \subseteq L$. Thus, $A \cap \mathcal{M}(B,J) = A \cap \mathcal{M}(D) \cap \mathcal{M}(B,J) = A \cap \mathcal{M}(D,K)$, i.e., $\Psi^{\text{up}}_{B,A}(J) = \Psi^{\text{up}}_{D,A}(K)$ for $K = \Psi^{\text{up}}_{B,D}(J)$.

(iii): Let $K \triangleleft D$. Then $I := \Psi^{\text{up}}_{D,A}(K) \subseteq \mathcal{M}(D,K)$ Thus $BDIDB \subseteq BD\mathcal{M}(D,K)DB \subseteq BKB$. Since DB is dense in B, we get $\Psi^{A,B}_{\text{down}}(\Psi^{\text{up}}_{D,A}(K)) \subseteq \Psi^{D,B}_{\text{down}}(K)$.

(vi): Let $J \triangleleft B$. Consider $K := \Psi^{\text{up}}_{B,D}(J)$ and $L := \Psi^{\text{up}}_{D,A}(K)$. We have $\Psi^{D,B}_{\text{down}}(K) \subseteq J$, because $K = \Psi^{\text{up}}_{B,D}(J) \subseteq \mathcal{M}(B,J)$ and $B\mathcal{M}(B,J)B \subseteq J$. On the other hand, $\Psi^{\text{up}}_{B,A}(J) = L$ by (ii), and $DLD \subseteq D\mathcal{M}(D,K)D \subseteq K$. Thus $BDLDB \subseteq BKB$. Since $DB = B$, it follows $\Psi^{A,B}_{\text{down}}(L) \subseteq \Psi^{D,B}_{\text{down}}(K)$.

(v): Let $L \triangleleft A$, and let $J := \overline{\text{span}(BLB)} = \Psi^{A,B}_{\text{down}}(L))$. For $x \in L$, bx^*xb is in $J := \overline{\text{span}(BLB)}$, which implies $xb \in J$. Thus $LB \subseteq J$ and $BL = (LB)^* \subseteq J$, i.e., $L \subseteq \Psi^{\text{up}}_{B,A}(J)$. □

Proof of Proposition 3.6.1. Recall that $\Psi_C(K) := \Psi^{\text{up}}_{D,C}(K) := C \cap \mathcal{M}(D,K)$ and that $\Psi_B(K) = \Psi^{D,B}_{\text{down}}(K)$ is defined as the closure of span(BKB) for $K \in \mathcal{I}(D)$.

(i): Suppose that $V\colon C \to B$ is $\Psi^{\text{up}}_{B,C}$-$\text{id}_{\mathcal{I}(B)}$– residually nuclear, and let I a closed ideal of D. Then $\mathcal{M}(D,I) \subseteq \mathcal{M}(B,BIB)$ (because $IB + BI \subseteq BIB$ and $DB = B = BD$), and $C \cap \mathcal{M}(D,I) = \Psi_C(I) \subseteq \Psi^{\text{up}}_{B,C}(BIB)$. It follows $V(\Psi_C(I)) \subseteq BIB = \Psi_B(I)$. Furthermore, $[V]_I\colon C/\Psi_C(I) \to B/BIB$ satisfies $[V]_I((C \cap \mathcal{M}(B,BIB))/\Psi_C(I)) = 0$, because $V(C \cap \mathcal{M}(B,BIB)) \subseteq BIB$. Thus, $[V]_I$ factorizes $[V]_I = [V]_J \circ \pi$ for the nuclear map $[V]_J\colon C/\Psi^{\text{up}}_{B,C}(J) \to B/J$ where $J := BIB$. It follows that V is Ψ_C-Ψ_B–residually nuclear.

Suppose that V is Ψ_C-Ψ_B–residually nuclear, and let K a closed ideal of C. Then $\Psi^{C,B}_{\text{down}}(K) = \text{span}(BKB) = BDKDB = BIB$ for $I := DCD$. Then $K \subseteq C \cap \mathcal{M}(D,I) = \Psi_C(I)$ and

$$V(K) \subseteq V(\Psi_C(I)) \subseteq \Psi_B(I) = \Psi^{C,B}_{\text{down}}(K)\,,$$

and $[V]_K\colon C/K \to B/\text{span}(BKB) = B/\Psi_B(I)$ factorizes through the nuclear map $[V]_I\colon C/\Psi_C(I) \to B/\Psi_B(I)$ because $K \subseteq \Psi_C(I)$. It follows that V is $\text{id}_{\mathcal{I}(C)}$-$\Psi^{C,B}_{\text{down}}$–residually nuclear.

Suppose that V is $\text{id}_{\mathcal{I}(C)}$-$\Psi^{C,B}_{\text{down}}$– residually nuclear, and let J a closed ideal of B. Then $K := C \cap \mathcal{M}(B,J) = \Psi^{\text{up}}_{B,C}(J)$ is a closed ideal of C with

$$\Psi^{C,B}_{\text{down}}(K) = \overline{\text{span}(BKB)} \subseteq J\,,$$

because $cB + Bc \subseteq J$ for all $c \in \mathcal{M}(B,J)$. It follows that $V(K) \subseteq \overline{\text{span}(BKB)} \subseteq J$, and that $[V]\colon C/K \to C/\overline{\text{span}(BKB)}$ is nuclear. Thus $[V]\colon C/K \to C/J$ is also nuclear and $K = \Psi^{\text{up}}_{B,C}(J)$.

Thus, $V\colon C \to B$ is $\Psi^{\text{up}}_{B,C}$-$\text{id}_{\mathcal{I}(B)}$– residually nuclear.

(ii)+(iii): First we consider all maps $S\colon C \to D_\omega$ with the property that the C^*-subalgebra $A_S := C^*(S(C))$ of D_ω is abelian and that there exist contractions

$s_1, s_2, \ldots \in D_\omega$ with $s_n^*(C + \mathbb{C}1)s_m = \{0\}$ for $n \neq m$ and $s_n^* c s_n = S(c)$ for all $c \in C$ and $n \in \mathbb{N}$. Clearly, the maps S are $\Psi^{\mathrm{up}}_{D_\omega, C}$-residually nuclear, and, for all contraction $b \in B_\omega$, the maps $c \in C \mapsto b^* S(c) b \in B_\omega$ are $\Psi^{\mathrm{up}}_{B_\omega, C}$-residually nuclear in $C \subseteq \mathcal{M}(D_\omega) \subseteq \mathcal{M}(B_\omega)$. By definition, the maps $c \mapsto b^* S(c) b$ are one-step approximately inner in $\mathcal{M}(B)_\omega \subseteq \mathcal{M}(B_\omega)$. (Here we use that $D_\omega \subseteq \mathcal{M}(B)_\omega \subseteq \mathcal{M}(B_\omega)$ is non-degenerate, i.e., $D_\omega B_\omega = B_\omega$.)

We are going to show:

(α) The above considered maps $c \mapsto b^* S(c) b$ are point-norm dense in the set of contractions of a matrix operator-convex cone $\mathcal{C} \subseteq \mathrm{CP}_{\mathrm{in}}(C, B_\omega)$.

(β) For every $c_0 \in C_+$ and $b_1, \ldots, b_n \in B_\omega$ with $\| \sum_j b_j^* b_j \| \leq 1$ there exist $S\colon C \to D_\omega$ as above descibed and a contraction $b \in B_\omega$ with $b^* S(c) b = \sum_j b_j^* c b_k$.

By (α) and (β), the operator-convex cone $\mathcal{C}$ is a sub-cone of the cone of approximately inner c.p. maps from $C \subseteq \mathcal{M}(B_\omega)$ to B_ω which has the property that the action $\Psi_{\mathcal{C}}$ of $\mathcal{I}(B_\omega) \cong \mathbb{O}(\mathrm{Prim}(B_\omega))$ on C defined by $\mathcal{C}$ is the same as $\Psi^{\mathrm{up}}_{B_\omega, C}$ (which is the action defined by the cone of approximately inner c.p. maps). It follows from Corollary 3.5.14(ii) that all $\Psi^{\mathrm{up}}_{B_\omega, C}$-residually nuclear contractions V from C into B_ω are in the point-norm closure of the set of maps $c \mapsto b^* S(c) b$ as described above. The $\Psi^{\mathrm{up}}_{B, C}$-residually nuclear contractions $V\colon C \to B$ define $\Psi^{\mathrm{up}}_{B_\omega, C}$-residually nuclear contractions $V\colon C \to B \subseteq B_\omega$. By (i) this shows that (α) and (β) imply (ii) and (iii).

For the proof of (α) and (β) we list the following facts (1)-(4) on ultrapowers D_ω of strongly purely infinite C^*-algebras D (taken from [**463**] and [**443**]):

(1) If X is a separable subset of $D_\omega + B_\omega$, then there exists positive contraction $e \in D_\omega$ with $ex = xe = x$ for all $x \in X$, and with $ec = ce$ and $\|ce\| = \|c\|$ for all $c \in C$.

(2) For every separable C^*-subalgebra $A \subseteq D_\omega$ and every commutative separable C^*-subalgebra $F \subseteq D_\omega$ there exists a contraction $d \in D_\omega$ with $df = fd$, $fd^*d = f$, $d^*adf = fd^*ad$, $d^*a^*dd^*ad = d^*add^*a^*d$ for all $f \in F$ and $a \in A$.

(3) For every separable commutative C^*-subalgebra $F \subseteq D_\omega$ there exists a *-morphism $h\colon F \otimes \mathcal{O}_\infty \to D_\omega$ with $h(f \otimes 1) = f$ for all $f \in F$.

(4) For every separable C^*-subalgebra $A \subseteq D_\omega$ and every approximately inner completely positive map $T\colon A \to D_\omega$ with commutative $C^*(T(A))$ there exists $d \in D_\omega$ with $\|d\|^2 \leq \|T\|$ and $d^* a d = T(a)$ for $a \in A$.

(α): `to be filled in` ??

(β): There are positive contractions $e, f \in C' \cap D_\omega$ with $eb_j = b_j$ and $fe = e$ for $j = 1, \ldots, n$ by (1), used twice. By (2), there is a contraction $d \in \{c_0 e, e, f\}' \cap D_\omega$ with $H := C^*(d^* f C f d \cup \{c_0 e, e, f\})$ commutative and $d^* d f = f$. Note $ed^* f c f d e = d^* e c e d = e d^* c d e$ for $c \in C$ and $d^* e (e c_0) e d = c_0 e^3$. There is *-monomorphism $k\colon H \otimes \mathcal{O}_\infty \to D_\omega$ with $k(h \otimes 1) = h$ for $h \in H$ by (3). Let $t_1, t_2, \ldots$ denote the canonical generators of $\mathcal{O}_\infty$ and let $S(c) := d^*eced$, $s_n := edk(f \otimes t_n)$, $b := \sum_j k(f \otimes t_j)b_j \in B_\omega$. Then $s_n^* c s_m = \delta_{n,m} S(c)$, $S(c_0) = c_0 e^3$, $C^*(S(C)) \subseteq H$ is commutative, $b^*b = \sum_j b_j^* b_j$ and $b^*S(c)b = \sum b_j^* S(c) b_j$. Thus S and $b \in B_\omega$ are as stipulated. □

Definition 3.6.3. Suppose that $\mathcal{C} \subseteq \mathrm{CP}(A,B)$ a point-norm closed matrix operator-convex sub-cone of $\mathrm{CP}(A,B)$, and that E, F are nuclear C^*-algebras.

We define $\mathrm{CP}(E,F) \otimes \mathcal{C} \subseteq \mathrm{CP}(E \otimes A, F \otimes B)$ as the point-norm closure $\mathcal{C}(\mathcal{S})$ of $\mathcal{C}_{\mathrm{alg}}(\mathcal{S})$, where $\mathcal{S} := \{V \otimes S\,;\ S \in \mathcal{C}, V \in \mathrm{CP}(E,F)\}$.

Notice the m.o.c. cone $\mathrm{CP}(E,F) \otimes \mathcal{C}$ is *not* the completion of some algebraic tensor product.

Corollary 3.6.4. *Suppose that $\mathcal{C} \subseteq \mathrm{CP}(A,B)$ is a point-norm closed operator-convex cone of completely positive maps, that E and F are nuclear C^*-algebras, and $T \in \mathrm{CP}(E \otimes A, F \otimes B)$. Then:*

(i) *If $\mathcal{S}_2$ is a generating set for $\mathcal{C}$ and $\mathcal{S}_1$ is a generating set for $\mathrm{CP}(E,F)$, then $\mathcal{S} := \{U \otimes V\,;\ U \in \mathcal{S}_1,\ V \in \mathcal{S}_2\}$ is a generating set for $\mathrm{CP}(E,F) \otimes \mathcal{C}$. In particular, $\mathrm{CP}(M_n, M_n) \otimes \mathcal{C}$ is the point-norm closure of $\mathcal{C}_{\mathrm{alg}}(\mathcal{S})$ for $\mathcal{S} := \{\mathrm{id} \otimes V\,;\ V \in \mathcal{C}\}$.*

(ii) *$T_1 T_2 \in \mathrm{CP}(E,F) \otimes \mathcal{C}$, if $T_1 \in \mathrm{CP}(G,F) \otimes \mathcal{C}_1$ and $T_2 \in \mathrm{CP}(E,G) \otimes \mathcal{C}_2$ for a nuclear C^*-algebra G and operator-convex cones $\mathcal{C}_1 \subseteq \mathrm{CP}(A,C)$ and $\mathcal{C}_2 \subseteq \mathrm{CP}(C,B)$ with $\mathcal{S}_2 \circ \mathcal{S}_1 \subseteq \mathcal{C}$ for generating subsets $\mathcal{S}_1 \subseteq \mathcal{C}_1$ and $\mathcal{S}_2 \subseteq \mathcal{C}_2$.*

(iii) *The union (over $n = 1, 2, \ldots$) of the compositions $S_1 S_2 S_3$ with $S_2 \in \mathrm{CP}(M_n, M_n) \otimes \mathcal{C}$, $S_1 \in \mathrm{CP}(M_n, F) \otimes \mathrm{CP}_{\mathrm{in}}(B,B)$, and $S_3 \in \mathrm{CP}(E, M_n) \otimes \mathrm{CP}_{\mathrm{in}}(A,A)$ is point-norm dense in $\mathrm{CP}(E,F) \otimes \mathcal{C}$.*

(iv) *$T \in \mathrm{CP}(E,F) \otimes \mathcal{C}$, if and only if, the c.p. maps*

$$a \in A \mapsto (\chi \otimes \mathrm{id}_B)(T(e \otimes a)) \in B$$

are in $\mathcal{C}$ for every $e \in E_+$ and for every pure state χ on F.

(v) *The action $\Psi \colon \mathcal{I}(F \otimes B) \cong \mathbb{O}(\mathrm{Prim}(F \otimes B))$ of $\mathrm{Prim}(F \otimes B) \cong \mathrm{Prim}(F) \otimes \mathrm{Prim}(B)$ on $E \otimes A$ satisfies*

$$\Psi(J) \;=\; E \otimes \Psi_{\mathcal{C}}(J_B)$$

for $J \lhd F \otimes B$ in $\mathcal{I}(F \otimes B)$, where J_B is the biggest of the ideals $I \lhd B$ with $F \otimes I \subseteq J$.

(vi) *The natural map Φ from $\mathcal{I}((F \otimes B) \otimes^{\max} C^*(F_2))$ into $\mathcal{I}((F \otimes A) \otimes^{\max} C^*(F_2))$ defined by $\mathrm{CP}(E,F) \otimes \mathcal{C}$ satisfies $\Phi(J) = F \otimes \Phi_1(I(J))$, where Φ_1 denotes the natural map from $\mathcal{I}(B \otimes^{\max} C^*(F_2))$ into $\mathcal{I}(A \otimes^{\max} C^*(F_2))$ defined by $\mathcal{C}$ and $I(J)$ is the biggest ideal I of $B \otimes^{\max} C^*(F_2)$ with $F \otimes I \subseteq J$.*

Recall that the operator-convex cone $\mathrm{CP}_{\mathrm{in}}(A,A)$ of approximately inner c.p. maps from A into A is nothing else $\mathcal{C}(\mathrm{id}_A)$, and that every nuclear map $V \in \mathrm{CP}_{\mathrm{nuc}}(C,C)$ is approximately inner if C is simple, e.g. $\mathrm{CP}(M_n, M_n) = \mathcal{C}_{\mathrm{alg}}(\mathrm{id})$.

Proof. Let $\mathcal{H}_2$ a Hilbert A-B–module with infinite repeats, that is naturally related to $\mathcal{C}$ in the sense of Proposition **??**, i.e., $\mathcal{C}$ is the point-norm closure of the c.p. coefficient maps $a \in A \mapsto \langle x, ax\rangle \in B$ for $x \in \mathcal{H}_2$. Further let $\mathcal{H}_1$ a Hilbert E-F–module (with infinite repeats) that corresponds to $\mathrm{CP}(E,F)$ in the same way. Then $\mathcal{H}_1 \otimes \mathcal{H}_2$ is an Hilbert $E\otimes A$-$F\otimes B$–module (with infinite repeats), corresponding to the m.o.c. cone $\mathrm{CP}(E,F)\otimes\mathcal{C}$, cf. Proposition **??**.

(i): If $\mathcal{S}_2 \subseteq \mathcal{C}$ is a generating subset of $\mathcal{C}$ than a suitable Hilbert A-B–module $\mathcal{H}_2$ can be constructed by infinitely often repeated Hilbert A-B–module sums of the Stinespring dilations of the $V \in \mathcal{S}_1$. We can elaborate a suitable Hilbert E-F-module $\mathcal{H}_1$ from $\mathcal{S}_2$ in the same way. Then $\mathcal{H}_1\otimes\mathcal{H}_2$ is just the Hilbert $E\otimes A$-$F\otimes B$–module sum of the dilations of the maps $U\otimes V$ with $U \in \mathcal{S}_1$ and $V \in \mathcal{S}_2$ (infinitely often repeated). Thus $\mathrm{CP}(E,F)\otimes\mathcal{C}$ is generated by $\{U\otimes V\,;\; U\in\mathcal{S}_1\,, V\in\mathcal{S}_2\,\}$.

Here end of proof of (i)? **??**

Let $J\lhd(F\otimes B)\otimes^{\max}C^*(F_2)$ a closed ideal and let $\Psi(J) := I\lhd(E\otimes A)\otimes^{\max}C^*(F_2)$ the maximal closed ideal with $T\otimes^{\max}\mathrm{id}(I) \subseteq J$ for all generators $T = V\otimes S$ of $\mathrm{CP}(E,F)\otimes\mathcal{C}$, where $S\in\mathcal{C}$ and $V\in\mathrm{CP}(E,F) = \mathrm{CP}_{\mathrm{nuc}}(E,F)$. By Proposition **??** , then T is in the operator-convex cone $\mathcal{C}\otimes\mathrm{CP}(E,F)$, if and only if, $T\otimes^{\max}\mathrm{id}(\Psi(J)) \subseteq J$ for all $J\lhd(F\otimes B)\otimes^{\max}C^*(F_2)$. Recall here, that it is enough to consider primitive ideals J of $(F\otimes B)\otimes^{\max}C^*(F_2) = F\otimes(B\otimes^{\max}C^*(F_2))$. Since F is nuclear, they are sums

$$J = J_F\otimes(B\otimes^{\max}C^*(F_2)) + F\otimes J_1\,,$$

where J_1 is a primitive ideal of $B\otimes^{\max}C^*(F_2)$ and J_F is a primitive ideal of F.

Now note that $\mathrm{CP}(E,F) = \mathrm{CP}_{\mathrm{nuc}}(E,F)$ is generated as an operator-convex point-norm closed cone by maps $e\in E\mapsto \xi(e)f$, for $f\in F_+$ and ξ is a pure state on E. Thus, $\Psi_{\mathrm{CP}(E,F)}(J) = 0$ if $J\lhd F$ and $J\neq F$ and, trivially, $\Psi_{\mathrm{CP}(E,F)}(F) = E$.

(iv): Let $e\in E_+$ and $\chi\colon F\to\mathbb{C}$ a pure state on F. Let $\mathcal{C}_3 \subseteq \mathrm{CP}(A,A)$ and $\mathcal{C}_1\subseteq\mathrm{CP}(B,B)$ denote the approximately inner c.p. maps. Then $\mathcal{C}\circ\mathcal{C}_3 = \mathcal{C}$ and $\mathcal{C}_1\circ\mathcal{C} = \mathcal{C}$. Consider the maps $V_3\colon z\in\mathbb{C}\to ze\in E$ and $V_1 := \chi\colon F\to\mathbb{C}$. Then $V_3\otimes\mathrm{id}_A\in\mathrm{CP}(\mathbb{C},E)\otimes\mathcal{C}_3$ and $V_1\otimes\mathrm{id}_B\in\mathrm{CP}(F,\mathbb{C})\otimes\mathcal{C}_1$. It follows $(V_1\otimes\mathrm{id}_B)\circ T\circ(V_3\otimes\mathrm{id}_A)\in\mathcal{C} = \mathcal{C}\otimes\mathrm{CP}(\mathbb{C},\mathbb{C})$ by (ii).

If $U\in\mathrm{CP}(E,F)$, $V\in\mathcal{C}$, $h\in M_{1,m}(E\odot A)$, and $k\in M_{m,1}(F\odot B)$, then $S_0(a) := \chi\otimes\mathrm{id}_B\big(k^*(U\otimes V\otimes\mathrm{id}_m(h^*(e\otimes a)h))k\big)$ defines a completely positive map that is in $\mathcal{C}$:

`orthogonalize the` $e_{i,j}$`-components of` h_i
`and the` $f_{i,j}$`-components of` k_i

Now let $T\in\mathrm{CP}(E,F)\otimes\mathcal{C}$, $a_1,\ldots,a_m\in A$, and $\varepsilon>0$. Then there are $n\in\mathbb{N}$, $U_j\in\mathrm{CP}(E,F)$, $V_j\in\mathcal{C}$, $f_j\in M_{1,n}(E\odot A)$, $g_j\in M_{n,1}(F\odot B)$, $j=1,\ldots,n$ with

$$\|T(e\otimes a_k) - \sum_j g_j^*(U_j\otimes V_j)\otimes\mathrm{id}_n(f_j^*(e\otimes a_k)f_j)g_j\| < \varepsilon\,.$$

It follows that there is $S\in\mathcal{C}$ with

$$\|\chi\otimes\mathrm{id}_B(T(e\otimes a_k)) - S(a_k)\| < \varepsilon \qquad \text{for} \quad k = 1,\ldots,m\,.$$

Thus $(\chi \otimes \mathrm{id})T(e \otimes (\cdot)) \in \mathcal{C}$.

`try again?`

$(\mathrm{id}_B \otimes \chi) \circ T \circ ((\cdot) \otimes e) \in \mathcal{C}$, because this happens if T is one of the generators where $S \in \mathcal{C}$ and $V \in \mathrm{CP}(E, F) = \mathrm{CP}_{\mathrm{nuc}}(E, F)$, and because

??????????????????

The set of $T \in \mathrm{CP}(A \otimes E, B \otimes F)$ with $(\mathrm{id}_B \otimes \chi) \circ T \circ ((\cdot) \otimes e) \in \mathcal{C}$ for all $e \in E_+$ and pure states χ on F does not change the ???????

??

Conversely, suppose that $(\mathrm{id}_B \otimes \chi) \circ T \circ ((\cdot) \otimes e) \in \mathcal{C}$ for every pure state χ on F and $e \in E_+$. Since $\mathrm{id}_B \otimes \chi$ is in the point-norm closure of the cone generated by ???? It suffices to show that $(\mathrm{id} \otimes UW) \circ V \in \mathcal{C} \otimes \mathrm{CP}(\mathbb{C}, F)$ for c.p. contractions $W : M_n \to F$ and $U : F \to M_n$.

Now, $(\mathrm{id} \otimes U) \circ \mathcal{C} \otimes \mathrm{CP}(\mathbb{C}, M_n) \subseteq \mathcal{C} \otimes \mathrm{CP}(\mathbb{C}, F)$ as one can see on the generating sets.

`Next question has a positive answer:`

QUESTION 3.6.5. Suppose that $\mathcal{C}_j \subseteq \mathrm{CP}(B_j, B_{j+1})$ $(j = 1, 2)$ and $\mathcal{C}_3 \subseteq \mathrm{CP}(B_1, B_3)$ are point-norm closed matrix-operator convex cones, and that $\mathcal{S}_j \subseteq \mathcal{C}_j$ a generating set for $\mathcal{C}_j$ $(j = 1, 2)$ in sense of Definition **??**.

Let $V \in \mathrm{CP}(B_2, B_3)$ such that $V \circ (b^* W(\cdot) b) \in \mathcal{C}_3$ for all $W \in \mathcal{S}_1$ and $b \in B_2$. Is $V \circ \mathcal{C}_2 \subseteq \mathcal{C}_3$?

Let $W \in \mathrm{CP}(B_1, B_2)$ and $V \circ (b^* W(\cdot) b) \in \mathcal{C}_3$ for all $V \in \mathcal{S}_2$. Is $\mathcal{C}_1 \circ W \subseteq \mathcal{C}_3$?

`What about situation of ⊕-closed generating system?`

REMARK 3.6.6. **??** Suppose that X and Y are T_0-spaces, $\Psi^0 : \mathbb{O}(Y) \to \mathbb{O}(X)$ lower semi-continuous and $\Psi_0 : \mathbb{O}(X) \to \mathbb{O}(Y)$ upper semi-continuous.

There are maps $\Phi_0 : \mathbb{O}(X) \to \mathbb{O}(Y)$ and $\Phi^0 : \mathbb{O}(Y) \to \mathbb{O}(X)$, determined by

$$\Phi_0(U) \subseteq V \quad \Leftrightarrow \quad \Psi^0(V) \subseteq U\,,$$

respectively

$$\Phi^0(V) \subseteq U \quad \Leftrightarrow \quad \Psi_0(U) \subseteq V\,.$$

The map Φ_0 is upper semi-continuous, and Φ^0 is lower semi-continuous.

QUESTION 3.6.7. Suppose that A is separable, $J \triangleleft A$ is a closed ideal and that $\mathrm{id}_{A/J}$ is not locally liftable (i.e., that $J \otimes \mathcal{L}(\ell_2) \to A \otimes \mathcal{L}(\ell_2) \to (A/J) \otimes \mathcal{L}(\ell_2)$ is not exact), and let $B := \mathcal{L}(\ell_2)$ (or at least $B := \mathcal{L}(\ell_2)/\mathbb{K}$).
Does there exist a non-nuclear c.p. contraction $W : A/J \to B$ such that $W \circ \pi_J : A \to B$ is nuclear?
The question for $B := \mathcal{L}(\ell_2)/\mathbb{K}$ seems to be less difficult.

QUESTION 3.6.8. Let $\mathcal{C} \subseteq \mathrm{CP}(A,B)$ a point-norm closed operator-convex cone, A and B separable. Let $\Psi_{A,\mathcal{C}}$ denote the action of $\mathrm{Prim}(B)$ on A induced by $\mathcal{C}$. Recall, that $\Psi_{A,\mathcal{C}}(J) := \bigcap_{V\in\mathcal{C}} V^{-1}(J)$ for $J \in \mathcal{I}(B)$.

Denote by $\mathcal{C}_{rn} \subseteq \mathrm{CP}(A,B)$ the point-norm closed operator-convex cone of Ψ-residually nuclear maps. (Then $\mathcal{C}_{rn} \subseteq \mathcal{C}$.)

Is $\mathcal{C}_{rn} \subseteq (\mathcal{C}_{rn})_{rn}$?

(Note here that $\Psi_{A,\mathcal{C}}(J) \subseteq \Psi_{A,\mathcal{C}_{rn}}(J)$ for $J \in \mathcal{I}(B)$.)

Is the answer positive if A locally reflexive?

QUESTION 3.6.9. Suppose that $\mathcal{S}_1 \subseteq \mathrm{CP}(A,B)$ is point-norm closed and is invariant under the operations (OC1) of Definition 3.2.2. Let $\mathcal{S}_2$ denote the point-norm closure of the smallest subset of $\mathrm{CP}(A,B)$ that contains $\mathcal{S}_1$ and is invariant under the operations (OC2).
Is $\mathcal{S}_2$ konvex?
(Examples show that the convexity of $\mathcal{S}_1$ alone is not enough to get convexity of $\mathcal{S}_2$.)

LEMMA 3.6.10. *Suppose that $\mathcal{C} \subseteq CP(A,B)$ is the matrix operator-convex cone of completely positive maps that is generated by a subset $\mathcal{S} \subseteq \mathcal{C}$.*

Then every contraction $T \in \mathcal{C}$ can be approximated in point norm by maps $S := \sum_{j=1}^{n} c_j^* V_j(r_j^*(\cdot)r_j)c_j$ with suitable $m,n \in \mathbb{N}$, $V_j \in \mathcal{S}$, rows $r_j \in M_{1,m}(A)$, and columns $c_j \in M_{m,1}(B)$, such that $\| \sum_{j=1}^{n} c_j^* V_j(r_j^* r_j)c_j\| \leq 1$.

PROOF. `to be filled in` ?? □

LEMMA 3.6.11. `Separation from cone` $\mathcal{C}$??

DEFINITION 3.6.12. A subset $\mathcal{S} \subseteq \mathrm{CP}(A,B)$ is **invariant under ε-generalized Cuntz addition**, if $d_1^* V(e(\cdot)e)d_1 + d_2^* W(e(\cdot)e)d_2 \in \mathcal{S}$ for every $V,W \in \mathrm{CP}(A,B)$, $e \in A_+$, $\varepsilon > 0$, and $d_1,d_2 \in B$ with $d_1^* d_2 = 0$ and $d_j^* d_j = (V(e^2) + W(e^2) - \varepsilon)_+$.

LEMMA 3.6.13. *Suppose that for every $b \in B_+$ and $\varepsilon > 0$ there exist $d_1,d_2 \in B$ with $d_1^* d_2 = 0$ and $\|b - d_j^* d_j\| < \varepsilon$ for $j = 1,2$ ([17]).*

If $\mathcal{S} \subseteq \mathrm{CP}(A,B)$ is invariant under ε-generalized Cuntz addition, then the operator-convex cone generated by $\mathcal{S}$ is contained in the point-norm closure of the smallest subset of $\mathrm{CP}(A,B)$ *that invariant under the operations (OC2) of Definition 3.2.2* and *contains $\mathcal{S}$.*

PROOF. ?? □

DEFINITION 3.6.14. Let $\mathcal{S} \subseteq \mathrm{CP}(A,B)$ a subset. Then the smallest subset $\mathcal{C}_{\mathrm{alg}}(\mathcal{S})$ of $\mathrm{CP}(A,B)$ that contains $\mathcal{S}$ and is invariant under the operations (OC1) and (OC2) of Definition 3.2.2 will be called the **operator-convex cone algebraically generated by $\mathcal{S}$**.

[17] It does not say that b itself is infinite, e.g. every stable B has this property.

The point-norm closure $\mathcal{C}(\mathcal{S})$ of $\mathcal{C}_{\mathrm{alg}}(\mathcal{S})$ is called the **point-norm closed** *operator-convex cone generated by* $\mathcal{S}$.

LEMMA 3.6.15. *Let $\mathcal{S} \subseteq \mathrm{CP}(A, B)$ a set of completely positive maps, and let $\mathcal{C}_{\mathrm{alg}}(\mathcal{S})$ denote the the smallest subset of $\mathrm{CP}(A, B)$ that contains $\mathcal{S}$ and is invariant under the operations (OC1) and (OC2) of Definition 3.2.2.*

(i) *The point-norm closure $\mathcal{C}$ of $\mathcal{C}_{\mathrm{alg}}(\mathcal{S})$ is again a matrix operator-convex cone.*

(ii) *Every contraction in $\mathcal{C}$ can be approximated in point-norm topology by maps of the form $\sum_{k=1}^{n} c_k^*(V_k \otimes \mathrm{id}_{n_k})(r_k^*(\,\cdot\,)r_k)c_k$ with $V_k \in \mathcal{S}$, row-matrices $r_k \in M_{1,n_k}(A)$, and column-matrices $c_k \in M_{n_k,1}(B)$, $k = 1, \ldots, n$, that satisfy*

$$\| \sum_{k=1}^{n} c_k^*(V_k \otimes \mathrm{id}_{n_k})(r_k^* r_k)c_k \| \leq 1\,.$$

(iii) *In particular, $\mathcal{C}$ is the point-norm closure of the convex hull of the set of maps $c^*(V \otimes \mathrm{id}_n)(r^*(\,\cdot\,)r)c$ with $V \in \mathcal{S}$, row-matrix $r \in M_{1,n}(A)$ and column-matrix $c \in M_{n,1}(B)$.*

PROOF. (i): The operations $(x, y) \in B \oplus B \mapsto b_1^* x b_1 + b_2^* y b_2$, $a \in A \mapsto r^* a r \in A \otimes M_n$, $x \in B \otimes M_n \mapsto c^* x c \in B$ are bounded and $V \in \mathrm{CP}(A, B) \mapsto V \otimes \mathrm{id}_n \in \mathrm{CP}(A \otimes M_n, B \otimes M_n)$ is continuous with respect to point-norm topology. Thus, the point-norm closure of a subset $K \subseteq \mathrm{CP}(A, B)$ that is invariant under the operations (OC1) and (OC2) is again invariant under the operations (OC1) and (OC2) in Definition 3.2.2.

(iii): Let $\mathcal{X}$ denote the set of maps $c^*(V \otimes \mathrm{id}_n)(r^*(\cdot)r)c$ with $V \in \mathcal{S}$, $r \in M_{1,n}(A)$, $c \in M_{n,1}(B)$, $n \in \mathbb{N}$. Then $\mathcal{X}$ is invariant under the operations (OC2), because, if $W := c_1^*(V \otimes \mathrm{id}_m)(r_1^*(\cdot)r_1)c_1$, then $c_2^*(W \otimes \mathrm{id}_n)(r_2^*(\cdot)r_2)c_2$ for is equal the map $c_3^*(V \otimes \mathrm{id}_{mn})(r_3^*(\cdot)r_3)c_3$, with $r_3 \in M_{1,mn}(A)$ given by $(r_3)_{1,\ell} := (r_1)_{1,j}(r_2)_{1,k}$ for $\ell = (j-1)n + k \in \{1 \ldots mn\}$ and the entries $(r_i)_{1,p}$ of r_i $(i = 1, 2, 3)$, and, similar, with $c_3 \in M_{1,mn}(B)$ given by $(c_3)_{\ell,1} := (c_1)_{j,1}(c_2)_{k,1}$ for $\ell = (j-1)m + k$.

If a subset $\mathcal{X} \subseteq \mathrm{CP}(A, B)$ is invariant under the operations (OC2), then (in particular) $f^* b^* V(a^* e^*(\cdot)ea)bf \in \mathcal{X}$ for every $a \in \mathcal{M}(A)$, $e \in A$, $b \in \mathcal{M}(B)$ and $f \in B$. If we use approximate units $\{e_\alpha\}$ of A and $\{f_\beta\}$ of B, then this shows that the point-norm closure $\mathcal{Y} := \overline{\mathcal{X}}$ of $\mathcal{X}$ contains all maps $b^* V(\cdot)b$ with $b \in B$ and $V \in \mathcal{X}$. With the arguments in proof of part(i), we obtain that $\mathcal{S} \subseteq \mathcal{Y}$, $\mathbb{R}_+ \cdot \mathcal{Y} \subseteq \mathcal{Y}$ and that $\mathcal{Y}$ contains $c^*(W \otimes \mathrm{id}_n)(r^*(\cdot)r)c$ if $W \in \mathcal{Y}$, $r \in M_{1,n}(\mathcal{M}(A))$, $c \in M_{n,1}(\mathcal{M}(B))$, $n \in \mathbb{N}$.

Thus, the set $\mathcal{Z}$ of finite sums $W_1 + \cdots + W_m$ with $W_j \in \mathcal{Y}$ is a cone that is invariant under the operations (OC1) and contains $\mathcal{S} \cup \mathcal{X} \subseteq \mathcal{Y}$. Since $\mathcal{Y}$ is invariant under (OC1) and since $c^*((W_1 + \cdots + W_m) \otimes \mathrm{id}_n)(r^*(\cdot)r)c = U_1 + \cdots + U_m$ for $U_j := c^*(W_j \otimes \mathrm{id}_n)(r^*(\cdot)r)c$, we get moreover that $\mathcal{Z}$ is also invariant under the operations (OC2).

It follows that $\mathcal{C}_{\mathrm{alg}}(\mathcal{S}) \subseteq \mathcal{Z}$. On the other hand, $\mathcal{X} \subseteq \mathcal{C}_{\mathrm{alg}}(\mathcal{S})$ and $\mathcal{Z}$ is contained in the point-norm closure of the set $\mathcal{W}$ of finite sums $V_1 + \cdots + V_m$ with $V_j \in \mathcal{X}$.

It follows that every element of the point-norm closure $\mathcal{C}(\mathcal{S})$ of $\mathcal{C}_{\mathrm{alg}}(\mathcal{S})$ can be approximated in point-norm by maps $W \in \mathcal{W}$, where $W := \sum_{k=1}^{n} c_k^*(V_k \otimes \mathrm{id}_{n_k})(r_k^*(\,\cdot\,)r_k)c_k$ with $V_k \in \mathcal{S}$, row-matrices $r_k \in M_{1,n_k}(A)$, column-matrices $c_k \in M_{n_k,1}(B)$, $k = 1, \ldots, n$. Obviously, $\mathcal{W} \subseteq \mathcal{C}_{\mathrm{alg}}(\mathcal{S}) \subseteq \mathcal{C}$.

(ii): The norm $\|W\|$ of $W \in \mathcal{W}$ is given by $\sup\{\|W(e)\|\,;\ e \in A_+,\ \|e\| \le 1\}$ which is equal to $\|\sum_{k=1}^{n} c_k^*(V_k \otimes \mathrm{id}_{n_k})(r_k^* r_k)c_k\|$. Since $W(e(\cdot)e) \in \mathcal{W}$ for $W \in \mathcal{W}$, we get from Lemma 3.1.8 that the contractions in the point-norm closure $\mathcal{C}$ of $\mathcal{W}$ can be approximated in point-norm by contractions in $\mathcal{W}$. It proves also part(ii). □

Definition 3.6.16. Let $\mathcal{C}_1 \subseteq \mathrm{CP}(A, B)$ and $\mathcal{C}_2 \subseteq \mathrm{CP}(E, F)$ point-norm closed matrix operator-convex cones.

We define the point-norm closed m.o.c. cone $\mathcal{C}_1 \otimes \mathcal{C}_2 \subseteq \mathrm{CP}(A \otimes E, B \otimes F)$ as the smallest point-norm closed m.o.c. cone that contains all tensor products $S \otimes T \in \mathrm{CP}(A \otimes E, B \otimes F)$ of $S \in \mathcal{C}_1$ and $T \in \mathcal{C}_2$.

The m.o.c. cone $\mathcal{C}_1 \otimes \mathcal{C}_2 \subseteq \mathrm{CP}(A \otimes E, B \otimes F)$ is called the "**minimal tensor product**" of the m.o.c. cones $\mathcal{C}_1$ and $\mathcal{C}_2$.

If $A = \mathrm{C}_0(X)$ and $F = \mathbb{C}$, respectively $E = \mathbb{C}$ and $B = \mathrm{C}_0(Y)$, then we write sometimes also $[X]\mathcal{C}$, respectively $\mathcal{C}[Y]$, to simplify notation.

The m.o.c. cone $\mathcal{C}_1 \otimes \mathcal{C}_2$ is not a tensor product in the usual sense because it contains usually elements that can not be approximated in point-norm by convex combinations of elementary tensors $S \otimes T$.

Corollary 3.6.17. *Suppose that $\mathcal{S}_1 \subseteq \mathrm{CP}(A, B)$, $\mathcal{S}_2 \subseteq \mathrm{CP}(E, F)$ are subsets and that $\mathcal{C}_1 \subseteq \mathrm{CP}(A, B)$, $\mathcal{C}_2 \subseteq \mathrm{CP}(E, F)$ are the point-norm closed matrix operator-convex cones generated by $\mathcal{S}_1$ respectively $\mathcal{S}_2$.*

Then the point-norm closed matrix operator-convex cone $\mathcal{C}_1 \otimes \mathcal{C}_2 \subseteq \mathrm{CP}(A \otimes E, B \otimes F)$ that is generated by $\{V \otimes W\,;\ V \in \mathcal{C}_1\,,\ W \in \mathcal{C}_2\,\}$ is also generated by $\{S \otimes T\,;\ S \in \mathcal{S}_1\,,\ T \in \mathcal{S}_2\,\}$.

Proof. Let $\mathcal{C}_3 \subseteq \mathrm{CP}(A \otimes E, B \otimes F)$ denote the point-norm closure of the operator-convex cone generated by $\{S \otimes T\,;\ S \in \mathcal{S}_1\,,\ T \in \mathcal{S}_2\,\}$. Then $\mathcal{C}_3 \subseteq \mathcal{C}_1 \otimes \mathcal{C}_2$ and $\mathcal{C}_3$ is point-norm closed, is convex and is invariant under the operations (OC1) and (OC2) by Lemma 3.6.15(i). Thus, $\mathcal{C}_1 \otimes \mathcal{C}_2 = \mathcal{C}_3$ if $\mathcal{C}_3$ contains every tensor product $V \otimes W$ with $V \in \mathcal{C}_1$ and $W \in \mathcal{C}_2$. By Lemma 3.6.15(ii,iii) and the convexity of the cone $\mathcal{C}_3$ is suffices to show that $(c_1^*(S \otimes \mathrm{id}_m)(r_1^*(\cdot)r_1)c_1) \otimes (c_2^*(T \otimes \mathrm{id}_n)(r_2^*(\cdot)r_2)c_2)$ is in $\mathcal{C}_3$ if $S \in \mathcal{S}_1$, $T \in \mathcal{S}_2$, $c_1 \in M_{m,1}(B)$, $r_1 \in M_{1,m}(A)$, $c_2 \in M_{n,1}(F)$ and $r_2 \in M_{1,m}(E)$. We have

$$(c_1^*(S \otimes \mathrm{id}_m)(r_1^*(\cdot)r_1)c_1) \otimes (c_2^*(T \otimes \mathrm{id}_n)(r_2^*(\cdot)r_2)c_2) = c_3^*((S \otimes T) \otimes \mathrm{id}_{mn})(r_3^*(\cdot)r_3)c_3$$

for $c_3 = c_1 \otimes c_2 \in M_{mn,1}(B \otimes F)$ and $r_3 := r_1 \otimes r_2 \in M_{1,mn}(A \otimes E)$ where we use the natural isomorphisms $M_{mn,1}(B \otimes F) \cong M_{m,1}(B) \otimes M_{n,1}(F)$, $M_{1,mn}(A \otimes E) \cong$

$M_{1,m}(A)\otimes M_{1,n}(E)$, $(A\otimes E)\otimes M_{mn}\cong(A\otimes M_m)\otimes(E\otimes M_n)$ and $(A\otimes E)\otimes M_{mn}\cong(A\otimes M_m)\otimes(E\otimes M_n)$ ([18]). Thus, $\mathcal{C}_3=\mathcal{C}_1\otimes\mathcal{C}_2$. □

Definition 3.6.18. Let A and B C^*-algebras. We define a **matrix-order** $S\leq T$ on the cone of completely positive maps $S,T\in \mathrm{CP}(A,B)$ by

$$S\leq T \quad \text{if and only if} \quad T-S\in \mathrm{CP}(A,B)\,.$$

Obviously, this definition says that: $S\leq T$ if and only if there exists $R\in \mathrm{CP}(A,B)$ with $T=S+R$. It is not enough to have $S(a)\leq T(a)$ for all $a\in A_+$. But $S\leq T$ is equivalent to the property that for each $n\in N$ and all positive matrices $a\in M_n(A)_+$ holds $S_n(a)\leq T_n(a)$, where S_n and T_n apply to $a=[a_{jk}]$ as $S_n(a)=[S(a_{jk})]$.

Corollary 3.6.19. *Every, with respect to the point-norm convergence topology closed, matrix operator-convex cone $\mathcal{C}\subseteq \mathrm{CP}(A,B)$ is* hereditary *with respect to the matrix-order on* $\mathrm{CP}(A,B)$ *in sense of Definition 3.6.18, i.e., if $S,T\in \mathrm{CP}(A,B)$ and $S+T\in\mathcal{C}$ then $S,T\in\mathcal{C}$.*

If $\mathcal{C}\subseteq \mathrm{CP}(A,B)$ is a point-norm closed hereditary convex sub-cone of $\mathrm{CP}(A,B)$, *then $\mathcal{C}$ is matrix operator-convex, if and only if, the maps $U_2^*V(U_1^*(\cdot)U_1)U_2$ are in $\mathcal{C}$ for every $V\in\mathcal{C}$, and for all unitaries $U_1:=\exp(ih)\in A+\mathbb{C}1$ and $U_2:=\exp(ik)\in B+\mathbb{C}1$ with $h^*=h\in A$, $\|h\|<\pi$, $k^*=k\in B$ and $\|k\|<\pi$.*

Proof. If $I\subseteq A\otimes^{\max}C^*(F_2)$ and $J\subseteq B\otimes^{\max}C^*(F_2)$ are closed ideals with $V\otimes^{\max}\mathrm{id}(I)\subseteq J$ for all $V\in\mathcal{C}$, then $((S+T)\otimes^{\max}\mathrm{id})(I)\subseteq J$ for $S,T\in \mathrm{CP}(A,B)$ with $S+T\in\mathcal{C}$. Let $e\in I_+$, $f:=S\otimes^{\max}\mathrm{id}(e)$ and $g:=T\otimes^{\max}\mathrm{id}(e)$ in $(B\otimes^{\max}C^*(F_2))_+$. Since $f+g\in J$ and $f,g\geq 0$, it follows that $f,g\in J_+$,i.e., $S\otimes^{\max}\mathrm{id}(I)\subseteq J$ and $T\otimes^{\max}\mathrm{id}(I)\subseteq J$ for all closed ideals $I\subseteq A\otimes^{\max}C^*(F_2)$ and $J\subseteq B\otimes^{\max}C^*(F_2)$ with the property $V\otimes^{\max}\mathrm{id}(I)\subseteq J$ for all $V\in\mathcal{C}$. It implies $S,T\in\mathcal{C}$ by Theorem 3.8.4.

Every point-norm closed matrix operator-convex cone $\mathcal{C}$ is convex, because V_1+V_2 and λV_1 are in $\mathcal{C}$ by condition (OC1), as one can see with help of an approximate unit of B. The maps $b^*V(a^*(\cdot)a)b$ are in $\mathcal{C}$ for every $V\in\mathcal{C}$, $a\in A$ and $b\in B$, by condition (OC2).

Suppose now that $\mathcal{C}$ is a hereditary point-norm closed convex sub-cone of $CP(A,B)$ such that the maps $U_2^*V(U_1^*(\cdot)U_1)U_2$ are in $\mathcal{C}$ for every $V\in\mathcal{C}$, and for all unitaries $U_1:=\exp(ih)\in A+\mathbb{C}1$ and $U_2:=\exp(ik)\in B+\mathbb{C}1$ with $h^*=h\in A$, $\|h\|<\pi$, $k^*=k\in B$ and $\|k\|<\pi$. Since $c+i(1-c^2)^{1/2}=\exp(ih)$ with $h^*=h$ of norm $\|h\|\leq 2\pi/3$ for $c^*=c$ with $\|c\|\leq 1/2$, and since $d^*xd+dxd^*=2(hxh+kxk)$ for $d=h+ik$ with $h^*=h$, $k^*=k$ in every C^*-algebra, we can use that the convex cone $\mathcal{C}$ is hereditary and that the c.p. maps $b^*V(a^*(\cdot)a)b$ are in $\mathcal{C}$ for every $V\in\mathcal{C}$, $a\in A$ and $b\in B$.

[18] The isomorphisms are (– up to the associativity transformation maps –) induced by the isomorphism $\mathbb{C}^{mn}\cong\mathbb{C}^m\otimes\mathbb{C}^n$ given by writing the rows of the tensors (on on the right side) as consecutive row (on the left side).

If $V \in \mathcal{C}$, $r = [a_1, \ldots, a_n] \in M_{1,n}(A)$ and $c = [b_1, \ldots, b_n]^\top \in M_{n,1}(B)$, then the map $Z(a) := (n(\sum_j a_j^* a a_j) \otimes 1_n) - r^* a r$ from A into $M_n(A)$ is completely positive by Lemma A.5.6. The maps $c^*(V \otimes \mathrm{id}_n)(a_j^*(\cdot)a_j \otimes 1_n)c = \sum_k b_k^* V(a_j(\cdots)a_j)b_k$ are in $\mathcal{C}$ (by additivity of $\mathcal{C}$). Since $a \mapsto n(\sum_j a_j^* a a_j) \otimes 1_n$ is the sum of the c.p. maps Z and $a \mapsto r^* a r$, we get that $c^*(V \otimes \mathrm{id}_n)(r^*(\cdot)r)c \in \mathcal{C}$, i.e., $\mathcal{C}$ is invariant under the operations (OC2) of Definition 3.2.2. It is also closed with respect to the operations (OC1), because $\mathcal{C}$ is point-norm closed, is convex and $b^* V(\cdot) b$ is in $\mathcal{C}$ for every $b \in B$. □

LEMMA 3.6.23. *Let $\mathcal{C} \subseteq \mathrm{CP}(A,B)$ a point-norm closed matrix operator-convex cone, A, B, E, F C^*-algebras.*

(i) *Every $W \in \mathcal{C} \otimes \mathrm{CP}_{\mathrm{nuc}}(E,F)$ can be approximated in point-norm by sums of maps*

$$W' = (\mathrm{id}_B \otimes U_2) \circ I_2 \circ (V \otimes \mathrm{id}_n) \circ I_1 \circ (\mathrm{id}_A \otimes U_1)$$

where $V \in \mathcal{C}$, $U_1 \in \mathrm{CP}(E, M_n)$, $U_2 \in \mathrm{CP}(M_n, F)$, and the maps $I_1 \colon A \otimes M_n \to A \otimes M_n$ and $I_2 \colon B \otimes M_n \to B \otimes M_n$ are both 1-step-inner c.p. maps.

(ii) *If $W' \in \mathrm{CP}(A \otimes E, B \otimes F)$ is as in (i) then $W' \in \mathcal{C} \otimes \mathrm{CP}_{\mathrm{nuc}}(E,F)$.*

PROOF. (i): Let $T = S_2 \circ S_1 \colon E \to F$ with $S_1 \colon E \to \mathbb{C}$ $S_2 \colon \mathbb{C} \to F$ given by $S_1(e) := \rho(e)$ for some pure state ρ on E, and $S_2 \colon z \in \mathbb{C} \to zf_0 \in F$ for some $f_0 \in F$. We know from Remark **??**// from Corollary **??**// that $\mathrm{CP}_{\mathrm{nuc}}(E,F)$ is generated by maps T of this kind. It implies by Corollary 3.6.17 that the maps $V \otimes T$ with $V \in \mathcal{C}$ and $T = S_2 \circ S_1 \in \mathrm{CP}(E,F)$ generate $\mathcal{C} \otimes \mathrm{CP}(E,F)$.

Thus, by Lemma **??**, every $W \in \mathcal{C} \otimes \mathrm{CP}_{\mathrm{nuc}}(E,F)$ can be approximated by finite sums of maps

$$W'(a) := \sum_{1 \le j,k \le m} (c_j)^* \, (V \otimes T)((r_j)^* a r_k) \, c_k$$

where $a \in A \otimes M_m$, $V \in \mathcal{C}$, $T = S_2 \circ S_2$ is of the above type, $r_1, \ldots, r_m \in A \odot E$, $c_1, \ldots, c_m \in B \odot F$.

We have $r_j = \sum_{i=1}^{p_j} x_{ij} \otimes e_{ij}$ and

$$S_1((e_{ij})^* e e_{i'k}) = \rho((e_{ij})^* e e_{i'k}) = \langle D(e)(D(e_{i'k})x), D(e_{ij}))x \rangle$$

for the irreducible representation $D\colon E \to \mathcal{L}(L_2(E,\rho))$ with cyclic vector $x \in L_2(E,\rho)$ corresponding to ρ. Thus we may suppose that $p_j = p$, $e_{ij} = e_i$ and that $\{D(e_i)x\}_{1\leq i\leq p}$ is an orthonormal basis of of the linear span of $\{D(e_{ij})x\}$, i.e., it suffices to consider the case, where $r_j = \sum_{i=1}^{p} a_{ij} \otimes e_i$ (some of the a_{ij} can be zero). Then

$$(\mathrm{id}_A \otimes S_1 \otimes \mathrm{id}_m)(r^*(\cdot)r) = J_1 \circ (\mathrm{id}_A \otimes R_1)(\cdot)\,,$$

where $r := [r_1,\ldots,r_m] \in M_{1,m}(A\otimes E) \subseteq A\otimes E\otimes M_m$, $J_1\colon A\otimes M_p \to A\otimes M_m$ given by $J_1(\cdot) := X^*(\cdot)X$ with $X := [a_{ij}] \in M_{p,n}(A)$, and $R_1(e) := [\rho(e_i^* e e_{i'})]_{i,i'} = \kappa^* D(e)\kappa$ is defined by the isometry $\kappa\colon \mathbb{C}^p \hookrightarrow L_2(E,\rho)$ with $\kappa(z_1,\ldots,z_p) := \sum z_i e_i x$. The map $J_1\circ(\mathrm{id}_A\otimes R_1)$ maps $A\otimes E$ to $A\otimes M_m$.

Consider $c_j := \sum_{i=1}^{q_j} y_{ji}\otimes f_{ij} \in B\odot F$ for $j=1,\ldots,m$. Let $f_1,\ldots,f_q$ a basis of the linear span of $\{f_{ij}\}$, then there are unique $b_{ji}\in B$ with $c_j = \sum_{i=1}^{q} b_{ji}\otimes b_i$. Let $Y := [b_{ji}]_{j,i} \in M_{m,q}(B)$, then $J_2(\cdot) := Y^*(\cdot)Y$ maps $B\otimes M_m$ into $B\otimes M_q$. Now we define $R_2\colon M_q \to E$ by $R_2(\cdot) := g^*(\cdot)g$ for the column-matrix $g := [f_0^{1/2}f_1,\ldots,f_0^{1/2}f_q]^\top \in M_{q,1}(F)$.

We get

$$c^*((\mathrm{id}_B\otimes S_2)\otimes \mathrm{id}_p(\cdot))c = (\mathrm{id}_B\otimes R_2)\circ J_2\,,$$

thus

$$W' = c^*((V\otimes S_2\circ S_1)\otimes \mathrm{id}_m(r^*(\cdot)r)c = (\mathrm{id}_B\otimes R_2)\circ J_2\circ(V\otimes \mathrm{id}_m)\circ J_1\circ(\mathrm{id}_A\otimes R_1)\,.$$

If we let $n := \max(m,p,q)$ and consider M_m, M_p and M_q as corners of M_n, then $X\in A\otimes M_n$, $Y\in B\otimes M_n$, J_1 (respectively J_2) can be considered as 1-step-inner c.p. map of $A\otimes M_n$ (respectively $B\otimes M_n$) R_1 becomes a c.p. map $U_1\colon E\to M_n$, and R_2 extends naturally to a c.p. map $U_2\colon M_n\to F$. Hence, $W' = (\mathrm{id}_B\otimes U_2)\circ I_2\circ(V\otimes \mathrm{id}_n)\circ I_1\circ(\mathrm{id}_A\otimes U_2)$ is as desired.

(ii): We show that $W'\in \mathcal{C}\otimes \mathrm{CP}_{\mathrm{nuc}}(E,F)$:
If $I_1 = \mathrm{id}_A\otimes \mathrm{id}_n$ and $I_2 = \mathrm{id}_B\otimes\mathrm{id}_n$ then $W_0 = V\otimes(U_2\circ U_1)\in \mathcal{C}\otimes \mathrm{CP}_{\mathrm{nuc}}(E,F)$.

??????????????

Since, $W_1 := I_2\circ(V\otimes\mathrm{id}_n)\circ I_1 \in \mathcal{C}\otimes\mathrm{CP}(M_n)$ is suffices to show that $W_2 = W_1\circ(\mathrm{id}_A\otimes U_1) \in (\mathcal{C}\otimes\mathrm{CP}(A,M_n))\circ(\mathrm{CP}_{\mathrm{in}}(A)\otimes\mathrm{CP}(E,M_n))$ is in $\mathcal{C}\otimes\mathrm{CP}_{\mathrm{nuc}}(E,M_n)$, and that $W' = (\mathrm{id}_B\otimes U_2)\circ W_2 \in \mathrm{CP}_{\mathrm{in}}(B)\otimes\mathrm{CP}(M_n,F)\circ(\mathcal{C}\otimes\mathrm{CP}_{\mathrm{nuc}}(E,M_n))$ is in $\mathcal{C}\otimes\mathrm{CP}_{\mathrm{nuc}}(E,F)$.

`Next needed in Chapter 8:` ??

Suppose that $\mathcal{C}_1\subseteq \mathrm{CP}(A,B)$ and $\mathcal{C}_2\subseteq\mathrm{CP}(B,C)$ are point-norm closed matrix operator-convex cones, that (E_1,ϕ_1) is a $\mathcal{C}_1$-compatible Hilbert (A,B)-module and (E_2,ϕ_2) is a $\mathcal{C}_2$-compatible Hilbert (B,C)-module.

Then the Hilbert (A,C)-module $(E_3,\phi_3) := (E_1\otimes_B E_2, \phi_1(\cdot)\otimes_B 1)$ is $\mathcal{C}_2\circ\mathcal{C}_1$-compatible.

The module (E_3, ϕ_3) is generating for $\mathcal{C}_2 \circ \mathcal{C}_1$ if – moreover – (E_1, ϕ_1) and (E_2, ϕ_2) are generating for $\mathcal{C}_1$ respectively $\mathcal{C}_2$.

`next needed in chp:5 and chp:8,`
`Stinespring-Kasparov dilation inside` $\mathcal{C}$
`perhaps shift to the appendix:`

Lemma 3.6.24. *Suppose that E is a (right) Hilbert B-module and $V\colon A \to \mathcal{L}(E)$ is a completely positive contraction.*

Let $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ denote the point-norm closed m.o.c. cone that is generated by the c.p. maps $V_e\colon a \in A \mapsto \langle V(a)e, e\rangle \in B$ with $e \in E$.

*Then there is a (left) Hilbert B-module F and a *-morphism $\phi\colon A \to \mathcal{L}(E \oplus_B F)$ such that for the natural projection $\pi_1\colon E \oplus_B F \to E$ holds*

(i) *$V(a)e = \pi_1(\phi(a)(e, 0))$ for all $e \in E$ and $a \in A$.*
(ii) *$\langle \phi(\cdot)(e, f), (e, f)\rangle \in \mathcal{C}$ for all $(e, f) \in E \oplus_B F$.*

If A is separable, B is σ-unital and E is countably generated over B then F and $\phi\colon A \to \mathcal{L}(E \oplus_B F)$ can be found such that F is again countably generated over B.

*If, furthermore, B is stable and $E = B$ (as right Hilbert B-module), then there is a *-morphisms $\psi\colon A \to \mathcal{M}(B)$ and isometries $s, t \in \mathcal{M}(B)$ such that $ss^* + tt^* = 1$, $V = s^*\phi(\cdot)s$, and $b^*\phi(\cdot)b \in \mathcal{C}$ for all $b \in B$.*

Proof. `to be filled in` ?? □

Definition 3.6.25. Let A and B graded C^*-algebras with gradings $\beta_A \in \mathrm{Aut}(A)$ and $\beta_B \in \mathrm{Aut}(B)$ and $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ a m.o.c.cone with $\mathcal{C} \circ \beta_A \subseteq \mathcal{C}$ and $\beta_B \circ \mathcal{C} \subseteq \mathcal{C}$.

We say that a (graded) Hilbert (A, B)-module (E, ϕ) **generates** $\mathcal{C}$ if (E, ϕ) is $\mathcal{C}$-compatible and the vector states

$$V_x\colon a \in A \mapsto \langle \phi(a)x, x\rangle \in B$$

generate $\mathcal{C}$.

`Next: What about (OC1)?` ??

Remark 3.6.26. One can show that *a set $\mathcal{V}$ of c.p. maps that is closed under operations (OC2) and under “local” generalized Cuntz addition has a point-norm closure that also satisfies (OC1).*

Corollary 3.6.27. *Suppose that $A \neq \mathbb{C}$ is simple and purely infinite and that X is locally compact.*

Then for every $a, b \in \mathrm{C}_0(X, A)_+$ with $\|b(x)\| \leq \|a(x)\|$ for all $x \in X$ and $\varepsilon \in (0, 1)$ there exists a contraction $d \in \mathrm{C}_0(X, A)$ with $\|b - d^*ad\| < \varepsilon$.

PROOF. Since A is simple, it follows that $b(x)$ is in the ideal generated by $c(x)$, where $c(x) := (a(x) - \delta\|a(x)\|)_+ \neq 0$ for $\delta := \varepsilon/2$.

Since $A \neq \mathbb{C}$ is simple and purely infinite the algebra A is strongly purely infinite, by Proposition 2.2.1(v). The *strong* pure infiniteness of A implies that $C_0(X, A)$ is strongly purely infinite (cf. Corollary 2.17.5), in particular $C_0(X, A)$ is purely infinite. Thus, there is $e \in C_0(X, A)$ with $e^*ce = (b - \varepsilon)_+$. □

COROLLARY 3.6.28. *A point-norm closed convex subcone $\mathcal{C}$ of $\mathrm{CP}(A, B)$ is matrix operator-convex, if and only if, $\mathcal{C}$ is invariant under compositions with inner automorphisms $\mathrm{Ad}(U)$ for unitary elements $U \in \mathcal{M}(A)$ or $U \in \mathcal{M}(B)$, and $\mathcal{C}$ is a hereditary sub-cone of $\mathrm{CP}(A, B)$, i.e., $T_1 + T_2 \in \mathcal{C}$ implies $T_1, T_2 \in \mathcal{C}$.*

PROOF. ?? Use Hahn-Banach separation for $\mathcal{C}$
and for the point-norm closed m.o.c. cone
generated by $\mathcal{C}$. □

LEMMA 3.6.29. *Suppose that J is a closed ideal of B, (X, ρ) a separable metric space, and $\mathcal{S}$ is a set of continuous maps $f\colon X \to B$ that has the following properties (i) and (ii).*

(i) *There exists a continuous function $\mu(t)$ on $\mathbb{R}_+$ with $\mu(0) = 0$ such that $\|f(x) - f(y)\| \leq \mu(\rho(x, y))$ for all $x, y \in X$ and $f \in \mathcal{S}$.*
(ii) *For every $f \in \mathcal{S}$, every finite subset $Y \subseteq X$, every $\varepsilon > 0$ and $g \in \mathcal{S}$, there exists $h \in \mathcal{S}$ with $\|\pi_J(h(y)) - \pi_J(g(y))\| < \varepsilon$ and $\|f(y) - h(y)\| < \varepsilon + \|\pi_J(f(y)) - \pi_J(g(y))\|$ for all $y \in Y$.*

Then for every map $F\colon X \to B/J$ in the point-norm closure of $\pi_J \circ \mathcal{S}$ there is point-wise convergent sequence $f_n \in \mathcal{S}$ such that $F(x) = \pi_J(\lim_n f_n(x))$.

The condition (ii) is automatically satisfied if the map

$$h(x) := e^{1/2} f(x) e^{1/2} + (1 - e)^{1/2} g(x) (1 - e)^{1/2}$$

is in $\mathcal{S}$, for every positive contraction $e \in J_+$ with $\|e\| < 1$ and for every $f, g \in \mathcal{S}$.

PROOF. Let $(x_1, x_2, \ldots)$ a dense sequence in X. Suppose that $F\colon X \to B/J$ is in the point-norm closure of $\pi_J \circ \mathcal{S}$. Then, for fixed $x, y \in X$, $\|F(x) - F(y)\| \leq \sup_{f \in \mathcal{S}} \|f(x) - f(y)\| \leq \mu(\rho(x, y))$, and there is a sequence $f_n \in \mathcal{S}$ such that $\|F(x_k) - \pi_J(f_n(x_k))\| < 2^{-n-2}$ for $k \leq n$. By property (ii) and induction, we find $h_n \in \mathcal{S}$ with $h_1 := f_1$,

$$\|h_n(x_k) - h_{n+1}(x_k)\| \leq 2^{-n-2} + \|\pi_J(h_n(x_k)) - \pi_J(f_{n+1}(x_k))\|$$

and $\|\pi_J(h_{n+1}(x_k)) - \pi_J(f_{n+1}(x_k))\| < 2^{-n-3}$ for $k \leq n+1$. Then $\lim_n \pi_J(h_n(x_k)) = F(x_k)$ for all $k \in \mathbb{N}$, and $\|h_n(x_k) - h_{n+1}(x_k)\| \leq 2^{-n}$ for $k \leq n$. Thus, $H(x_k) = \lim_n h_n(x_k)$ exists for all $k \in \mathbb{N}$. It follows, $\|H(x_k) - H(x_j)\| \leq \mu(\rho(x_k, x_j))$ for $k, j \in \mathbb{N}$. Since $\{x_1, x_2, \ldots\}$ is dense in X, we get that H extends uniquely to a continuous map G from X into B with $\|G(x) - G(y)\| \leq \mu(\rho(x, y))$. For $x \in X$ and $\varepsilon > 0$ there exist x_k with $\mu(\rho(x, x_k)) < \varepsilon/3$. Then $\|G(x) - h_n(x)\| \leq \|H(x_k) - h_n(x_k)\| + 2\varepsilon/3$. Thus $G(x) = \lim_n h_n(x)$ for all $x \in X$. Since $\pi_J(G(x_k)) = F(x_k)$

and F is continuous, it follows $\pi_J \circ G = F$. In particular, $F(x) = \pi_J(\lim_n h_n(x))$ for all $x \in X$, and (h_n) is a sequence in $\mathcal{S}$ that converges point-wise to G.

We show that the condition (ii) is satisfied if the map

$$h(x) := e^{1/2} f(x) e^{1/2} + (1-e)^{1/2} g(x) (1-e)^{1/2}$$

is in $\mathcal{S}$, for every positive contraction $e \in J_+$ with $\|e\| < 1$ and for every $f, g \in \mathcal{S}$:

Consider the continuous function $\psi(\xi) := (1-\xi^2)^{1/2}$ for $\xi \in [0,1]$. Let $Y \subset X$ a finite subset, $\varepsilon \in (0,1)$ and $\delta := \varepsilon/4$.

If we let $e := d^2$ for $d \in J_+$ with $\|d\| < 1$ then $h(\cdot)$ becomes

$$h(\cdot) := h_d(\cdot) := d f(\cdot) d + \psi(d) g(\cdot) \psi(d)$$

depending on d. Then $\pi_J(h(x)) = \pi_J(g(x))$ for all $x \in X$. Notice here that $\pi_J(d) = 1$ because $\psi(d) \in C^*(d, 1)$. It follows

$$\|f(y) - h(y)\| \leq \|[f(y), d]\| + \|[f(y), \psi(d)]\| + \|\psi(d)(f(y) - g(y))\psi(d)\| .$$

Since B/J is a Banach quotient of B by J, there exists for each $y \in Y$ an element $c(y) \in J$ with

$$\|f(y) - g(y) + c(y)\| \leq \delta + \|\pi_J(f(y)) - \pi_J(g(y))\| .$$

Consider the finite sets $Q := \{c(y)\,;\ y \in Y\} \subset J$ and $R := \{f(y)\,;\ y \in Y\} \subset B$. The ideal J contains sequence of elements $d_n \in J_+$ with $\|d_n\| < 1$ and

$$\lim_n (\|q - d_n q\| + \|d_n q - q\|) = 0$$

for all $q \in Q$ and $\lim_n \|[r, d_n]\| = 0$ for all $r \in R$ by the existence of a quasi-central approximate unit in J_+ for B, cf. [**616**][thms. 1.4.2, 3.12.14]. It follows that $\lim_n \|\psi(d_n) q \psi(d_n)\| = 0$ for $q \in Q$ and $\lim_n \|[r, \psi(d_n)]\| = 0$ for $r \in R$. Thus, we find $n \in \mathbb{N}$ such that for $d := d_n$ the inequalities

$$\|\psi(d)(f(y) - g(y))\psi(d)\| \leq \delta + \|\psi(d)(f(y) - g(y) + c(y))\psi(d)\| .$$

and

$$\|[f(y), d]\| + \|[f(y), \psi(d)]\| < 2\delta .$$

Notice that

$$\|\psi(d)(f(y) - g(y) + c(y))\psi(d)\| \leq 2\delta + \|\pi_J(f(y)) - \pi_J(g(y))\| .$$

Summing up gives $\|f(y) - h(y)\| < \varepsilon + \|\pi_J(f(y)) - \pi_J(g(y))\|$ for all $y \in Y$. □

Proposition 3.6.30. *Suppose that A is separable, that $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ is a matrix operator-convex cone in sense of Definition 3.2.2, and that J is a closed ideal of B.*

Then $\pi_J \circ \mathcal{C} := \{\pi_J \circ V\,;\ V \in \mathcal{C}\} \subseteq \mathrm{CP}(A, B/J)$ is a matrix operator-convex cone.

The m.o.c. cone $\pi_J \circ \mathcal{C}$ is closed with respect to the point-norm topology in $\mathcal{L}(A, B/J)$ if $\mathcal{C}$ is closed with respect to the point-norm topology in $\mathcal{L}(A, B)$.

Moreover, for every $W \in \pi_J \circ \mathcal{C}$ *there exists* $V \in \mathcal{C}$ *with* $\|V\| = \|W\|$ *and* $W = \pi_J \circ V$ *if* $\mathcal{C}$ *is point-norm closed.*

PROOF. Clearly, $\pi_J \circ \mathcal{C} \subseteq \mathrm{CP}(A, B/J)$. By Definition 3.2.2 of m.o.c. cones $\mathcal{C}$ we have to check that for $V_1, V_2, V \in \mathcal{C}$, elements $s, t \in B/J$, rows $r = [r_1, \ldots, r_n] \in M_{1,n}(A)$ and columns $c = [c_1, \ldots, c_n]^\top \in M_{n,1}(B/J)$ there exist $W_0, W \in \mathcal{C}$ such that $\pi_J(W_0(a)) = s^* \pi_J(V_1(a))s + t^* \pi_J(V_2(a))t$ and $\pi_J(W(a)) = c^*((\pi_J \circ V) \otimes \mathrm{id}_n)(r^* a r)c$ for $a \in A$.

Since π_J is surjective, we find $b_1, b_2, d_k \in B$ with $\pi_J(b_1) = s$, $\pi_J(b_2) = t$ and $\pi_J(d_k) = c_k$ for $k = 1, \ldots, n$. Let $W_0(a) := b_1^* V_1(a) b_1 + b_2^* V_1(a) b_2$ and $W(a) := d^*(V \otimes \mathrm{id}_n)(r^* a r)d$ for the column $d := [d_1, \ldots, d_n]^\top \in M_{n,1}(B)$ with $(\pi_J \otimes \mathrm{id}_n)(d) = c$.

Then W_0 and W are in in $\mathcal{C}$ and have the desired properties, i.e., $\pi_J \circ \mathcal{C}$ is a (not necessarily closed) m.o.c. cone.

It follows that the point-norm closure $\mathcal{C}'$ of $\pi_J \circ \mathcal{C}$ is again an m.o.c. cone, and that every element of of $T \in \mathcal{C}'$ is the limit in point-norm convergence of a sequence $\pi_J \circ V_n \in \pi_J \circ \mathcal{C}$ with $\|\pi_J \circ V_n\| \leq \|T\|$, cf. Lemma 3.1.8.

We show that $\pi_J \circ \mathcal{C}$ itself is closed in point-norm topology if $\mathcal{C}$ is closed in point norm topology, i.e., that the set $\pi_J \circ \mathcal{C}$ of images of c.p. maps $V \in \mathcal{C}$ under the map $\mathcal{C} \ni V \to \pi_J \circ V \in \mathrm{CP}(A, B/J)$ is closed under point-wise convergence.

Notice first that $V := e^{1/2} V_1(\cdot) e^{1/2} + (1-e)^{1/2} V_2(\cdot)(1-e)^{1/2}$ is in $\mathcal{C}$ for contractions $e \in J_+$ with $\|e\| \leq 1$ and $V_1, V_2 \in \mathcal{C}$, and that $\|V\| \leq \max(\|V_1\|, \|V_2\|)$.

To see that V is in the point-norm closure of $\mathcal{C}$ it suffices to observe that for an approximative unit $\{c_\tau\} \subset B_+$ of B the maps $a \in A \mapsto (1-e)^{1/2} c_\tau V_2(a) c_\tau (1-e)^{1/2}$ converge point-wise to $(1-e)^{1/2} V_2(\cdot)(1-e)^{1/2}$.

Thus the condition (ii) of Lemma 3.6.29 is satisfied for $X := A$, $\rho(x, y) = \|x - y\|$, the set $\mathcal{C}$ of c.p. maps $V \in \mathcal{C} \subset \mathrm{CP}(A, B)$ (in place of $\mathcal{S}$ there) and the map $f \colon V \mapsto \pi \circ V$. The condition (i) of Lemma 3.6.29 is also satisfied, with $\mu(t) := t$.

Thus, $\pi_J \circ \mathcal{C} \subseteq \mathrm{CP}(A, B/J)$ is point-norm closed by Lemma 3.6.29.

The same arguments apply if we apply Lemma 3.6.29 to the set $\mathcal{S}$ of $V \in \mathcal{C} \subset$ with $\|V\| \leq 1$: This $\mathcal{S}$ is closed in the point-norm topology (if $\mathcal{C}$ is closed in point-norm topology), $X := A$ is separable and

$$V := e^{1/2} V_1(\cdot) e^{1/2} + (1-e)^{1/2} V_2(\cdot)(1-e)^{1/2} \in \mathcal{S}$$

for $V_1, V_2 \in \mathcal{S}$ and $e \in J_+$ with $\|e\| \leq 1$.

Thus the image $\pi_J \circ \mathcal{S}$ is closed in the topology of point-norm convergence on A.

Since $\pi_J \circ \mathcal{S}$ is closed under point-wise convergence, it suffices to show that $\pi_J \circ \mathcal{S}$ is dense in the set of $W \in \pi_J \circ \mathcal{C}$ with $\|W\| \leq 1$, to get that each $W \in \pi_J \circ \mathcal{C}$ with $\|W\| \leq 1$ is in $\pi_J \circ \mathcal{S}$ itself.

Let $W \in \pi_J \circ \mathcal{S}$ with $\|W\| \leq 1$. Above we have shown that there exists $V \in \mathcal{C}$ with $\pi \circ V = W$. Since A is separable, there exists a strictly positive contraction $c \in A_+$. It satisfies for all $n \in \mathbb{N}$ that

$$\operatorname{dist}(V(c^{2/n}), J) = \|\pi_J(V(c^{2/n}))\| = \|W(c^{2/n})\| \leq \|c\|^{2/n} \leq 1 \,.$$

The sequence of c.p. contractions $a \in A \mapsto W(c^{1/n}ac^{1/n})$ converge point-wise to W, because $a = \lim_{n\to\infty} c^{1/n}ac^{1/n}$ for each $a \in A$.

Thus, it suffices to find for each contraction $c \in A_+$ a sequence of positive contractions $b_m \in B_+$ such that $\|b_m V(c^2) b_m\| \leq 1$ and

$$\lim_m \|\pi_J(b_m)W(cac)\pi_J(b_m) - W(cac)\| = 0 \qquad \text{for each } \ a \in A \ .$$

Since $W(cAc)$ is contained in the hereditary C^*-subalgebra of B/J generated by $W(c^2)$, it suffices to find contractions $b_m \in C^*(V(c^2))_+$ with $\pi_J(b_m) = W(c^2)^{1/m}$ and $\|b_m^2 V(c^2)\| \leq 1$, e.g. we can take $b_m := \varphi(V(c^2)^{1/m})$ for the function $\varphi(\xi) := \min(\xi, 1)$. □

Proposition 3.6.30 and the surjectivity in Proposition 3.1.9(iii) together imply the following equivalent formulation of the Choi-Effros lifting theorem for nuclear maps [**140**], cf. also [**43**].

Corollary 3.6.31. *If A is separable, and J is a closed ideal of B, then*

$$\pi_J \circ \mathrm{CP}_{\mathrm{nuc}}(A, B) = \mathrm{CP}_{\mathrm{nuc}}(A, B/J) \,.$$

Proof. Clearly, $\pi_J \circ \mathrm{CP}_{\mathrm{nuc}}(A, B) \subseteq \mathrm{CP}_{\mathrm{nuc}}(A, B/J)$. Proposition 3.1.9(iii) says that $\pi_J \circ \mathrm{CP}_f(A, B) = \mathrm{CP}_f(A, B/J)$. The m.o.c. cones $\mathrm{CP}_{\mathrm{nuc}}(A, B)$ and $\mathrm{CP}_{\mathrm{nuc}}(A, B/J)$ are the point-norm closures of $\mathrm{CP}_f(A, B)$ respectively of $\mathrm{CP}_f(A, B/J)$. It follows

$$\mathrm{CP}_f(A, B/J) \subseteq \pi_J \circ \mathrm{CP}_{\mathrm{nuc}}(A, B) \subseteq \mathrm{CP}_{\mathrm{nuc}}(A, B/J) \,.$$

But $\pi_J \circ \mathrm{CP}_{\mathrm{nuc}}(A, B)$ is point-norm closed by Proposition 3.6.30. □

7. Operator-convex Cones versus Actions by topological Spaces

Lemma 3.7.1. *Suppose that $\mathcal{C} \subseteq \mathrm{CP}(B, A)$ is an m.o.c. cone and that $\Phi\colon \mathcal{I}(B) \to \mathcal{I}(A)$ is the related upper s.c. action defined by $\mathcal{C}$ (i.e., $\Phi(J) :=$ the closed ideal of A, that is generated by $\{V(b)\,;\ b \in J_+,\ V \in \mathcal{C}\}$).*

Let $J_b := \mathrm{span}(BbB)$. Then $\{V(b)\,;\ b \in J_+,\ V \in \mathcal{C}\} = \Phi(J)_+$, and, for every $b \in B_+$, $a \in \Phi(J_b)_+$ and $\varepsilon > 0$, there exist $V \in \mathcal{C}$ with $\|V(b) - a\| < \varepsilon$.

Conversely:
Let $\Phi\colon \mathcal{I}(B) \to \mathcal{I}(A)$ an upper semi-continuous action, and $\Psi\colon \mathcal{I}(A) \to \mathcal{I}(B)$ its lower semi-continuous Galois adjoint. Suppose that $\mathcal{C} := \mathrm{CP}_{\mathrm{rn}}(\Psi; B, A)$ realizes Ψ, in the sense that $\Psi = \Psi_{\mathcal{C}}$. Then $\Phi_{\mathcal{C}} = \Phi$.

Proof. **??** □

Give (or refer to) definitions of $\mathrm{CP}_{\mathrm{rn}}(\Psi;\, B, A)$, $\mathrm{CP}_{\mathrm{rn}}(\mathrm{Prim}(B), \Psi, \mathrm{id}; A, B)$, $\mathrm{CP}_{\mathrm{rn}}(\mathrm{Prim}(A), \mathrm{id}, \Phi; A, B)$, $\mathrm{CP}_{\mathrm{rn}}(\mathrm{Prim}(B), \mathrm{id}, \mathrm{id}; B, B)$, $\mathrm{CP}_{\mathrm{in}}(B, B) = \mathcal{C}(\mathrm{id}_B)$, $\mathrm{CP}(\mathrm{Prim}(B);\, B, B)$.

LEMMA 3.7.2. *Let $\Psi\colon \mathcal{I}(B) \to \mathcal{I}(A)$ a lower s.c. action and $\Phi\colon \mathcal{I}(A) \to \mathcal{I}(B)$ its upper s.c. Galois adjoint. Then*

$$\mathrm{CP}_{\mathrm{rn}}(\mathrm{Prim}(B), \Psi, \mathrm{id}; A, B) = \mathrm{CP}_{\mathrm{rn}}(\mathrm{Prim}(A), \mathrm{id}, \Phi; A, B)$$

and

$$\mathrm{CP}(\mathrm{Prim}(B), \Psi, \mathrm{id}; A, B) = \mathrm{CP}(\mathrm{Prim}(A), \mathrm{id}, \Phi; A, B)\,.$$

PROOF. **??** □

REMARK 3.7.3. Let $\mathrm{CP}_{\mathrm{rn}}(B) := \mathrm{CP}_{\mathrm{rn}}(B, B) := \mathrm{CP}_{\mathrm{rn}}(\mathrm{Prim}(B), \mathrm{id}, \mathrm{id}; B, B)$. Then

$$\mathrm{CP}_{\mathrm{rn}}(B) \subseteq \mathrm{CP}_{\mathrm{in}}(B, B) = \mathcal{C}(\mathrm{id}_B) \subseteq \mathrm{CP}(\mathrm{Prim}(B);\, B, B)\,.$$

If B is separable and nuclear, then all this 3 m.o.c. cones are identical. (For the *proof* one can use that then $B \otimes \mathcal{O}_2$ contains a regular Abelian C^*-subalgebra, cf. [**359**], and – therefore – can apply Proposition **??** about non-commutative selection.)

`The content of ref. to missing Prop. should be:`
If B is separable and nuclear, and $B \otimes \mathcal{O}_2$ contains a "regular Abelian C^*-subalgebra" (here only cited) then this implies the existence of sufficient many "n.c. selections" that generate $\mathrm{CP}(\mathrm{Prim}(B);\, B, B)$???

If separable $B \neq \{0\}$ is simple and is *not* nuclear, then $\mathrm{CP}_{\mathrm{rn}}(B)$, $\mathrm{CP}_{\mathrm{in}}(B, B)$ and $\mathrm{CP}(B, B)$ are all different m.o.c. cones, but define the same lower s.c. action of $\mathrm{Prim}(B) = \{\{0\}\}$ on B. This happens e.g. for the exact simple C^*-algebra $B := C^*_{\mathrm{red}}(SL(2, \mathbb{Z}))$.

PROPOSITION 3.7.4. *If B is separable and $B \otimes \mathcal{O}_2$ contains a regular abelian C^*-subalgebra (cf. Definition B.4.1) $C \subseteq B \otimes \mathcal{O}_2$, then, for every lower semi-continuous action $\Psi\colon \mathcal{I}(B) \to \mathcal{I}(A)$ of* $\mathrm{Prim}(B)$ *on a separable C^*-algebra A is realizable by* $\mathrm{CP}_{\mathrm{rn}}(\Psi;\, A, B)$, *i.e., $\Psi = \Psi_{\mathcal{C}}$ for $\mathcal{C} := \mathrm{CP}_{\mathrm{rn}}(\mathrm{Prim}(B), \Psi, \mathrm{id}; A, B)$.*

PROOF. `to be filled in ??`

`transfer proof from chp. 12 to here !` □

Proposition 3.7.4 implies immediately:

COROLLARY 3.7.5. *If B is separable and $B \otimes \mathcal{O}_2$ contains a regular abelian C^*-subalgebra (cf. Definition B.4.1) $C \subseteq B \otimes \mathcal{O}_2$, then B has residual nuclear separation (cf. Definition 1.2.3).*

PROPOSITION 3.7.6. *Suppose that B has residually nuclear separation (cf. Definition 1.2.3). Then B has the Weyl–von-Neumann property (cf. Definition 1.2.3), if and only if, B is strongly purely infinite (cf. Definition 1.2.2).*

PROOF. To be filled in ??

Proof was somewhere outlined, perhaps in Chp. 1 ? □

8. Separation of m.o.c. cones by actions

There are proofs of some of the following corollaries, that are more elementary than given below. But we want to invite the reader to use (and think about) the conceptional ideas presented here. For possible future classification of some classes of stably finite algebras with non-trivial traces, one has to produce more refined tools, that give a "applicable" answers e.g. to the following more difficult question:

When is a given completely positive map V in a given cone $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ of completely positive maps compatible with a given map $T(B) \to T(A)$?

Here $T(B)$ means the set of lower semi-continuous 2-quasi-traces $\tau \colon B_+ \to [0, \infty]$ – possibly with values only in $\{0, \infty\}$. Our results together contain an answer in the special case where $\tau(B_+) \subseteq \{0, \infty\}$ for all $\tau \in T(B)$, because then the problem reduces to to the determination of $\mathrm{CP}_{\mathrm{nuc}}(\Psi;\, A, B)$ for a lower semi-continuous action $\Psi \colon \mathcal{I}(B) \cong \mathbb{O}(\mathrm{Prim}(B)) \to \mathcal{I}(A)$, if we identify a $\{0, \infty\}$-valued lower semi-continuous 2-quasi-trace $\tau \colon B_+ \to [0, \infty]$ by its kernel $J := \mathrm{span}\{a \in B_+\,;\; \tau(a) = 0\}$. Notice that we do not require operator convexity in the following definition.

Compare for next Def. also Def. 3.12.1

DEFINITION 3.8.1. Let $\mathcal{S} \subseteq \mathrm{CP}(A, B)$ any subset and $J \in \mathcal{I}(B)$.

We define the ideal $\Psi_{\mathcal{S}}(J) \in \mathcal{I}(A)$ by its positive part $\Psi_{\mathcal{S}}(J)_+$ as the set of all $a \in A_+$ with $V(\exp(-ih)a\exp(ih)) \in J$ for all $h^* = h \in A$ with $\|h\| < \pi$ and for all $V \in \mathcal{S}$. Then $\Psi_{\mathcal{S}}(J)_+$ is the positive part of a closed ideal $\Psi_{\mathcal{S}}(J)$ of A, and

$$\Psi_{\mathcal{S}} \colon \mathcal{I}(B) \cong \mathbb{O}(\mathrm{Prim}(B)) \cong \mathbb{O}(\mathrm{prime}(B)) \to \mathcal{I}(A)$$

is a lower semi-continuous action of $\mathrm{Prim}(B)$ on A, cf. Lemma 3.12.2(iv).

Let I any closed ideal of A. We denote by $\Psi^{\mathcal{S}}(I) \in \mathcal{I}(B)$ the smallest closed ideal of B that contains $\{V(a)\,;\; a \in I, V \in \mathcal{S}\}$. The map

$$\Psi^{\mathcal{S}} \colon \mathcal{I}(A) \cong \mathbb{O}(\mathrm{Prim}(A)) \cong \mathbb{O}(\mathrm{prime}(B)) \to \mathcal{I}(B)$$

is an upper semi-continuous action, cf. Lemma 3.12.2 (xii).

Let X a topological space, and let $\Psi_A \colon \mathbb{O}(X) \to \mathcal{I}(A)$ and $\Psi_B \colon \mathbb{O}(X) \to \mathcal{I}(B)$ increasing maps, i.e., *actions* of X on A and B. We define the **cone of Ψ-equivariant c.p. maps** as the set $\mathcal{C}_\Psi := \mathrm{CP}(\Psi_A, \Psi_B; A, B) \subseteq \mathrm{CP}(A, B)$ of maps $V \in \mathrm{CP}(A, B)$ with $V(\Psi_A(U)) \subseteq \Psi_B(U)$ for all open subsets $U \subseteq X$. In the special case, where $X := \mathrm{Prim}(B)$ and $\Psi_B \colon \mathbb{O}(\mathrm{Prim}(B)) \to \mathcal{I}(B)$ is given by the natural identification of the open subsets U of $\mathrm{Prim}(B)$ with the corresponding closed ideal J_U of B, where J_U denotes the intersection of all primitive ideals $I \in \mathrm{Prim}(B) \setminus U$, we write $\Psi := \Psi_A$ and drop Ψ_B, i.e., write $\mathcal{C}_\Psi := \mathrm{CP}(\Psi;\, A, B) \subseteq \mathrm{CP}(A, B)$ where $\Psi \colon \mathbb{O}(\mathrm{Prim}(B)) \to \mathcal{I}(A)$ is a lower semi-continuous action.

The use of the notation $\mathcal{C}_\Psi$, in place of $\mathcal{C}_{\Psi_A,\Psi_B}$, becomes justified in a different way in part (i) of Lemma 3.12.2.

`Compare next with Lemma 3.12.2 in eksec3-Part2 .tex`

LEMMA 3.8.2. *Let A and B C^*-algebras, $\mathcal{S} \subseteq \mathrm{CP}(A,B)$ a set of completely positive maps, $\mathcal{C} \subseteq \mathrm{CP}(A,B)$ a m.o.c. cone, X a topological space, $\Psi_A \colon \mathbb{O}(X) \to \mathcal{I}(A)$ and $\Psi_B \colon \mathbb{O}(X) \to \mathcal{I}(B)$ actions of X on A respectively B,*

Suppose that ?????????????

List of necessary assumptions? ??

Look for minimal m.o.c. cone assumptions!!!

Part (i) is only lattice stuff?

(i) *There exists a lower semi-continuous action $\Psi' \colon \mathbb{O}(\mathrm{Prim}(B)) \cong \mathcal{I}(B) \to \mathcal{I}(A)$ with $\Psi'(\Psi_B(U)) \supseteq \Psi_A(U)$), which is* minimal *in the sense that $\Phi(J) \supset \Psi'(J)$ for every $J \in \mathcal{I}(B)$ if $\Phi \colon \mathcal{I}(B) \to \mathcal{I}(A)$ is lower semi-continuous and $\Phi(\Psi_B(U)) \supset \Psi_A(U)$.*
This (minimal) action satisfies $\mathcal{C}_{\Psi'} = \mathcal{C}_\Psi$.

(ii) *The point-norm closure of an m.o.c. cone (in the algebraic sense) is a matrix operator-convex cone.*
The intersection of a family of m.o.c. cones is am m.o.c. cone.

(iii) *Let $\mathcal{C}_{\mathrm{alg}}(\mathcal{S})$ denote the smallest "algebraic" m.o.c. cone that contains a subset $\mathcal{S} \subseteq \mathrm{CP}(A,B)$.*
Every contraction V in the point-norm closure $\mathcal{C}(\mathcal{S})$ of can be approximated by maps $W \in \mathcal{C}_{\mathrm{alg}}(\mathcal{S})$ of the particular form $W := \sum_k c_k^*(V_k \otimes \mathrm{id}_n)(r_k^*(\cdot)r_k)c_k$ with $V_k \in \mathcal{S}$, $r_k \in M_{1,n}(A)$, $c_k \in M_{n,1}(B)$ and $\|\sum_k c_k^* V_k(r_k^* r_k)c_k\| \leq 1$.

(iv) *$\Psi_{\mathcal{S}}(J)_+$ is the positive part of the closed ideal $\Psi_{\mathcal{S}}(J)$ of A defined in Definition 3.8.1, and*

$$\Psi_{\mathcal{S}} \colon \mathbb{O}(\mathrm{Prim}(B)) \cong \mathcal{I}(B) \ni J \;\mapsto\; \Psi_{\mathcal{S}}(J) \in \mathcal{I}(A)$$

is a lower semi-continuous action of $\mathrm{Prim}(B)$ *on A.*
The action $\Psi_{\mathcal{S}}$ satisfies $\Psi_{\mathcal{S}}(B) = A$ and $V(\Psi_{\mathcal{S}}(J)) \subseteq J$ for all $J \in \mathcal{I}(B)$ and $V \in \mathcal{S}$.

(v) *$\Psi_{\mathcal{S}} = \Psi_{\mathcal{C}}$ for $\mathcal{C} := \mathcal{C}(\mathcal{S})$.*

(vi) *If $\mathcal{S}_1 \subseteq \mathcal{S}$ then $\Psi_{\mathcal{S}}(J) \subseteq \Psi_{\mathcal{S}_1}(J)$ for all $J \in \mathcal{I}(B)$.*

(vii) *The set $\mathcal{C}_\Psi$ is a point norm-closed m.o.c. cone of completely positive maps.*

(viii) *$\mathcal{C}_{\Psi_1} \subseteq \mathcal{C}_\Psi$ if $\Psi(J) \subseteq \Psi_1(J)$ for all $J \in \mathcal{I}(B)$.*

(ix) *$\mathcal{C} \subseteq \mathcal{C}_{\Psi_{\mathcal{C}}}$.*

(x) *$\Psi_{\mathcal{C}_\Psi}(J) \supset \Psi(J)$ for $J \in \mathcal{I}(B) \cong \mathbb{O}(\mathrm{Prim}(B))$.*

(xi) *If $\mathcal{C}' \subseteq \mathrm{CP}(A \otimes^{\max} D, B \otimes^{\max} D)$ is a point-norm closed m.o.c. cone, then the set $\mathcal{C} \subseteq \mathrm{CP}(A,B)$ of $T \in \mathrm{CP}(A,B)$ with $T \otimes^{\max} \mathrm{id}_D \in \mathcal{C}'$ is a point-norm closed m.o.c. cone.*

(xii) *Let M a W^*-algebra and $B \subseteq M$ a $\sigma(M, M_*)$-dense C^*-subalgebra of M, and let $\mathcal{C} \subseteq \mathrm{CP}(A, B) \subseteq \mathrm{CP}(A, M)$ an m.o.c. cone. Then the point-*ultra-strong closure $\overline{\mathcal{C}} \subseteq \mathrm{CP}(A, M)$ of $\mathcal{C}$ is an m.o.c. cone that is also closed in the point-ultra-weak topology ($\sigma(M, M_*)$-topology on M).*

(xiii) *$\Psi^{\mathcal{S}} \colon \mathcal{I}(A) \to \mathcal{I}(B)$ is an upper semi-continuous action of $\mathrm{Prim}(A)$ on B. $I \subseteq \Psi_{\mathcal{S}}(\Psi^{\mathcal{S}}(I))$ for every closed ideal I of A and every subset $\mathcal{S} \subseteq \mathrm{CP}(A, B)$. It says that $\Psi^{\mathcal{S}}$ is the Galois adjoint of $\Psi_{\mathcal{S}}$ and vice-versa*

(ix) *What about $\Psi^{\mathcal{S}} \circ \Psi_{\mathcal{S}}$?*

PROOF. (iv): Let J a closed ideal of B and $T \colon A \to B$ a positive map. The set of $a \in A_+$ with $(\pi_J \circ T)(a) = 0$ is a *hereditary* closed convex sub-cone $C_{T,J}$ of A_+. Thus, the set $C_{\mathcal{S},J}$ of $a \in A_+$ with $T(a) \in J$ for all $T \in \mathcal{S}$ is a hereditary closed convex sub-cone of A_+, and $\Psi_{\mathcal{S}}(J)_+ \subseteq A_+$ of Definition 3.8.1 is the set of $a \in A_+$ with $\exp(ih)a\exp(-ih) \in C_{\mathcal{S},J}$.

By Lemma A.25.1, $\Psi_{\mathcal{S}}(J)_+$ is the positive part of a closed ideal $\Psi_{\mathcal{S}}(J)$ of A. Clearly, $\Psi_{\mathcal{S}}(B) = A$, and $V(\Psi_{\mathcal{S}}(J)_+) \subseteq J$ for $J \in \mathcal{I}(B)$ and $V \in \mathcal{S}$, by definition of $\Psi_{\mathcal{S}}$.

If $\{J_\sigma\}_{\sigma \in \Sigma}$ is a family of closed ideals and $a \in A_+$ and let $J := \bigcap_\sigma J_\sigma$. then $V(\exp(ih)a\exp(-ih)) \in J$ for all $V \in \mathcal{S}$ and $h^* = h \in A$ with $\|h\| < \pi$, if and only if, $V(\exp(ih)a\exp(-ih)) \in J_\sigma$ for all $V \in \mathcal{S}$ and $h^* = h \in A$ with $\|h\| < \pi$, i.e., $a \in \Psi_{\mathcal{S}}(J)_+$ if and only if $a \in \bigcap_\sigma \Psi_{\mathcal{S}}(J_\sigma)_+ = (\bigcap_\sigma \Psi_{\mathcal{S}}(J_\sigma))_+$. Thus,

$$\Psi_{\mathcal{S}} \colon \mathbb{O}(\mathrm{Prim}(B)) \cong \mathcal{I}(B) \ni J \mapsto \Psi_{\mathcal{S}}(J) \in \mathcal{I}(A)$$

is a lower semi-continuous map. The lower semi-continuity of the map $\Psi_{\mathcal{S}}$ implies that $\Psi_{\mathcal{S}}$ is monotone. Thus, $\Psi_{\mathcal{S}}$ is a lower s.c. action of $\mathrm{Prim}(B)$ on A.

(vii): Since $\Psi_B(U)$ is a closed ideal, the set of maps $V \in \mathrm{CP}(A, B)$ with $V(a) \in \Psi_B(U)$ for all $a \in \Psi_A(U)$ is point-norm closed. Thus, $\mathcal{C}_\Psi$ is point-norm closed. Similar arguments show:
Let $V_1, V_2 \in \mathrm{CP}(A, B)$ with $V_k(\Psi_A(U)) \subseteq \Psi_B(U)$ for all $U \in \mathbb{O}(X)$ ($k = 1, 2$), $t \in [0, \infty)$, and $r \in M_{1,n}(A)$, $c \in M_{n,1}(B)$. Then $(V_1 + tV_2)(a) \in \Psi_B(U)$ and $c^*(V_1 \otimes \mathrm{id}_n)(r^* a r)c \in \Psi_B(U)$ for $U \in \mathbb{O}(X)$ and $a \in \Psi_A(U)$. Thus $\mathcal{C}_\Psi$ is a point-norm closed m.o.c. cone of c.p. maps.

(i): If we use the natural isomorphisms $\mathcal{I}(A) \cong \mathbb{O}(\mathrm{Prim}(A))$ and $\mathcal{I}(B) \cong \mathbb{O}(\mathrm{Prim}(B))$, and Lemma ??, then we get that there is a unique minimal lower semi-continuous action $\Psi' \colon \mathcal{I}(B) \to \mathcal{I}(A)$ of $\mathbb{O}(\mathrm{Prim}(B))$ on $\mathcal{I}(A)$ with $\Psi'(\Psi_B(U)) \supset \Psi_A(U)$.

If $V \in \mathcal{C}_{\Psi'}$, then $V(\Psi_A(U)) \subseteq V(\Psi'(\Psi_B(U))) \subseteq \Psi_B(U)$ for $U \in \mathbb{O}(X)$, because $\Psi_A(U) \subseteq \Psi'(\Psi_B(U))$. Thus, $\mathcal{C}_{\Psi'} \subseteq \mathcal{C}_\Psi = \mathcal{C}_{\Psi_A, \Psi_B}$.

Let $\mathcal{S} := \mathcal{C}_\Psi$, then $\Psi_{\mathcal{S}} \colon \mathcal{I}(B) \cong \mathbb{O}(\mathrm{Prim}(B)) \to \mathcal{I}(A)$ is a lower semi-continuous action by part (iv) with $V(\Psi_{\mathcal{S}}(J)) \subseteq J$ for all $V \in \mathcal{S}$.

Since $V(\exp(ih)a\exp(-ih)) \in \Psi_B(U)$ for all $a \in \Psi_A(U)_+$ and $h^* = h \in A$, $\Psi_{\mathcal{S}}(\Psi_B(U))_+ \supset \Psi_A(U)_+$ for $U \in \mathbb{O}(X)$. Thus $\Psi_{\mathcal{S}}(J) \supset \Psi'(J)$ for every $J \in \mathcal{I}(B)$

by minimality of Ψ'. It implies that $V(\Psi'(J)) \subseteq V(\Psi_{\mathcal{S}}(J)) \subseteq J$, i.e., $V \in \mathcal{C}_{\Psi'}$, for all $V \in \mathcal{C}_\Psi = \mathcal{C}_{\Psi_A,\Psi_B}$.

(ii): The point-norm closure $\mathcal{C}$ of an m.o.c. cone $\mathcal{C}_0$ is an m.o.c. cone, because the topology of point-norm convergence on $\mathcal{L}(A,B)$ coincides with the strong operator topology, and because $V_\alpha \otimes \mathrm{id}_n$ converges in point-norm to $V \otimes \mathrm{id}_n$ if $V_\alpha \in \mathcal{C}_0$ converges to V.

(iii): Let $n \in \mathbb{N}$ and let $\mathcal{C}^{(n)}$ denote the set of completely positive maps $W := \sum_k c_k^*(V_k \otimes \mathrm{id}_n)(r_k^*(\cdot)r_k)c_k$ with $V_k \in \mathcal{S}$, $r_k \in M_{1,n}(A)$ and $c_k \in M_{n,1}(B)$, and let $\mathcal{C}_0 := \bigcup_n \mathcal{C}^{(n)}$. Clearly, $\mathcal{C}^{(n)} \subseteq \mathcal{C}$ for every matrix operator-convex cone $\mathcal{C} \subseteq \mathrm{CP}(A,B)$ with $\mathcal{S} \subseteq \mathcal{C}$, and the set $\mathcal{C}^{(n)}$ is closed under multiplication with positive scalars and under addition.

Moreover, $c^*(W \otimes \mathrm{id}_m)(r^*(\cdot)r)c \in \mathcal{C}^{(mn)}$ if $W \in \mathcal{C}^{(n)}$, $r \in M_{1,m}(A)$ and $c \in M_{n,1}(B)$, because

$$c^*(W_k \otimes \mathrm{id}_m)(r^*(\cdot)r)c = C^* V_k \otimes \mathrm{id}_{mn}(R^*(\cdot)R)C$$

for $W_k := c_k^*(V_k \otimes \mathrm{id}_n)(r_k^*(\cdot)r_k)c_k$, $R = [R_1,\ldots,R_{mn}] \in M_{1,mn}(A)$ and $C = [C_1,\ldots,C_{mn}]^\top \in M_{mn,1}(B)$, where $R_{jm+y} := r_y r_j^{(k)}$ and $C_{jm+y} := c_j^{(k)} c_y$ with $r_k = [r_1^{(k)},\ldots,r_n^{(k)}] \in M_{1,n}(A)$, $r = [r_1,\ldots,r_m] \in M_{1,m}(A)$, $c_k = [c_1^{(k)},\ldots,c_n^{(k)}]^\top \in M_{n,1}(B)$, and $c = [c_1,\ldots,c_m]^\top \in M_{m,1}(B)$.

If we fill the rows $r_k \in M_{1,n}(A)$ and columns $c_k \in M_{n,1}(B)$ with zeros, then we see that $\mathcal{C}^{(n)} \subseteq \mathcal{C}^{(n+k)}$ for all $n,k \in \mathbb{N}$. Thus $\mathcal{C}_0 = \bigcup_n \mathcal{C}^{(n)}$ is a (not necessarily closed) m.o.c. cone that is contained in every matrix operator convex cone $\mathcal{C}$ with $\mathcal{S} \subseteq \mathcal{C}$.

Since A has an approximate unit $\{e_\tau\}$ of positive contractions, we get $\|W\| = \|\sum_k c_k^* V_k(r_k^* r_k)c_k\|$ for $W \in \mathcal{C}_0$, and that every element $V \in \mathcal{S}$ is in the point-norm closure of $\mathcal{C}^{(1)} \subseteq \mathcal{C}_0$.

By part (ii), the point-norm closure $\mathcal{C}_1$ of $\mathcal{C}_0$ is an m.o.c. cone that contains $\mathcal{S}$. Since $\mathcal{C}_0$ is contained in every point-norm closed m.o.c. cone $\mathcal{C}$ with $\mathcal{S} \subseteq \mathcal{C}$, we get $\mathcal{C}(\mathcal{S}) = \mathcal{C}_1$. The contractions T in the point-norm closure of $\mathcal{C}_0$ can be approximated by contractions $W \in \mathcal{C}_0$ with $\|W\| \le 1$ by Lemma 3.1.8.

(v): Since $\mathcal{S} \subseteq \mathcal{C}(\mathcal{S}) =: \mathcal{C}$, it holds $\Psi_{\mathcal{C}}(J) \subseteq \Psi_{\mathcal{S}}(J)$ for all $J \in \mathcal{I}(B)$, cf. part (vi).

If $a \in \Psi_{\mathcal{S}}(J)_+$ then $V(\exp(ih)a\exp(-ih)) \in J$ for all $h^* = h \in A$ with $\|h\| < \pi$ and all $V \in \mathcal{S}$.

By part (iv), this implies that $c_\ell^* V(r_\ell^* \exp(ih)a\exp(-ih)r_k)c_k \in J$ for $V \in \mathcal{S}$, $h^* = h \in A$, $r_1,\ldots,r_n \in A$, $c_1,\ldots,c_n \in B$. Thus, $W(\exp(ih)a\exp(-ih)) \in J$ for all $W \in \mathcal{C} := \mathcal{C}(\mathcal{S})$ and $h^* = h$ by part (iii), i.e., $a \in \Psi_{\mathcal{C}}(J)_+$, and $\Psi_{\mathcal{S}} = \Psi_{\mathcal{C}}$ for $\mathcal{C} := \mathcal{C}(\mathcal{S})$.

(vi): Straight from definition of $\Psi_{\mathcal{S}}$.

(viii): If $V \in \mathcal{C}_{\Psi_1}$ and $\Psi(J) \subseteq \Psi_1(J)$, then $V(\Psi(J)) \subseteq V(\Psi_1(J)) \subseteq J$. Thus, $V \in \mathcal{C}_\Psi$ if $\Psi(J) \subseteq \Psi_1(J)$ for all $J \in \mathcal{I}(B)$.

(ix): For $J \in \mathcal{I}(B)$ and $a \in \Psi_{\mathcal{C}}(J)$ holds $V(a) \in J$ for all $V \in \mathcal{C}$ by definition of $\Psi_{\mathcal{C}}$.

(x): Let $J \in \mathcal{I}(B)$, and let $a \in \Psi(J)_+ \subseteq A_+$, $V \in \mathcal{C}_\Psi$ and $h^* = h \in A$. Then $V(\exp(ih)a\exp(-ih)) \in J$ by definition of $\mathcal{C}_\Psi$, i.e., $a \in \Psi_{\mathcal{C}_\Psi}(J)_+$ by definition of $\Psi_{\mathcal{C}}$. Thus, $\Psi(J) \subseteq \Psi_{\mathcal{C}_\Psi}(J)$.

(xi): If $\{T_\gamma\}_{\gamma\in\Gamma} \subseteq \mathrm{CP}(A, B)$ is a (norm-)bounded net that converges in point-norm to $T \in \mathcal{L}(A, B)$, then $T \in \mathrm{CP}(A, B)$ and the net

$$\{T_\gamma \otimes^{\max} \mathrm{id}\}_{\gamma\in\Gamma} \subseteq \mathrm{CP}(A \otimes^{\max} D, B \otimes^{\max} D)$$

converges point-wise to $T_\gamma \otimes^{\max} \mathrm{id}$, because $A \odot D$ is dense in $A \otimes^{\max} D$. Thus, if $T_\gamma \otimes^{\max} \mathrm{id} \in \mathcal{C}'$ for all $\gamma \in \Gamma$, then $T \otimes^{\max} \mathrm{id} \in \mathcal{C}'$. Clearly, the set $\mathcal{C}$ of $T \in \mathrm{CP}(A, B)$ with $T \otimes^{\max} \mathrm{id} \in \mathcal{C}'$ is convex. If $T \otimes^{\max} \mathrm{id} \in \mathcal{C}'$, $r \in M_{1n}(A)$, $c \in M_{n1}(B)$, $e \in D_+$, then $R := r \otimes e \in M_{1n}(A \otimes D)$, $C := c \otimes e \in M_{n1}(B \otimes D)$, and

$$R^*((T \otimes^{\max} \mathrm{id}) \otimes (\mathrm{id}_n))(C^*(\cdot)C)R = T' \otimes^{\max} S_e$$

for $T' := r^*(T \otimes \mathrm{id}_n)(c(\cdot)c^*)r$ $S_e(d) := e^2de^2$ $(d \in D)$. Since $\mathcal{C}'$ is matrix operator convex and is point-norm closed,it follows that $T' \otimes^{\max} \mathrm{id} \in \mathcal{C}'$. Thus, the set $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ of $T \in \mathrm{CP}(A, B)$ with $T \otimes^{\max} \mathrm{id}_D \in \mathcal{C}'$ is a point-norm closed m.o.c. cone.

(xii): The point-norm closure $\mathcal{C}_0 := \overline{\mathcal{C}}^{\mathrm{norm}}$ of $\mathcal{C}$ is a convex cone with $c^*(V \otimes \mathrm{id}_n)(r^*(\cdot)r)c \in \mathcal{C}_0$ for $r \in M_{n,1}(A)$, $c \in M_{1,n}(B)$ and $V \in \mathcal{C}_0$. Since the point-*strong closures of $\mathcal{C}$ and $\mathcal{C}_0$ in $\mathcal{L}(A, M)$ coincide, and since $V_\gamma \otimes \mathrm{id}_n \to W \otimes \mathrm{id}_n$ point-*strongly if $V_\gamma \to W$ point-*strongly , we obtain that the point-*strong closure $\overline{\mathcal{C}} \subseteq \mathcal{L}(A, M)$ is a convex cone that satisfies $c^*(W \otimes \mathrm{id}_n)(r^*(\cdot)r)c \in \mathcal{C}_0$ for $r \in M_{n,1}(A)$, $c \in M_{1,n}(B)$ and $W \in \overline{\mathcal{C}}$. The unit-ball of $M_n(B)$ is *-ultra-strongly dense in the unit-ball of $M_n(M)$ by Kaplansky density theorem ([**616**, Thm. 2.3.3]). Thus, for $c \in M_{1,n}(M)$, there exists a net $c_\gamma \in M_{1,n}(B)$ with $\|c_\gamma\| \le \|c\|$ that *strongly converges to c. Hence, the point-*strong closure $\overline{\mathcal{C}}$ satisfies (OC2).

If $\{V_\gamma\} \subseteq \overline{\mathcal{C}}$ is a directed net that converges in point-$\sigma(M, M_*)$ topology to $W \in \mathrm{Lin}(A, M)$, then $W(e^2) \ge 0$ for every $e \in A_+$. In particular, W is positive and bounded, thus $\limsup_\gamma \|V_\gamma(e)\| =: \mu(e) < \infty$ for every $e \in A_+$, and $\mu := \limsup_\gamma \|V_\gamma\| < \infty$ by two-fold application of the Banach-Steinhaus theorem. It implies that W is also in the point-$\sigma(M, M_*)$ closure of the convex set of $V \in \overline{\mathcal{C}}$ with $\|V\| \le 1 + \nu$. Now a Hahn-Banach separation argument shows that $W \in \overline{\mathcal{C}}$.

(xiii): $\Psi^{\mathcal{S}}(\overline{\sum_\gamma I_\gamma}) = \overline{\sum_\gamma \Psi^{\mathcal{S}}(I_\gamma)}$ and $a \in \Psi_{\mathcal{S}}(\Psi^{\mathcal{S}}(I))$ for $a \in I \triangleleft A$ follow straight from the definitions of $\Psi_{\mathcal{S}}$ and $\Psi^{\mathcal{S}}$. □

`Compare also Example 3.12.3!!!`

EXAMPLE 3.8.3. We consider the action $\Psi_{nuc} \colon \mathcal{I}(B) \to \mathcal{I}(A)$ defined by $\mathrm{CP}_{\mathrm{nuc}}(A, B)$ and examine some possible generating subsets $\mathcal{S}_0 \subseteq \mathrm{CP}(A, B)$ for $\mathrm{CP}_{\mathrm{nuc}}(A, B)$.

Let $S \subseteq A^*_+$ denote an "almost separating" set of positive functionals on A that is invariant under inner automorphisms of A, more precisely:

for each $a \in A_+$ there is $\varphi \in S$ and $h^* = h \in A$ with $\|h\| < \pi$ such that with $\varphi(\exp(ih)a\exp(-ih)) > 0$.

For example we can take as S the set of pure states of A, or any set S of pure-states φ of A such that the family $\{d_\varphi\}_{\varphi\in S}$ of irreducible representations of A is separating for A.
Furthermore, let $P \subseteq B_+$ a set of positive elements of B that generates B as a closed ideal of B, i.e., for each $c \in B_+$ and $\varepsilon > 0$, there is $n \in \mathbb{N}$ and are $b_1, \ldots, b_n \in P$ and $d_1, \ldots, d_n \in B$ with $\|c - \sum_k d_k^* b_k d_k\| < \varepsilon$.

We consider the set of $\mathcal{S}_0 := \mathcal{S}_{S,P} \subseteq \mathrm{CP}(A,B)$ of c.p. maps $V_{\varphi,b}(a) := \varphi(a)b$, where $\varphi \in S$ and $b \in P$, and calculate the action $\Psi_0 \colon \mathcal{I}(B) \to \mathcal{I}(A)$ defined by $\mathcal{S}_0$:

Lemma 3.12.2(iv) shows that $\Psi_{\mathcal{S}_0}(B) = A$. Let $J \neq B$ a closed ideal of B. Then there is $b \in P$ that is not in J. If $0 \neq a \in A_+$ then there is $h^* = h \in A$ with $\|h\| < \pi$ and $\varphi \in S$ with $\varphi(\exp(ih)a\exp(-ih)) > 0$. It follows that $V_{\varphi,b}(\exp(ih)a\exp(-ih))$ is not contained in J.

Thus $\Psi_{\mathcal{S}_0}(J) = \{0\}$ for every closed ideal $J \neq B$ and $\Psi_{\mathcal{S}_0}(B) = A$.

Since $\mathcal{S}_0 \subseteq \mathrm{CP}_f(A,B) \subseteq \mathrm{CP}_{\mathrm{nuc}}(A,B) \subseteq \mathrm{CP}(A,B)$ we get

$$\Psi_{\mathrm{CP}(A,B)} = \Psi_{\mathrm{CP}_{\mathrm{nuc}}(A,B)}(J) \subseteq \Psi_{\mathcal{C}_0}(J)$$

for all closed ideals J of B. It says that the possibly different m.o.c. cones induce the same action

$$\Psi_{\mathrm{CP}(A,B)} = \Psi_{\mathrm{CP}_{\mathrm{nuc}}(A,B)} = \Psi_{\mathcal{S}_0}\,.$$

The special case where $A = B$ is not nuclear shows that,
in general, the lower semi-continuous action $\Psi_{\mathcal{C}} \colon \mathcal{I}(B) \cong \mathbb{O}(\mathrm{Prim}(B)) \to \mathcal{I}(A)$ *defined by an m.o.c. cone* $\mathcal{C} \subseteq \mathrm{CP}(A,B)$ *does not identify* $\mathcal{C}$ *itself.*

In particular, different non-degenerate m.o.c. cones can define the same corresponding l.s.c. action.

It implies that there is not a unique way to define KK-theory corresponding to a given lattice action, e.g. as defined for $\mathbb{O}(X)$ on $\mathrm{C}(X)$-algebras.

The situation of example 3.8.3 changes considerably if we consider, instead of $\Psi_{\mathcal{C}}$, the action $\Psi' \colon \mathcal{I}(B \otimes^{\max} C) \to \mathcal{I}(A \otimes^{\max} C)$ that is defined by the point-norm closed m.o.c.c. $\mathcal{C} \otimes^{\max} \mathrm{CP}_{\mathrm{in}}(C,C) \subseteq \mathrm{CP}(A \otimes^{\max} C, B \otimes^{\max} C)$, where $C := C^*(F_\infty)$ denotes the full group C^*-algebra over the free group F_∞ on countably many generators and where $\mathcal{C} \otimes^{\max} \mathrm{CP}_{\mathrm{in}}(C,C)$ is generated by the tensor products $V \otimes^{\max} \mathrm{id}_C$ with $V \in \mathcal{C}$. Then the following separation theorem of “Hahn-Banach type” holds for all point-norm closed m.o.c. cones.

Compare Thm. 3.8.4

Theorem 3.8.4 (Separation of m.o.c. cones). *Let* $C := C^*(F_\infty)$ *and* $\mathcal{S} \subseteq \mathrm{CP}(A,B)$ *a set of c.p. maps, and denote by* $\Psi' \colon \mathcal{I}(B \otimes^{\max} C) \to \mathcal{I}(A \otimes^{\max} C)$ *the action on the ideal that is defined by the set* $\mathcal{S}'$ *of c.p. maps*

$$\{\, V \otimes^{\max} \mathrm{id}_C \colon A \otimes^{\max} C \to B \otimes^{\max} C\,;\;\; V \in \mathcal{S}\,\}\,.$$

Then a c.p. map $T\colon A \to B$ is in the point-norm closed matrix operator-convex cone $\mathcal{C}(\mathcal{S})$ generated by $\mathcal{S}$, if and only if, $T \otimes^{\max} \mathrm{id}_C$ is Ψ'-equivariant.

It implies that we can "essentially" define point-norm-closed m.o.c. cones $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ with help of suitable lower semi-continuous actions Ψ of prime($B \otimes^{\max} C^*_{\max}(F_2)$) on $A \otimes^{\max} C^*_{\max}(F_2)$. But this does not say (and is wrong) that a point-norm-closed m.o.c. cone $\mathcal{C}$ is defined by the action $\Psi_{\mathcal{C}}\colon \mathcal{I}(B) \to \mathcal{I}(A)$ defined by $\mathcal{C}$. Only for the later considered "residual nuclear" case there is really some sort of bijective duality.

Proof. Let $\Psi' := \Psi_{\mathcal{S}'}\colon \mathcal{I}(B \otimes^{\max} C) \to \mathcal{I}(A \otimes^{\max} C)$ be the l.s.c. action of $\mathrm{Prim}(B \otimes^{\max} C)$ on $A \otimes^{\max} C$ defined by the set $\mathcal{S}'$ of c.p. maps

$$V \otimes^{\max} \mathrm{id}_C\colon A \otimes^{\max} C \to B \otimes^{\max} C$$

with $V \in \mathcal{S}$, cf. Lemma 3.12.2(iv). We denote by

$$\mathcal{C}' \subseteq \mathrm{CP}(A \otimes^{\max} C\,,\, B \otimes^{\max} C)$$

the m.o.c. cone

$$\mathcal{C}' := \mathcal{C}_{\Psi'} = \mathrm{CP}(\Psi'; A \otimes^{\max} C, B \otimes^{\max} C)$$

of Ψ'-equivariant maps.

Then $\mathcal{C}'$ is a point-norm closed matrix operator convex cone by Lemma 3.12.2(vii).

The set $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ of all $T \in \mathrm{CP}(A, B)$ with $T \otimes^{\max} \mathrm{id}_D \in \mathcal{C}'$ is a point-norm closed matrix operator convex cone that contains $\mathcal{S}$, cf. Lemma 3.12.2(xi), i.e., $\mathcal{C}(\mathcal{S}) \subseteq \mathcal{C}$ and

$$(V \otimes^{\max} \mathrm{id}_C)(\Psi'(J)) \subseteq J$$

for all closed ideals J of $B \otimes^{\max} C$.

Let $T \in \mathcal{C}$. We want to show that $T \in \mathcal{C}(\mathcal{S})$. Since $\mathcal{C}(\mathcal{S}) \subseteq \mathcal{L}(A, B)$ is point-norm closed (by definition of $\mathcal{C}(\mathcal{S})$), it suffices to show that for (contractions) $a'_1, \ldots, a'_n \in A$ and $\varepsilon > 0$ there is $V \in \mathcal{C}(\mathcal{S})$ with $\max_k \|V(a'_k) - T(a'_k)\| < \varepsilon$. Since $\mathcal{C}(\mathcal{S})$ is convex, the Hahn-Banach separation applied to the convex cone $K := \{(V(a'_1), \ldots, V(a'_n))\,;\ V \in \mathcal{C}(\mathcal{S})\,\}$ in $B \otimes \ell_\infty(1, \ldots, n)$ says that $(T(a'_1), \ldots, T(a'_n))$ is in the closure of K, if and only if,

$$\Re \sum_k f_k(T(a'_k)) \geq 0$$

for every linear functionals $f_1, \ldots, f_n \in B^*$ on B with $\Re \sum_k f_k(V(a'_k)) \geq 0$ for all $V \in \mathcal{C}(\mathcal{S})$.

Now let $f_1, \ldots, f_n \in B^*$ such that $0 \leq \Re(\sum_k f_k(V(a'_k)))$ for all $V \in \mathcal{C}(\mathcal{S})$.

By Lemma 3.1.4 there is a cyclic representation $d\colon B \to \mathcal{L}(\mathcal{H})$ with cyclic vector $\xi \in \mathcal{H}$ (we can suppose that $\|\xi\| = 1$) and $r_1, \ldots, r_n \in d(B)'$ with $f_k(b) = \langle d(b)\xi, r_k^*\xi\rangle$. We find unitary operators in $v_1, \ldots, v_m \in C^*(1, r_1, \ldots, r_m) \subseteq d(B)'$ such that $\{r_1, \ldots, r_n\}$ is contained in the linear span of $\{v_1, \ldots, v_m\}$. Let $G :=$

$C^*(v_1,\dots v_m) = C^*(1, r_1,\dots,r_m) \subseteq d(B)'$. It implies, that there are $a_1,\dots,a_m \in A$ such that $\sum_k a'_k \otimes r_k = \sum_j a_j \otimes v_j$ in the *algebraic* tensor product $A \odot G$. In particular,

$$\sum_j \langle d(L(a_j))\xi, v_j^*\xi\rangle = \sum_k \langle d(L(a'_k))\xi, r_k^*\xi\rangle = \sum_k f_k(L(a'_k))$$

for *every linear map* $L\colon A \to B$.

Consider the unital *-epimorphism $\lambda\colon C \to G$ with $\lambda(u_j) = v_j$ for $j = 1,\dots,m$ and $\lambda(u_j) = 1$ for $j > m$. (Here the unitaries $u_1, u_2, \dots \in F_\infty$ are canonical generators of F_∞.)

It defines a C^*-morphism $D\colon B \otimes^{\max} C \to \mathcal{L}(\mathcal{H})$ with $D(b\otimes c) = d(b)\lambda(c)$ for $b \in B$, $c \in C$. We let $J \subseteq B \otimes^{\max} C$ denote the kernel of D. The cyclic vector $\xi \in \mathcal{H}$ defines a positive state $\rho(y) := \langle D(y)\xi,\xi\rangle$ with $\rho(J) = \{0\}$ and

$$\rho((W \otimes^{\max} \mathrm{id})(x)) = \sum_j \langle d(W(a_j))\xi, v_j^*\xi\rangle = \sum_k f_k(W(a'_k))$$

for $x := \sum_j a_j \otimes u_j \in A \otimes C$ and every completely positive map $W\colon A \to B$. In particular, we get for the real part $\Re$ the inequalities

$$\Re(\rho((V \otimes^{\max} \mathrm{id})(x)) \geq 0 \quad \text{for all } V \in \mathcal{C}(\mathcal{S})\,.$$

Next we show that the property $\Re(\rho((V \otimes^{\max} \mathrm{id})(x)) \geq 0$ for all $V \in \mathcal{C}(\mathcal{S})$ implies that $(x^* + x) + \Psi'(J)$ is positive in $(A \otimes^{\max} C)/\Psi'(J)$. It is the crucial point of the proof.

Let P denote the set of positive functionals $g_V \in (A \otimes^{\max} C)^*$ with $g_V := \rho((V \otimes^{\max} \mathrm{id}_C)(\cdot))$ $(V \in \mathcal{C}(\mathcal{S}))$. The set P of the positive linear functionals g_V has the following properties:

(α) $g_V(y) = 0$ for all $g_V \in P$ (i.e., for $V \in \mathcal{C}(\mathcal{S})$), if and only if, $y \in \Psi'(J)$.
(β) $g_V(z^*(\cdot)z)$ is in the point-$\sigma(A^*, A)$ closure of P for every $z \in A \otimes^{\max} C$
(γ) $(y^*+y)+\Psi'(J)$ is positive in $(A\otimes^{\max} C)/\Psi'(J)$, if and only if, $\Re(g_V(y)) \geq 0$ for all $V \in \mathcal{C}(\mathcal{S})$.

(α): If $V \in \mathcal{C}(\mathcal{S})$, $y \in \Psi'(J)$ then $V \otimes^{\max} \mathrm{id}(y) \in J$ and $g_V(y) = \rho(V \otimes^{\max} \mathrm{id}(y)) = 0$, i.e., $g_V(\Psi'(J)) = \{0\}$ for all $g_V \in P$.

If $y \in A \otimes^{\max} C$, $V \in \mathrm{CP}(A, B)$ and $\rho\big((b^* \otimes 1)(V \otimes^{\max} \mathrm{id})(y)(b \otimes 1)\big) = 0$ for all $b \in B$, then $(V \otimes^{\max} \mathrm{id})(y) \in J$. Indeed, $\rho((b\otimes 1)^* z(b\otimes 1)) = \langle D(z)d(b)\xi, d(b)\xi\rangle$ for $z \in B\otimes^{\max} C$, $d(B)\xi$ is dense in $\mathcal{H}$ and J is the kernel of $D\colon B\otimes^{\max} C \to \mathcal{L}(\mathcal{H})$.

We have that $W := b^*V(\cdot)b \in \mathcal{C}(\mathcal{S})$ and $g_W(y) = \rho((b^* \otimes 1)(V \otimes^{\max} \mathrm{id})(y)(b \otimes 1)$ for $V \in \mathcal{C}(\mathcal{S})$ and $b \in B$. Thus, $g_V(y) = 0$ for all $V \in \mathcal{C}(\mathcal{S})$ implies that $(V \otimes^{\max} \mathrm{id})(y) \in J$ for all $V \in \mathcal{C}(\mathcal{S})$. Conversely, $g_V(y) = \rho((V \otimes^{\max} \mathrm{id})(y)) = 0$ if $(V\otimes^{\max}\mathrm{id})(y) \in J$. Thus, $g_V(y) = 0$ for all $g_V \in P$, if and only if, $(V\otimes^{\max}\mathrm{id})(y) \in J$ for all $V \in \mathcal{C}(\mathcal{S})$.

For $y \in A \otimes^{\max} C$, $a \in A$, $c \in C$ and $V \in \mathrm{CP}(A, B)$ holds $(V \otimes^{\max} \mathrm{id})((a \otimes c)^* y(a\otimes c)) = (1\otimes c)^* W \otimes^{\max} \mathrm{id}(y)(1\otimes c)$ where $W = V(a^*(\cdot)a)$. Since $V(a^*(\cdot)a) \in \mathcal{C}(\mathcal{S})$ for $V \in \mathcal{C}(\mathcal{S})$, it follows that the closed linear subspace K of $y \in A \otimes^{\max} C$

with $(V \otimes^{\max} \mathrm{id})(y) \in J$ for all $V \in \mathcal{C}(\mathcal{S})$ (i.e., with $g_V(y) = 0$ for all $g_V \in P$) satisfies $(a \otimes c)^* K (a \otimes c) \subseteq K$. If we use the polar formula for bilinear maps (several times) and the linearity of K, we get that that the closed subspace K is a two-sided ideal of $A \otimes^{\max} C$. Since $(V \otimes^{\max} \mathrm{id})(K) \subseteq J$ for all $V \in \mathcal{S} \subseteq \mathcal{C}(\mathcal{S})$ and since $\Psi'(J) \subseteq K$, we get $K = \Psi'(J)$ (cf. definition of $\Psi'(J)$).

(β): Since the algebraic tensor product $A \odot C$ is dense in $A \otimes^{\max} C$, it suffices to consider $z = \sum_{k=1}^{m} a_k \otimes c_k \in A \odot C$ ([19]). Then

$$g_V(z^* y z) = \sum_{k,j=1}^{m} \langle D(V \otimes^{\max} \mathrm{id}((a_j^* \otimes 1) y (a_k \otimes 1))) \lambda(c_k)\xi, \lambda(c_j)\xi \rangle \, .$$

Let $F_n := [b_1^{(n)}, \ldots, b_m^{(n)}]^\top \in M_{m1}(B)$ such that $\lim_n d(b_k^{(n)})\xi = \lambda(c_k)\xi$ in $\mathcal{H}$ for every $k = 1, \ldots, m$. If we let $E := [a_1, \ldots, a_m] \in M_{1m}(A)$ and take $V_n := F_n^* \big(V \otimes \mathrm{id}_\ell\big)(E^*(\cdot)E\big) F_n \in \mathcal{C}(\mathcal{S})$, then $g_V(z^* y z) = \lim_n g_{V_n}(y)$ for every $y \in A \otimes^{\max} C$.

(γ): Let $y = (\ell - k) + ih$ with $h^* = h$, $k \geq 0$, $\ell \geq 0$, and $k\ell = 0$, $W \in \mathcal{C}(\mathcal{S})$. Then $\Re g_W(kyk) = -g_V(k^3)$ and $y^* + y = \ell - k$.

By (β), we get that $g_W(k(\cdot)k)$ is a point-wise limit of g_V $(V \in \mathcal{C}(\mathcal{S}))$. Thus, $\Re g_V(y) \geq 0$ for all $V \in \mathcal{C}(\mathcal{S})$ implies $g_W(k^3) = 0$ for all $W \in \mathcal{C}(\mathcal{S})$, which means $k^3 \in \Psi'(J)$ by (α). It follows that $(y^* + y) + \Psi'(J) = \ell + \Psi'(J)$ is positive in $(A \otimes^{\max} C)/\Psi'(J)$.

Conversely, we have $\Re(g_V(y)) = g_V(y^* + y) \geq 0$ if $(y^* + y) + \Psi'(J)$ is positive in $(A \otimes^{\max} C)/\Psi'(J)$, because $g_V(\Psi'(J)) = \{0\}$ by (α).

Above we have shown that there exist $a_1, \ldots, a_m \in A$, a closed ideal J of $B \otimes^{\max} C$, and a state ρ on $B \otimes^{\max} C$, such that ρ and the element $x := \sum_k a_k \otimes u_k \in A \otimes^{\max} C$ *satisfy the following conditions (i)–(iii):*

(i) $\rho((W \otimes^{\max} \mathrm{id}_C)(x)) = \sum_k f_k(W(a_k))$ for all $W \in \mathrm{CP}(A, B)$,
(ii) $\rho(J) = \{0\}$, and
(iii) $(x^* + x) + \Psi'(J)$ is positive in $(A \otimes^{\max} C)/\Psi'(J)$.

Notice that the property in (iii) follows from property (γ), because

$$\Re(g_V(x)) = \Re(\rho((V \otimes^{\max} \mathrm{id})(x))) \geq 0 \quad \text{for all } V \in \mathcal{C}(\mathcal{S})\,.$$

The properties (i)–(iii) imply, that $T \in \mathrm{CP}(A, B)$ with $T \otimes^{\max} \mathrm{id}(\Psi'(J)) \subseteq J$ satisfies

$$2\Re \sum_k f_k(T(a_k')) = \rho((T \otimes^{\max} \mathrm{id}_C)(x^* + x)) \geq 0\,,$$

because then $(T \otimes^{\max} \mathrm{id})(x^* + x) + J$ is positive in $(B \otimes^{\max} C)/J$. (Notice here, that if E and F are C^*-algebras, $I \triangleleft E$ and $J \triangleleft F$ are closed ideals, and if $L \colon E \to F$ a is positive map with $L(I) \subseteq J$, then $L(y) + J$ is positive in F/J if $y + I$ is positive in E/I.) □

[19] Here $m \in \mathbb{N}$ and $a_k \in A$, $c_k \in C$ are arbitrary, i.e., are not the specific ones for the definition of the element x above.

EXAMPLE 3.8.5. Let A, B and C denote C^*-algebras. We describe the action

$$\Psi' := \Psi_{\mathcal{C}'} : \mathcal{I}(B \otimes^{\max} C) \to \mathcal{I}(A \otimes^{\max} C)$$

that is induced from $\mathcal{C}' := \mathrm{CP}_{\mathrm{nuc}}(A,B) \otimes^{\max} \mathrm{CP}_{\mathrm{in}}(C,C)$:

More generally, we consider $\Psi' := \Psi_{\mathcal{C}'}$ induced from $\mathcal{C}' = \mathcal{C}(\mathcal{S}')$, where $\mathcal{S}' := \{V \otimes^{\max} \mathrm{id}_C\,;\ V \in \mathcal{S}_0\}$ with $\mathcal{S}_0 := \mathcal{S}_{S,P} \subseteq \mathrm{CP}(A,B)$ the set $\mathcal{S}_{S,P}$ of c.p. maps $V_{\varphi,b}(a) := \varphi(a)b$, where $\varphi \in S$ and $b \in P$, $S \subseteq A^*_+$ and $P \subseteq B_+$ as in Example 3.8.3.

Let $\pi_{A,C} : A \otimes^{\max} C \to A \otimes C := A \otimes^{\min} C$ the natural epimorphism from the maximal C^*-tensor product to the minimal C^*-tensor product of A with C, let $I_{A,C}$ denote its kernel, and let $S_\varphi : A \otimes^{\max} C \to C = \mathbb{C} \otimes C$ the map $S_\varphi := (\varphi \otimes \mathrm{id}_C) \circ \pi_{A,C}$. We denote by $K(J)$ the biggest closed ideal of C with $B \otimes^{\max} K(J) \subseteq J$. (It can happen that $K(J) = \{0\}$.)

Let $Y \subseteq C$ a closed linear subspace. The space $F(A,Y;A \otimes C) \subseteq A \otimes C$ is defined as the set of $z \in A \otimes C$ such that $\varphi \otimes \mathrm{id}(z) \in Y$ for all $\varphi \in A^*$. Since $M \overline{\otimes} N_1 = F_\sigma(M,N_1; M \overline{\otimes} N)$ (by the tensorial bi-commutation theorem for vN-algebras) for the weakly continuous W*-algebra analog and all W*-subalgebras $N_1 \subseteq N$, one has $F(A,Y;\, A \otimes C) = (A \otimes C) \cap (A^{**} \overline{\otimes} Y^{**})$ in $A^{**} \overline{\otimes} C^{**}$ if Y is a C^*-subalgebra of C. Thus $F(A,Y;\, A \otimes C)$ is a C^*-subalgebra (respectively is a closed ideal) of $A \otimes C$ if Y is a C^*-subalgebra (respectively a closed ideal) of C. It is not difficult to see that $z \in F(A,Y;A \otimes C)$ if $\varphi \otimes \mathrm{id}((a^* \otimes 1)z(a \otimes 1)) \in Y$ for all $a \in A$ and $\varphi \in S \subseteq A^*_+$, where $\mathrm{span}(a^*Sa)$ is $\sigma(A^*, A)$ dense in A^* (which is the case if S is separates all non-zero positive elements of A from zero).

An element $x \in (A \otimes^{\max} C)_+$ is in $\Psi'(J)_+$, if and only if, $(V_{\varphi,b} \otimes \mathrm{id})(y) = b \otimes S_\varphi(y) \in J$ for all $y := \exp(ih)x\exp(-ih)$ $(h^* = h \in A \odot C)$, $\varphi \in S$ and $b \in P$. Since $\Psi'(J)_+$ is the positive part of a closed ideal of $A \otimes^{\max} C$, this happens also for $(a \otimes c)^* x (a \otimes c)$ (in place of x, and for all $a \in A$ and $c \in C$). If we apply the property that $P \subseteq B_+$ generates B as a two-sided ideal, then we obtain – for $x \in (A \otimes^{\max} C)_+$ – that $x \in \Psi'(J)_+$ if and only if $S_\varphi((a \otimes 1)^* x (a \otimes 1)) \in K(J)$ for all $\varphi \in S$, $a \in A$ and , i.e., $\pi_{A,C}(x) \in F(A,K(J);A \otimes C)$.

We get $\Psi'(J) = \pi^{-1}_{A,B}(F(A,K(J);A \otimes C))$ for every closed ideal J of $B \otimes^{\max} C$. We see that $\Psi'(J)$ does not depend from from the special choice of $P \subseteq B_+$ and $S \subseteq A^*_+$.

If I is a closed ideal of C, then $K(B \otimes^{\max} I) = I$, in particular, $\Psi'(J) = \Psi'(B \otimes^{\max} K(J))$ for all closed ideals J of $B \otimes^{\max} C$.

It follows that $T \otimes^{\max} \mathrm{id}_C$ is Ψ'-residually equivariant, i.e., $T \otimes^{\max} \mathrm{id} \in \mathcal{C}_{\Psi'} = \mathrm{CP}(\Psi', A \otimes^{\max} C, B \otimes^{\max} C)$, if and only if, for every closed ideal I of C,

$$T \otimes^{\max} \mathrm{id}(\pi^{-1}_{A,B}(F(A,I;A \otimes C))) \subseteq B \otimes^{\max} I\,.$$

Every linear map $T : A \to B$ of finite rank has this property, because $T = \sum_k \alpha_k \varphi_k(\cdot) b_k$ with $\varphi_k \in A^*_+$, $b_k \in B_+$, $\alpha_k \in \mathbb{C}$. If we let $C = C^*(F_\infty)$, then

Theorem 3.8.4 implies

$$\mathcal{C}(\mathcal{S}_{S,P}) = \overline{\mathrm{CP}_f(A,B)} =: \mathrm{CP}_{\mathrm{nuc}}(A,B)\,,$$

for all $S \subseteq A^*_+$ and $P \subseteq B_+$ as in Example 3.8.3.

One can also say something in the case of $\mathcal{C} := \mathrm{CP}(A,B) \otimes^{\max} \mathrm{CP}_{\mathrm{in}}(C,C)$: We obtain from the above considered nuclear case, and from the trivial inclusions $V \cdot \mathrm{id}(A \cdot K(J)) \subseteq B \cdot K(J) \subseteq J$ that – for all closed ideals J of $B \otimes^{\max} C$ –,

$$A \otimes^{\max} K(J) \subseteq \Psi_{\mathcal{C}}(J) \subseteq \pi^{-1}_{A,B}(F(A, K(J); A \otimes C))\,.$$

The general study of actions $J \in \mathcal{I}(B) \mapsto \Psi_{\mathcal{C}}(J) \in \mathcal{I}(A)$ defined by $\mathcal{C} \subseteq \mathrm{CP}(A,B)$ seems to be difficult, because related slice map problems for non-exact C^*-algebras have no suitable answer.

Corollary 3.8.6. *Each point-norm closed m.o.c. cone $\mathcal{C} \subseteq \mathrm{CP}(A,B)$ is* hereditary *inside* $\mathrm{CP}(A,B)$*, i.e., if $V, W \in \mathrm{CP}(A,B)$ and $V + W \in \mathcal{C}$ then $V, W \in \mathcal{C}$.*

Proof. By Theorem 3.8.4 the action

$$\Psi' \colon \mathcal{I}(B \otimes^{\max} C^*(F_2)) \to \mathcal{I}(A \otimes^{\max} C^*(F_2))$$

determines the elements of $\mathcal{C}$ by being Ψ'-equivariant in the sense that $T \in \mathcal{C}$ if and only if $(T \otimes \mathrm{id})(\Psi'(J)) \subseteq J$ for all $J \in \mathcal{I}(B \otimes^{\max} C^*(F_2))$. If we let here $T := V + W$ then this implies that the c.p. maps V and W satisfy this condition, because $((V + W) \otimes \mathrm{id}) = (V \otimes \mathrm{id}) + (W \otimes \mathrm{id})$ and all are completely positive maps on $A \otimes^{\max} C^*(F_2)$. Use here that $x + y \in J_+$ for $x \geq 0$ and $y \geq 0$ implies that $x, y \in J_+$. □

9. Temporary demands from other places

Prove and Move next blue to reasonable place !!!

Corollary 3.9.1. *Let A and B stable and separable C^*-algebras and let $\Psi \colon \mathcal{I}(B) \to \mathcal{I}(A)$ a lower semi-continuous action of* $\mathrm{Prim}(B)$ *on A, such that $\Psi(0) = 0$ and $\Psi^{-1}(A) = \{B\}$.*

*And let $\mathcal{C}(\Psi) \subseteq \mathrm{CP}(A,B)$ the point-norm closed m.o.c. cone of "all Ψ-*equivariant *c.p. maps $V \in \mathrm{CP}(A,B)$", i.e., of all that satisfy $V(\Psi(J)) \subseteq J$ for all $J \in \mathcal{I}(B)$ and $V \in \mathcal{C}$, and suppose that $\mathcal{C}(\Psi)$ is* separating *for the action $\Psi \colon \mathcal{I}(B) \to \mathcal{I}(A)$, – i.e., that for each $J \in \mathcal{I}(B)$,*

$$\Psi(J) \;=\; \{\, a \in A\,;\; V(a) \in J, \;\; \textit{for all } V \in \mathcal{C} \,\}\;.$$

If $\mathcal{C} \subseteq \mathcal{C}(\Psi)$ is a point-norm closed m.o.c. cone that defines Ψ.

Then $\mathcal{C}$ contains all Ψ-residually nuclear c.p. maps $V \colon A \to B$, i.e., all $V \in \mathrm{C_b}(A,B)$ with the property that $V(\Psi(J)) \subseteq J$ for all $J \in \mathcal{I}(B)$, and that all the quotient maps $[V] \colon A/\Psi(J) \to B/J$ are again nuclear.

I.e., $\mathcal{C}$ contains the m.o.c. cone $\mathcal{C}_{\mathrm{nuc}}(\Psi)$ of all Ψ-residually nuclear c.p. maps $V \colon A \to B$ with $V(\Psi(J)) \subseteq J$ for all $J \in \mathcal{I}(B)$ and $[V] \colon A/\Psi(J) \to B/J$ is nuclear.

PROOF. ??

Idea of proof:

Consider the closed ideal J of $A \otimes^{\max} C^*(F_\infty)$ that is defined by the intersection of the kernels of the c.p. maps $V \otimes^{\max} \mathrm{id}_{C^*(F_\infty)}$ into $B \otimes^{\max} C^*(F_\infty)$.

Citation: Corollary 3.9.2

For the following Corollary 3.9.2 we refere to Remark 5.1.1(8) for the existence – and uniqueness up to unitary equivalence – of the "*infinite repeat*" endomorphism $\delta_\infty \colon \mathcal{M}(B) \to \mathcal{M}(B)$ for stable C^*-algebras B.

COROLLARY 3.9.2. *Let A and B stable σ-unital C^*-algebras and let $H_k \colon A \to \mathcal{M}(B)$, $k \in \{1, 2\}$, two non-degenerate C^*-morphisms, i.e., $H_k(A)B$ is dense in B.*

If A is separable and if $\mathcal{C}(H_1) = \mathcal{C}(H_2)$ for the point-norm closed m.o.c. cones $\mathcal{C}(H_k) \subseteq \mathrm{CP}(A, B)$, generated by the coefficient maps $A \ni a \mapsto b^* H_k(a) b \in B$, then there exists a norm-continuous path $t \in [0, \infty) \to U(t)$ of unitaries in $\mathcal{M}(B)$ such that, for all $a \in A$, $\delta_\infty \circ H_1(a)U(t) - U(t)\delta_\infty \circ H_2(a) \in B$ for all $t \in [0, \infty)$ and $\lim_{t\to\infty} \|\delta_\infty \circ H_1(a)U(t) - U(t)\delta_\infty \circ H_2(a)\| = 0$, i.e., $\delta_\infty \circ H_1$ and $\delta_\infty \circ H_2$ are unitary homotopic in the sense of Definition 5.0.1.

10. Non-simple algebras and the WvN-property

HERE STARTS eksec3-Part2.tex !!

We generalize some parts of the above results on simple C^*-algebras to non-simple C^*-algebras. In fact, we replace some of the above considered general properties of simple p.i. algebras by more useful suitable *definitions* in the non-simple situation. See, for example, the WvN-property in Definition 1.2.3.

DEFINITION 3.10.1. Let C be a C^*-subalgebra of the multiplier algebra $\mathcal{M}(B)$ of a C^*-algebra B and $V \colon C \to B$ a completely positive map. We call the map V **inner** if there are $m \in \mathbb{N}$ and $d_i \in B$, $i = 1, \ldots, m$, such that

$$V(a) = \sum_{i=1}^{m} d_i^* a d_i \,.$$

The c.p. map V is **1-step inner** if we can take here $m = 1$, i.e., $V := d^*(\cdot)d$.

A completely positive map $V \colon C \subseteq M(B) \to B$ is **approximately inner** if V is the point-norm limit of inner completely positive maps. The map V is **1-step approximately inner** if V can be approximated by 1-step inner c.p. maps.

Let J denote a closed ideal of a C^*-algebra B, then define

$$\mathcal{M}(B, J) := \{T \in \mathcal{M}(B) \colon TB + BT \subseteq J\} \,.$$

Let $C \subseteq \mathcal{M}(B)$ a C^*-subalgebra of the multiplier algebra of a C^*-algebra B. We call a completely positive map $V: C \to B$ **residually nuclear** if $V(C \cap \mathcal{M}(B,J)) \subseteq J$ and $[V]: C/(C \cap \mathcal{M}(B,J)) \to B/J$ is nuclear for every closed ideal J of B.

Let $h: C \to M$ a C^*-morphism into a von-Neumann algebra. The morphism h **weak-approximately majorizes** a c.p. contraction $W: C \to M$ if there is a net (T_γ) of inner completely positive maps from M into M such that W is the point-weak limit of the net $(T_\gamma \circ h)$.

A C^*-morphism $h: D \to \mathcal{M}(B)$ **approximately majorizes** a completely positive map $V: D \to B$ if there exists a net (d_γ) of elements $d_\gamma \in B$, such that V is the point-norm limit of the net of maps $d_\gamma^* h(\cdot) d_\gamma$.

The morphism h **majorizes** a completely positive *contraction* $V: D \to B$ if there is a *contraction* $d \in B$ with $V = d^* h(\cdot) d$.

The homomorphism $h: D \to \mathcal{M}(B)$ **approximately-inner majorizes** a completely positive contraction $V: D \to B$ if h weak-approximately majorizes V in the von-Neumann algebra $M := B^{**} \supset \mathcal{M}(B)$.

If one uses an approximate unit of C, then one can see that one can choose the d_j and T_γ in Definition 3.10.1 such that $\| \sum d_j^* d_j \| \leq \|V\|$ respectively $\|T_\gamma\| \leq \|W\|$, cf. Lemma 3.1.8. Recall Definition 3.1.1

LEMMA 3.10.2. *Suppose that $A \subseteq M$ a C^*-subalgebra of a von-Neumann factor M, and that $W: A \to M$ a weakly nuclear contraction, i.e., $\|W\| \leq 1$ and W can be approximated in the point-$\sigma(M, M_*)$ topology by a net of maps*

$$(W_\gamma : A \to M)_{\gamma \in \Gamma},$$

that are factorable maps in the sense of Definition 3.1.1. Then there is a net $(V_\lambda : M \to M)_{\lambda \in L}$ of inner completely positive contractions on M, such that W is the point-$\sigma(M, M_*)$-limit of the net $(V_\lambda | A : A \to M)$.

PROOF. There is even a net $(W_\gamma : A \to M)$ of factorable maps that converges in point-strong topology to W, because the set of factorable maps from A into M is convex by Remark 3.1.2(o). The Lemma 3.1.8 shows that we can suppose that the net $(W_\gamma : A \to M)$ consists of contractions. Therefore, again by Lemma 3.1.8, it suffices to show that every factorable contraction $W = T \circ S : A \to M$ can be approximated in point-$\sigma(M, M_*)$ topology by inner c.p. maps on M.

If M is of type I_n, II_1 or if M is *countably decomposable* and of type III, then M is simple, and Corollary 3.2.20 gives that W can be approximated by inner completely positive contractions (even in point norm topology).

If M is a semi-finite II_∞-factor, then the Breuer ideal D of M is simple. (Recall that the Breuer ideal of M is generated as C^*-algebra by the finite projections in M.) If M is of type III, then the ideal D generated by the countably decomposable projections is simple.

In both cases M is the multiplier algebra $\mathcal{M}(D)$ of a simple C^*-algebra D which contains an approximating unit consisting of projections.

For every projection $q \in D$, the factorable c.p. contraction $W_q\colon a \in A \subseteq \mathcal{M}(D) \mapsto qW(a)q \in D$ is the point-norm limit of a net of inner completely positive contractions by Corollary 3.2.20, i.e., W_q is approximately inner on D in the sense of Definition 3.10.1.

Since W_q converges point-strongly to W for $q \nearrow 1$ strongly, also W is the point-strong limit of a net of inner completely positive contractions. □

The following Lemma 3.10.3 shows that we can replace in the above definition of the residually nuclear completely positive maps the set $\mathcal{I}(B)$ of all closed ideals J of B by the *factorial* ideals I of B.

Recall that $I \triangleleft B$ is **factorial** if it is the kernel of a factorial representation of B. All primitive ideals are factorial ideals, and factorial ideals are prime (with respect to intersection in the lattice of closed ideals), as one can easily see, cf. e.g. proof of [**616**, prop. 3.13.10]. Since $\mathrm{Prim}(B)$ has the Baire property for C^*-algebras B, all prime ideals of *separable* C^*-algebras B are primitive if B is separable, cf. [**616**, prop. 4.3.6]. (This does not hold for *non-separable* C^*-algebras B, cf. [**815**].)

LEMMA 3.10.3. *Let C a C^*-subalgebra of $\mathcal{M}(B)$.*

(i) *For every family $\{J_\gamma\}$ of closed ideals of B holds* $\mathcal{M}(B, \bigcap J_\gamma) = \bigcap \mathcal{M}(B, J_\gamma)$ *and*
(ii) $\mathrm{dist}(a, \mathcal{M}(B, \bigcap J_\gamma)) = \sup_\gamma \mathrm{dist}(a, \mathcal{M}(B, J_\gamma))$ *for $a \in \mathcal{M}(B)$.*
(iii) *If B is σ-unital then $\mathcal{M}(B, J_1) + \mathcal{M}(B, J_2) = \mathcal{M}(B, J_1 + J_2)$ for every pair of closed ideals J_1 and J_2 of B.*
(iv) *Suppose that $J_0 \subseteq B$ is a closed ideal and that $V\colon C \to B$ is a completely positive map, such that $V(C \cap \mathcal{M}(B, J)) \subseteq J$ and*

$$[V]_J := [\pi_J \circ V]\colon\ C/(C \cap \mathcal{M}(B, J)) \ \to\ B/J$$

is nuclear for every factorial *ideal J of B with $J_0 \subseteq J$, then*

$$[V]_{J_0}\colon C/(C \cap \mathcal{M}(B, J_0)) \to B/J_0$$

is nuclear.
(v) *If $V\colon C \to B$ is residually nuclear, then for every non-degenerate* factorial **-representation $\rho\colon B \to N$ of B holds:* $\mathcal{M}(B, \ker(\rho)) = \ker \mathcal{M}(\rho)$, $V(C \cap \ker \mathcal{M}(\rho)) \subseteq \ker(\rho)$ *and the restricted map $\mathcal{M}(\rho)|C\colon C \to N$ majorizes $\rho \circ V$ approximately with respect to the weak topology.*

PROOF. The easy proofs of (i)-(iii) are left to the reader: Use an approximate unit of B for the straight calculations.

(iv): We have $V(C \cap \mathcal{M}(B, J_0)) \subseteq V(C \cap \mathcal{M}(B, J)) \subseteq J$ for all primitive ideals J of B with $J \supseteq J_0$. The closed ideal J_0 is the intersection of the primitive ideals J that contain J_0 (cf. [**616**, cor. 3.13.8]). Hence $V(C \cap \mathcal{M}(B, J_0)) \subseteq J_0$.

By Remark 3.1.2(i), a map $T\colon D \to E$ is nuclear, if and only if,

$$T \otimes^{\max} \mathrm{id}\colon D \otimes^{\max} C^*(F) \to E \otimes^{\max} C^*(F)$$

annihilates the kernel I of the natural epimorphism $D \otimes^{\max} C^*(F) \to D \otimes C^*(F)$.

It is easy to see that an irreducible representations ρ of $E \otimes^{\max} C^*(F)$ factorizes over $(E/K) \otimes^{\max} C^*(F)$ for some factorial ideal K of E.

In particular, *the family of quotient maps* $\pi_K \otimes^{\max} C^*(F)$ *from* $E \otimes^{\max} C^*(F)$ *to* $(E/K) \otimes^{\max} C^*(F)$ *is separating for* $E \otimes^{\max} C^*(F)$ ([20]). Hence, T is nuclear, if and only if, $(\pi_K T) \otimes^{\max} \mathrm{id}(I) = 0$ for all factorial ideals K of E, if and only if, $\pi_K \circ T\colon D \to E/K$ is nuclear for all factorial ideals J of E.

Now apply this to $D := C/(C \cap \mathcal{M}(B, J_0))$, $E := B/J_0$, $T := [V]_{J_0}$, and use that $\pi_{J/J_0} \circ [V]_{J_0} = [V]_J \circ \eta_J$ for $\eta_J\colon D \to C/(C \cap \mathcal{M}(B, J_0))$, and that $K := J/J_0$ runs through all factorial ideals of E if J runs through all factorial ideals $J \supset J_0$ of B.

(v): Let $E := \rho(B) \subseteq N \subseteq \mathcal{L}(\mathcal{H})$. Since $\rho\colon B \to \mathcal{L}(\mathcal{H})$ is non-degenerate, the normalizer algebra $\mathcal{N}(E) := \{t \in \mathcal{L}(\mathcal{H})\,;\ tE + Et \subseteq E\}$ of E in $\mathcal{L}(\mathcal{H})$ is unital and can be identified with the multiplier algebra $\mathcal{M}(E)$ of E in a natural way. It is easy to see that $\mathcal{N}(E) \subseteq E'' \subseteq N$. The representation ρ defines a *-epimorphism from B onto E. Thus, ρ uniquely extends to a unital strictly continuous map $\mathcal{M}(\rho)\colon \mathcal{M}(B) \to \mathcal{M}(E) = \mathcal{N}(E) \subseteq N$ such that $\mathcal{M}(\rho)(c)\rho(b) = \rho(cb)$ for $c \in \mathcal{M}(B)$ and $b \in B$. It follows that the kernel $\ker(\mathcal{M}(\rho))$ of $\mathcal{M}(\rho)$ is $\mathcal{M}(B, J) := \{c \in \mathcal{M}(B)\,;\ cB + Bc \subseteq J\}$ for $J := \ker(\rho)$. Let $\Psi(J) := C \cap \mathcal{M}(B, J) = C \cap \ker(\mathcal{M}(\rho))$.

If we let $A := \mathcal{M}(\rho)(C) \subseteq N$, then $\mathcal{M}(\rho)$ defines a natural isomorphism γ from $C/\Psi(J)$ onto A with $h := \mathcal{M}(\rho)|C = \gamma \circ \pi_{\Psi(J)}$, i.e., $\gamma(c + \Psi(J)) = \mathcal{M}(\rho)(c)$ for $c \in C$.

We define $W\colon A \to N$ by $W := [\rho]_J \circ [V]_J \circ \gamma^{-1}\colon A \to E \subseteq N$. Here $[\rho]_J$ denotes the natural isomorphism from $B/\ker(\rho) = B/J$ onto $E = \rho(B) \subseteq N$ with $[\rho]_J(b + J) = \rho(b)$ for $b \in B$, i.e., $[\rho]_J \circ \pi_J = \rho$. The map $[V]_J\colon C/\Psi(J) \to B/J$ with $[V]_J \circ \pi_{\Psi(J)} = \pi_J \circ V$ is nuclear, because V is residually nuclear. Therefore $W\colon A \to N$ is nuclear. By Lemma 3.10.2, there is a net of inner c.p. maps $(V_\lambda\colon N \to N)$ with $\|V_\lambda\| \leq 1$ such that $(V_\lambda|A)$ converges in point-$\sigma(N, N_*)$ topology to W.

Thus the net $V_\lambda \circ h$ tends in point-$\sigma(N, N_*)$ topology to $W \circ h = [\rho]_J \circ [V]_J \circ \pi_{\Psi(J)} = \rho \circ V$. It means that h weak-approximately majorizes $\rho \circ V$ (in the sense of Definition 3.10.1). □

Proposition 3.10.4. *Suppose that* C *is a* C^**-subalgebra of* $\mathcal{M}(B)$ *and that* $V\colon C \to B$ *is a completely positive contraction. Then the following are equivalent:*

(i) V *is approximately inner (in the sense of Def. 3.10.1).*

---

[20] Moreover, by an reduction to certain separable C^*-subalgebras of E with an argument in Chapter 12, one can show that the family of maps $\pi_K \otimes^{\max} \mathrm{id}$ is separating for $E \otimes^{\max} C^*(F)$ if K runs through all primitive ideals of E. Therefore one can replace the factorial or prime ideals by *primitive* ideals in Lemma 3.10.3(iv) and in Proposition 3.10.4(ii).

(ii) *For every prime ideal J of B, $V(\Psi(J)) \subseteq J$ and $[V]\colon C/\Psi(J) \to B/J$ is approximately inner (cf. Def. 3.10.1), where $\Psi(J) := C \cap \mathcal{M}(B,J)$ and $C/\Psi(J) \subseteq \mathcal{M}(B)/\mathcal{M}(B,J) \subseteq \mathcal{M}(B/J)$.* ([21])

(iii) *For every non-degenerate factorial representation $\rho\colon B \to N$, the natural extension $h := \mathcal{M}(\rho)|C\colon C \to N$ of ρ to C weak-approximately majorizes $W := \rho \circ V$, where $N := \rho(B)''$ in the sense of Definition 3.10.1.*

Proof. From Definition 3.10.1 we can see that (i) implies (ii) and that (ii) implies (iii). The latter, because the kernel of each factorial representation of B is a prime ideal J of B.

(iii)⇒(i): Suppose that (iii) holds, but that V is not approximately inner.

Let $\eta\colon C \hookrightarrow \mathcal{M}(B)$ denote the inclusion map. The Hahn-Banach separation argument in the proofs of [**426**, lem.2,lem.3] shows that there exist $c_1, \ldots, c_n \in C$ and a cyclic representation $d\colon B \to \mathcal{L}(H)$ with cyclic vector $x \in H$ and $f_1, \ldots, f_n \in d(B)'$, such that:

(*) The positive linear functional $\psi \circ d_1 \circ (V \otimes^{\max} \mathrm{id}_F)$ is not weakly contained in the representation $k := d_1 \circ (\eta \otimes^{\max} \mathrm{id}_F)$ of $C \otimes^{\max} F$ on H.

Here $F := C^*(1, f_1, \ldots, f_n) \subseteq \mathcal{L}(H)$, d_1 denotes the *natural extension of* d to a unital *-representation of $\mathcal{M}(B) \otimes^{\max} F$ into $\mathcal{L}(H)$ such that $d_1(c \otimes f)d(b) = d(cb)f$ for $c \in \mathcal{M}(B)$, $b \in B$, $f \in F$, and where ψ is the vector state on $\mathcal{L}(H)$ given by x.

Since there is $p \in (C \otimes^{\max} F)_+$ with $0 = k(p) = d_1((\eta \otimes^{\max} \mathrm{id}_F)(p))$ and $0 \neq d((V \otimes^{\max} \mathrm{id}_F)(p)) \in d(B \otimes^{\max} F)$, there is a pure state φ on $d(B \otimes^{\max} F)$ with $\varphi(d((V \otimes^{\max} \mathrm{id}_F)(p))) > 0$, and we obtain:

(**) *There is a pure state φ on $d(B \otimes^{\max} F)$ which is weakly contained in $d\colon B \otimes^{\max} F \to H$ such that the positive functional $\varphi \circ d \circ (V \otimes^{\max} \mathrm{id}_F)$ on $C \otimes^{\max} F$ is not weakly contained in k.*

There is a unique extension λ of the pure state φ to a pure state of $d_1(\mathcal{M}(B) \otimes^{\max} F)$, because $d(B \otimes^{\max} F)$ is an ideal of $d_1(\mathcal{M}(B) \otimes^{\max} F)$. Thus, $\lambda \circ k$ is weakly contained in k.

But, φ is the cyclic vector of an irreducible representation d_2 of $B \otimes^{\max} F$ over a Hilbert space H_1 with corresponding cyclic vector y such that $\varphi d_1 = \langle d_2(.)y, y \rangle$.

The irreducible representation d_2 decomposes into a commuting pair of factorial representations ρ and d_3 of B and F respectively.

If d_4 denotes the natural extension of d_2 to $\mathcal{M}(B) \otimes^{\max} F$ then $\lambda(.) = \langle d_4(.)y, y \rangle$, and $c \mapsto d_4(c \otimes 1)$ is the natural extension $\mathcal{M}(\rho)$ of ρ to $\mathcal{M}(B)$.

The representation d_4 is weakly contained in d_1, because d_2 is weakly contained in d and is non-degenerate. Thus $d_4(\eta \otimes^{\max} \mathrm{id}_F)$ is weakly contained in k.

[21] The inclusions are defined by the natural monomorphisms.

By the assumptions of (iii), $h := \mathcal{M}(\rho)|C$ weak-approximately majorizes ρV in $N := \rho(B)''$. Thus, $\varphi \circ d \circ V \otimes^{\max} \mathrm{id}_F)$ is weakly contained in $d_4(\eta \otimes^{\max} \mathrm{id}_F)$, and, therefore, it is weakly contained in k.

We have derived a contradiction to (**), which was implied from the assumption that V is not approximately inner. □

Suppose that $h_1, h_2 \colon A \to B$ are C^*-morphisms and that $s, t \in \mathcal{M}(B)$ are two isometries with orthogonal ranges. Then we define for this chapter the Cuntz addition by

$$(h_1 \oplus h_2)(a) := (h_1 \oplus_{s,t} h_2)(a) := sh_1(a)s^* + th_2(a)t^*, \qquad \text{for} \quad a \in A$$

defines a C^*-morphism from A into B ([22]). The C^*-algebra generated by s and t contains a unital copy of $\mathcal{O}_\infty$. Therefore one can define in a similar way the k-fold sum $h \oplus h \oplus \cdots \oplus h$ of k copies of h, $k = 2, 3, \ldots$. (Compare Chapter 4 for more details in the particular situation where B contains a copy of $\mathcal{O}_2$ unitally.)

LEMMA 3.10.5. *Suppose that A is a separable C^*-algebra, E is a C^*-algebra such that $\mathcal{M}(E)$ contains isometries s, t with ortogonal ranges (i.e., $s^*t = 0$), $h \colon A \to E$ is a C^*-morphism, and that $(V_k \colon E \to E)_k$ is a sequence of approximately inner c.p. contraction.*

(i) *If h majorizes (respectively approximately majorizes) the C^*-morphism*
$$h \oplus h := sh(\cdot)s^* + th(\cdot)t^*,$$
then there exists a C^*-morphism g from $A \otimes \mathcal{O}_\infty$ into E, – respectively into $E_\infty := \ell_\infty(E)/c_0(E)$ –, with $g(a \otimes 1) = h(a)$ for $a \in A$.

(ii) *If there is a C^*-morphism g from $A \otimes \mathcal{O}_\infty$ into E (respectively into E_∞) with $g(a \otimes 1) = h(a)$ for $a \in A$, then there exists a sequence d_n of contractions in E such with the properties $d_n^* b d_{n+m} = 0$ (respectively $\lim_{n\to\infty} d_n^* b d_{n+m} = 0$) for $b \in h(A) + \mathbb{C}1$, $m > 0$, and $\lim_{n\to\infty} \| d_n^* h(a) d_n - V_n(h(a)) \| = 0$ for $a \in A$.*

Note that in general (i) does *not* imply the existence of isometries $s_1, s_2, \ldots \in h(A)' \cap E$ with orthogonal ranges. But this could happen modulo the two-sided annihilator of $h(A)$ in E.

PROOF. (i): If there is a contraction $d \in E$ with $d^* h(\cdot) d = h \oplus h$, then the proof of Proposition 4.3.5(v) works and gives that there is a C^*-morphism $g \colon A \otimes \mathcal{O}_\infty \to E$ with $g(a \otimes 1) = h(a)$ for $a \in A$.

Suppose that h approximately majorizes $h \oplus h$. The C^*-morphism $h \oplus h$ is a contraction. By Lemma 3.1.8 $h \oplus h$ is in the point-norm closure of the set of maps $d^* h(\cdot) d$ with contractions $d \in E$. Since A is separable, we can select a sequence $(d_1, d_2, \ldots)$ of contractions in E such that $h(a) \oplus h(a) = \lim_n d_n^* h(a) d_n$ for $a \in A$. Thus $h \oplus h = d_\infty^* h(\cdot) d_\infty$ in E_∞ for the contraction $d_\infty := (d_1, d_2, \ldots) + c_0(E) \in E_\infty$.

[22] The here given definition of $h_1 \oplus h_2$ is a bit more general than the definition of the Cuntz Addition in Chapters 1 and 4, where we require that moreover $ss^* + tt^* = 1$.

(ii): We fix a strictly positive contraction $c \in A_+$. Let $X_1 \subseteq X_2 \subseteq \cdots \subseteq A$ an approximate filtration of A by finite-dimensional linear subspaces X_n, and let $s_1, s_2, \ldots$ the canonical generators of $\mathcal{O}_\infty$. By Lemma 3.1.8, for each $n \in \mathbb{N}$ we find $k(n) \in \mathbb{N}$ and $f_1^{(n)}, \ldots, f_{k(n)}^{(n)} \in E$ with

$$\| \sum_{j=1}^{k(n)} (f_j^{(n)})^* f_j^{(n)} \| \leq 1$$

and $\|V_n(h(a)) - W_n(h(a))\| \leq 2^{-n}\|a\|$ for $a \in X_n$, where W_n is the inner c.p. contraction on E given by

$$W_n(b) := \sum_j (f_j^{(n)})^* b (f_j^{(n)}) \qquad \text{for} \quad b \in E\,.$$

We find $p(n) \in \mathbb{N}$ such that $\|c^{1/p(n)} a c^{1/p(n)} - a\| \leq 2^{-n}\|a\|$ for $a \in X_n$. Now let $c_n := c^{1/p(n)}$, $r(n) := k(1) + k(2) + \cdots + k(n-1)$ for $n > 1$ and $r(1) := 0$. We define $e_n := \sum_j g(c_n \otimes s_{r(n)+j}) f_j^{(n)}$ for $n = 1, 2, \ldots$. Then $e_n \in E_\infty$, $e_n^* b e_m = 0$ for $m \neq n$ and $e_n^* b e_n = W_n(c_n b c_n)$ for $b \in h(A) + \mathbb{C} \cdot 1$. In particular, $\|e_n\| \leq 1$ and, for $a \in X_n$,

$$\|e_n^* h(a) e_n - V_n(h(a))\| \leq 3 \cdot 2^{-n} \|a\|\,.$$

If $g(A \otimes \mathcal{O}_\infty) \subseteq E$, then the elements $d_n := e_n$ are contractions in E and have the desired properties.

In the case where $g(A \otimes \mathcal{O}_\infty) \subseteq E_\infty$, we can select from the representing sequences of contractions for e_n suitable elements d_n that have the in part (ii) desired properties. □

Corollary 3.10.6.

(I) *If $C \subseteq \mathcal{M}(B)$ and $T\colon C \to B$ is residually nuclear, then T is approximately inner in the sense of Definition 3.10.1.*

(II) *Suppose $h\colon A \to \mathcal{M}(B)$ is a C^*-morphism and $V\colon A \to B$ is a completely positive contraction that satisfy the following conditions:*
  - (α) *$h(A)$ commutes elementwise with a unital copy of $\mathcal{O}_\infty$ in $\mathcal{M}(B)$,*
  - (β) *$V(\Psi(J)) \subseteq J$, and*
  - (γ) *$[V]\colon A/\Psi(J) \to B/J$ is nuclear for every factorial ideal $J \subseteq B$, where $\Psi(J) := h^{-1}(h(A) \cap \mathcal{M}(B, J))$.*

  Then h approximately majorizes V in the sense of Definition 3.10.1.

Proof. (I) follows from Proposition 3.10.4(iii) and Lemma 3.10.3(v).

(II): Let $C := h(A)$. For $J = 0$, J_A is the kernel of h. Thus there is a completely positive map $T\colon C \to B$ such that $Th = V$. Then (β) and (γ) say that T is residually nuclear. By (I), T is approximately inner. But since C commutes with a copy of $\mathcal{O}_\infty$, we get that T is moreover one-step approximately inner. This means that h approximately majorizes V. □

By Remark 3.1.2(iv), Corollary 3.10.6 implies:

Corollary 3.10.7. *Suppose that $C \subseteq \mathcal{M}(B)$, C is exact, $V: C \to B$ is nuclear, and $V(C \cap \mathcal{M}(B, J)) \subseteq J$ for every closed ideal J of B, then V is approximately inner in the sense of Definition 3.10.1.*

Corollary 3.10.8. *Suppose that $\mathcal{M}(B)$ contains two isometries with orthogonal ranges, A is separable, $h: A \to B$ is a C^*-morphism that approximately majorizes $h \oplus h$ and that $T: A \to B$ is a completely positive contraction.*

Assume that T is nuclear and A is exact, or that $[T]: A/J \to B/J_T$ is nuclear for every closed ideal J of A, where J_T denotes the closed ideal of B which is generated by $T(J)$.

Then the following are equivalent:

(i) *h approximately majorizes T.*
(ii) *$T(J)$ is contained in the closure of $Bh(J)B$ for every closed ideal J of A.*
(iii) *$T(h^{-1}(h(A) \cap K)) \subseteq K$, i.e., $a \mapsto V(a) + K$ annihilates the kernel of $a \mapsto h(a) + K$, for every primitive ideal K of B.*

Proof. The implication (i)⇒(ii) is trivial. (ii)⇒(iii), because, with $J := h^{-1}(h(A) \cap K)$, $h(J) \subseteq K$ and, therefore, $T(J) \subseteq K$.

(iii) ⇒ (i): By induction, h approximately majorizes the k-fold sum of h for $k = 1, 2, \ldots$. Therefore, and since A is separable, it suffices to show that T is in the point norm closure of the convex set of maps $S \circ h$, where the S runs through the inner complete contractions on B. For the kernel J of h we have $T(J) = 0$, because $J \subseteq h^{-1}(h(A) \cap K$ and, therefore, $T(J) \subseteq K$ for every primitive ideal K of B.

Let $C := h(A)$ and let V be the unique completely positive contraction with $Vh = T$. Then, for every primitive ideal K of B, $J := C \cap K$ is a closed ideal of C and $V(J)$ is contained in K. If K_0 is any closed ideal, then $V(C \cap K_0) \subseteq V(C \cap K) \subseteq K$ for every primitive ideal K of B with $K_0 \subseteq K$. Thus $V(C \cap K_0) \subseteq K_0$.

If A is exact and T is nuclear, then C is exact and V is nuclear by Remark 3.1.2(iv). Thus V is approximately inner by Corollary 3.10.7.

If A is not exact, but $[T]: A/J \to B/J_T$ is nuclear for every closed ideal J of A, then with $J := h^{-1}(C \cap K)$ we get $V(C \cap K) \subseteq T(J) \subseteq K$ and, therefore, $T(J) \subseteq J_T \subseteq K$, $[T]: A/J \to B/K$ is nuclear. Under the natural isomorphism $A/J \cong C/(C \cap K)$, $[V]: C \cap K \to B/K$ is the same as $[T]$. Thus V is residually nuclear, and is approximately inner by Corollary 3.10.6(I).

Since V is a contraction, it is then, moreover, in the point-norm closure of the convex set of restrictions $S|C$ of inner complete contractions on B. □

Let us recall here the Definition 1.2.3 of : ??????

Remark 3.10.9.

(i) We shall see in Chapter 5 that σ-unital C^*-algebras B with the WvN–property satisfy a generalized Weyl–von-Neumann–Voiculescu type theorem for weakly residually nuclear completely positive contractions.

(ii) Proposition 3.2.13 says that simple purely infinite C^*-algebras have the WvN–property.

(iii) C^*-algebras B with the WvN-property are p.i. in the sense of Definition 1.2.1:

Let $a \in B_+$. We consider $C = C^*(\mathrm{diag}(a, 0))$ and the *-monomorphism V from C into $M_2(B)$ which sends $\mathrm{diag}(a, 0)$ to $\mathrm{diag}(a, a)$. V is residually nuclear. Therefore, by the WvN-property, for every $\varepsilon > 0$, there exists a contraction $d \in M_2(B)$ with $d^* \,\mathrm{diag}(a, 0)d = (\mathrm{diag}(a, a) - \varepsilon)_+$. This implies that B is p.i.

(iv) It follows from joint work with M. Rørdam and from [**443**] that all strongly p.i. algebras (in the sense of Definition 1.2.2) have the WvN–property, and that in several particular cases p.i. algebras are strongly p.i., see the Remarks 2.15.12, 3.11.1, 3.11.6 and 12.2.9.

(v) Residually nuclear separation passes to hereditary C^*-subalgebras.

(vi) It is easy to see that the non-commutative Michael selection principle for $B \otimes \mathbb{K}$ in Conjecture 12.3.6 implies residually nuclear separation for B in the sense of Definition 1.2.3, cf. Remarks 12.3.7, 12.3.8.
(Every simple stable C^*-algebra trivially satisfies the non-commutative Michael selection principle.)

(vii) It follows from [**463**] and [**443**] that C^*-algebras with the WvN–property and residually nuclear separation are strongly p.i. in the sense of Definition 1.2.2.

(viii) Since all separable C^*-algebras have Abelian factorization, each C^*-algebra has residually nuclear separation.

`Since every separable C*-algebra has abelian factorization, we get that they all also have residually nuclear separation`

`??`

Corollary 3.10.10. *Suppose that B has the WvN–property.*

(i) *If C is an exact subalgebra of $\mathcal{M}(B)$ such that that $V : C \to B$ is nuclear and $V(C \cap \mathcal{M}(B, J)) \subseteq J$ for every primitive ideal of B, then V is 1-step approximately inner, i.e. if V is approximately majorized by id_C in the sense of Definition 3.10.1.*
(ii) *If A is exact, $h : A \to B$ is a nuclear C^*-morphism, and $\mathcal{M}(B)$ contains two isometries s, t with orthogonal ranges, then h approximately majorizes $h \oplus_{s,t} h$.*

Proof. (i) follows from Corollary 3.10.7 and Definition 1.2.3.

(ii): Let $C := h(A)$. C is exact and $\varepsilon_C : C \hookrightarrow B$ is nuclear by Remark 3.1.2(iv). Since h and $h \oplus h$ have the same kernel, there is a C^*-morphism $V : C \to B$ such that $Vh = h \oplus h$, in fact $V = \varepsilon_C \oplus \varepsilon_C$, which is nuclear with ε_C. Thus (i) applies. □

Corollary 3.10.11. *Let $c \in (\mathcal{O}_2)_+$ be an element with $Spec(c) = [0, 1]$. If $a, b \in A_+$ and $\varrho \geq 0$ satisfy $\|b + J\| \leq \|a + J\| + \varrho$ for all primitive ideals J*

of A, then, for every $\delta > 0$ there exist an isometry $s \in \mathcal{M}(A \otimes \mathcal{O}_2)$ such that $\| s^*(a \otimes c)^k s - ((b \otimes c) - \varrho)_+^k \| < \delta$ for $k = 1, 2$.

Thus $\| s^*(a \otimes c)^k s - (b \otimes c)^k \| < \delta + \varrho \max(1, 2\|b\|)$ for $k = 1, 2$.

Proof. The assumptions imply that $\|b \otimes c\| = \|b\|$ and, for every closed ideal I of A,

$$\|b + I\| = \sup\{ \|b + J\| : \ J \in \mathrm{Prim}(A), \quad I \subseteq J \} \ \leq \ \|a + I\| + \varrho \, .$$

In particular, $\|d\| \leq \|a\|$ where $d := ((b \otimes c) - \varrho)_+$.

Let $h_0 \colon \mathrm{C}([0,1]) \to \mathcal{O}_2$ denote the unital *-monomorphism with $h_0(f) := f(c)$ for $f \in \mathrm{C}([0,1])$. By Corollary 3.10.10, h_0 approximately majorizes $h_0 \oplus h_0$, because $\mathrm{C}([0,1])$ is nuclear, $\mathcal{O}_2$ is a simple p.i. algebra and, therefore, by Proposition 3.2.13, $\mathcal{O}_2$ has the WvN–property.

Let $C := \mathrm{C}([0, \|a\|])$, and $\gamma \colon C \to C \otimes \mathrm{C}([0,1])$ the unital *-monomorphism given by $\gamma(f)(x,y) := f(xy)$. We define C^*-morphisms h and k from C into the unitization of $A \otimes \mathcal{O}_2$, and h_1 from C into the unitization of A, by $h(f) := f(a \otimes c)$, $k(f) := f(d)$ and $h_1(f) := f(a)$.

Then $h_1 \otimes h_0$ and, therefore, $h = (h_1 \otimes h_0)\gamma$ approximately majorizes their two-fold sums $(h_1 \otimes h_0) \oplus (h_1 \oplus h_0) = h_1 \otimes (h_0 \oplus h_0)$ and $h \oplus h$.

Note that, for every closed ideal J of A and $e \in A_+$, the spectrum of $\pi_J(e) \otimes c$ is the closed interval $[0, \|e + J\|]$. By Proposition B.4.2, for every closed ideal K of $A \otimes \mathcal{O}_2$ there exist a closed ideal J of A with $K = J \otimes \mathcal{O}_2$.

Thus, for every factorial ideal $K = J \otimes \mathcal{O}_2$ of $A \otimes \mathcal{O}_2$, the spectrum of $\pi_K(d)$ is $[0, (\|b + J\| - \varrho)_+]$, which is contained in the spectrum $[0, \|a + J\|]$ of $\pi_K(a \otimes c)$.

Hence, by Corollary 3.10.8, h approximately majorizes k. This implies easily the stated result. □

Corollary 3.10.12. *Let $\kappa(a)$ denote the convex set of elements $c = \sum d_k^* a d_k$ in A_+, where the d_k are in the unitization of A with $\sum d_k^* d_k = 1$ in $\mathcal{M}(A)$, $k = 1, \ldots, n$, $n \in \mathbb{N}$.*

Then, for $a, b \in A_+$,

$$\mathrm{dist}(b, \kappa(a)) = \max(0, \sup\{ \|b + J\| - \|a + J\| \colon J \in \mathrm{Prim}(A)\}) \, .$$

Proof. Let $\delta > 0$.

There exists $V = \sum d_k^*(\,\cdot\,) d_k$, such that $\|b - V(a)\| < \delta + \mathrm{dist}(b, \kappa(a))$.

For every closed ideal J, $\|V(a) + J\| \leq \|a + J\|$ and $\|b - V(a) + J\| \leq \|b - V(a)\|$.

Thus, $\|b + J\| - \|a + J\| \leq \delta + \mathrm{dist}(b, \kappa(a))$.

The other direction, i.e.,
$\mathrm{dist}(b, \kappa(a)) \leq \varrho$ for every $\varrho > 0$ with $\|b + J\| - \|a + J\| \leq \varrho$ for all primitive ideals J of A, follows from Corollary 3.10.11 by the method in the proof of Corollary 3.2.20,

because there exists by Proposition 3.2.13 a sequence of isometries $d_n \in \mathcal{O}_2$ with $d_n^* c d_n \to 1$. □

REMARK 3.10.13. There are strictly continuous versions of Corollaries 3.10.11 and 3.10.12 for $a, b \in \mathcal{M}(A)_+$ and weakly continuous versions for a, b in the positive part of a von Neumann algebra N. Of course, one has to modify all what is needed, beginning with Definition 3.10.1, but in a *very* straightforward way. The outcome is, e.g., the following modifications of Corollary 3.10.12:

Let $\kappa(a)_{st}$ and $\kappa(a)_s$ denote the strict closure of $\kappa(a)$ in $\mathcal{M}(A)$ and the strong closure of $\kappa(a)$ in N, respectively. Then, for $a, b \in \mathcal{M}(A)_+$,

$$\mathrm{dist}(b, \kappa(a)_{st}) \;=\; \max\big(0, \sup\{\|b + \mathcal{M}(A,J)\| - \|a + \mathcal{M}(A,J)\|\,;\; J \in \mathrm{Prim}(A)\}\big)\,.$$

Let $\mathcal{PZ}$ denote the set of projections in the center of N. Then, for $a, b \in N_+$,

$$\mathrm{dist}(b, \kappa(a)_s) = \max(0, \sup\{\|bp\| - \|ap\|\,;\; p \in \mathcal{PZ}\}).$$

COROLLARY 3.10.14. *Suppose that B and $D \subseteq \mathcal{M}(B)$ are σ-unital and stable, where D has the WvN–property and DB is dense in B.*

*Let $A \subseteq \mathcal{M}(D) \subseteq \mathcal{M}(B)$ a separable C^*-subalgebra. Suppose that there exists a *-monomorphism $h\colon A \hookrightarrow \mathcal{M}(D)$ such that, for every closed ideal J of D,*

$$h(A \cap \mathcal{M}(D,J)) = h(A) \cap \mathcal{M}(D,J)$$

and, for every $d \in D$, the c.p. map $a \in A \mapsto d^* h(a) d$ is residually nuclear.

with respect to which action? l.s.c. from $\mathcal{I}(B)$ to $\mathcal{I}(D)$ and then from $\mathcal{I}(D)$ to A???

Furthermore, let $V\colon A \to B$ a completely positive contraction such that

(i) *$V(A \cap \mathcal{M}(D,J))$ is contained in the closed linear span of BJB, and*
(ii) *$[V]\colon A/(A \cap \mathcal{M}(D,J)) \to B/J_B$ is nuclear for every closed ideal J of D.*

Then V is 1-step approximately inner in the sense of Definition 3.10.1, i.e., there exists a sequence of contractions $b_n \in B$ such that $V(a) = \lim b_n^* a b_n$ for every $a \in A$.

PROOF. First we show, that V is approximately majorized by an infinite repeat of h, – cf. Remark 5.1.1(8) and Lemma 5.1.2(i,ii) in Chapter 5 concerning infinite repeats $\delta_\infty \circ h$.

Let $s_1, s_2, \ldots$ be a sequence of isometries in $\mathcal{M}(D)$ such that $s_n^* s_m = \delta_{nm}$ and $\sum s_n s_n^*$ strictly converges to the unit element of $\mathcal{M}(D)$. We define an **infinite repeat** δ_∞ on $\mathcal{M}(B)$ by $\delta_\infty(a) := \sum s_n a s_n^*$.

Since $\delta_\infty(\mathcal{M}(D,J)) = \delta_\infty(\mathcal{M}(D)) \cap \mathcal{M}(D,J)$ for every closed ideal J of D, the infinite repeat $\delta_\infty \circ h$ of h satisfies that $(\delta_\infty \circ h)(A \cap \mathcal{M}(D,J))$ coincides with $((\delta_\infty \circ h)(A)) \cap \mathcal{M}(D,J)$ $h\colon A \hookrightarrow \mathcal{M}(D)$ for every closed ideal J of D,

and that $\delta_\infty \circ h$ is again residually nuclear ???? For which action of what lattice?

Therefore, we can assume that the image $C := h(A)$ of A in $\mathcal{M}(D)$ commutes elementwise with a unital copy of $\mathcal{O}_\infty$ in $\mathcal{M}(D)$. (It is *not* the copy that is defined by the isometries $s_1, s_2, \ldots$.)

Let us denote by $\Psi^{D,B}_{\mathrm{down}}(J)$ the closed linear span of BJB in B for ideals J of D.

We also use the notations $\Psi^{\mathrm{up}}_{D,A}(J) := A \cap \mathcal{M}(D,J)$, and, similarly $\Psi^{\mathrm{up}}_{D,C}(J)$, for closed ideals $J \subseteq D$, and $\Psi^{\mathrm{up}}_{B,C}(I) := C \cap \mathcal{M}(B,I)$, $\Psi^{\mathrm{up}}_{B,D}(I)$, for closed ideals $I \subseteq B$, as introduced at the end of Chapter 1.

Let $I_A := h^{-1}(\Psi^{\mathrm{up}}_{B,C}(I))$ and $J_A := h^{-1}(\Psi^{\mathrm{up}}_{D,C}(J))$.

Our assumptions say that, in particular, $\Psi^{\mathrm{up}}_{D,A}(J) =: J_A$, V maps $\Psi^{\mathrm{up}}_{D,A}(J)$ into $\Psi^{D,B}_{\mathrm{down}}(J)$ and that $[V]\colon A/J_A \to B/\Psi^{D,B}_{\mathrm{down}}(J)$ is nuclear.

Suppose that I is an ideal of B, then

$$\Psi^{\mathrm{up}}_{B,C}(I) \subseteq \Psi^{\mathrm{up}}_{D,C}(\Psi^{\mathrm{up}}_{B,D}(I))\,,$$

because $t \in \mathcal{M}(D)$ and $tB \subseteq I$ imply $tDB \subseteq I$ and, therefore, $tD \subseteq \mathcal{M}(B,I) \cap D$. Further $\Psi^{D,B}_{\mathrm{down}}(\Psi^{\mathrm{up}}_{B,D}(I)) \subseteq I$, because $B(D \cap \mathcal{M}(B,I))B \subseteq I$.

Thus we get $h^{-1}(\Psi^{\mathrm{up}}_{B,C}(I)) \subseteq J_A$ and $\Psi^{D,B}_{\mathrm{down}}(J) \subseteq I$ for $J := D \cap \mathcal{M}(B,I)$.

Therefore, the conditions (α)-(γ) of Corollary 3.10.6(ii) are satisfied for A, h and V. Thus, there exists a sequence of contractions d_n in B such that $d_n^* h(.) d_n$ converges in point-norm to V.

Since DB is dense in B, we find a net e_n of contractions in D_+ such that $e_n d_n - d_n$ converges to zero.

But, by assumption, $e_n h(\cdot) e_n$ is residually nuclear on $A \subseteq \mathcal{M}(D)$, and D has the WvN–property. Thus, there is a sequence f_n of contractions in D such that $f_n^* a f_n - e_n h(a) e_n$ tends to zero for every $a \in A$.

Let $b_n := f_n d_n$, then $V(a) = \lim b_n^* a b_n$ for every $a \in A$. The b_n are contractions in B. □

Proposition 3.10.15. *For every σ-unital C^*-algebra B, $F := B \otimes \mathcal{O}_\infty \otimes \mathcal{O}_\infty \otimes \ldots$ and $\mathrm{C_b}(\mathbb{R}_+, F)/\,\mathrm{C_0}(\mathbb{R}_+, F)$ have both the WvN–property.*

Proof. Let D be a stable hereditary σ-unital C^*-subalgebra of $F \otimes \mathbb{K}$ (respectively of $E \otimes \mathbb{K}$).

It is not difficult to see that such D have the property that we can find, for given $\eta > 0$, $f_1, \ldots, f_n \in D$ and $m \in \mathbb{N}$, isometries $s_1, \ldots, s_m$ in the multiplier algebra $\mathcal{M}(D)$ of D such that $\|[s_i, f_j]\| < \eta$ and $s_k^* s_i = \delta_{i,k}$ for $j = 1, \ldots, n$, $i, k = 1, \ldots, m$.

To see this, e.g. for $D \subseteq E \otimes \mathbb{K}$, one can at first show that the unital *-monomorphisms $b \mapsto 1 \otimes b$ and $b \mapsto 1 \otimes b$ from $\mathcal{O}_\infty$ to $\mathcal{O}_\infty \otimes \mathcal{O}_\infty$ are homotopic in $\mathcal{O}_\infty \otimes \mathcal{O}_\infty$. This can be seen by examination of finite subsets $t_1, \ldots, t_n$ of the generators of $\mathcal{O}_\infty$ by Theorem E, [**172**] and Künneth theorem applied to $\mathrm{K}_*(\mathcal{O}_\infty \otimes \mathcal{O}_\infty)$.

This can be used to show that there is a unital copy of $\mathcal{O}_\infty$ in the multiplier algebra of $(F \otimes \mathbb{K})_\omega$ (respectively of $\mathrm{Q}(\mathbb{R}_+, F \otimes \mathbb{K})$) that commutes with D. Since D is hereditary, we get such a copy of $\mathcal{O}_\infty$ also in $\mathcal{M}(D_\omega)$.

Let $C \subseteq \mathcal{M}(D)$ and suppose that $V \colon C \to D$ is residually nuclear. By Corollary 3.10.6, for $1 > \varepsilon > 0$ and $c_1, \ldots, c_n \in C$, there exist $d_1, \ldots, d_m \in D$ such that $\|V(c_j) - \sum d_i^* c_j d_i\| < \varepsilon/3$ for $j = 1, \ldots, n$.

Let $\gamma := 1 + \|\sum d_i^* d_i\| + \max\{\|c_j\|\}^2$ and $\eta := \varepsilon/(3m^2\gamma)$.

There is a contraction $e \in D_+$ with $\|ed_i - d_i\| < \eta$ for $i = 1, \ldots, m$. We find isometries $s_1, \ldots, s_m$ in the multiplier algebra of D such that $\|[s_i, ec_je]\| < \eta$ and $s_k^* s_i = \delta_{i,k}$ for $j = 1, \ldots, n$, $i, k = 1, \ldots, m$. Then $\|V(c_j) - d^* c_j d\| < \varepsilon$ for $d := e \sum s_i d_i$, $j = 1, \ldots, n$. □

11. More on strongly purely infinite algebras

The following remarks give an outline of some of the results of joint work with M. Rørdam and E. Blanchard on purely infinite algebras. See also end of Chapter 2.

REMARK 3.11.1. Let (A_n) be a sequence of unital C^*-algebras that contain a copy of $\mathcal{O}_\infty$ unitally.

Let $F := B \otimes A_1 \otimes A_2 \otimes \ldots$, then the same arguments as in the proof of Proposition 3.10.15 show that F, F_ω and $\mathrm{Q}(\mathbb{R}_+, F)$ have the WvN–property. An approximately commuting copy of $\mathcal{O}_\infty$ can also be used to show that F, F_ω and $\mathrm{Q}(\mathbb{R}_+, F)$ are strongly purely infinite.

Since in the middle of Chapter 10 we finish the proof of Theorem B, we can then use Corollary H and see from Proposition 3.10.15 and its proof that $B \otimes \mathcal{O}_\infty$ always has the WvN–property and is strongly purely infinite. This yields a proof that $B \otimes C$ has the WvN–property and is strongly purely infinite if C is a simple purely infinite separable nuclear C^*-algebra.

Conversely, $B \cong B \otimes \mathcal{O}_\infty$ if B has the WvN–property and is separable, stable and nuclear, by Corollary 10.3.8.

It is an open question whether or not (non-simple) purely infinite separable stable *nuclear* C^*-algebras B tensorial absorb $\mathcal{O}_\infty$. (It is the case if and only if B is s.p.i.).

Lemma 3.2.22 shows, that $\mathrm{C}(X, D)$ has the WvN–property for compact X and simple purely infinite D.

REMARK 3.11.2. *A stable C^*-algebra D has the WvN–property, if for every separable subalgebra A of the ultrapower D_ω of D, every approximately inner completely positive contraction $V \colon A \to D_\omega$ into a commutative subalgebra $C^*(V(A))$ of D_ω is 1-step approximately inner.*

PROOF. The following observations (1)–(6) together prove the sufficiency criterium for the WvN-property:

(1) The assumption immediately implies that D_ω is purely infinite, by the argument in Definition 1.2.3.

(2) This implies that D is purely infinite.

(3) For every separable C^*-subalgebra A of the ultrapower D_ω of a p.i. algebra D and every separable commutative C^*-subalgebra C of A there is a completely positive residually nuclear contraction V from A into a commutative C^*-subalgebra $C^*(V(A))$ of D_ω, such that $V|C = \mathrm{id}\,|C$. (see [**443**], compare also Lemma 12.1.6 for the first step in this direction, and use the semigroup structure argument of the proof of Lemma 12.1.6).

(4) The set C_A of approximately inner completely positive contractions $V\colon A \to D_\omega$ with commutative $C^*(V(A))$ is closed under Cuntz addition (see Chapter 4 or the remark before Corollary 3.10.8), and, therefore, by the observation (3) and the below given generalization of Lemma 3.2.7, C_A generates a dense subset of the convex set X of the residually nuclear completely positive contractions from A into D_ω, where one gets X if one applies to the set C_A only Cuntz addition and the operations in part (OC2) of Definition 3.2.2.

(5) The set of 1-step approximately inner completely positive maps is stable under point-norm limits and under the operations in part (OC2) of Definition 3.2.2, and, therefore, the assumptions and observation (4) together imply that all residually nuclear completely positive maps from A into D_ω are 1-step approximately inner.

(6) Stable D (and moreover D_ω) has the WvN–property if, for every separable C^*-subalgebra A of D_ω, every residually nuclear completely positive contraction V from A into D_ω is 1-step approximately inner:
if C is a separable C^*-subalgebra of $\mathcal{M}(D)$ and $V\colon C \to D$ is a residually nuclear completely positive contraction, then V is approximately inner by Corollary 3.10.6(I). If we use a suitable, approximately with C commuting, approximate unit e_n of D, we get a contraction $e \in (D_\omega)_+$ with $ec = ce$ for $c \in C$ and an approximately inner completely positive contraction $W\colon A \to D_\omega$ from the C^*-subalgebra A of D_ω, which is generated by $\{e^n c\colon c \in C, n \in \mathbb{N}\}$, such that $V(c) = W(a^n c)$ for $c \in C$ and $n \in \mathbb{N}$. The residual nuclearity of V then implies the residual nuclearity of W, see Proposition 2.12.8 for a step in this direction. If (d_k) is a sequence of contractions in D_ω such that $d_k^*(.)d_k$ converges to W in point norm, then one can pick up from the representing sequences $(e_n d_{kn})$ of ed_k elements f_m such that $f_m^* c f_m$ converges to $V(c)$ for every $c \in C$. □

A generalization of the sixth observation shows that D_ω has the WvN–property if every approximately inner map is

locally 1-step approximately inner.

Since D_ω has residually nuclear separation in the sense of Definition 1.2.3, it follows that D_ω is strongly purely infinite.

Therefore, D is strongly purely infinite if, for every separable C^*-subalgebra A of D_ω, every residually nuclear contraction $V: A \to D_\omega$ is 1-step approximately inner.

We replace the assumption of Lemma 3.2.7 and its conclusion in the following manner to get a generalization of Lemma 3.2.7 :

We suppose that $A \subseteq \mathcal{M}(B)$ and replace the assumption of Lemma 3.2.7 by the following *strict non-degeneracy* criteria where $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ denotes a point-norm closed m.o.c. cone:

Property (OC-snd):
Let $A \subseteq \mathcal{M}(B)$. Consider the following property of a subset $\mathcal{C} \subseteq \mathrm{CP}(A, B)$:

For every $a \in A_+ \subseteq \mathcal{M}(B)_+$, and every $b \in B_+$ with the property that

$$\|b + J\| \leq \|a + \mathcal{M}(B, J)\|$$

holds for every closed ideal J of B, there exists for every $\varepsilon > 0$ a c.p. contraction $T \in \mathcal{C}$, that satisfies $\|T(a) - b\| < \varepsilon$ and has the property that $T(A \cap \mathcal{M}(B, J)) \subseteq J$ for every closed ideal J of B.

If $A \cdot B$ is dense in B and $\mathcal{C}$ contains all inner c.p. maps $a \mapsto c^*ac$ with $c \in B$, then condition (OC-snd) is satisfied:

Indeed, if $\|b+J\| \leq \|a+\mathcal{M}(B, J)\|$ for all $J \in \mathcal{I}(B)$, then $b \in J_0 := \overline{\mathrm{span}(BaB)}$, because $a \in \mathcal{M}(B, J_0)$.

Thus, for given $\varepsilon \in (0, 1)$, let $\gamma := \gamma(\varepsilon) := (2\|b\|^{1/2} + 1)^{-1}\varepsilon$ there are $c_1, \ldots, c_n, d_1, \ldots, d_n \in B$ with $\|b^{1/2} - e\| < \gamma$ for $e := \sum_k d_k a^{1/2} c_k$. This implies $\|b - e^*e\| < \varepsilon$.

Notice that

$$e = [d_1, \ldots, d_n] \cdot \mathrm{diag}(a, \ldots, a)^{1/2} \cdot [c_1, \ldots, c_n]^\top .$$

Therefore,

$$e^*e \leq \| \sum_k d_k d_k^* \| \cdot \sum_k c_k^* a c_k .$$

It follows that there is $f \in B$ such that $V(a) := \sum_k (c_k f)^* a (c_k f)$ satisfies $(b-\varepsilon)_+ = V(a)$.

The question is, if property (OC-snd) also implies that $\mathcal{C}$ contains all c.p. maps $V(a) := c^*ac$ with $c \in B$. This *seems to be* the case if $A \subseteq \mathcal{M}(B)$, A is *exact* and B is *weakly injective*.

But it would be sufficient that B has residual nuclear separation and $\mathrm{CP}_{\mathrm{nuc}}(A, B) \subseteq \mathcal{C}$.

We would get that $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ satisfies property (OC-snd) in case $A \subseteq \mathcal{M}(B)$, if and only if, $\mathrm{CP}_{\mathrm{nuc}}(A, B) \subseteq \mathcal{C}$.

Modified version of Lemma 3.2.7:
If $A \subseteq \mathcal{M}(B)$ satisfies (OC-snd), and if $\Psi_A(J) = A \cap \mathcal{M}(B, J)$ denotes the l.s.c. action of $\mathrm{Prim}(B)$ *on A, then every Ψ-residually nuclear contraction $V\colon A \to B$ can be approximated in point norm by contractions in $\mathcal{C} :=$* $\mathrm{CP}_{\mathrm{in}}(A, B)$.

The proof is similar to the proof of Lemma 3.2.7. But one has to use the arguments in the proof of Lemma 3.10.3 and of Proposition 3.10.4. In fact, it is easier to use Stinespring-Kasparov dilation directly. Then, by (OC1), (OC2) and (OC-snd), for an residually nuclear contraction $V\colon A \to B$, one finds a σ-unital hereditary subalgebra $E \subseteq B$ and a *-monomorphism $h\colon A \hookrightarrow \mathcal{M}(E \otimes \mathbb{K})$ such that $A \cup V(A) \subseteq E$, and, for every contraction $d \in E \otimes \mathbb{K}$, $(1 \otimes p_{11})d^* h(.)d(1 \otimes p_{11})$ is of form $T(\cdot) \otimes p_{11}$ for some

`approximately inner???`

T

`in the point norm closure of` $K =$?????,

and $h(A \cap J) = h(A) \cap \mathcal{M}(E \otimes \mathbb{K}, J \otimes \mathbb{K})$ for every closed ideal J of E. Moreover, we can replace h by its infinite repeat $\delta_\infty \circ h$. Thus, we may assume that $h(A)' \cap \mathcal{M}(E \otimes \mathbb{K})$ contains a copy of $\mathcal{O}_2$ unitally.

Now we are in position to apply Corollary 3.10.6(II) on A, h and $a \in A \mapsto V(a) \otimes p_{11}$ to get a proof of the above given generalization of Lemma 3.2.7.

The general idea of the application of the above modified Lemma 3.2.7 is the following observation:

Suppose that, for every separable C^*-subalgebra A of the ultrapower $B = D_\omega$ of a stable σ-unital C^*-algebra D, there exists a set $\mathcal{S}$ of 1-step approximately inner completely positive contractions $V\colon A \to B$ into commutative C^*-subalgebras of B, such that $\mathcal{S}$ is closed under Cuntz addition, and for every $a \in A_+$ there exist V in $\mathcal{S}$ and $d \in B$ such that $\|a - d^* V(a) d\| < 1$.

Then, by the *modified version* of Lemma 3.2.7, every residually nuclear $T\colon A \to B$ is 1-step approximately inner.

As we have seen above, this implies that D and its ultrapower D_ω have the WvN–property and are strongly p.i.

The above given third, fourth and fifth observations also show that the modified version of Lemma 3.2.7 yields the following result:

Suppose that A is a separable C^*-subalgebra of D_ω, and that for every residually nuclear contraction $V\colon A \to D_\omega$ with commutative image $C^*(V(A))$, there is a sequence of contractions $d_n \in D_\omega$ such that, for $a \in A_+$ and $k > 0$,

$$\begin{aligned} \lim d_n^* a d_n &= V(a), \qquad \text{and} \\ \lim d_n^* a d_{n+k} &= 0. \end{aligned}$$

Then such a sequence (d_n) exists also for every *residually nuclear contractions $V\colon A \to D_\omega$ with non-commutative image $V(A)$.*

Note that, with help of a countable approximate unit of A, we can modify the sequence d_n such that it also satisfies $\lim d_n^* d_{n+k} = 0$ for $k > 0$.

Proof. Consider the set I_A of all contractions $V : A \to D_\omega$ such that there exist a sequence d_n with the above properties.

It is easy to see, that the operations (OC2) in Definition 3.2.2 let I_A invariant.

The assumption says that C_A of the above fourth observation is contained in I_A.

By the third and fourth observation, the smallest subset of I_A, that contains C_A and is invariant under the operations (OC2) in Definition 3.2.2, satisfies the assumptions of the above given modified version of Lemma 3.2.7.

It is not very hard to check that I_A is closed under point norm limits. Thus, by the modified version of Lemma 3.2.7, every residually nuclear contraction V from A into D_ω is in I_A. □

FIND END OF NEXT REMARK !!!

Remark 3.11.3. We list here some later needed properties of strongly purely infinite C^*–algebras. (See [**463**] for details of the here outlined proofs.)

In the following let $[x, y]$ denote the commutator $xy - yx$.

Suppose that A is strongly purely infinite.

Let $b, a_1, \ldots, a_n \in A_+$ *commuting* elements, $c \in A_+$, $F := [f_{jk}] \in M_m(A)_+$ a positive $m \times m$ matrix, and let $\varepsilon > 0$.

(i) A_ω and $A \otimes \mathbb{K}$ are strongly purely infinite.
    Every quotient and every hereditary C^*-subalgebra of A is strongly purely infinite.
(ii) There exist contractions $d_1, \ldots, d_m \in A$, such that

$$\| D^* F D - \operatorname{diag}(f_{11}, \ldots, f_{mm}) \| < \varepsilon \,,$$

where $D := \operatorname{diag}(d_1, \ldots, d_m)$.
(iii) There exist contractions $v_1, v_2 \in A$ with
$\|[v_i, a_k]\| < \varepsilon$ and $\|v_i^* b v_j - \delta_{i,j} b\| < \varepsilon$ for $i, j \in \{1, 2\}$, $k = 1, \ldots, n$.
(iv) There exist contractions $s_1, s_2 \in A$ with
$\|s_i^* a_k s_i - a_k\| < \varepsilon$, $\|[s_i, a_k]\| < \varepsilon$, $\|s_1^* s_2\| < \varepsilon$, $\|s_1^* c s_2\| < \varepsilon$, and $\|[s_i^* c s_i, a_k]\| < \varepsilon$, for $i = 1, 2$, $k = 1, \ldots, n$.

Property (ii) is an inductive repeat of the defining property of 'strongly p.i.' in Definition 1.2.2. (ii) implies (iii) and (iv). The proof of this implication is not trivial. It uses appropriate decompositions of the unit of the unitization of $C^*(a_1, \ldots, a_n, b)$ respectively of $C^*(a_1, \ldots, a_n)$, to translate (iii) and (iv) to problems, which are solvable by property (ii). The proofs can be found in [**463**].

It follows from [**463**] that p.i. algebras with (iii) and (iv) have the WvN-property of Definition 1.2.3.

In fact we show that properties (iii) and (iv), applied to the strongly p.i. algebra A_ω, yield the following stronger results (v)-(vii).

Suppose that A is strongly p.i., that C is a separable commutative C^*-subalgebra of A_ω, that B is a separable C^*-subalgebra of A_ω, and that V is a residually nuclear contraction from B into C. Then:

(v) There is a *-monomorphism h from $C\otimes\mathcal{O}_\infty$ into A_ω with $h((.)\otimes 1) = \mathrm{id}\,|C$,
(vi) For pairwise commuting $a_1,\ldots,a_n \in (A_\omega)_+$, arbitrary $y_1,\ldots,y_m \in A_\omega$ and $\varepsilon > 0$, there is a contraction $d \in A_\omega$, such that $\|d^*a_id - a_i\| < \varepsilon$ for $1 \le i \le n$ and that $\{d^*a_1d,\ldots,d^*a_nd, d^*y_1d,\ldots,d^*y_md\}$ generates a commutative C^*-subalgebra of A_ω.
(vii) There is a sequence of contractions $d_n \in A_\omega$ with $\lim d_n^*bd_n = V(b)$ and $\lim d_n^*bd_{n+k} = \{0\}$ for $b \in B$, $k > 0$.

Here (vii) follows from (v) and (vi).

Now we can apply the ideas of Remark 3.11.2:

In [**463**] it is shown that for a C^*-algebra A the following properties (1)–(4) and (8) are equivalent. The equivalence of (1) and (5)–(7) follows from [**443**] and the results of Chapter 7.

(1) *A is strongly purely infinite in the sense of Definition 1.2.2.*
(2) *The ultrapower A_ω of A is strongly purely infinite.*
(3) *A admits no non-zero character, and, for every separable C^*-subalgebra B of A_ω and every approximately inner completely positive contraction $V\colon B \to A_\omega$ into a commutative C^*-subalgebra C of A_ω there is a contraction $d \in A_\omega$ with $V(b) = d^*bd$ for $b \in B$.*
(4) *For every residually nuclear contraction V from a separable C^*-subalgebra C of A_ω into A_ω there is a sequence of contractions $d_n \in A_\omega$ with $d_n^*cd_n = V(c)$ for $c \in C$, $d_m^*d_n = 0$, and $d_m^*Cd_n = \{0\}$ for $m \ne n$, $m,n = 1,2,\ldots$.*
(5) *The asymptotic corona $\mathrm{Q}(\mathbb{R}_+,A)$ of A is strongly purely infinite.*
(6) $\mathrm{Q}(\mathbb{R}_+,A)$ *has the WvN-property of Definition 1.2.3.*
(7) *A admits no non-zero character, and for every* separable *C^*-subalgebra B of $\mathrm{Q}(\mathbb{R}_+,A)$ the following property holds:*

Let $t \in \mathbb{R}_+ \mapsto V(t)$ a strongly continuous map from $\mathbb{R}_+$ into the approximately inner completely positive contractions from A into A and let T the completely positive contraction from $\mathrm{Q}(\mathbb{R}_+,A)$ into $\mathrm{Q}(\mathbb{R}_+,A)$ given by

$$T(a + \mathrm{C}_0(\mathbb{R}_+,A)) := V(a) + \mathrm{C}_0(\mathbb{R}_+,A)\,,$$

where $a \in \mathrm{C_b}(\mathbb{R}_+,A)$ and $V(a)(t) := V(t)(a(t))\,.$

The property of A in question is:

If $T|B$ is residually nuclear, then there exists a contraction $d \in \mathrm{Q}(\mathbb{R}_+,A)$ such that $T(b) = d^*bd$ for $b \in B$.
(8) *For every $a,b \in A_+$ and $\varepsilon > 0$ there exist* contractions *$s,t \in A$ such that $\|a^2 - s^*a^2s\|$, $\|b^2 - t^*b^2t\|$ and $\|s^*abt\|$ are all less than ε.*

The property in (8) implies that *the class of strongly purely infinite algebras is closed under inductive limits.*

REMARK 3.11.4. Propositions 3.2.13 and 3.2.15 are used to prove a Weyl-von Neumann–Voiculescu type theorem in Chapter 5 and its asymptotic version in Chapter 7.

The reader can observe that our proofs of Propositions 3.2.13 and 3.2.15 works also in the following more general and non-simple case:

Suppose that D is σ-unital, stable and strongly purely infinite, and that for every separable C^*-subalgebra A of D there exists a *-monomorphism $h\colon A \hookrightarrow \mathcal{M}(D)$, such that:

(1) $h(A \cap J) = h(A) \cap \mathcal{M}(D, J)$, and
(2) $[h]_J\colon A/(A \cap J) \to \mathcal{M}(D/J)$ is weakly nuclear for every closed ideal J of D.
(3) The closures of DKD and $Dh(K)D$ in D coincide for every closed ideal K of A.
(4) For every sequence Ω_n of compact subsets of A, and for every approximately commutative unit of D for $h(A)$ with $e_n e_{n+1} = e_n$, there exists a sequence f_n of contractions in D such that $\|f_n^* a f_n - e_n h(a) e_n\| < 2^{-n}$, $\|f_n^* a f_{n+k}\| < 2^{-n}$ and $\|f_n^* f_{n+k}\| < 2^{-n}$ for $a \in \Omega_n$, $k > 0$.

From Corollary 3.10.6(I) we get, that if we assume (1) and (2), then (3) is equivalent to:

(3') $Dh(A)D$ is dense in DAD.

It follows from a result with M. Rørdam [**463**] that the property (4) in Remark 3.11.3 implies, that a σ-unital stable purely infinite C^*-algebra D has residually nuclear separation in the sense of definition 1.2.3, if and only if, for every separable C^*-subalgebra $A \subseteq D$, there exists a *-monomorphism $h\colon A \hookrightarrow \mathcal{M}(D)$ with properties (1)-(4) of Remark 3.11.4.

The modifications in the assumptions of Propositions 3.2.13 and 3.2.15 are then: B is σ-unital, $D \subseteq \mathcal{M}(B)$ with $D \cdot B$ dense in B, and D has the above considered property.

In the general version of Proposition 3.2.13, C has to be a separable C^*-subalgebra of $\mathcal{M}(D) \subseteq \mathcal{M}(B)$, and $V\colon C \to B$ is a completely positive contraction such that $V(\Psi^{\mathrm{up}}_{D,C}(J)) \subseteq \Psi^{D,B}_{\mathrm{down}}(J)$ and $[V]\colon C/\Psi^{\mathrm{up}}_{D,C}(J) \to B/\Psi^{D,B}_{\mathrm{down}}(J)$ is nuclear for every closed ideal $J \subseteq D$. See the last part of the introduction or the proof of Corollary 3.10.14 for the definition of the Ψ's.

In the modified version of Proposition 3.2.15, C has to be a separable C^*-subalgebra of $\mathrm{C_b}(X, D)$ and the point-norm continuous family of complete contractions V_y from D into B must consist of residually nuclear maps.

Note that (1)-(4) imply also the assumptions of Corollary 3.10.14.

PROPOSITION 3.11.5. *Let B a stable σ-unital strongly p.i. algebra, A a separable exact algebra, and $h\colon A \to \mathrm{Q}(B) := \mathcal{M}(B)/B$ a nuclear C^*-morphism. Then $A' \cap \mathrm{Q}(B)$ is strongly p.i.*

PROOF. ?? `to be filled in` □

REMARK 3.11.6. In [**462**], [**463**], [**92**], [**93**] and [**443**] it is shown, that p.i. algebras in several cases are strongly p.i. (and thus have the WvN–property). We list some related results:

(i) Locally purely infinite C^*-algebras of real rank zero are strongly purely infinite, cf. [**463**] and [**93**].

(ii) The algebra A of sections of a continuous field of C^*-algebras over a locally compact space is strongly purely infinite, if it is purely infinite and if the field has simple fibers. This is just the case where A is purely infinite and $\mathrm{Prim}(A)$ is Hausdorff. (Joint work with E. Blanchard, [**92**], [**93**].)

In particular, $\mathrm{C}_0(X, D)$ is strongly purely infinite, if D is simple and purely infinite.

(iii) $\mathrm{C}_0(X, D)$ is strongly purely infinite if D is strongly purely infinite and X is locally compact ([**443**]).

(iv) $\mathcal{M}(D)$ is strongly purely infinite if D is strongly purely infinite and σ-unital ([**443**]).

(v) Extension of strongly purely infinite algebras are strongly purely infinite ([**443**]).

It follows that $\mathrm{Q}(\mathbb{R}_+, B)$ is strongly purely infinite if B is strongly purely infinite.

12. Collection of some topics

`Next: from old proof of Proposition 3.6.1`

????? (i):

Let $J \triangleleft B$ and $C \subseteq \mathcal{M}(B)$ a C^*-subalgebra of $\mathcal{M}(B)$. Recall that $\Psi^{\mathrm{up}}_{B,C}(J) := C \cap \mathcal{M}(B, J)$, that $\mathcal{M}(B, J) := \{t \in \mathcal{M}(B)\,;\, tB + Bt \subseteq J\}$ is the same as the closure of $J \triangleleft B$ in the strict topology on $\mathcal{M}(B)$, and that every strictly closed ideal I of $\mathcal{M}(D)$ coincides with $\mathcal{M}(D, I \cap D)$.

Since DB and BD are dense in B (by assumption), we get that the natural unital *-monomorphism $\mathcal{M}(D) \hookrightarrow \mathcal{M}(B)$ is strictly continuous. Thus, $\mathcal{M}(B, J) \cap \mathcal{M}(D) = \mathcal{M}(D, D \cap \mathcal{M}(B, J))$ and $\Psi^{\mathrm{up}}_{B,C}(J) = \Psi^{\mathrm{up}}_{C,D}(K) =: \Psi_C(K)$ for $K := D \cap \mathcal{M}(B, J)$. The ideal $J_1 := \Psi_B(K) := \Psi^{D,B}_{\mathrm{down}}(K)$ of B is defined as the closure of $\mathrm{span}(BKB)$ and is contained in $B \cap \mathcal{M}(B, J) = J$. Indeed, $\mathrm{span}(BKB) \subseteq \mathcal{M}(B, J)$, because $K \subseteq \mathcal{M}(B, J)$.

$\Psi^{\mathrm{up}}_{D,B}(\Psi_D(I)) =$??????

something missing ???

Suppose that V is Ψ_C-Ψ_B–residually nuclear, and $J \in \mathcal{I}(B)$. Let $K := \Psi^{\mathrm{up}}_{B,D}(J)$. Then $L := \Psi_C(K) = \Psi^{\mathrm{up}}_{B,C}(J)$ by Lemma 3.6.2(ii).

Thus, $V(L) = V(\Psi_C(K)) \subseteq \Psi_B(K)$, and $[V] \colon C/\Psi_C(K) \to B/\Psi_B(K)$ is nuclear. Since $\Psi_B(K) \subseteq J$ (by Lemma 3.6.2(iv)), it follows that $V(\Psi^{\mathrm{up}}_{B,C}(J)) \subseteq J$, and that $[V]_J \colon C/\Psi^{\mathrm{up}}_{B,C}(J) \to B/J$ is nuclear. Hence, V is $\Psi^{\mathrm{up}}_{B,C}$-residually nuclear.

Conversely, suppose that V is $\Psi^{\mathrm{up}}_{B,C}$–residually nuclear, and let $N \triangleleft D$. Consider the ideal $J := \Psi_B(N) := \overline{\mathrm{span}(BNB)}$. We get $N \subseteq K := D \cap \mathcal{M}(B,J)$ and $J = BNB \subseteq BKB \subseteq J$. Thus $\mathcal{M}(D,N) \subseteq \mathcal{M}(D,K) = \mathcal{M}(D) \cap \mathcal{M}(B,J)$ and $\Psi_C(N) \subseteq \Psi^{\mathrm{up}}_{B,C}(J)$.

Since $V(\Psi^{\mathrm{up}}_{B,C}(J)) \subseteq J$ and $[V]_J \colon C/\Psi^{\mathrm{up}}_{B,C}(J) \to B/J$ is nuclear, we get that $V(\Psi_C(N)) \subseteq J = \Psi_B(N)$ and $[V] = [V]_J \circ \pi \colon C/\Psi_C(N) \to B/J$ is nuclear, where $\pi \colon C/\Psi_C(N) \to C/\Psi^{\mathrm{up}}_{B,C}(J)$ is the natural epimorphism. Hence, V is Ψ_C-Ψ_B–residually nuclear.

End of old proof-parts. Missing somewhere? Remove above??

Used in Remark **??** and quoted to Chapter 3:

Suppose that B is strongly purely infinite. Then, for every finitely generated Abelian C-subalgebra $A \subseteq B_\omega$ with at most 1-dimensional maximal ideal space* $\mathrm{Prim}(A)$*, there exists a C*-morphism*

$$h \colon A \otimes \mathcal{O}_\infty \to B_\omega \quad \text{with} \quad h(a \otimes 1) = a \ \ \forall\, a \in B\,.$$

Overlap with Chp.3 Part 2 beginning here

Compare below with Section 7

See also begin of Section 8 for next:

There are proofs of some the following corollaries, that are more elementary than given below. But we want to invite the reader to use (and think about) the more conceptional ideas presented here. For the classification of stably finite algebras with non-trivial traces, one has to produce refined tools, that answer e.g. the more difficult question (by a *non-trivial* and *applicable* answer):

When there is a given completely positive map V in a given cone $\mathcal{C}$ of completely positive maps $\mathcal{C} \subseteq \mathrm{CP}(A,B)$ that are compatible with a given map $T(B) \to T(A)$?

Here $T(B)$ means the set of lower semi-continuous (unbounded) 2-quasi-traces $\tau \colon B_+ \to [0\infty]$. Our results together contain an answer in a special case where $\tau(B_+) \subseteq \{0,\infty\}$ for all $\tau \in T(B)$, because then the problem reduces to the study of $\mathrm{CP}_{\mathrm{nuc}}(\Psi;\, A, B)$ for a lower semi-continuous action $\Psi \colon \mathcal{I}(B) \cong \mathbb{O}(\mathrm{Prim})(B) \to \mathcal{I}(A)$, if we identify a $\{0,\infty\}$-valued lower semi-continuous 2-quasi-trace $\tau \colon B_+ \to [0,\infty]$ by its kernel $J := \mathrm{span}\{a \in B_+\,;\ \tau(a) = 0\}$.

Compare for next Def. also Def. 3.8.1

DEFINITION 3.12.1. Let $\mathcal{S} \subseteq \mathrm{CP}(A, B)$.

We define $\Psi_{\mathcal{S}}(J)_+$ as the set of $a \in A_+$ with $V(\exp(-ih)a\exp(ih)) \in J$ for all $h^* = h \in A$ with $\|h\| < \pi$ and for all $V \in \mathcal{S}$. Then $\Psi_{\mathcal{S}}(J)_+$ is the positive part of a closed ideal $\Psi_{\mathcal{S}}(J)$ of A, and

$$\Psi_{\mathcal{S}} \colon \mathcal{I}(B) \cong \mathbb{O}(\mathrm{Prim}(B)) \to \mathcal{I}(A)$$

is a lower semi-continuous action of $\mathrm{Prim}(B)$ on A, cf. Lemma 3.12.2(iv).

Let I a closed ideal of A. We denote by $\Psi^{\mathcal{S}}(I))$ the smallest closed ideal of B that is contains $\{V(a)\,;\; a \in I, V \in \mathcal{S}\}$. The map

$$\Psi^{\mathcal{S}} \colon \mathcal{I}(A) \cong \mathbb{O}(\mathrm{Prim}(A)) \to \mathcal{I}(B)$$

is an upper semi-continuous action, cf. Lemma 3.12.2(xii).

Let X a topological space, and let $\Psi_A \colon \mathbb{O}(X) \to \mathcal{I}(A)$ and $\Psi_B \colon \mathbb{O}(X) \to \mathcal{I}(B)$ increasing maps, i.e., *actions* of X on A and B. We define the **cone of Ψ-equivariant c.p. maps** as the set $\mathcal{C}_\Psi := \mathrm{CP}(\Psi_A, \Psi_B; A, B) \subseteq \mathrm{CP}(A, B)$ of maps $V \in \mathrm{CP}(A, B)$ with $V(\Psi_A(U)) \subseteq \Psi_B(U)$ for all open subsets $U \subseteq X$. In the special case, where $X := \mathrm{Prim}(B)$ and $\Psi_B \colon \mathbb{O}(\mathrm{Prim}(B)) \to \mathcal{I}(B)$ is given by the natural identification of the open subsets U of $\mathrm{Prim}(B)$ with the corresponding closed ideal J_U of B, where J_U denotes the intersection of all primitive ideals $I \in \mathrm{Prim}(B) \setminus U$, we write $\Psi := \Psi_A$ and drop Ψ_B, i.e., write $\mathcal{C}_\Psi := \mathrm{CP}(\Psi; A, B) \subseteq \mathrm{CP}(A, B)$ for $\Psi \colon \mathbb{O}(\mathrm{Prim}(B)) \to \mathcal{I}(A)$.

The use of the notation $\mathcal{C}_\Psi$, in place of $\mathcal{C}_{\Psi_A, \Psi_B}$, becomes justified in a different way in part (i) of Lemma 3.12.2.

PROOF. (iv): Let J a closed ideal of B and $T \colon A \to B$ a positive map. The set of $a \in A_+$ with $(\pi_J \circ T)(a) = 0$ is a *hereditary* closed convex sub-cone $C_{T,J}$ of A_+. Thus, the set $C_{\mathcal{S},J}$ of $a \in A_+$ with $T(a) \in J$ for all $T \in \mathcal{S}$ is a hereditary closed convex sub-cone of A_+, and $\Psi_{\mathcal{S}}(J)_+ \subseteq A_+$ of Definition 3.12.1 is the set of $a \in A_+$ with $\exp(ih)a\exp(-ih) \in C_{\mathcal{S},J}$. By Lemma **??**, $\Psi_{\mathcal{S}}(J)_+$ is the positive part of a closed ideal $\Psi_{\mathcal{S}}(J)$ of A. Clearly, $\Psi_{\mathcal{S}}(B) = A$, and $V(\Psi_{\mathcal{S}}(J)_+) \subseteq J$ for $J \in \mathcal{I}(B)$ and $V \in \mathcal{S}$, by definition of $\Psi_{\mathcal{S}}$.

If $\{J_\sigma\}_{\sigma \in \Sigma}$ is a family of closed ideals and $a \in A_+$ and let $J := \bigcap_\sigma J_\sigma$. then $V(\exp(ih)a\exp(-ih)) \in J$ for all $V \in \mathcal{S}$ and $h^* = h \in A$ with $\|h\| < \pi$, if and only if, $V(\exp(ih)a\exp(-ih)) \in J_\sigma$ for all $V \in \mathcal{S}$ and $h^* = h \in A$ with $\|h\| < \pi$, i.e., $a \in \Psi_{\mathcal{S}}(J)_+$ if and only if $a \in \bigcap_\sigma \Psi_{\mathcal{S}}(J_\sigma)_+ = (\bigcap_\sigma \Psi_{\mathcal{S}}(J_\sigma))_+$. Thus,

$$\Psi_{\mathcal{S}} \colon \mathbb{O}(\mathrm{Prim}(B)) \cong \mathcal{I}(B) \ni J \mapsto \Psi_{\mathcal{S}}(J) \in \mathcal{I}(A)$$

is a lower semi-continuous map. The lower semi-continuity of the map $\Psi_{\mathcal{S}}$ implies that $\Psi_{\mathcal{S}}$ is monotone. Thus, $\Psi_{\mathcal{S}}$ is a lower s.c. action of $\mathrm{Prim}(B)$ on A.

(vii): Since $\Psi_B(U)$ is a closed ideal, the set of maps $V \in \mathrm{CP}(A, B)$ with $V(a) \in \Psi_B(U)$ for all $a \in \Psi_A(U)$ is point-norm closed. Thus, $\mathcal{C}_\Psi$ is point-norm closed. Similar arguments show:

Let $V_1, V_2 \in \mathrm{CP}(A,B)$ with $V_k(\Psi_A(U)) \subseteq \Psi_B(U)$ for all $U \in \mathbb{O}(X)$ $(k=1,2)$, $t \in [0,\infty)$, and $r \in M_{1,n}(A)$, $c \in M_{n,1}(B)$. Then $(V_1 + tV_2)(a) \in \Psi_B(U)$ and $c^*(V_1 \otimes \mathrm{id}_n)(r^*ar)c \in \Psi_B(U)$ for $U \in \mathbb{O}(X)$ and $a \in \Psi_A(U)$. Thus $\mathcal{C}_\Psi$ is a point-norm closed matrix operator convex cone of c.p. maps.

(i): If we use the natural isomorphisms $\mathcal{I}(A) \cong \mathbb{O}(\mathrm{Prim}(A))$ and $\mathcal{I}(B) \cong \mathbb{O}(\mathrm{Prim}(B))$, and Lemma **??**, then we get that there is a minimal lower semi-continuous action $\Psi' \colon \mathbb{O}(\mathrm{Prim}(B)) \to \mathcal{I}(A)$ with $\Psi'(\Psi_B(U)) \supset \Psi_A(U)$.

If $V \in \mathcal{C}_{\Psi'}$, then $V(\Psi_A(U)) \subseteq V(\Psi'(\Psi_B(U))) \subseteq \Psi_B(U)$ for $U \in \mathbb{O}(X)$, because $\Psi_A(U) \subseteq \Psi'(\Psi_B(U))$. Thus, $\mathcal{C}_{\Psi'} \subseteq \mathcal{C}_\Psi = \mathcal{C}_{\Psi_A,\Psi_B}$.

Let $\mathcal{S} := \mathcal{C}_\Psi$, then $\Psi_{\mathcal{S}} \colon \mathcal{I}(B) \cong \mathbb{O}(\mathrm{Prim}(B)) \to \mathcal{I}(A)$ is a lower semi-continuous action by part (iv) with $V(\Psi_{\mathcal{S}}(J)) \subseteq J$ for all $V \in \mathcal{S}$.

We have $\Psi_{\mathcal{S}}(\Psi_B(U))_+ \supset \Psi_A(U)_+$ for $U \in \mathbb{O}(X)$, because $V(e{-}ihae^{ih}) \in \Psi_B(U)$ for $a \in \Psi_A(U)_+$ and $h^* = h \in A$. Thus, $\Psi_{\mathcal{S}}(J) \supset \Psi'(J)$ for every $J \in \mathcal{I}(B)$ by minimality of Ψ'. It implies that $V(\Psi'(J)) \subseteq V(\Psi_{\mathcal{S}}(J)) \subseteq J$, i.e., $V \in \mathcal{C}_{\Psi'}$, for all $V \in \mathcal{C}_\Psi = \mathcal{C}_{\Psi_A,\Psi_B}$.

(ii): The point-norm closure $\mathcal{C}$ of a matrix operator-convex cone $\mathcal{C}_0$ is a matrix operator-convex cone, because the topology of point-norm convergence on $\mathcal{L}(A,B)$ coincides with the strong operator topology, and because $V_\alpha \otimes \mathrm{id}_n$ converges in point-norm to $V \otimes \mathrm{id}_n$ if $V_\alpha \in \mathcal{C}_0$ converges to V.

(iii): Let $n \in \mathbb{N}$ and let $\mathcal{C}^{(n)}$ denote the set of completely positive maps $W := \sum_k c_k^*(V_k \otimes \mathrm{id}_n)(r_k^*(\cdot)r_k)c_k$ with $V_k \in \mathcal{S}$, $r_k \in M_{1,n}(A)$ and $c_k \in M_{n,1}(B)$, and let $\mathcal{C}_0 = \bigcap_n \mathcal{C}^{(n)}$. Clearly, $\mathcal{C}^{(n)} \subseteq \mathcal{C}$ for every matrix operator-convex cone $\mathcal{C} \subseteq \mathrm{CP}(A,B)$ with $\mathcal{S} \subseteq \mathcal{C}$, and the set $\mathcal{C}^{(n)}$ is closed under multiplication with positive scalars and under addition.

Moreover, $c^*(W \otimes \mathrm{id}_m)(r^*(\cdot)r)c \in \mathcal{C}^{(mn)}$ if $W \in \mathcal{C}^{(n)}$, $r \in M_{1,m}(A)$ and $c \in M_{n,1}(B)$, because

$$c^*(W_k \otimes \mathrm{id}_m)(r^*(\cdot)r)c = C^*V_k \otimes \mathrm{id}_{mn}(R^*(\cdot)R)C$$

for $W_k := c_k^*(V_k \otimes \mathrm{id}_n)(r_k^*(\cdot)r_k)c_k$, $R = [R_1, \ldots, R_{mn}] \in M_{1,mn}(A)$ and $C = [C_1, \ldots, C_{mn}]^\top \in M_{mn,1}(B)$, where $R_{jm+y} := r_y r_j^{(k)}$ and $C_{jm+y} := c_j^{(k)} c_y$ with $r_k = [r_1^{(k)}, \ldots, r_n^{(k)}] \in M_{1,n}(A)$, $r = [r_1, \ldots, r_m] \in M_{1,m}(A)$, $c_k = [c_1^{(k)}, \ldots, c_n^{(k)}]^\top \in M_{n,1}(B)$, and $c = [c_1, \ldots, c_m]^\top \in M_{m,1}(B)$.

If we fill the rows $r_k \in M_{1,n}(A)$ and columns $c_k \in M_{n,1}(B)$ with zeros, then we see that $\mathcal{C}^{(n)} \subseteq \mathcal{C}^{(n+k)}$ for all $n, k \in \mathbb{N}$. Thus $\mathcal{C}_0 := \bigcup_n \mathcal{C}^{(n)}$ is a (not necessarily closed) matrix operator convex cone that is contained in every matrix operator convex cone $\mathcal{C}$ with $\mathcal{S} \subseteq \mathcal{C}$.

Since A has an approximate unit $\{e_\tau\}$ of positive contractions, we get $\|W\| = \|\sum_k c_k^* V_k(r_k^* r_k)c_k\|$ for $W \in \mathcal{C}_0$, and that every element $V \in \mathcal{S}$ is in the point-norm closure of $\mathcal{C}^{(1)} \subseteq \mathcal{C}_0$.

By part (ii), the point-norm closure $\mathcal{C}_1$ of $\mathcal{C}_0$ is a m.o.c. cone that contains $\mathcal{S}$. Since $\mathcal{C}_0$ is contained in every point-norm closed m.o.c. cone $\mathcal{C}$ with $\mathcal{S} \subseteq \mathcal{C}$, we get $\mathcal{C}(\mathcal{S}) = \mathcal{C}_1$. The contractions T in the point-norm closure of $\mathcal{C}_0$ can be approximated by contractions $W \in \mathcal{C}_0$ with $\|W\| \leq 1$ by Lemma 3.1.8.

(v): Since $\mathcal{S} \subseteq \mathcal{C}(\mathcal{S}) =: \mathcal{C}$, it holds $\Psi_{\mathcal{C}}(J) \subseteq \Psi_{\mathcal{S}}(J)$ for all $J \in \mathcal{I}(B)$, cf. part (vi).

If $a \in \Psi_{\mathcal{S}}(J)_+$ then $V(\exp(ih)a\exp(-ih)) \in J$ for all $h^* = h \in A$ with $\|h\| < \pi$ and for all $V \in \mathcal{S}$.

By part (iv), this implies that $c_\ell^* V(r_\ell^* \exp(ih)a\exp(-ih)r_k)c_k \in J$ for $V \in \mathcal{S}$, $h^* = h \in A$, $r_1, \ldots, r_n \in A$ and $c_1, \ldots, c_n \in B$. Thus, $W(\exp(ih)a\exp(-ih)) \in J$ for all $W \in \mathcal{C} := \mathcal{C}(\mathcal{S})$ and $h^* = h$ by part (iii), i.e., $a \in \Psi_{\mathcal{C}}(J)_+$, and $\Psi_{\mathcal{S}} = \Psi_{\mathcal{C}}$ for $\mathcal{C} := \mathcal{C}(\mathcal{S})$.

(vi): Straight from definition of $\Psi_{\mathcal{S}}$.

(viii): If $V \in \mathcal{C}_{\Psi_1}$ and $\Psi(J) \subseteq \Psi_1(J)$, then $V(\Psi(J)) \subseteq V(\Psi_1(J)) \subseteq J$. Thus, $V \in \mathcal{C}_\Psi$ if $\Psi(J) \subseteq \Psi_1(J)$ for all $J \in \mathcal{I}(B)$.

(ix): For $J \in \mathcal{I}(B)$ and $a \in \Psi_{\mathcal{C}}(J)$ holds $V(a) \in J$ for all $V \in \mathcal{C}$ by definition of $\Psi_{\mathcal{C}}$.

(x): Let $J \in \mathcal{I}(B)$, and let $a \in \Psi(J)_+ \subseteq A_+$, $V \in \mathcal{C}_\Psi$ and $h^* = h \in A$. Then $V(\exp(ih)a\exp(-ih)) \in J$ by definition of $\mathcal{C}_\Psi$, i.e., $a \in \Psi_{\mathcal{C}_\Psi}(J)_+$ by definition of $\Psi_{\mathcal{C}}$. Thus, $\Psi(J) \subseteq \Psi_{\mathcal{C}_\Psi}(J)$.

(xi): If $\{T_\gamma\}_{\gamma\in\Gamma} \subseteq \mathrm{CP}(A,B)$ is a (norm-)bounded net that converges in point-norm to $T \in \mathcal{L}(A,B)$, then $T \in \mathrm{CP}(A,B)$ and the net

$$\{T_\gamma \otimes^{\max} \mathrm{id}\}_{\gamma\in\Gamma} \subseteq \mathrm{CP}(A \otimes^{\max} D, B \otimes^{\max} D)$$

converges point-wise to $T_\gamma \otimes^{\max} \mathrm{id}$, because $A \odot D$ is dense in $A \otimes^{\max} D$. Thus, if $T_\gamma \otimes^{\max} \mathrm{id} \in \mathcal{C}'$ for all $\gamma \in \Gamma$, then $T \otimes^{\max} \mathrm{id} \in \mathcal{C}'$. Clearly, the set $\mathcal{C}$ of $T \in \mathrm{CP}(A,B)$ with $T \otimes^{\max} \mathrm{id} \in \mathcal{C}'$ is convex. If $T \otimes^{\max} \mathrm{id} \in \mathcal{C}'$, $r \in M_{1n}(A)$, $c \in M_{n1}(B)$, $e \in D_+$, then $R := r \otimes e \in M_{1n}(A \otimes D)$, $C := c \otimes e \in M_{n1}(B \otimes D)$, and

$$R^*((T \otimes^{\max} \mathrm{id}) \otimes (\mathrm{id}_n))(C^*(\cdot)C)R = T' \otimes^{\max} S_e$$

for $T' := r^*(T \otimes \mathrm{id}_n)(c(\cdot)c^*)r$ and $S_e(d) := e^2 d e^2$ $(d \in D)$. Since $\mathcal{C}'$ is matrix operator convex and is point-norm closed,it follows that $T' \otimes^{\max} \mathrm{id} \in \mathcal{C}'$. Thus, the set $\mathcal{C} \subseteq \mathrm{CP}(A,B)$ of $T \in \mathrm{CP}(A,B)$ with $T \otimes^{\max} \mathrm{id}_D \in \mathcal{C}'$ is a point-norm closed matrix operator convex cone.

(xii): The point-norm closure $\mathcal{C}_0 := \overline{\mathcal{C}}^{\mathrm{norm}}$ closure of $\mathcal{C}$ is a convex cone with $c^*(V \otimes \mathrm{id}_n)(r^*(\cdot)r)c \in \mathcal{C}_0$ for $r \in M_{n,1}(A)$, $c \in M_{1,n}(B)$ and $V \in \mathcal{C}_0$. Since the point-*strong closures of $\mathcal{C}$ and $\mathcal{C}_0$ in $\mathcal{L}(A,M)$ coincide, and since $V_\gamma \otimes \mathrm{id}_n \to W \otimes \mathrm{id}_n$ point-*strongly if $V_\gamma \to W$ point-*strongly , we obtain that the point-*strong closure $\overline{\mathcal{C}} \subseteq \mathcal{L}(A,M)$ is a convex cone that satisfies $c^*(W \otimes \mathrm{id}_n)(r^*(\cdot)r)c \in \mathcal{C}_0$ for $r \in M_{n,1}(A)$, $c \in M_{1,n}(B)$ and $W \in \overline{\mathcal{C}}$. The unit-ball of $M_n(B)$ is *-ultrastrongly dense in the unit-ball of $M_n(M)$ by Kaplansky density theorem ([**616**, Thm. 2.3.3]). Thus, for $c \in M_{1,n}(M)$ there exists a net $c_\gamma \in M_{1,n}(B)$ with $\|c_\gamma\| \leq \|c\|$ that *strongly converges to c. Thus, the point-*strong closure $\overline{\mathcal{C}}$ satisfies (OC2).

`check next argument` ??(xii) If $V_\gamma \in \overline{\mathcal{C}}$ converges in point-$\sigma(M, M_*)$ topology to $W \in \mathrm{Lin}(A, M)$, then $W(e^2) \geq 0$ for every $e \in A_+$. In particular, W is positive and bounded, thus $\limsup_\gamma \|V_\gamma(e^2)\| =: \mu < \infty$ by uniform boundedness theorem (Banach-Steinhaus). It implies that W is also in the point-$\sigma(M, M_*)$ closure of the convex set of $V \in \overline{\mathcal{C}}$ with $\|V\| \leq \mu$. An Hahn-Banach separation argument shows now that $W \in \overline{\mathcal{C}}$.

(xiii): $\Psi^{\mathcal{S}}(\overline{\sum_\gamma I_\gamma}) = \overline{\sum_\gamma \Psi^{\mathcal{S}}(I_\gamma)}$ and $a \in \Psi_{\mathcal{S}}(\Psi^{\mathcal{S}}(I))$ for $a \in I \triangleleft A$ follow straight from the definitions of $\Psi_{\mathcal{S}}$ and $\Psi^{\mathcal{S}}$. □

`Compare also Example 3.8.3!!!`

EXAMPLE 3.12.3. We consider the action $\Psi_{nuc} \colon \mathcal{I}(B) \to \mathcal{I}(A)$ defined by $\mathrm{CP}_{\mathrm{nuc}}(A, B)$ and examine some possible generating subsets $\mathcal{S}_0 \subseteq \mathrm{CP}(A, B)$ for $\mathrm{CP}_{\mathrm{nuc}}(A, B)$.

Let $S \subseteq A_+^*$ denote an "almost separating" set of positive functionals on A that is invariant under inner automorphisms of A, more precisely:
for each $a \in A_+$ there is $\varphi \in S$ and $h^* = h \in A$ with $\|h\| < \pi$ such that with $\varphi(\exp(ih)a\exp(-ih)) > 0$. For example we can take as S the set of pure states of A, or any set S of pure-states φ of A such that the family $\{d_\varphi\}_{\varphi \in S}$ of irreducible representations of A is separating for A.
Furthermore, let $P \subseteq B_+$ a set of positive elements of B that generates B as a closed ideal of B, i.e., for each $c \in B_+$ and $\varepsilon > 0$, there are $b_1, \ldots, b_n \in P$ and $d_1, \ldots, d_n \in B$ with $\|c - \sum_k d_k^* b_k d_k\| < \varepsilon$.

We consider the set of $\mathcal{S}_0 := \mathcal{S}_{S,P} \subseteq \mathrm{CP}(A, B)$ of c.p. maps $V_{\varphi,b}(a) := \varphi(a)b$, where $\varphi \in S$ and $b \in P$, and calculate the action $\Psi_0 \colon \mathcal{I}(B) \to \mathcal{I}(A)$ defined by $\mathcal{S}_0$: We have $\Psi_(\mathcal{S}_0)(B) = A$ by Lemma 3.12.2(iv). Let $J \neq B$ a close ideal of B. Then there is $b \in P$ that is not in J. If $0 \neq a \in A_+$ then there is $h^* = h \in A$ with $\|h\| < \pi$ and $\varphi \in S$ with $\varphi(\exp(ih)a\exp(-ih)) > 0$. It follows that $V_{\varphi,b}(\exp(ih)a\exp(-ih))$ is not contained in J.
Thus $\Psi_{\mathcal{S}_0}(J) = \{0\}$ for every closed ideal $J \neq B$ and $\Psi_{\mathcal{S}_0}(B) = A$.

Since $\mathcal{S}_0 \subseteq \mathrm{CP}_f(A, B) \subseteq \mathrm{CP}_{\mathrm{nuc}}(A, B) \subseteq \mathrm{CP}(A, B)$ we get $\Psi_{\mathrm{CP}(A,B)} = \Psi_{\mathrm{CP}_{\mathrm{nuc}}(A,B)}(J) \subseteq \Psi_{\mathcal{C}_0}(J)$ for all closed ideals J of B. Thus,

$$\Psi_{\mathrm{CP}(A,B)} = \Psi_{\mathrm{CP}_{\mathrm{nuc}}(A,B)} = \Psi_{\mathcal{S}_0}\,.$$

The special case where $A = B$ is not nuclear shows that,
in general, the lower semi-continuous action $\Psi_{\mathcal{C}} \colon \mathbb{O}(\mathrm{Prim}(B)) \to \mathcal{I}(A)$ defined by a m.o.c.c. $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ does identify $\mathcal{C}$ itself.

The situation of example 3.12.3 changes considerably if we consider, instead of $\Psi_{\mathcal{C}}$, the action $\Psi' \colon \mathcal{I}(B \otimes^{\max} C) \to \mathcal{I}(A \otimes^{\max} C)$ that is defined by the point-norm closed m.o.c.c. $\mathcal{C} \otimes^{\max} \mathrm{CP}_{\mathrm{in}}(C, C) \subseteq \mathrm{CP}(A \otimes^{\max} C, B \otimes^{\max} C)$, where $C := C^*(F_\infty)$ denotes the full group C^*-algebra over the free group F_∞ on countably many generators and where $\mathcal{C} \otimes^{\max} \mathrm{CP}_{\mathrm{in}}(C, C)$ is generated by the tensor products $V \otimes^{\max} \mathrm{id}_C$ with $V \in \mathcal{C}$. Then the following theorem holds:

THEOREM 3.12.4 (Separation of m.o.c.c.'s). *Let* $\mathcal{S} \subseteq \mathrm{CP}(A, B)$ *a set of c.p. maps, and denote by* $\Psi' : \mathcal{I}(B \otimes^{\max} C) \to \mathcal{I}(A \otimes^{\max} C)$ *the action that is defined by the set* $\mathcal{S}'$ *of c.p. maps* $V \otimes^{\max} \mathrm{id}_C : A \otimes^{\max} C \to B \otimes^{\max} C$.

Then a c.p. map $T : A \to B$ *is in the point-norm closed matrix operator-convex cone* $\mathcal{C}(\mathcal{S})$ *generated by* $\mathcal{S}$*, if and only if,* $T \otimes^{\max} \mathrm{id}_C$ *is* Ψ'*-equivariant.*

Compare also Thm. 3.8.4

PROOF. Let $\Psi' := \Psi_{\mathcal{S}'} : \mathcal{I}(B \otimes^{\max} C) \to \mathcal{I}(A \otimes^{\max} C)$ be the l.s.c. action of $\mathrm{Prim}(B \otimes^{\max} C)$ on $A \otimes^{\max} C$ defined by the set $\mathcal{S}'$ of c.p. maps $V \otimes^{\max} \mathrm{id}_C : A \otimes^{\max} C \to B \otimes^{\max} C$ for $V \in \mathcal{S}$, cf. Lemma 3.12.2(iv).

We denote by $\mathcal{C}' \subseteq \mathrm{CP}(A \otimes^{\max} C, B \otimes^{\max} C)$ the cone $\mathcal{C}' := \mathcal{C}_{\Psi'} = \mathrm{CP}(\Psi'; A \otimes^{\max} C, B \otimes^{\max} C)$ of Ψ'-equivariant maps.

Then $\mathcal{C}'$ is a point-norm closed matrix operator convex cone by Lemma 3.12.2(vii).

The set $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ of all $T \in \mathrm{CP}(A, B)$ with $T \otimes^{\max} \mathrm{id}_D \in \mathcal{C}'$ is a point-norm closed matrix operator convex cone that contains $\mathcal{S}$, cf. Lemma 3.12.2(xi), i.e., $\mathcal{C}(\mathcal{S}) \subseteq \mathcal{C}$ and $(V \otimes^{\max} \mathrm{id}_C)(\Psi'(J)) \subseteq J$ for all closed ideals J of $B \otimes^{\max} C$.

?????????

□

13. Graded m.o.c. cones

Needed topics:

Graded Hilbert B-modules E and interplay with grading on B.

Opposite E^{op} module: Interchange of the $\mathbb{Z}_2$ "eigen" spaces.

Opposite grading on B for E^{op}?

Gradings on E^{op}. Induced grading on $\mathcal{L}(E)$ is given by conjugation with the grading operator α on E:

$T \in \mathcal{L}(E)^{(0)}$ if and only if T commutes with α.

$T \in \mathcal{L}(E)^{(1)}$ if and only if T anti-commutes with $\alpha T \alpha = -T$, i.e., $\alpha T + T\alpha = 0$.

Notation on graded C^*-algebras A:

α or α_A is a C^*-automorphism of order 2.

$A^{(0)} := \{a \in A;\ \alpha_A(a) = a\}$, $A^{(1)} := \{a \in A;\ \alpha_A(a) = -a\}$,

(also denoted by A_0, A_1)

$a \in A^{(0)} \cup A^{(1)}$ are "homogeneous". Depending if $a \in A^{(0)}$ or $a \in A^{(1)}$ for homogeneous $a \in A$ is defined a *degree* $\deg(a) := j =: \partial a$ if $a \in A^{(j)}$.

The graded commutator $[a, b]_{\mathrm{gr}}$ in a graded algebra A with grading automorphism $\alpha \in \mathrm{Aut}(A)$ is defined by $[a, b] = ab - ba$ if $\alpha(a) = a$ or $\alpha(b) = b$ i.e., if

$a, b \in A_0$. Defined in general by:

$$[a,b]_{\text{gr}} := ab - (-1)^{\deg(a)\cdot\deg(b)} ba$$

It gives $[a,b]_{\text{gr}} = ab - ba$ if at least one of a, b has degree zero. if both have degree one, i.e., $\deg(a) = 1 = \deg(b)$, then $[a,b]_{\text{gr}} := ab + ba \in A^{(0)}$.

Gradings on m.o.c. cones $\mathcal{C}$. $\widehat{\mathcal{H}_B}$ for graded B. Effect to passage to opposite grading on B, $\mathcal{H}_B$ and $\widehat{\mathcal{H}_B} := \mathcal{H}_B \oplus \mathcal{H}_B^{op}$.

Related grading on $H_{\mathcal{C}} \colon A \to \mathcal{L}(\mathcal{H}_B)$???

Interplay of grading with on A and B with $\mathrm{CP}(A,B) \subset \mathcal{L}(A,B)$? What kind of compatibility of m.o.c. cones $\mathcal{C} \subseteq \mathrm{CP}(A,B)$ is necessary to get that $H_{\mathcal{C}} \colon A \to \mathcal{L}(\widehat{\mathcal{H}_B})$ becomes grading preserving?

Change on E the "eigen" spaces but not the grading on $\mathcal{L}(E)$?

$E = E^{(0)} \oplus E^{(1)}$ (Is this really the orthogonal sum ?)

The action of graded B should be (all calculated modulo 2):

$E^{(m)} B^{(n)} \subseteq E^{(m+n)}$

and

$E^{(m)}, E^{(n)} \subseteq B^{(m+n)}$

$E^{op} = (E^{op})^{(0)} \oplus (E^{op})^{(1)}$ is same E, but with $(E^{op})^{(0)} := E^{(1)}$ and $(E^{op})^{(1)} := E^{(0)}$.

Means replacing the order-2 grading isomorphism α by $(-1)\cdot\alpha$.

(Don't know what happens if $E^{(1)} = 0$, then only 0 is fixed?)

See sec. 14.2 of Blackadar K-theory.

Standard *odd* grading on $A \oplus A$ is given by $(A \oplus A)^{(0)} = \{(a,a)\,;\ a \in A\}$ and $(A \oplus A)^{(1)} = \{(a,-a)\,;\ a \in A\}$.

If $A = \mathbb{C}$ then $\mathbb{C}_1$ is a Clifford algebra, isomorphic to the group C^*-algebra of $\mathbb{Z}_2$.

Standard *even* grading on $M_2(A)$ is given by conjugation with $\mathrm{diag}(1,-1)$, i.e., $M_2(A)^{(0)}$ are the diagonal matrices, and $M_2(A)^{(1)}$ are the matrices with zero diagonal.

If α is grading on A and β grading on Hilbert B-module E and $\phi \colon A \to \mathcal{L}(B)$ is grading preserving. Then:

(0.) $\beta := -\alpha$ is the opposite grading on E.

(1.) $\psi := \phi \circ \beta \colon A \to \mathcal{L}(E)$ is grading preserving for E^{op} if ϕ was grading preserving for for the grading on $\mathcal{L}(E)$.

(2.) If (E, ϕ, F) is a Kasparov module then $(E^{op}, \psi, -F)$, $(E \oplus E^{op}, \phi \oplus \psi, G(t))$ are Kasparov module for the 2×2-matrix $G(t)$ with entries $G(t)_{11} := \cos(t\pi/2)F$, $G(t)_{22} := -\cos(t\pi/2)F$, $G(t)_{12} := \sin(t\pi/2)$ and $G(t)_{12} := \sin(t\pi/2)$.

The $G(t)$ is a linear combination of $\mathrm{diag}(F,-F) = G(1)$ and $G(0)$. Both have degree 1 under the grading $\mathrm{diag}(\alpha,-\alpha)(\cdot)\,\mathrm{diag}(\alpha,-\alpha)$ in $\mathrm{Lin}(E\oplus E^{op})$. The $G(0)$ commutes with $\phi(a)\oplus\psi(a) = \mathrm{diag}(\phi(a),\psi(a))$ for all $a\in A$ with $\alpha_A(a)=a$, and "anti-commutes" for all $a\in A$ with $\alpha_A(a)=-a$. This is because $\deg(G(0))=1$, $A\in a\mapsto \mathrm{diag}(\phi(a),\psi(a))$ is grading preserving, i.e., $\deg(\mathrm{diag}(\phi(a),\psi(a)))=1$ in $M_2(\mathcal{L}(E))$ if $\deg(\mathrm{diag}(\phi(a),\psi(a)))=1$ and

$$[\,G(0),\mathrm{diag}(\phi(a),\psi(a))\,]_{\mathrm{gr}} = G(0)\cdot\mathrm{diag}(\phi(a),\psi(a)) + \mathrm{diag}(\phi(a),\psi(a))\cdot G(0) = 0$$

In a the graded C^*-algebra $\mathcal{L}(E\oplus E^{op})$ we have the grading automorphism $\alpha(\cdot)\alpha$ for the grading $\alpha := \alpha_E\oplus(-\alpha_E)$ coming from the grading on $E\oplus E^{op}$:

And $\alpha\cdot G(1)\cdot\alpha = -G(1)$???

CHAPTER 4

Comparison and Addition of some C^*-morphisms

Actual plan:

(A) Remove 2-fold explanations/definitions

(B) Finish proof of Thm. 4.4.6.

(C) Outline ''germ'' of un-suspended but stable variant of E-theory. In particular:

(C1) Derive central sequences of copies of $\mathcal{O}_2$ for $\mathcal{O}_2$

(C2) Derive approximate unitary equivalence of all unital endomorphisms of $\mathcal{O}_2$ and of $\mathcal{O}_\infty$.

(C3) Derive needed central sequences from this.

(C4) Also quasi-central asymptotic paths of copies of $\mathcal{O}_2$ and of $\mathcal{O}_\infty$ ... ??

(C?? from Into 1.)

"Squeezing Property" implies K_1-injectivity. See Chp. 4. for definitions!

Here a question remains:

When K_1-injectivity implies the Squeezing Property?

At least in unital separable nuclear case ??

(Would be very nice ! But have no idea about this)

We study here some properties of **Cuntz addition**, that is, a "sum" of morphisms in the category of C^*-algebras, more generally we consider "sums" of general maps between C^*-algebras. This idea of an addition has been used implicitly in the topological K-theory of C^*-algebras since a long time, but without precise description e.g. of the "almost ridiculous " relationship between the isomorphisms of $\mathbb{K}$ with $M_2(\mathbb{K})$ and unital representations of the Cuntz algebra $\mathcal{O}_2$ in $\mathcal{M}(\mathbb{K}) = \mathcal{L}(\mathcal{H})$, needed for precise algebraic definition of equivalence classes of asymptotic and in some sense "equivariant" C^*-morphisms. It was J. Cuntz ([**172**], [**169**]) who pointed out in a more general context that a unital copy of $\mathcal{O}_2$ or at least of $\mathcal{O}_\infty$ is needed to adjust them carefully. The natural transformations between those copies of $\mathcal{O}_2$ are present for our definitions of sorts of equivariant theories by actions of groups, ideal-lattices or categories of matrix-convex cones.

The point is that we use them later to describe the constructive aspects of the used Ext-, KK-theories and unsuspended variants of cone-depending $\mathcal{E}$-theory that corresponds to them.

The general notion of Cuntz addition is related to K_*-theory (cf. Lemma 4.2.6 and Proposition 4.4.3). It is taylor-made for our study of nuclear asymptotic C^*-morphisms into non-simple purely infinite algebras in Chapters 3, 5 and 7. And it helps to describe the construction of our more general $\mathrm{KK}(\mathcal{C}\,;\cdot,\cdot)$-theory for operator-convex cones $\mathcal{C}$ in Chapter 8. The Cuntz addition is neither a direct product nor a direct sum in the usual sense of category theory – here on the category of C^*-algebras. This restricts "straight borrowing" from category theory analogies.

The considered situations and constructed objects appear only modulo various ideals in its applications in Chapters 5, 7, 8 and 9. We apply the here proved results, after dividing by suitable ideals in question. But this has to be done with some care:

Two C^*-morphisms $h_1, h_2 \colon D \to E$ into a unital C^*-algebra E can become unitarily equivalent after dividing out an ideal J of E. In general, then there is no unitary u in the original algebra with $h_1(a) - u^* h_2(a) u \in J$ for all $a \in D$. But in the particular situation where this unitary equivalence in E/J can be realized by a unitary in the connected component $\mathcal{U}_0(E/J)$ of 1 in $\mathcal{U}(E/J)$, then this unitary can be lifted to a unitary in E. This is, for example, the case if there exists an isometry $r \in E/J$ with $r^* \pi_J(h_1(d) + h_2(d)) r = 0$ for $d \in D$, cf. Proposition 4.3.6(iv). It applies e.g. to equivalence of stable extensions, cf. Chapter 5, and to asymptotic C^*-morphisms into stable σ-unital algebras, cf. Chapter 7 and Corollary 4.6.7.

Recall here that $\mathcal{U}(E)$ denotes the unitary group of a unital C^*-algebra E and $\mathcal{U}_0(E) \subseteq \mathcal{U}(E)$ the connected component of $1 \in \mathcal{U}(E)$.

We consider also some real C^*-algebras and real versions $E = E_{\mathbb{R}}$ of C^*-algebras E, e.g. the real versions $(\mathcal{O}_2)_{\mathbb{R}}$, $(\mathcal{E}_2)_{\mathbb{R}}$ and $C^*(P,Q,1)_{\mathbb{R}}$ of $\mathcal{O}_2$, $\mathcal{E}_2$ and the universal unital (complex) C^*-algebra $C^*(P,Q,1)_{\mathbb{R}} \otimes_{\mathbb{R}} \mathbb{C}$ generated by two projections.

We do not discuss KK-theory of real C^*-algebras here, but it seems natural to use the real basic algebras, because the complex versions are often just natural complexification of the real version. In the real cases $E = E_{\mathbb{R}}$, $(\mathcal{O}_2)_{\mathbb{R}}$ and $(\mathcal{E}_2)_{\mathbb{R}}$ we use also the notations "unitary", $\mathcal{U}(E)$ and $\mathcal{U}_0(E)$ instead of "orthogonal operator", $O(E)$ and $SO(E)$, for the orthogonal operators $u \in E$, respectively for $u \in E$ in the connected component of 1 in $O(E)$.

Formulas that cover also the "real" case look sometimes more complicate.

If the reader wants simpler formulas for complex C^*-algebras E then he can replace e.g. the order 4 unitary

$$(1 - zz^* - z^*z) + (z^* - z) = \exp((\pi/2)(z^* - z)) \in \mathcal{U}_0(E)$$

for partial isometries z with $z^2 = 0$ by the symmetry $(1 - zz^* - z^*z) + (z^* + z)$. Symmetries are not necessarily in $\mathcal{U}_0(E)$ if E is a real C^*-algebra. But there are also real C^*-algebras where every symmetry is connected inside the orthogonal operators with 1 by a path of orthogonal operators. Examples are all real unital

C^*-algebras that have a central sequence of unital copies of $M_2(\mathbb{R})$, i.e., that absorb the real UHF algebra $M_2(\mathbb{R}) \otimes M_2(\mathbb{R}) \otimes \cdots$ tensorial.

This is one of the reasons that we try to express canonical transformations as products of Halmos unitaries (defined in Remark 4.2.4), because those are also for real unital C^*-algebras A connected to 1 in $\mathcal{U}(A)$.

We need the verification of the homotopy invariance for definitions and constructions, those "soft" homotopy invariances will be later used to prove "hard" *unitary* homotopy in the sense of Definition 5.0.1. The passage to unitary homotopy is a basic tool in our proofs of classification results from stable homotopy coming from KK_X-equivalences or from the more general $\mathrm{KK}(\mathcal{C}; \cdot, \cdot)$-equivalences.

The results of Lemmata 4.2.6, 4.2.10 and Propositions 4.2.11, 4.2.15, 4.3.6 and 4.4.3 will be used in the proofs in Chapters 5, 7, 8, 9 and 11. Theorem 4.4.6 plays a crucial role in the proof of the first parts of Theorems B and M, that are given in Chapters 6 and 9 – in case of Theorem M with an additional separation assumption that will be removed later in Chapter 12 by the last step in the proof of Theorem K that uses the very special case of Theorem M proven before in Chapter 6.

DEFINITION 4.0.1. Let E a C^*-algebra such that its multiplier algebra $\mathcal{M}(E)$ contains a copy of $\mathcal{O}_2$ unitally. For a fixed pair of generators s_1, s_2 of $\mathcal{O}_2$ in $\mathcal{M}(E)$, we define the **Cuntz addition** $\oplus_{s_1,s_2}$ in E as follows:

$$a \oplus_{s_1,s_2} b \;=\; s_1 a s_1^* + s_2 b s_2^* \,; \quad a, b \in E\,.$$

We define and use in the "overview" Lemma 4.2.6 also a generalization of this addition, that is more natural, up to certain transformations and up to uniqueness depending from K_1-injectivity. A careful study of all transformations is in particular necessary if one wants to go into further research concerning equivariant actions of lattices, groups, quantum groups, groupoids, etc. After discussing some basic material on absorbing elements in Abelian semigroups and compatibility of projections, we study some less trivial properties of the generalized Cuntz addition of C^*-morphisms. This is not new, but gives a constructive "algebraic" base for our in applications used versions of K-theory, cone-depending KK-theory and unsuspended "continuous" $\mathcal{E}$-theory.

REMARK 4.0.2. The above defined *Cuntz addition* is a unital *-monomorphism from $E \oplus E$ into E. It is, up to unitary equivalence in E, independent of the choice of copies of $\mathcal{O}_2$: If s_1, s_2 and t_1, t_2 are generators of two copies of $\mathcal{O}_2$ in E, then

$$a \oplus_{s_1,s_2} b \;:=\; u(a \oplus_{t_1,t_2} b)u^* \qquad \text{for all} \;\; a, b \in E$$

where $u \;:=\; s_1 t_1^* + s_2 t_2^* \in E$ is a unitary.

More generally, one can add n elements of E along generators of a unitally contained copy of $\mathcal{O}_{\mathrm{n}}$ in E with generators $s_1, \ldots, s_n$ in the natural way:

$$(a_1, a_2, \ldots, a_n) \mapsto \sum s_i a_i s_i^*\,.$$

As before the sum is independent of the choice of generators – up to unitary equivalence by a fixed unitary. Notice that $\mathcal{O}_2$ contains all Cuntz algebras $\mathcal{O}_n$, $n \in \mathbb{N}$, unitally, e.g. $\mathcal{O}_3 \cong C^*(s_1, s_2 s_1, s_2^2)$. (In fact every separable unital exact C^*-algebra is isomorphic to a unital C^*-subalgebra of $\mathcal{O}_n$ by – cite: Kirchberg-Phillips.)

Computation shows that adding along $\mathcal{O}_n$ is the same as successively adding along $\mathcal{O}_2$ – up to unitary equivalence. In particular, Cuntz addition is associative and commutative up to (global) unitary equivalence.

The uniqueness up to unitary equivalence allows us to write sometimes simply $\oplus$ instead of $\oplus_{s_1,s_2}$ if we consider unitary equivalence classes and different unital copies of $\mathcal{O}_2$ in a given C^*-subalgebra of E.

The generators of a copy of $\mathcal{O}_2$ define an "almost inner" *-isomorphism ψ from $M_2(E)$ onto E, by

$$\psi\colon [a_{ik}] \in M_2(E) \mapsto v[a_{ik}]v^\top = \sum_{ik} s_i a_{ik} s_k^* \in E\,,$$

where v is the row matrix $v := [s_1, s_2] \in M_{1,2}(E)$.

There exists a unitary matrix $V \in M_4(E)$ (a Halmos unitary as in Remark 4.2.4) such that $V^* \operatorname{diag}(p;\, 0, 0)V = \operatorname{diag}(\psi(p), 0;\, 0, 0)$ for all projections $p \in M_2(E)$ and $V^* \operatorname{diag}(u; 1, 1)V = \operatorname{diag}(\psi(u), 1; 1, 1)$ for all unitaries $u \in M_2(E)$, cf. proof of Lemma 4.2.6(v,2).

Therefore, equivalence and homotopy in $M_{2^n}(E)$ can be over-carried to equivalence and homotopy in E itself.

In some calculations it plays a role if this can be made only up to unitary equivalence or, moreover, up to unitary homotopy. This difference has usually to do with problems related to K_1-injectivity and has forced us to show at least all (not necessarily simple) purely infinite unital C^*-algebras are K_1-injective, cf. Proposition 4.2.15(b), respectively Lemma 4.2.13 for the "squeezing property" of Definition 4.2.14 that induces K_1-injectivity by Proposition 4.2.15(?).

discover what???

!!! HIER BIN ICH !!!!

KUERZE DAS ZEUG ODER GEBE GENAUE DEF'S, FORMELN AN ...

A detailed discussion of the required transformation and precise conditions for uniqueness – up to unitary homotopy – will be given in the proofs of Lemma 4.2.6, that considers a generalized version of Cuntz addition on A in the case where here $E := \mathcal{M}(A)$ is properly infinite.

The below given Lemmata 4.1.3, 4.2.3 and 4.2.6 collect some basic facts concerning the description of $\mathrm{K}_*(E)$ for properly infinite unital C^*-algebras E by Murray–von Neumann equivalence classes of properly infinite projections in E (respectively by homotopy classes of unitaries in E), and they rephrase some technics appearing in proofs of [**172**] and of [**180**]. In particular the notions of absorption and domination will be discussed in connection with some technics to surround a possibly *missing* K_1-injectivity for some properly infinite C^*-algebra.

We show that all purely infinite unital C^*-algebras have the more general "squeezing property" of Definition 4.2.14 that induces K_1-injectivity by ???????

1. Two projections in C^*-algebras

We have often, but sometimes only "implicit", to do with two projections and their relative positions, e.g. with the open support projections of two closed left ideals, or with positions of two hereditary C^*-subalgebras of a C^*-algebra A. We consider in this Section 4.1 only selfadjoint projections, i.e. in the following a "*projection*" p in a C^*-algebra $A \subseteq \mathcal{L}(\mathcal{H})$ means always an orthogonal projection on a real or complex Hilbert space $\mathcal{H}$, i.e., $p = p^*p$. Then $0 \leq p = p^2$ and we denote the set of projections in A by $\mathrm{Proj}(A)$. The group of unitary elements in the unitization $\widetilde{A}$ will be denoted by

Or if we study orthogonality of positive elements of A ...

This ??????

Projections $p, q \in A$ (respectively unitaries u, v in the unitization $\widetilde{A}$ of A) are *homotopic* — denoted by $p \sim_h q$ (respectively $u \sim_h v$) —, if there is a (continuous) path $t \in [0,1] \mapsto p(t) \in \mathrm{Proj}(A)$ (respectively $t \in [0,1] \mapsto u(t) \in \mathcal{U}(\widetilde{A})$) such that $p(0) = p$ and $p(1) = q$ (respectively $u(0) = u$ and $u(1) = v$).

Here $a \sim_{MvN} b$ for $a, b \in A_+$ means **Murray–von-Neumann equivalence** – also denoted by $[a]_{MvN} = [b]_{MvN}$ or simply by $a \sim b$ – and is defined as the existence of $d \in A$ with $d^*d = a$ and $dd^* = b$.

The notation $p \sim q$ (more precisely $p \sim_{MvN} q$) for projections $p, q \in A$ denotes Murray–von-Neumann equivalence, i.e., the existence of $v \in A$ with $v^*v = p$ and $vv^* = q$. Recall that this implies $[p] = [q]$ in $\mathrm{K}_0(A)$.

`Beginning from HERE some text of old Appendix has to be integrated !!!`
`Ends up ????`

Integrate next into the further below considerations!!!

LEMMA 4.1.1. *Suppose that A is a C^*-algebra, and let $p, q \in A$ projections.*

(i) *If $\|pq\| < 1$, then 0 is isolated in $\mathrm{Spec}(p+q)$. And $q \sim_h (1_B - p)$ inside the* unital *C^*-subalgebra $B := C^*(p, q) \subseteq \overline{(p+q)A(p+q)}$.*
(Is identical with $(p+q) - \xi 1_{\mathcal{M}(A)}$ invertible in $\mathcal{M}(A)$ for all non-zero $\xi \in \mathbb{C}$ with $0 < |\xi| <$???? for small ????. Explicit bound ????)

(ii ???) *There is a (norm-continuous) path $[0,1] \ni t \mapsto u(t) \in \mathcal{U}(\widetilde{A})$ with $u(0) = 1$ and $u(1)^*pu(1) = q$, if and only if, $p \sim_h q$ in A.*
(If A is unital, then a path $t \mapsto u(t)$ with $u(0) = 1$ and $u(1)^*pu(1) = q$. can be found in $\mathcal{U}(A)$ itself.)

(ii,iii): See [**692**, prop. 2.2.6]*, or* [**73**, prop. 4.3.3, prop. 4.6.3]*, or* [**207**, prop. IV.1.2, lem.IV.1.4].

(iii ???) *If* $\|pq\| < 1$*, and if there exists a partial isometry* $z \in A$ *with* $z^*z = p$ *and* $zz^* = q$*, then* $p \sim_h q$*.*

Proof: (ii,iii): See [**692**, prop. 2.2.6], or [**73**, prop. 4.3.3, prop. 4.6.3], or [**207**, prop. IV.1.2, lem.IV.1.4].

(iii): By (i), there is a path $t \mapsto q(t) \in \operatorname{Proj}(A)$ with $q(0) = q$ and $q(1)p = 0$, and by (ii), there is a unitary $u \in \mathcal{U}_0(\widetilde{A})$ with $u^*qu = q(1)$. Then $w := u^*z$ satisfies $w^*w = p$ and $ww^* = q(1)$. Thus, $s := w^* + w + (1 - p - q(1))$ is a self-adjoint unitary in $\widetilde{A}$ with $sps = q(1)$. Hence, $(us)p(us)^* = q$ and $us \in \mathcal{U}_0(\widetilde{A})$. If $t \mapsto U(t) \in \mathcal{U}(\widetilde{A})$ is a path with $U(0) = 1$ and $U(1) = (us)^*$, then $t \to p(t) := U(t)^*pU(t)$ is the desired path, and $p \sim_h q$.

Recall that a hereditary C^*-subalgebra $D \subseteq A$ is *full* in A if the ideal of A generated by D is dense in A. An element $b \in A$ is *full* in A if the linear span of AbA is dense in A, i.e., if $A = J(b)$ for the closed ideal $J(b)$ of A generated by $\{b\}$. In particular, a projection $p^*p = p \in A$ is a full projection of A if the hereditary C^*-subalgebra pAp of A is full in A.

REMARK 4.1.2. Let $D \subseteq A$ a *full* hereditary C^*-subalgebra of A, then the inclusion map $\eta\colon a \in D \mapsto a \in A$ defines an isomorphism η_* from $\mathrm{K}_*(D)$ onto $\mathrm{K}_*(A)$.

In particular, $[q_1] = [q_2]$ in $\mathrm{K}_0(D)$ if $q_1, q_2 \in M_n(D)$ and there are projections $p_1, p_2 \in A$ with $[p_1] = [p_2]$ in $\mathrm{K}_0(A)$ and $p_k \sim_{MvN} q_k$ in $M_n(A)$ for $k = 1, 2$.

The study of sufficient and necessary criteria for K_1-injectivity of a given properly infinite unital C^*-algebra A requires some basics on pairs of projections $p, q \in A$ that are "almost compatible" in the sense that $\min(\|(1-q)p\|, \|(1-p)q\|) < 1$. The notation M_2 means in the following lemma the algebras $M_2(\mathbb{R})$ or $M_2(\mathbb{C})$ – depending if we consider a real or complex C^*-algebra $C^*(p, q, 1)$ generated by projections p, q. The Lemma itself should be "folklore", but since we use it in several proofs for estimates and check of "controlled" homotopy we give a careful detailed and elementary proof. Some of it can be also obtained by observing first that the "universal" unital C^*-algebra $C^*(P, Q, 1) := C^*(P, Q, 1;\ P^*P = P,\ Q^*Q = Q)$ is naturally isomorphic to the group C^*-algebra $C^*(\mathbb{Z} \rtimes \mathbb{Z}_2)$. The viewpoint of Lemma 4.1.3 is to derive algebraic and geometric informations from the behaviour of the norms (i.e., the "distance") about the kind of algebra they generate and how looks a unitary that transforms the symmetries into each other. We extract rules for moving near elements with help of a path in the inner automorphisms. A mainly operator theoretic and algebraic big overview is contained in [**101**], but there with some different terminology.

LEMMA 4.1.3. *Let* A *a real or complex unital* C^**-algebra and* $p, q \in A$ *projections.*

(i) *The C^*-algebra $C^*(p,q,1)$ has a character χ with $|\chi(p-q)| = 1$ and $\chi(pq) = 0$, if and only if, $\|p-q\| = 1$, if and only if, $\|(1-q)p\| = 1$ or $\|(1-p)q\| = 1$.*

If $\|p-q\| < 1$ then $\|p-q\| = \|(1-q)p\| = \|(1-p)q\|$. In particular, always $\|p-q\| = \max(\|(1-q)p\|, \|(1-p)q\|)$.

In more detail: If $\|(1-q)p\| < 1$ then the following properties (a)–(d) *are equivalent:*

(a) $\|(1-p)q\| = 1$.

(b) $\|p-q\| = 1$.

(c) *There exist a projection $p_0 \neq 0$ in $C^*(p,q)$ with $q_0 \leq 1-p$, $q_0 \leq q$.*

(d) *There exists a character χ on $C^*(p,q,1)$ with $\chi(q) = 1$ and $\chi(p) = 0$.*

(ii) *Always* $\mathrm{Spec}(p+q) \subseteq \{0\} \cup [1-\|pq\|, 1+\|pq\|]$.

In particular, if $\|pq\| < 1$ then 0 is isolated in $\mathrm{Spec}(p+q)$*, and $q \sim_h (1_B - p)$ inside the* unital *C^*-subalgebra $B := C^*(p,q) \subseteq \overline{(p+q)A(p+q)}$. The hereditary C^*-subalgebra $\overline{(p+q)A(p+q)}$ of A – generated by $p+q$ – is unital and coincides with the algebraic *-algebra $(p+q)A(p+q)$ with unit $g_\delta(p+q) \leq \delta^{-1} \cdot (p+q)$, where $\delta := (1-\|pq\|)/2$ and $g_\delta(t) :=$* $\min(1, \max(0, t-\delta))$.

(iii) *The* universal *unital real (or complex) C^*-algebra $C^*(P,Q,1)$ generated by two projections P, Q is naturally isomorphic to the C^*-subalgebra of* $\mathrm{C}([0,\pi/2], M_2)$*, that is generated by $1 := 1_2 \in M_2$, $P =: e_{11} = [\eta_{jk}] \in M_2$ with $\eta_{11} = 1$ and $\eta_{jk} = 0$ for $(j,k) \neq (1,1)$, and $Q := \exp(-H)P\exp(H)$, where $H \in \mathrm{C}([0,\pi/2], M_2)$ is given by $H(\varphi) := \varphi \cdot Z$ ($\varphi \in [0,\pi/2]$) for $Z := [\zeta_{jk}] \in M_2$ with $\zeta_{jk} := j-k$, $j,k \in \{1,2\}$.*

(iv) *If A is unital and $\|(1-q)p\| < 1$, then exist $h \in C^*(p,q) \subseteq A$ and a projection $q_0 \in C^*(p,q)$ with $q_0 p = 0$, $php = 0 = (1-p)h(1-p)$, $h^* = -h$ ([1]), and $\|h\| = \arcsin \|(1-q)p\| < \pi/2$, such that $hq_0 = q_0 h$ and*

$$\exp(-h)p\exp(h) + q_0 = \exp(-h)(p+q_0)\exp(h) = q\,.$$

The projection q_0 is non-zero if and only if $\|(1-p)q\| = 1$.

(v) *If A is unital and $\|p-q\| < 1$ then there exists $h \in C^*(p,q) \subseteq \overline{(p+q)A(p+q)}$ with $h^* = -h$ such that $\exp(-h)p\exp(h) = q$, $\|h\| =$* $\arcsin\|p-q\| < \pi/2$ *and $php = 0 = (1-p)h(1-p)$.*

(vi) *If $\|pq\| < 1$ and $\|p-q\| < 1$, then there exists $h \in (p+q)A(p+q)$ with $h^* = -h$, $php = 0 = (1-p)h(1-p)$ and $\|h\| = \arcsin\|p-q\|$ such that $\exp(h) \in (p+q)A(p+q)$ and $q = \exp(-h)p\exp(h)$.*

(old i) *If $\|pq\| < 1$, then 0 is isolated in* $\mathrm{Spec}(p+q)$*. And $q \sim_h (1_B - p)$ inside the* unital *C^*-subalgebra $B := C^*(p,q) \subseteq \overline{(p+q)A(p+q)}$.*

(Is identical with $(p+q) - \xi 1_{\mathcal{M}(A)}$ invertible in $\mathcal{M}(A)$ for all non-zero $\xi \in \mathbb{C}$ with $0 < |\xi| <$???? for small ????. Explicit bound????)

(old i and ii ???) *There is a (norm-continuous) path $[0,1] \ni t \mapsto u(t) \in \mathcal{U}(\widetilde{A})$ with $u(0) = 1$ and $u(1)^* p u(1) = q$, if and only if, $p \sim_h q$ in A.*

[1] Thus, if A is complex then $(ih)^* = ih$.

(If A is unital, then a path $t \mapsto u(t)$ with $u(0) = 1$ and $u(1)^* p u(1) = q$. can be found in $\mathcal{U}(A)$ itself.)

The elementary realization $C^*(P, Q, 1) \subset \mathrm{C}([0, \pi/2], M_2)$ of the universal unital C^*-algebra generated by two projections – as defined in Part (iii) – and its properties will be used in the proofs of Parts (iv) and (vi) and on other places, e.g. Remark 4.5.7. Compare Remark 4.5.8 for an alternative approach if A is complex.

Proof of Lemma 4.1.3. (i): The C^*-subalgebra $C^*(p, q) \subseteq A$ generated by p and q is an ideal of $C^*(p, q, 1)$. If $p+q$ is not invertible in $C^*(p, q, 1)$ then $C^*(p, q)$ is the kernel of the character χ_0 on $C^*(p, q, 1)$ with $\chi_0(p) = \chi_0(q) = 0$. Notice that $(p + q)/2$ is a strictly positive contraction of the C^*-algebra $C^*(p, q)$.

The W*-algebras generated by two projections $p^* = p = p^2$ and $q^* = q = q^2$ are described in [**767**, chp.V, thm. 1.41]. It implies in particular the below listed observations concerning the characters and the irreducible representations of any unital C^*-algebras $C^*(p, q, 1)$ generated by two projections p, q.

It does not matter here if we consider here real or complex C^*-algebras.

Real or complex unital C^*-algebras $C^*(p, q, 1)$ generated by (self-adjoint) projections p, q have only 1- or 2-dimensional irreducible *-representations.

The algebra $C^*(p, q, 1)$ admits at most 4 different characters.

Alternatively, one can obtain the above and below listed properties of $C^*(p, q, 1)$ by straight calculation from the identities $(p - q)^2 p = p(p - q)^2$ and $(p - q)^2 q = q(p - q)^2$, i.e., from the fact that the positive self-adjoint contraction $(p - q)^2$ is always in the center of $C^*(p, q, 1)$.

The selfadjoint contraction $(D(p) - D(q))^2$ is necessarily a non-negative scalar for each irreducible representation $D\colon C^*(p, q, 1) \to \mathcal{L}(\mathcal{H})$, which implies immediately that the Hilbert space $\mathcal{H}$ has dimension ≤ 2. It has dimension $= 2$ if and only if the projections $D(p)$ and $D(q)$ do not commute. The latter can only happen if the projections $D(p)$ and $D(p)$ have rank one and $D(pqp) = \alpha D(p)$ for some $\alpha \in (0, 1)$. The scalar α defines our parameter $\varphi := \arccos(\alpha^{1/2}) = \arcsin \|D(p - q)\|$ that determines D up to unitary equivalence (respectively *orthogonal* equivalence in the real case).

The parameter

$$\varphi := \arcsin \|D(p(1 - q))\| = \arccos \|D(pq)\| \ \in \ (0, \pi/2)$$

determines all *unitary* equivalence classes of 2-dimensional irreducible *-representations $D\colon C^*(p, q, 1) \to M_2$ uniquely, because $\arccos \|rs\|$ determines all pairs (r, s) of *non-commuting* orthogonal projections $r, s \in M_2$ (necessarily both of rank one) up to unitary equivalence in M_2:

If $r, s \in M_2$ are projections that do not commute, there exists $u \in \mathrm{O}(2)$ (respectively $u \in \mathcal{U}(2)$) such that $u^* r u = P := e_{11} := [\eta_{jk}]$ with $\eta_{11} = 1$ and $\eta_{jk} = 0$ for $(j, k) \neq (1, 1)$ and that $u^* s u = [\alpha_{jk}]$ with real $\alpha_{12} < 0$.

It follows that there is unique $\varphi \in (0, \pi/2)$ such that

$$u^* s u = Q(\varphi) := [\cos(\varphi), -\sin(\varphi)]^\top \cdot [\cos(\varphi), -\sin(\varphi)] .$$

Thus, $P - Q(\varphi) = \sin(\varphi) \cdot T$ where $T^* = T = [t_{jk}]$ with $t_{11} = \sin(\varphi) = -t_{22}$, $t_{1,2} = t_{2,1} = \cos(\varphi)$ for some $\varphi \in (0, \pi/2)$. It follows $T^2 = 1_2$ and $(P - Q(\varphi))^2 = \sin(\varphi)^2 1_2$, $u^*(r - rsr)u = P - PQ(\varphi)P = \sin(\varphi)^2 P$ and $u^*(1-r)s(1-r)u = \sin(\varphi)^2(1-P)$. Thus, if $r, s \in M_2$ are projections with $rs \neq sr$ then $0 < \|r - s\| < 1$ and $\varphi := \arcsin(\|r - s\|) \in (0, \pi/2)$ satisfies

$$\sin(\varphi) = \|r - s\| = \|(1-s)r\| = \|(1-r)s\| .$$

Let $p, q \in A$ projections with $p \neq q$. Since e.g. $(1-q)(p-q) = (1-q)p$, we get that $\|p - q\| \geq \max\big(\|(1-q)p\| , \|(1-p)q\| \big)$. If $\|(1-q)p\| = 0 = \|(1-p)q\|$, then $p \leq q$ and $q \leq p$, i.e., $\|p - q\| = 0$.

If $0 < \|p-q\| < 1$, then there exists a pure state ρ on $C^*(p, q, 1)$ with $|\rho(p-q)| = \|p - q\|$.

Since $0 < |\rho(p - q)| < 1$, the state ρ can not be multiplicative on $C^*(p, q)$, i.e., the corresponding irreducible representation is necessarily 2-dimensional.

Let $D \colon C^*(p, q, 1) \to M_2$ the irreducible GNS representation of $C^*(p, q, 1)$ defined by ρ and let λ a state on M_2 with $\rho = \lambda \circ D$. Then we get that $r := D(p)$ and $s := D(q)$ satisfy

$$|\lambda(r - s)| \leq \|r - s\| \leq \|p - q\| = |\rho(p - q)| = |\lambda(r - s)| ,$$

i.e., $\|r - s\| = \|p - q\| < 1$. It leads to

$$\|(1-q)p\| \leq \|p - q\| = \|r - s\| = \|(1-s)r\| \leq \|(1-q)p\|$$

and

$$\|(1-p)q\| \leq \|p - q\| = \|r - s\| = \|(1-r)s\| \leq \|(1-p)q\|$$

by the above mentioned properties of non-commuting projections (r, s) in M_2.

If $\|p - q\| = 1$ then $C^*(p - q, 1)$ has a character ρ with $|\rho(p - q)| = 1$. Since $\chi(1) = 1$ and $\|\chi\| \leq 1$, the character ρ extends to a state χ on $C^*(p, q, 1)$ by Hahn-Banach extension. The state χ satisfies $\chi(p), \chi(q) \in [0, 1]$ and $|\chi(p) - \chi(q)| = 1$. It follows that $\chi(p), \chi(q) \in \{0, 1\}$ and $\chi(p)\chi(q) = 0$. In particular, 1, p and q are in the multiplicative domain of the unital completely positive map χ from $C^*(p, q, 1)$ into $\mathbb{R}$ (respectively into $\mathbb{C}$), because in both cases $\chi(p)^2 = \chi(p) = \chi(p^2)$ and $\chi(q)^2 = \chi(q^2)$.

It follows that χ is a character on $C^*(p, q, 1)$ with $|\chi(p) - \chi(q)| = 1$.

Thus, χ is a character on $C^*(p, q, 1)$ with $\chi(p - q) \in \{+1, -1\}$. This implies that $(\chi(p), \chi(q))$ is equal to $(1, 0)$ or to $(0, 1)$. In particular, $1 = \chi(p - pqp)$ or $1 = \chi(p - qpq)$. The latter implies $1 = \|p - pqp\| = \|(1-q)p\|^2$ or $1 = \|q - qpq\| = \|(1-p)q\|^2$.

It yields that $\|p - q\| = \max(\|(1-p)q\|, \|(1-q)p\|)$ and that $\|(1-p)q\| = \|(1-q)p\|$ if $\|p - q\| < 1$.

We show the equivalence of the properties (a)–(d) in Part (i) under the pre-assumption $\|(1-q)p\| < 1$, in row (a)→(b)→(d)→(a)→(c)→(a), where (b)→(d) is a consequence of the pre-assumption, and only (a)→(c) is non-trivial.

(a)⇒(b): Since $(1-p)q = -(1-p)(p-q)$, $1 \geq \|p-q\| \geq \|(1-p)q\|$. Thus $\|(1-p)q\| = 1$ implies $\|p-q\| = 1$.

(b)⇒(d): Above we have seen that $\|p-q\| = 1$ implies the existence of a character χ on $C^*(p,q,1)$ with $|\chi(p) - \chi(q)| = 1$. It follows that $(\chi(p), \chi(q))$ is equal to $(0,1)$ or to $(1,0)$ and implies that $\max(\chi(p), \chi(q)) = 1$ and $\chi(qp) = 0$. Since

$$1 > \|(1-q)p\| \geq |\chi((1-q)p)| = |\chi(p)|\,,$$

only the cases $\chi(p) = 0$ and $\chi(q) = 1$ remain.

(d)⇒(a): Suppose that there exists a character χ on $C^*(p,q)$ with $\chi(p) = 0$ and $\chi(q) = 1$. Then $\|(1-p)q\| = 1$, because

$$1 = 1 - \chi(p) = \chi(q - qpq) \leq \|q - qpq\| = \|(1-p)q\|^2 \leq 1\,.$$

(a)⇒(c): Suppose that $\|(1-p)q\| = 1$. Then $\|q - qpq\| = \|(1-p)q\|^2 = 1$ and the positive element qpq of the C^*-algebra $qC^*(p,q,1)q$ has necessarily 0 in its spectrum:

$$0 \in \operatorname{Spec}(qpq, qC^*(p,q,1)q)\,.$$

Since our pre-assumption is equivalent to $\|1 - (pqp + (1-p))\| = \|(1-q)p\|^2 < 1$, it follows that the positive elements $T := pqp + (1-p)$ and $Tp = pTp$ are invertible in $C^*(p,q,1)$ respectively in $pC^*(p,q,1)p$. Then $S := T^{-1/2} \in C^*(p,q,1)$ is a (bounded) positive invertible element with

$$\|T\|^{-1} \cdot 1 \leq S^2 \leq \|T^{-1}\| \cdot 1\,.$$

Since $T(1-p) = (1-p) = (1-p)T$, the positive operator S commutes with p and $S(1-p) = 1-p$.

The element $v := qpS$ satisfies $v^*v = p$ and $r := vv^* \leq q$, i.e., v is a partial isometry and r a projection in $qC^*(p,q,1)q$.

Moreover, using that $\|T\|^{-1} \leq S^2 \leq \|T^{-1}\|$ by definition of S,

$$\|T\|^{-1} qpq \leq vv^* \leq \|T^{-1}\| qpq\,.$$

Thus $qpq \leq r$ and qpq is invertible in $rC^*(p,q,0)r$ and 0 is isolated in the spectrum of qpq in $qC^*(p,q,1)q$ with non-zero support projection $q_0 := q - r$. The projection q_0 satisfies $q_0 p = 0$, because $T^{-1}pqp = p$ and $v = qpS$ satisfy

$$pq_0p = p(q - vv^*)p = pqp - pqpS^2pqp = pqp - pqpT^{-1}pqp = 0\,.$$

(c)⇒(a): If $p_0 \in C^*(p,q)$ is a non-zero projection with $q_0 \leq 1-p$ and $q_0 \leq q$, then $q_0(1-p)q = q_0$. It follows that $1 \geq \|(1-p)q\| \geq \|q_0\| = 1$.

(ii): $\operatorname{Spec}(p+q) \subseteq \{0\} \cup [1 - \|pq\|, 1 + \|pq\|]$ can be seen from the spectrum of the Murray–von-Neumann equivalent 2×2-matrix $X := [p,q]^\top \cdot [p,q]$, because $[p,q] \cdot [p,q]^\top = (p+q) \oplus 0$ in $M_2(C^*(p,q))$. The projection $Y := \operatorname{diag}(1-p, 1-q)$

satisfies $YX = 0 = XY$ and $X + Y = 1_2 + T$ for the self-adjoint 2×2-matrix $T := [\beta_{jk}]$ with $\beta_{11} = \beta_{22} = 0$ and off-diagonal entries $\beta_{12} := pq$, $\beta_{21} := qp$. Thus $p+q$ has – up to the possible spectral values $\{0\,,\,1\}$ – the same spectrum as 1_2+T. Clearly $\operatorname{Spec}(1_2 + T) \subseteq [1 - \|T\|, 1 + \|T\|]$ and $\|T\| = \|pq\|$.

(iii): Each unital C^*-algebra $C^*(p, q, 1)$ generated by projections p, q is in a natural way a quotient of the *universal* unital C^*-algebra $C^*(P_u, Q_u, 1)$ with defining relations $P_u^* = P_u = P_u^2$ and $Q_u^* = Q_u = Q_u^2$.

In particular, there is a unique unital C^*-morphism Φ with $\Phi(P_u) = P$ and $\Phi(Q_u) = Q$ from the universal unital C^*-algebra $C^*(P_u, Q_u, 1)$ onto the unital C^*-subalgebra $C^*(P, Q, 1)$ of $\mathrm{C}([0, \pi/2], M_2)$ generated by $1, P \in M_2 \subset \mathrm{C}([0, \pi/2], M_2)$ and $Q := \exp(-H)P\exp(H) \in \mathrm{C}([0, \pi/2], M_2)$, with $H \in \mathrm{C}([0, \pi/2], M_2)$ as defined in Part (iii).

The natural *-epimorphism Φ from $C^*(P_u, Q_u, 1)$ onto $C^*(P, Q, 1) = \Phi(C^*(P_u, Q_u, 1))$ is *faithful* because $C^*(P, Q, 1)$ has 4 different characters and every irreducible 2-dimensional representation D factorizes over Φ. The factorization property for the irreducible representations D of $C^*(P_u, Q_u, 1)$ can be seen by using the parameter φ of the unitary equivalence class of D:

$$\arcsin \|(P - Q)|_{\{\varphi\}}\| = \arcsin \|P - Q(\varphi)\| = \varphi := \arcsin \|D(P_u) - D(Q_u)\|$$

for $Q(\varphi) := \exp(-H(\varphi))P\exp(H(\varphi)) = \exp(-\varphi Z)P\exp(\varphi Z)$. Notice that $\exp(\varphi Z) =: [\alpha_{jk}(\varphi)]$ is an orientation preserving rotation with angle φ, i.e., $\alpha_{11}(\varphi) = \alpha_{22}(\varphi) = \cos(\varphi)$ and $\alpha_{21}(\varphi) = \sin(\varphi) = -\alpha_{12}(\varphi)$.

Since $C^*(P, Q, 1)$ is naturally isomorphic to the universal unital C^*-algebra $C^*(P_u, Q_u, 1)$ generated by two projections, each unital C^*-algebra $C^*(p, q, 1)$ generated by two self-adjoint projections p, q is in a natural way a *quotient* of $C^*(P, Q, 1)$ by the unique unital *-epimorphism $\eta\colon C^*(P, Q, 1) \to C^*(p, q, 1)$ that satisfies $\eta(P) = p$ and $\eta(Q) = q$. This completes the proof of Part (iii).

We add here some additional information on the realisation $C^*(P, Q, 1) \subset \mathrm{C}([0, \pi/2], M_2)$ that can be useful to get alternative and less abstract proofs of Parts (iv)–(vi):

There is no essential difference in the properties of the real or complex version of the universal algebra $C^*(P, Q, 1)$, i.e., we can define it as the real C^*-subalgebra of $\mathrm{C}([0, \pi/2], M_2(\mathbb{R}))$ or as the complex C^*-subalgebra of $\mathrm{C}([0, \pi/2], M_2(\mathbb{C}))$ generated by $\{P, Q, 1\}$: Simply replace $\mathbb{R}$ by $\mathbb{C}$ and the in Part (iii) defined order 4 orthogonal operator Z with $Z = -Z^*$ by the self-adjoint (unitary) symmetry $-iZ = (-iZ)^* \in M_2(\mathbb{C})$ to get the complex case.

The definition of $(P, Q, 1)$ shows that $C^*(P, Q, 1)$ is the C^*-subalgebra of $\mathrm{C}([0, \pi/2], M_2)$ given by all continuous sections of the continuous field on $[0, \pi/2]$ with full fibers M_2 at $\varphi \in (0, \pi/2)$, “diagonal” fibers $C^*(1_2, P) = C^*(P, 1_2 - P) \subset M_2$ at $\varphi = 0$ and the fiber generated by $\{P, Q(\pi/2)\} = \{P, 1_2 - P\} \subset M_2$ at $\varphi = \pi/2$. I.e., the C^*-algebra $C^*(P, Q, 1)$ consists of all continuous matrix-valued functions $f\colon [0,\pi/2] \to M_2$ in $\mathrm{C}([0,\pi/2],M_2)$ that take values $f(0)$ and $f(\pi/2)$ in the diagonal matrices of M_2

An element $f \in \mathrm{C}([0,\pi/2],M_2)$ is in $C^*(P,Q)$, if and only if, $f \in C^*(P,Q,1)$ and $f(0) = \alpha P$ for some $\alpha \in \mathbb{R}$ (respectively $\alpha \in \mathbb{C}$). Therefore the in Part (iii) above defined elements $Z \in M_2$, $H, \exp(H) \in \mathrm{C}([0,\pi/2],M_2)$ are *not contained* in $C^*(P,Q,1)$, but the restrictions $H|[0,\psi]$ are in $C^*(P,Q)|[0,\psi]$ for each $\psi \in [0,\pi/2)$. Moreover, $\exp(H)|[\psi_1,\psi_2]$ is in $C^*(P,Q)|[\psi_1,\psi_2]$ for $0 < \psi_1 \leq \psi_2 < \pi/2$.

The quotient $C^*(P,Q)|[\psi,\pi/2] \subset \mathrm{C}([\psi,\pi/2],M_2)$ of $C^*(P,Q)$ (given by restriction to $[\psi,\pi/2]$) is *unital* for $0 < \psi \leq \pi/2$, because $(P+Q)|[\psi,\pi/2]$ is invertible in $\mathrm{C}([\psi,\pi/2],M_2)$.

The ideal $\mathrm{C}_0((0,\pi/2),M_2)$ of $\mathrm{C}([0,\pi/2],M_2)$ is the intersection of the kernels of the 4 characters of $C^*(P,Q,1)$ and is strictly contained in $C^*(P,Q)$, because the C^*-algebra $C^*(P,Q)$ has 3 characters.

Let $\psi \in (0,\pi/2)$ and define a function

$$f_\psi(\varphi) := (\varphi-\psi)_+ := \max(0,\varphi-\psi) \in \mathrm{C}_0(0,\pi/2]_+ \,.$$

The element $f_\psi \cdot P \in C^*(P,Q)$ generates the closed ideal J_ψ of $C^*(P,Q) \subset \mathrm{C}([0,\pi/2],M_2)$. The closed subspace J_ψ is also an ideal of $C^*(P,Q,1)$, because $C^*(P,Q)$ is an ideal of $C^*(P,Q,1)$.

If $0 < \psi < \pi/2$, then the quotient $C^*(P,Q,1)/J_\psi$ of $C^*(P,Q,1)$ is naturally isomorphic to

$$C^*(P,Q,1)|[0,\psi] \;\oplus\; (\mathbb{R}\cdot Q|\{\pi/2\}) \;\subset\; \mathrm{C}([0,\psi]\cup\{\pi/2\}\,,M_2)\,,$$

and the algebra $C^*(P,Q,1)|[0,\psi]$ is equal to

$$\mathbb{R}\cdot P + \mathbb{R}\cdot(1-P) + \mathrm{C}_0((0,\psi],M_2) \subset \mathrm{C}([0,\psi],M_2)\,.$$

The parameter φ for $Q(\varphi)$ is *natural* in the sense that the restrictions $P = P|_{\{\varphi\}} = P|_{\{0\}}$ and $Q(\varphi) := Q|_{\{\varphi\}}$ satisfy $\|(1-Q(\varphi))P\| = \sin(\varphi)$, $\|(1-P)Q(\varphi)\| = \sin(\varphi)$, $\|Q(\varphi)P\| = \cos(\varphi)$ and $\|P-Q(\varphi)\| = \sin(\varphi)$. Thus, for all $\varphi \in [0,\pi/2]$,

$$\|P(1-Q(\varphi))P\| + \|PQ(\varphi)P\| = 1\,.$$

E.g., the matrix $(P-Q)|_{\{\varphi\}} \in M_2$ is given by $[\alpha_{jk}] := P - \exp(-\varphi Z)P\exp(\varphi Z)$ and has entries $\alpha_{11} := \sin^2(\varphi)$, $\alpha_{12} := \alpha_{21} := -\sin(\varphi)\cos(\varphi)$ and $\alpha_{22} := -\sin^2(\varphi)$. It is $\sin(\varphi)$-times an orthogonal matrix, thus $\|\,(P-Q)|_{\{\varphi\}}\,\| = \sin(\varphi)$.

Since the norms of $(1-Q(\varphi))P$, $(1-P)Q(\varphi)$ and $P-Q(\varphi)$ are increasing and since the norms of $Q(\varphi)P$ are decreasing with respect to the parameter φ, we get the equal value $\sin(\varphi)$ for the norms of restrictions of $(1-Q)P$, $(1-P)Q$ and $P-Q$ to $[0,\varphi]$, and that $\|PQ|[\varphi,\pi/2]\| = \cos(\varphi)$.

(iv): Recall that $\widetilde{A} := A + \mathbb{R}\cdot 1 \subseteq \mathcal{M}(A)$ (respectively $\widetilde{A} := A + \mathbb{C}\cdot 1$) if A is not unital and $\widetilde{A} := A$ if A is unital.

Let $\gamma\colon C^*(P,Q,1) \to \widetilde{A}$ denote the canonical C^*-morphism from the universal C^*-algebra $C^*(P,Q,1)$ onto $C^*(p,q,1) \subseteq \widetilde{A}$. The kernel of γ is the intersection of the kernels of $\rho\circ\gamma$, where ρ runs through all irreducible representations of $C^*(p,q,1)$.

The natural C^*-morphism

$$\gamma\colon C^*(P,Q,1) \to C^*(p,q,1) \subseteq A$$

satisfies $\gamma((P(1-Q)P-\|(1-q)p\|^2)_+) = 0$ if $\|(1-q)p\| < 1$. Since $P(1-Q(\varphi))P = \sin(\varphi)^2 P$, this implies that the element $(P(1-Q)P - \|(1-q)p\|^2)_+ \in C^*(P,Q)$ and the in proof of Part (iii) defined element $f_\psi \cdot P \in C^*(P,Q) \subset \mathrm{C}([0,\pi/2], M_2)$ generate the same ideal of $C^*(P,Q,1)$ for $\psi := \arcsin\|(1-q)p\|$.

Thus, γ factorizes over the restriction $C^*(P,Q,1)|([0,\varphi_1]\cup\{\pi/2\})$ with $\varphi_1 := \arcsin\|(1-q)p\| < \pi/2$ and maps $P|\{\pi/2\} = P(1-Q)P|\{\pi/2\}$ to zero.

The projection $Q_0 \in C^*(P,Q,1)|([0,\varphi_1]\cup\{\pi/2\})$ defined by $Q_0(\varphi) = 0$ on $[0,\varphi_1]$ and by $Q_0(\pi/2) = 1 - P = Q|\{\pi/2\}$ at $\{\pi/2\}$ is *not* in the kernel of γ, if and only if, $C^*(p,q,1)$ has a character χ with $\chi(p) = 0$ and $\chi(q) = 1$. Compare the equivalence of (c) and (d) in Part(i).

This character χ is "isolated" in the sense that the image $C^*(p,q)$ of the C^*-morphism $\gamma\colon C^*(P,Q) \to A$ is isomorphic to a direct sum $C^*(p,q) \cong B \oplus \mathbb{C}$ such that q corresponds to $q_1 \oplus 1$, q_0 to $0 \oplus 1$ and p to $p \oplus 0$. It shows that the character χ is given by the projection of $B \oplus \mathbb{C}$ onto $0 \oplus \mathbb{C} \cong \mathbb{C}$.

The restriction $H' := H|[0,\varphi_1]$ is contained in the non-unital C^*-subalgebra $C^*(P,Q)|[0,\varphi_1]$, the restriction $\exp(H')|[0,\varphi_1]$ of the unitary exponential $\exp(H')$ to $[0,\varphi_1]$ is contained in $C^*(P,Q,1)|[0,\varphi_1]$ and

$$\exp(-H')P|[0,\varphi_1]\exp(H') \;=\; Q|[0,\varphi_1] \;\le\; Q|([0,\varphi_1]\cup\{\pi/2\}).$$

If $C^*(p,q,1)$ has a character χ with $\chi(p) = 0$ and $\chi(q) = 1$, then the character $\chi\circ\gamma$ on $C^*(P,Q,1)|[0,\varphi_1]\cup\{\pi/2\}$ is necessarily supported at the isolated one-point set $\{\pi/2\}$, and is given on $C^*(P,Q,1)|\{\pi/2\} \cong \mathrm{diag}(M_2)$ by $\chi\circ\gamma(\mathrm{diag}(1,0)) = 0$ and $\chi\circ\gamma(\mathrm{diag}(0,1)) = 1$. It follows that in this case, and only in this case, γ contains in its support $\subseteq [0,\pi/2]$ also the isolated point $\pi/2$, and $P|\{\pi/2\}$ is in the kernel of γ.

Thus $h := \gamma(H')$ is a skew adjoint element that is contained in $C^*(p,q)$.

The elements h and $q_0 := \gamma(Q_0) \le q := \gamma(Q)$ fulfill the quoted properties in Part (iv), because $q_0\exp(h) = \exp(h)q_0 = q_0$, $q_0 \le q$ and $q_0 p = 0$.

This *completes* the proof of Part (iv).

(v): By Part (i), $\|p-q\| < 1$ implies that $1 > \|p-q\| = \|(1-p)q\| = \|(1-q)p\|$. Thus, Part (iv) applies with $\|h\| = \arcsin\|p-q\|$ and $q_0 = 0$.

(vi): By Part (ii), the inequality $\|pq\| < 1$ implies that the algebraic *-algebra $(p+q)A(p+q)$ is a unital C^*-algebra. Since we require also that $\|p-q\| < 1$, the Part (v) applies to $p,q \in (p+q)A(p+q)$ and the, in this case unital, C^*-algebra $(p+q)A(p+q)$ in place of A. Then h $(= -h^*)$ and the unitary $\exp(h)$ can be defined inside the unital C^*-algebra $(p+q)A(p+q)$.

(old ?? ii,iii ??): See [**692**, prop. 2.2.6], or [**73**, prop. 4.3.3, prop. 4.6.3], or [**207**, prop. IV.1.2, lem.IV.1.4].

□

REMARKS 4.1.4. Following remarks about the natural $\mathbb{Z}_2$-grading α of the universal algebra $C^*(P, Q, 1)$ can be easily deduced from Lemma 4.1.3:

There is a unique grading automorphism $\beta \colon C^*(P, Q, 1) \to C^*(P, Q, 1)$ with $\beta(P) := 1-P$ and $\beta(Q) := 1-Q$ that is well-defined by universality of $C^*(P, Q, 1)$.

If we use the canonical embedding $C^*(P, Q, 1) \subseteq \mathrm{C}([0, 1], M_2)$ then β extends to $\mathrm{C}([0, 1], M_2)$ by the "odd", not "inner" in $C^*(P, Q, 1)$, grading of M_2, here by the order 2 outer automorphism $\beta(a)(t) := -Za(t)Z = Z^{-1}a(t)Z$ for the orthogonal matrix $Z = \exp((\pi/2)Z)$ in $M_2(\mathbb{R})$ of order 4, as defined in Part (iii) of Lemma 4.1.3, i.e., with $Z := [\zeta_{j,k}] \in M_2$ where $\zeta_{j,k} := j - k$, $j, k \in \{1, 2\}$.

The elements of degree $= 0$ are given by $f \cdot 1_2 + g \cdot Z$ $(f, g \in \mathrm{C}[0, 1])$ and the elements of degree $= 1$ by $f \cdot X + g \cdot ZX$ $(f, g \in \mathrm{C}[0, 1])$ with $X := \mathrm{diag}(1, -1)$.

Thus, in the case of real $M_2(\mathbb{R})$ and $f, g \in \mathrm{C}([0, 1], \mathbb{R})$ the elements of degree $= 0$ are just the natural images of complex-valued continuous functions $t \mapsto f_1(t)+if_2(t)$ in its "real" interpretation.

Let B a unital C^*-algebra, $\alpha \in \mathrm{Aut}(B)$ a grading of B, i.e., $\alpha^2 = \mathrm{id}_B$ and let $p, q \in B$ projections. Then $1 - 2p$ is of degree $= 1$, i.e., $\alpha(1 - 2p) = 2p - 1$, if and only if, $\alpha(p) = 1 - p$.

Notice that $\|(1 - 2q) - (1 - 2p)\| < 2$ if and only if $\|p - q\| < 1$.

If $A := C^*(p, q, 1) \subset B$ is the unital C^*-subalgebra of B generated by p, q that satisfy $\alpha(1 - 2p) = -(1 - 2p)$ and $\alpha(1 - 2q) = -(1 - 2q)$, then the natural C^*-morphism φ from $C^*(P, Q, 1)$ onto $C^*(p, q, 1)$ satisfies $\varphi \circ \beta = \alpha \circ \varphi$.

In particular, $\alpha(C^*(p, q, 1)) = C^*(p, q, 1)$.

If $\|(1 - 2q) - (1 - 2p)\| < 2$ then $\|p - q\| < 1$ and there exists $H \in C^*(p, q)$ with $\alpha(H) = H$, $H^* = -H$, $\|H\| < \pi/2$ and $q = \exp(-H)p\exp(H)$.

The grading $\alpha|C^*(p, q, 1)$ itself is given by an inner automorphism of $C^*(p, q, 1)$, if and only if, $\|p - q\| < 1$ and $\|pq\| < 1$, i.e., *both* inequalities must be valid.

REMARK 4.1.5. Let A a not-necessarily unital C^*-algebra. Consider in the non-unital case $A + \mathbb{C} \cdot 1_{\mathcal{M}(A)} \subseteq \mathcal{M}(A)$. Each $u \in \mathcal{U}_0(A)$ with $\pi_A(u) = 1$ is a product $u = \exp(h_1) \cdot \exp(h_2) \cdot \ldots \exp(h_n)$ of exponentials of elements $-h_k^* = h_k \in A$. We can here suppose that $\|h_k\| < \pi/2$. If $p, q \in A$ projections, then $p \sim_h q$ in A, i.e., p and q are (norm-) homotopic inside the metric space of of projections in A, then Lemma 4.1.3(v) shows that there exists a unitary $u \in \mathcal{U}_0(A + \mathbb{C} \cdot 1) \cap (A + 1)$ with $u^*pu = q$. Clearly, for each $u \in \mathcal{U}_0(A + \mathbb{C} \cdot 1)$ the projection $q := u^*pu \sim_h p$ in the projections of A.

2. On K-theory of properly infinite C^*-algebras

Recall that a projection $p \neq 0$ in a (not necessarily unital) C^*-algebra A is **properly infinite** if there are projections $r \leq p$ and $s \leq p$ such that $r + s \leq p$ and r, s are both Murray–von-Neumann equivalent to p.

A unital C^*-algebra E is called **properly infinite** if its unit element 1_E is properly infinite.

We can reduce *our* calculations related to K_*-theory and $\mathrm{KK}(\mathcal{C}; \cdot, \cdot)$ to the case of properly infinite unital C^*-algebras E or to C^*-algebras A with properly infinite $E := \mathcal{M}(A)$ by using – among others – the following lemmata and remarks.

This observation ???? has a partial converse in the class of full properly infinite projections, as the following lemma of J. Cuntz [**172**] shows.

Recall that projections $p \in A$ are *full* in A if the linear span of ApA is dense in A. Some elementary observations on properly infinite projections – considered first by J. Cuntz [**172**] – are collected in the following Lemma:

LEMMA 4.2.1. *Let $p \in A$ a* properly *infinite projection in a C^*-algebra A, i.e., there exist partial isometries $u, v \in A$ with*

$$u^*u = v^*v = p \quad \textit{and} \quad uu^* + vv^* \leq p\,.$$

Let $B := \overline{\mathrm{span}(ApA)}$ (the closed ideal of A generated by p) and $q \in B \otimes M_n \cong M_n(B)$ a projection, then there exist a partial isometry $z \in M_n(B) \subseteq M_n(A)$ with $zz^* \leq p \otimes e_{11}$ and $z^*z = q$.

Let $r := p - vv^*$. There exist partial isometries $s, t \in rAr$ with $s^*s = t^*t = r$ and $s^*t = 0$.

The projection $r := p - vv^*$ is a full projection in B and the elements of $\mathrm{K}_0(B)$ are the classes $[q] \in \mathrm{K}_0(B)$ given by properly infinite projections $q \leq r$ that are full in B and have the property that $r - q$ is also properly infinite and full in B.

The addition can be carried out inside the classes of Murray–von-Neumann equivalent projections of $rBr = rAr$ itself via the operation $[q_1] + [q_2] = [q_1 \oplus q_2]$ (where $\oplus = \oplus_{s,t}$, i.e., $q_1 \oplus q_2 := sq_1s^* + tq_2t^*$).

If, in addition, $q \in A$ is also properly infinite, $[q] = [p] \in \mathrm{K}_0(A)$ and $p \in \overline{\mathrm{span}(AqA)}$, then there exists a partial isometry $w \in \overline{\mathrm{span}(ApA)}$ with $w^*w = p$ and $ww^* = q$.

In particular, full properly infinite projections $p, q \in A$ satisfy $[p] = [q] \in \mathrm{K}_0(A)$ if and only if p and q are M-vN-equivalent, i.e., if there exists a partial isometry $v \in A$ with $v^*v = p$ and $vv^* = q$.

If A contains a full properly infinite projection $p \in A$ then for each $x \in \mathrm{K}_0(A)$ there exists a properly infinite full projection $q \in A$ with $q \leq p$ and $x = [q] \in \mathrm{K}_0(A)$.

We omit the proof of Lemma 4.2.1. It is easy to see, except that for each unital C^*-algebra A with properly infinite unit element $1 \in A$ and $[1] = 0$ in $\mathrm{K}_0(A)$ there exist isometries $s, t \in A$ with $s^*t = 0$ and $ss^* + tt^* = 1_A$, see the "basic property" (Cu) of full properly infinite projections in the proof of Lemma 4.2.6(i,ii). Combined with Lemma 4.2.3 it delivers all other statements. Plus$^+$ some extra service for the reader concerning of pairs of near odd graded isometries and others.

If A is unital (with properly infinite unit), then a projection $p \in A$ is (called) **splitting** if p and $1 - p$ are both full and properly infinite.

Recall that A is K_1**-injective**, if $u \in \mathcal{U}(\widetilde{A})$ and $0 = [u] \in \mathrm{K}_1(\widetilde{A})$ together always imply that $u \in \mathcal{U}_0(\widetilde{A})$, i.e., $u \sim_h 1$ in $\mathcal{U}(\widetilde{A})$. It implies that unitaries u_1 and u_2 in $\widetilde{A}$ are homotopic inside $\mathcal{U}(\widetilde{A})$, if and only if, $[u_1] = [u_2]$ in $\mathrm{K}_1(\widetilde{A})$.

There is a natural group-morphism $\mathcal{U}(E) \ni u \mapsto [u] \in \mathrm{K}_1(E)$ from the unitary group $\mathcal{U}(E)$ of E into $\mathrm{K}_1(E)$ if E is unital. Its kernel contains the connected component $\mathcal{U}_0(E)$ of the identity element $1 \in E$.

Definition 4.2.2. A unital C^*-algebra E is called K_1**-surjective** if the natural group-morphism $u \mapsto [u]$ is a surjective map from $\mathcal{U}(E)$ onto $\mathrm{K}_1(E)$.

The C^*-algebra E is K_1**-injective** if the connected component $\mathcal{U}_0(E)$ of 1_E in $\mathcal{U}(E)$ is equal to the kernel of $\mathcal{U}(E) \to \mathrm{K}_1(E)$, i.e., the induced map from $\mathcal{U}(E)/\mathcal{U}_0(E)$ to $\mathrm{K}_1(E)$ is *faithful* (= injective).

The C^*-algebra E is K_1**-bijective** if E is K_1-surjective and K_1-injective, i.e., $\mathcal{U}(E)/\mathcal{U}_0(E) \cong \mathrm{K}_1(E)$ by the natural group morphism.

The K_1-bijectivity of stable coronas obtained in Proposition 4.2.15 with help of the "squeezing" property defined in Definition 4.2.14 plays later a role in some of our computations.

It is (Feb 2021) not known if the unital (full) free product C^*-algebras $\mathcal{O}_\infty * \mathcal{O}_\infty$, $\mathrm{C}(S^1) * \mathcal{O}_2 \cong \mathcal{O}_2 * \mathcal{O}_2$ or $\mathrm{C}(S^1) * \mathcal{E}_2$ are K_1-injective.

Where is a proof of $\mathrm{C}(S^1) * \mathcal{O}_2 \cong \mathcal{O}_2 * \mathcal{O}_2$?

The proof of Lemma 4.2.10(i) shows that the question *"Is every unital C^*-algebra with properly infinite unit K_1-bijective?"* is equivalent to the question – if the unitary $U^* \cdot (1 - s_1 s_1^* + s_1 U s_1^*)$ in the unital full free product $A := \mathrm{C}(S^1) * \mathcal{E}_2$ is in $\mathcal{U}_0(A)$, where U denotes the canonical unitary generator of $\mathrm{C}(S^1)$ and the $s_1, s_2 \in \mathcal{E}_2$ denote the generating isometries of $\mathcal{E}_2$ ([2])

If S is an Abelian semigroup then we denote by $\mathrm{Gr}(S)$ the Grothendieck group of S, i.e., the formally defined group of "formal differences" of elements of the *cancellation semi-group* build by stable equivalence classes of elements in S. The

[2] This was also mentioned in a talk of B. Blackadar in Barcelona (2007). Compare also Lemma 4.2.10(iii).

natural semigroup morphism from S into $\mathrm{Gr}(S)$ is given by $x \mapsto [x]$ and maps onto the cancellation semi-group $[S] \subseteq \mathrm{Gr}(S)$, where $[x] \subseteq S$ denotes the stable equivalence class of x in S given by

$$[x] := \{ y \in S ; \ \exists \ s \in S \text{ with } x + s = y + s \} .$$

In general the natural injective additive morphism from the Abelian cancellation semigroup $[S]$ of S into the Grothendieck group $\mathrm{Gr}(S)$ is not surjective, $[S]$ is not identical with $\mathrm{Gr}(S)$, i.e., $[S]$ is not itself a group.

The proof of the following Lemma 4.2.3 is straight calculation and is left to the reader. It gives some sufficient conditions for cases where $[S] = \mathrm{Gr}(S)$, i.e., where $[S]$ is itself is a group .

LEMMA 4.2.3. *Let S a commutative semigroup and denote, for $z \in S$, by $S(z) \subseteq S$ the set of all elements $x \in S$ with the property that there exists $y \in S$ with $x + y = z$.*

(i) *If $e \in S$ satisfies $e + e = e$, and that for every $x \in S$ there exists some $y \in S$ with $x + y = e$, i.e., $S(e) = S$, then e is the only element of S with this property and the sub-semigroup $G := S + e$ is a sub*group *of S.*

An element $x \in S$ is in G, if and only if, x absorbs *e, i.e., if $x = x+e$.*

The map $x \in S \mapsto x + e \in S$ is a semigroup homomorphism that extends to a natural isomorphism from G onto the Grothendieck group $\mathrm{Gr}(S)$ of S in the following manner:

By universality of $\mathrm{Gr}(S)$ there is a well-defined natural group homomorphism φ from $\mathrm{Gr}(S)$ into G, given by $\varphi([x]) := x + e$ on the classes $[x] \in \mathrm{Gr}(S)$ for $x \in S$.

This homomorphism is a group isomorphism *from $\mathrm{Gr}(S)$ onto G with inverse isomorphism $x + e \mapsto [x + e] \in \mathrm{Gr}(S)$.*

(ii) *More generally, if S contains a element $z_0 \in S$ such that for each $x \in S$ there exists $y \in S$ with $x + y = z_0$, i.e., $S = S(z_0)$, then there exists an element $y_0 \in S$ with $2z_0 + y_0 = z_0$.*

The element $e := z_0+y_0$ and pair (S, e) have the in Part (i) considered properties.

(iii) *If $z_0 \in S$ is an element that satisfies only $2z_0 \in S(z_0)$, i.e., if there exists $y_0 \in S$ with $2z_0 + y_0 = z_0$, then $e := e(z_0) := z_0 + y_0$ satisfies $S(e(z_0)) = S(z_0)$ and $e + e = e$.*

The subset *$S(z_0)$ of S is a sub-semigroup of S such that $G(e(z_0)) := S(z_0) + e(z_0) \subseteq S(z_0)$ and $G(e(z_0))$ is a sub*group *of S, that is natural isomorphic to the Grothendieck group of $S(z_0)$.*

(iv) *If $z_0, z_1 \in S$ satisfy $z_0 \in S(z_1)$ and $2z_j \in S(z_j)$ for $j = 0, 1$, then $e(z_1) = e(z_0) + e(z_1)$ and the mapping*

$$y \in S(z_0) + e(z_0) \mapsto y + e(z_1) \in S(z_1) + e(z_1)$$

is a group homomorphism from $G(e(z_0))$ into $G(e(z_1))$.

□

There are examples of group homomorphism of the type described in Part (iv) of Lemma 4.2.3 that are neither injective nor surjective.

An element $a \in A_+$ of a (not-necessarily unital) C^*-algebra A will be called **full** in A if span(AaA) is dense in A, i.e., if $\overline{aAa}$ is full hereditary C^*-subalgebra of A. (For example, all strictly positive elements of A are full in A.)

Recall that the unit element 1_E of a unital C^*-algebra E is properly infinite in E, if and only if, there are isometries $s_1, s_2 \in E$ with $s_1^* s_2 = 0$. Then we say that E is a **properly infinite** unital C^*-algebra.

We let $p_{[-1]} := 1 - s_1 s_1^* - s_2 s_2^*$. This projection becomes zero if and only if s_1, s_2 are the canonical generators of a unital copy of $\mathcal{O}_2$ in E. It holds $[p_{[-1]}] = -[1]$ in $\mathrm{K}_0(E)$.

Then a ***generalized*** *variant of the* ***Cuntz addition*** using isometries s_1, s_2 with $s_1^* s_2 = 0$ is defined by

$$a \oplus b \; := \; a \oplus_{s_1,s_2} b \; := \; s_1 a s_1^* + s_2 b s_2^* \quad \text{for } \; a, b \in E \, .$$

If we consider unitaries $u, v \in \mathcal{U}(E)$ then we can use the **corrected version** of generalized Cuntz addition given with $p_{[-1]} := 1 - s_1 s_1^* - s_2 s_2^*$ by

$$u \oplus' v := \; u \oplus'_{s_1,s_2} v := \; s_1 u s_1^* + s_2 v s_2^* + p_{[-1]} \, .$$

We say that a projection $p \in E$ in a unital C^*-algebra E is **splitting** if p and $1-p$ are both properly infinite projections and are full elements of E.

The definitions of proper infiniteness and fullness yield that this property is equivalent to the property that there exist isometries $t_1, t_2 \in E$ with $t_1 t_1^* \leq p$ and $t_2^* t_2 \leq 1 - p$.

The notion of splitting projections generalizes the notion of a **proper projection** p defined by the property that p and $1-p$ are both MvN-equivalent to 1. Most of the following results on splitting projections have been obtained before by J. Cuntz and N. Higson for the special case of proper projections in place of the more general "splitting" projections (introduced by B. Blackadar, 2007).

It is easy to see, e.g. using Lemma 4.1.3(v), that projections $p, q \in E$ are homotopic inside the subset of projections in E, if and only if, there is a unitary $u \in \mathcal{U}_0(E)$ with $u^* p u = q$.

REMARK 4.2.4. The **Halmos unitary** $U(c)$ in $M_2(E)$, build from a contraction $c \in E$, is an "orientation-preserving rotation" given by the unitary matrix (respectively by the "special orthogonal" matrix if E is a *real* C^*-algebra) $U(c) := [a_{jk}(c)]$ with entries $a_{11}(c) := c$, $a_{12}(c) := -(1 - cc^*)^{1/2}$, $a_{21}(c) := (1 - c^* c)^{1/2}$ and $a_{22}(c) := c^*$.

Each Halmos unitary $U(c)$ is in $\mathcal{U}_0(M_2(E))$ because $U(1) = 1_2$ and $c \mapsto U(c)$ is uniformly Hölder continuous on the closed unit ball of E with very rough estimate

(?????? see commented lines !!!?)

$$\|U(c_1) - U(c_2)\| \leq (2\|c_1 - c_2\|)^{1/2} + \|c_1 - c_2\| \leq 3\|c_1 - c_2\|^{1/2} \tag{2.1}$$

It shows that each Halmos unitary $U(c)$ is in $\mathcal{U}_0\big(M_2(C^*(c,1))\big)$ and has an exponential length $\text{cel}(U(c))$, – i.e., the "geodesic" distance of $U(c)$ from 1_2 inside the metric space $\mathcal{U}_0(M_2(E))$ –, of value $\text{cel}(U(c)) < 3\pi/2$.

If one considers the very special case $E := \mathrm{C}([0,1])$ then it cuts down to the case of $E := \mathbb{C}$. And in this case one can use the estimates of $\text{cel}(U(c))$ for $c \in \mathbb{C}$ with $|c| \leq 1$.

check this estimate $3\pi/2$ again!!
How long is the path $t \in [0,1] \mapsto U(tc + (1-t))$ in $\mathcal{U}_0(E)$
for fixed $c \in E$ with $c \in E$ with $\|c\| < 1$?
How good is the estimate for positive contraction?
Very important:
Give precise citation/reference to definition of cel of a unitary
or change and DEFINE notation !!!

In the special case of $U(T)$ for an isometry $T \in E$ we can take a new parametrization $\varphi \in [0, \pi/2] \mapsto U(\cos(\varphi) \cdot T) \in M_2(E)$ and get a continuously differentiable curve of length $\leq \pi/2$.

For $h^* = h \in E$ with $0 \leq h \leq \pi \cdot 1$, the matrix $Z = [z_{ij}] \in M_2$ with $z_{ij} := i - j$, and $X_h := h \otimes Z \in M_2(E)$ holds $\exp(X_h) = U(\cos(h))$. Therefore we have changed the original definition of P. Halmos [**352**] into our formula for $U(c)$ to make it fitting to other terminology used for the terms in our estimates.

The original definition given by Halmos was $\text{diag}(1, -1) \cdot U(c) \cdot \text{diag}(1, -1)$, if we express it with our definition of $U(c)$. Some authors define the matrix $U(c) \cdot \text{diag}(1, -1)$ as Halmos unitary.

Compare above text about estimates and arc-length
with below blue - including blue text in proof of Lemma 4.2.6!!!

The estimate (2.1) follows from

$$\|U(c_1) - U(c_2)\| \leq \|c_1 - c_2\| + \big(\max\{\|c_1^*c_1 - c_2^*c_2\|, \|c_1c_1^* - c_2c_2^*\|\}\big)^{1/2} \leq 3\|c_1 - c_2\|^{1/2},$$

where we have used that $\|a^{1/2} - b^{1/2}\| \leq \|a - b\|^{1/2}$ for $a, b \in E_+$. More precise is $\|U(c_1) - U(c_2)\| \leq \gamma(\|c_1 - c_2\|)$ with the function $\gamma(\xi) := \xi + (2\xi)^{1/2}$ for $\xi \in [0, 2]$. This estimate can be applied to the special pairs of contractions $(c_1, c_2) := ((1/2)c, 0)$ and $(c, (1/2)c)$. It shows that $U(c) = U(0)\exp(H_1)\exp(H_2)$ for $H_1, H_2 \in E$ with $H_k^* = -H_k$ and $\|H_k\| < \pi/2$. Since $U(0)$ is a 90° rotation, it implies that $U(c)$ has exponential length bounded by $3\pi/2$.

But this estimate (with this parametrization) does not imply that the arc $[0,1] \ni t \mapsto U(tc)$ is a rectifiable path (of finite length), that requires Lipschitz continuity (and not only this obtained Hölder continuity). In more detail: $\|U(tc) - U(sc)\| \leq (t - s) + (t^2 - s^2)^{1/2}$ for $0 \leq s < t \leq 1$.

Recall here $|\exp(i\varphi)-1| \leq x < 2$ for $\varphi \in [-\pi, \pi]$ if and only if $2-x^2 \leq 2\cos(\varphi)$, i.e., $|\varphi| \leq \arccos(1-x^2/2) < \pi$.

Thus, $\|U(tc) - U(0)\| \leq 2t < 2$ for $t \in [0,1)$, implies that there is a unique $H \in E$ with $U(tc) = U(0)\exp(H)$, $H^* = -H$, and $\|H\| \leq \arccos(1-2t^2) < \pi$ and $U(tc) = U(0)\exp(H)$ if $t \in [0,1)$, i.e., $\|H\| \leq \arccos(1/2) < \pi/2$ if $t = 1/2$. If $\delta \in [0,1)$, then

$$\|U(c) - U((1-\delta)c)\| \leq \delta + (1-(1-\delta)^2)^{1/2} \leq 3\delta < \pi\,,$$

and we get for $\delta := 1/2$, that $\|U(c) - U((1/2)c)\| \leq x$ with $1 < x := (1+\sqrt{3})/2 < \sqrt{2}$ and $1 - x^2/2 = (2-\sqrt{3})/4 > 0$ and there exists $K \in E$ with $K^* = -K$, $U(c) = U((1/2)c)\exp(K)$ and $\|K\| \leq \arccos((2-\sqrt{3})/4) < \pi/2$.

(It seems that the Hölder continuous map $t \in [0,1] \to U(t\cdot c) \in \mathcal{U}_0(M_2(E))$ itself is not always rectifiable, because it is not Lipschitz continuous for arbitrary contractions $c \in E$.)

In case of $U(T)$ for an isometry $T \in E$ we can take a parametrization $\varphi \in [0, \pi/2] \mapsto U(\cos(\varphi)\cdot T) \in M_2(E)$ and get a continuously differentiable curve of length $\leq \pi/2$, because, for $s \in [0,1]$,

$$U(s\cdot T) = \operatorname{diag}(T,1)U(s\cdot 1)\operatorname{diag}(1,T^*) + X\,,$$

where $X = [x_{jk}]$ is given by $x_{12} := 1 - TT^*$ and $x_{11} = x_{21} = x_{22} := 0$.

We use often the following general equation for isometries $t \in E$ and unitaries $v \in \mathcal{U}(E)$:

$$[(1-tt^*) + tvt^*] = [v] \quad \text{in} \quad \mathrm{K}_1(E)\,. \tag{2.2}$$

Indeed, the diagonal matrices $\operatorname{diag}(v,1)$ and $\operatorname{diag}\big((1-tt^*) + tvt^*\,,\,1\big)$ are unitary and are unitary equivalent in $M_2(E)$ by the Halmos unitary $U(t) \in \mathcal{U}_0(M_2(E))$, i.e.,

$$U(t)\operatorname{diag}(v,1) = \operatorname{diag}\big((1-tt^*) + tvt^*\,,\,1\big)U(t)\,.$$

Remark 4.2.5. Recall that C^*-algebra E has a properly infinite unit, if and only if, E contains two isometries t_1, t_2 with orthogonal ranges, i.e., with relations $t_i^* t_j = \delta_{i,j} 1_E$.

Obviously the elements $s_n := (t_1)^{n-1} t_2$ satisfy $s_k^* s_\ell = \delta_{k,\ell} 1_E$, i.e., generate a copy of $\mathcal{O}_\infty$ that is unitally contained in E, cf. the proof of Proposition 4.2.11.

It implies that for every contraction $a \in E$ there exists a unitary $u \in \mathcal{U}_0(E)$ such that $s_1^* u s_2 = a$ with the isometries s_1, s_2 are taken from this fixed copy of $\mathcal{E}_3$.

It shows that any separable C^*-algebra E with a properly infinite unit element is a quotient of the unital free product $\mathrm{C}(S^1) * \mathcal{E}_2$, because all separable C^*-algebras with properly infinite unit are singly generated by Proposition B.17.2.

Indeed, we can use the Halmos unitary $U(a) \in M_2(a)$ and the projection $p := 1 - s_1 s_1^* - s_2 s_2^* \in E$. Then the unitary $u := p + [s_1, s_2]U(a)[s_2, -s_1]^* \in E$ has this properties, because $U(a) \in \mathcal{U}_0(A)$ is connected in $\mathcal{U}_0(A)$ to $U(0)$ and $[s_1, s_2]U(0)[s_2, -s_1]^* = 1 - p$.

LEMMA 4.2.6. *Let E a unital C^*-algebra with properly infinite unit 1_E. Then there exist isometries $s_1, s_2 \in E$ with orthogonal ranges, i.e., with $s_1^* s_2 = 0$, such that s_1 and s_2 satisfy the following non-degeneracy condition* (ND):

(ND) *The projection*

$$p_{[-1]} := 1 - s_1 s_1^* - s_2 s_2^* = 1 - (1 \oplus 1)$$

is either *full and properly infinite* or $p_{[-1]} = 0$.

The s_1, s_2 can be always found such that $p_{[-1]}$ is full and properly infinite, s_1, s_2 with $p_{[-1]} = 0$ exists if and only if $[1] = 0$ in $\mathrm{K}_0(E)$.

The (generalized) Cuntz addition $\oplus_{s_1,s_2}$ defined by isometries $s_1, s_2 \in E$, that satisfy $s_1^* s_2 = 0$ and condition (ND), *has following properties and connections to unitary operators and splitting projections:*

(o) Commutativity and Associativity of $\oplus$ up to unitary homotopy:

There exist $U_c, U_d \in \mathcal{U}_0(C^*(s_1, s_2)) \subseteq \mathcal{U}_0(E)$ with exponential length $\mathrm{cel}(U_c) \leq \pi/2$ and $\mathrm{cel}(U_d) \leq \pi$

`Look up definition of ''cel'' in published papers, change notation?`

`Give Citation!!!`

that satisfy $p_{[-1]} U_c = p_{[-1]} = p_{[-1]} U_d$, $U_c^* (a \oplus b) U_c = (b \oplus a)$, for $a, b \in E$, and

$$U_d^* \big(a \oplus_{s_1,s_2} (b \oplus_{s_1,s_2} c)\big) U_d = \big((a \oplus_{s_1,s_2} b) \oplus_{s_1,s_2} c\big) \qquad \text{for } a, b, c \in E\,.$$

(i) *The map $(p, q) \mapsto p \oplus_{s_1,s_2} q$ is a commutative and associative operation up to unitary equivalence by unitary elements $u \in \mathcal{U}_0(E)$, i.e., up to homotopy in the projections of E. It is compatible with unitary equivalence, homotopy and Murray–von Neumann equivalence.*

If $p, q \in E$ are projections then $\mathrm{diag}(p \oplus q, 0)$ is MvN-equivalent to $\mathrm{diag}(p, q)$ in $M_2(E)$. The projection $p \oplus q$ is MvN-equivalent to $p + q$ if $pq = 0$.

In particular, $[p \oplus q] = [p] + [q] \in \mathrm{K}_0(E)$ for projections $p, q \in E$, and $[p \oplus q] = [p + q]$ if $pq = 0$.

(ii) *Suppose that $p, q \in E$ are projections and that there exist isometries $s, t \in E$ with $ss^* \leq p$ and $tt^* \leq q$, i.e., p and q are full and properly infinite.*

Then p and q are Murray–von Neumann equivalent in E if and only if $[p] = [q] \in \mathrm{K}_0(E)$.

If p and q are splitting *projections, – i.e., if each of the projections p, $1 - p$, q and $1 - q$ are full and properly infinite –, then p and q are unitary equivalent in E if and only if $[p] = [q] \in \mathrm{K}_0(E)$.*

If $p, q \in E$ are unitary equivalent projections and p is full and properly infinite then there exists $u \in \mathcal{U}(E)$ with $0 = [u] \in \mathrm{K}_1(E)$ and $u^* p u = q$.

Any projection $q \in M_n(E)$ is MvN-equivalent to a projection $q' \in E$ such that $q' \leq p$ for some splitting projection $p \in E$ ([3]).

(iii) *The* unitary *equivalence classes $[p]_u$ of splitting projections $p \in E$ build a group with generalized Cuntz addition $[p]_u + [q]_u := [p \oplus q]_u$, and the natural map $[p]_u \to [p] \in \mathrm{K}_0(E)$ defines an* isomorphism *from this group onto $\mathrm{K}_0(E)$.*

(iv) (a) (*cf.* [**94**, prop. 2.5]) *If p and q are full and properly infinite projections with $[p] = [q] \in \mathrm{K}_0(E)$, and if there exists an isometry $t \in E$ with $t^*(p+q)t = 0$, then there exists a unitary $u \in \mathcal{U}_0(E)$ such that $u^*pu = q$, i.e., p and q are homotopic in the projections of E.*
(b) *Special case: Two projections $p, q \in E$ represent the same element $[p] = [q]$ of $\mathrm{K}_0(E)$, if and only if, there exists a unitary $u \in \mathcal{U}_0(E)$ such that $u^*(p \oplus 1 \oplus 0)u = q \oplus 1 \oplus 0$.* ([4])

(v) *Let $u \sim_h v$ denote homotopy of $u, v \in \mathcal{U}(E)$ inside the unitary group $\mathcal{U}(E)$ of E, and let $\mathcal{U}_0(E)$ the connected component of 1 in $\mathcal{U}(E)$.*

The natural map $u \mapsto [u]$ from the group of unitary operators $\mathcal{U}(E)$ of E into $\mathrm{K}_1(E)$ is an epimorphism, *i.e., E is* K_1-surjective. *It has following properties – expressed with the "corrected" Cuntz sum $u \oplus' v := (u \oplus v) + p_{[-1]}$ on the unitary group:*

(1) $[u \oplus' v] = [u] + [v] = [uv]$ *in* $\mathrm{K}_1(E)$,
(2) $[u] = [v] \in \mathrm{K}_1(E)$, *if and only if,* $u \oplus' 1 \sim_h v \oplus' 1$.
In particular, $u \oplus' 1 \in \mathcal{U}_0(E)$ *if* $[u] = 0 \in \mathrm{K}_1(E)$.
(Recall $u \oplus' 1 := s_1 u s_1^* + (1 - s_1 s_1^*)$ *.)*
(3) *The unitary operators* $u^* \oplus' u$ *are in* $\mathcal{U}_0(E)$.
(4) $u \oplus' v \sim_h vu \oplus' 1 \sim_h v \oplus' u$.
(5) *Let $p \in E$ a projection such that $1 - p$ is full and properly infinite.*
If $u \in \mathcal{U}(pEp)$ is a unitary with $[u + (1-p)] = 0$ in $\mathrm{K}_1(\mathcal{U}(E))$ then $u + (1-p) \in \mathcal{U}_0(E)$.
If $p \in E$ is moreover a splitting *projection, then $\eta \colon pEp \hookrightarrow E$ defines an isomorphism η_* from $\mathrm{K}_*(pEp)$ onto $\mathrm{K}_*(E)$.*
It satisfies $\eta_1([u]) = [u + (1-p)]$ for $u \in \mathcal{U}(pEp)$ and $\eta_0([q]) = [q]$ for projections $q \in pEp$.
In particular, for splitting $p \in E$ and $u \in \mathcal{U}(pEp)$ holds:

$$0 = [u] \in \mathrm{K}_1(pEp) \iff u + (1-p) \in \mathcal{U}_0(E) \,.$$

(6) *If $z \in E$ is a partial isometry with $z^2 = 0$ then the "rotation" unitary*

$$R(z) := z - z^* + (1 - z^*z - zz^*) = \exp((\pi/2)(z - z^*))$$

is in $\mathcal{U}_0(E)$. If E is a complex *C^*-algebra, then the "symmetry"*

$$S(z) := z + z^* + (1 - z^*z - zz^*)$$

[3] Identify $p \in E$ with $p \otimes e_{11} \in E \otimes M_n \cong M_n(E)$.
[4] $(1 \oplus 1) \oplus 0$ and $1 \oplus 1$ are MvN-equivalent but are not unitarily equivalent.

is in $\mathcal{U}_0(E)$.

It holds $R(z)^* a R(z) = zaz^* = S(z)aS(z)$ *for all* $a \in z^*zEz^*z$.

(vi) (*cf.* [**94**, lem. 2.4(ii)].) *Let* $p \in E$ *a splitting projection in* E.

If $u_1, u_2 \in \mathcal{U}(E)$ *satisfy* $[u_1] = [u_2] \in \mathrm{K}_1(E)$ *and* $\|u_k p - p u_k\| < 1$ *for* $k = 1, 2$, *then* $u_1 \sim_h u_2$ *in* $\mathcal{U}(E)$.

Special cases are:

(α) $u \in \mathcal{U}_0(E)$ *if* $\|up - pu\| < 1$ *and* $0 = [u] \in \mathrm{K}_1(E)$.

Thus, $u \in \mathcal{U}_0(E)$ *if* $up = pu$ *and* $[u] = 0$ *in* $\mathrm{K}_1(E)$.

`COMPARE, also clever:`

(iv,old): If $u \in \mathcal{U}(A)$, $p \in A$ *is a* splitting *(!!!) projection, and* $\|up - pu\| < 1$, *then there exists a unitary* $v \in \mathcal{U}(pAp)$ *such that* u *is homotopic to* $v + (1 - p)$ *in* $\mathcal{U}(A)$.

(Proof: iv,old): If w *is unitary with* $wp = pw$, *and* $z \in A$ *with* $zz^* = (1 - p)$ *and* $z^*z \le p$, *then* $p + (1 - p)w$ *is unitary and is homotopic to* $z^*wz + (p - z^*z) + (1 - p)$ *(using that* $C^*(z, 1-p) \cong M_2$ *has unit* $z^*z + (1 - p)$*).*

Thus, $w \sim_h v + (1 - p)$ *with* $v := pw(z^*uz + (p - z^*z)) \in \mathcal{U}(pAp)$.

If $\|up - pu\| < 1$, *then* $\|u - a\| < 1$ *for* $a := pup + (1 - p)u(1 - p)$. *The polar decomposition* $a = w(a^*a)^{1/2}$ *in* $pAp + (1 - p)A(1 - p)$ *gives a unitary* $w \in A$ *with* $-1 \notin \mathrm{Spec}(w^*u)$ *and* $wp = pw$. *Thus,* $u \sim_h w \sim_h v + (1 - p)$ *for suitable* $v \in \mathcal{U}(pAp)$.

(β) *If* $t_1, t_2 \in E$ *are isometries with* $\|t_1^* t_2\| < 1$ *and if* $u \in \mathcal{U}(E)$ *satisfies* $\|t_1^* u t_2\| < 1$ *and* $[u] = 0 \in \mathrm{K}_1(E)$, *then* $u \in \mathcal{U}_0(E)$.

(v,old) `FROM: lem:old.A.K-basic1:`

(vii) Independence of $\oplus$ from the isometries $s_1, s_2 \in E$ with $\oplus := \oplus_{s_1,s_2}$ *and non-degeneracy property* (NP) *up to unitary equivalence:*

Suppose that $t_1, t_2 \in E$ are isometries with orthogonal ranges such that $q_{[-1]} := 1 - t_1t_1^* - t_2t_2^*$ is full and properly infinite if $p_{[-1]} \neq 0$ and is $q_{[-1]} = 0$ if $p_{[-1]} = 0$.

Then there exists a unitary $U \in \mathcal{U}(E)$ such that $Us_k = t_k$ $(k = 1, 2)$, and $U(a \oplus_{s_1,s_2} b)U^* = a \oplus_{t_1,t_2} b$ and $Up_{[-1]}U^* = q_{[-1]}$ for $a, b \in E$.

If $p_{[-1]}$ and $q_{[-1]}$ are full and properly infinite, then the unitary $U \in \mathcal{U}(E)$ can be chosen such that $[U] = 0$ in $\mathrm{K}_1(E)$.

In the cases where $p_{[-1]} \neq 0$ and E is K_1-injective, or where there exists a full and properly infinite projection $r \in E$ with $r \leq p_{[-1]}$ and $r \leq q_{[-1]}$, one can find $U \in \mathcal{U}_0(E)$ with $Us_k = t_k$.

Before we start with the proofs of the part ???? of Lemma **??** here hint of one of its limited applicability: ?????

`This comes from old appendix!!! Transfer old Lemma partly into other Lemmata. Trash remains.`

LEMMA 4.2.7. *(v) FROM: lem:old.A.K-basic1:*

If $u \in \mathcal{U}(A)$ with $0 = [u] \in \mathrm{K}_1(A)$, and if there exists a splitting projection $p \in A$ with $\|up - pu\| < 1$, then $u \in \mathcal{U}_0(A)$.

In particular, A is K_1-injective if for every $u \in \mathcal{U}(A)$ with $0 = [u] \in \mathrm{K}_1(A)$ there exists a splitting projection $p \in A$ with $\|up - pu\| < 1$, then $u \in \mathcal{U}_0(A)$.

(v): Let $u \in \mathcal{U}(A)$ with $0 = [u] \in \mathrm{K}_1(A)$, and suppose that there is a splitting projection $p \in A$ with $\|pu - up\| < 1$. By (iv), $u \sim_h v + (1 - p)$ for some unitary $v \in \mathcal{U}(pAp)$. It follows $[v + (1 - p)] = [u] = 0$ in $\mathrm{K}_1(A)$. Since $[v + (1 - p)] = 0$, there exists $n \in \mathbb{N}$ such that $(v + (1 - p)) \oplus 1_n \in \mathcal{U}_0(M_{n+1}(A))$, i.e., there is a path $W(t) \in \mathcal{U}(M_{n+1}(A))$ with $W(0) = 1_{n+1}$ and $W(1) = (v + (1 - p)) \oplus 1_n$. Since $1 - p$ is full and properly infinite in A, the projection $(1 - p) \oplus 0_n$ is full and properly infinite in $M_{n+1}(A)$. Thus, there is a partial isometry $Z \in M_{n+1}(A)$ with $Z^*Z = (1 - p) \oplus 1_n$ and $ZZ^* \leq (1 - p) \oplus 0_n$. Let $w(t) := (p + Z)W(t)(Z^* + p) + ((1 - p) \oplus 0_n - ZZ^*)$. Then $w(t)^*w(t) = 1 \oplus 0_n = w(t)w(t)^*$, $w(0) = 1 \oplus 0_n$ and $w(1) = (v + (1 - p)) \oplus 0_n$. If we naturally identify A with the corner $A \oplus 0_n$ of $M_{n+1}(A)$, then $w(t)$ becomes a continuous path in $\mathcal{U}(A)$ that connects $v + (1 - p)$ with 1. Thus, $u \sim_h 1$.

(vi) *If, for any two splitting projection $p, q \in A$, there are splitting projections $r, s \in A$ with $r \leq p$, $s \leq q$ and $\|rs\| < 1$, then all splitting projections with same class $[p] = [q]$ in $\mathrm{K}_0(A)$ are homotopic.*

(vi): If A does not contain splitting projections then (vi) is true. Suppose that A contains splitting projections. (Then the unit of A is properly infinite, and if $S, T \in A$ are isometries with $S^*T = 0$, then SS^* and TT^* are splitting projections.)

Let $p, q \in A$ splitting projections with $[p] = [q]$ in $\mathrm{K}_0(A)$.

By assumptions, there are splitting projections $r \leq p$ and $s \leq q$ with $\|rs\| < 1$. Since, r and s are properly infinite and full, there exists partial isometries $y, z \in A$ with $y^*y = p$, $r_1 := yy^* \leq r$, $z^*z = q$, and $s_1 := zz^* \leq s$. It implies, that r_1 and s_1 are splitting projections, and that $\|r_1 s_1\| \leq \|rs\| < 1$.

*Since $[p] = [q]$, we get $[r_1] = [s_1]$. Thus, the properly infinite projections r_1 and s_1 are MvN-equivalent (cf. [**172**]), i.e., there is $x \in A$ with $x^*x = r_1$ and $xx^* = s_1$. Now parts (iii) gives that $r_1 \sim_h s_1$.*

Since p is splitting, $1 - p$ is full and properly infinite, and there is $w \in A$ with $w^*w = p$ and $ww^* \leq 1 - p$. It follows $ww^* \sim_h p$ by part (iii). Part (iii) applies also to $ww^* = (yw^*)^*(yw^*)$ and $r_1 = (yw^*)(yw^*)^*$, and gives $ww^* \sim_h r_1$. Thus, $p \sim_h r_1$. Similar arguments show $q \sim_h s_1$. It follows $p \sim_h q$.

(vii) *If A has a properly infinite unit, then A is K_1-injective, if and only if, all splitting projections with same class $[p] = [q]$ in $\mathrm{K}_0(A)$ are homotopic.*

(viii) *????? For every isometries s and t with orthogonal ranges (i.e., $s^*t = 0$) and every unitary $u \in \mathcal{U}(A)$ the projections tt^* and u^*tt^*u are homotopic inside the projections of A, noted by $tt^* \sim_h u^*tt^*u$.*

(Requires K_1-injectivity !!!???)

(ix) *For every isometries s and t with orthogonal ranges (i.e., $s^*t = 0$) and every unitary $u \in \mathcal{U}(A)$ the projections tt^* and u^*tt^*u are homotopic inside the projections of A, – noted by $tt^* \sim_h u^*tt^*u$ –, for every unitary $u \in A$, if and only if, A is K_1-injective.*

Remark 4.2.8. The Part (v,5) of Lemma 4.2.6 has to be considered with some care, because it can happen for some $u \in \mathcal{U}(pEp)$ that $u + (1 - p) \in \mathcal{U}_0(E)$ but $0 \neq [u] \in \mathrm{K}_1(pEp)$ if the projection p is *not* full in E, e.g. :

Let $E = \mathcal{M}(\mathrm{C}(S^1) \otimes \mathbb{K})$, $u_0 \in \mathcal{U}(\mathrm{C}(S^1))$ the canonical generator of $\mathrm{C}(S^1)$, $p = 1 \otimes e_{11} \in \mathrm{C}(S^1) \otimes \mathbb{K}$. Then $pEp \cong \mathrm{C}(S^1)$. If $u := u_0 \otimes e_{11}$, then $u + (1 - p) \in \mathcal{U}_0(E) = \mathcal{U}(E)$ by the generalized Kuiper theorem [**180**], but $0 \neq [u] \in \mathrm{K}_1(pEp)$.

Proof. (vii): By assumption, the unit 1 is properly infinite in A, i.e., there are isometries $s, t \in A$ with $s^*t = 0$. Thus A contains a splitting projection p, e.g. $p := ss^*$.

Suppose that *all splitting projections with same class in* $\mathrm{K}_0(A)$ *are homotopic*, and let $u \in \mathcal{U}(A)$ with $[u] = 0$ in $\mathrm{K}_1(A)$. The projection u^*pu is again splitting, and is MvN-equivalent to p. Thus, $[p] = [u^*pu]$ in $\mathrm{K}_0(A)$, and $p \sim_h u^*pu$. By part(ii), there is $v \in \mathcal{U}_0(A)$ with $v^*u^*puv = p$. We have $[uv] = [u] + [v] = 0$. The arguments in the proof of part (vi) show that $uv \in \mathcal{U}_0(A)$. Thus $u \sim_h 1$.

Suppose, conversely, that A is K_1-injective. Let $p, q \in A$ splitting projections with $[p] = [q]$ in $\mathrm{K}_0(A)$. It follows $[1-p] = [1]-[p] = [1-q]$. Since p, q, $1-p$ and $1-q$ are all full and properly infinite (by definition of splitting projections), it follows from “an observation in [**172**]”, that $p \sim q$ and $1 - p \sim 1 - q$ (WvN-equivalence).

Thus, there exists a unitary $W \in A$ with $W^*pW = q$. Since $1-p$ is full and properly infinite, there exists an isometry $s \in A$ with $ss^* \leq 1-p$. The projection $1-ss^*$ satisfies $[1-ss^*]=0$. Thus, the properly infinite full projections $0 \oplus 1$ and $(1-ss^*)\oplus 1$ are MvN-equivalent in $M_2(A)$, and there is a partial isometry $Z \in M_2(A)$ with $Z^*Z = 0 \oplus 1$ and $ZZ^* = (1-ss^*)\oplus 1$. Let $V := (s\oplus 0)+Z$, then V is unitary and $((1-ss^*)+sWs^*)\oplus 1 = V(W\oplus 1)V^*$. In particular, $[(1-ss^*)+sWs^*] = [W]$ in $\mathrm{K}_1(A)$. The operator $u := ((1-ss^*)+sW^*s^*)W$ is unitary, satisfies $u^*pu = q$, and $[u] = [W]-[(1-ss^*)+sWs^*] = 0$ in $\mathrm{K}_1(A)$. Since A is K_1-injective, we get $u \in \mathcal{U}_0(A)$, i.e., $p \sim_h q$.

(ix): If $s,t \in A$ are isometries with $s^*t = 0$, then $p := tt^*$ is a splitting projection. Now suppose that $u \in \mathcal{U}(A)$ satisfies $0 = [u] \in \mathrm{K}_1(A)$, and that $p \sim_h u^*pu$. Then, by part (ii), there is $w \in \mathcal{U}_0(A)$ with $p = w^*(u^*pu)w$, i.e., $vp = pv$ for the unitary $v = uw$. We get $[v] = [u]+[w] = 0$, because, $[u] = 0 = [w]$. It follows $v \in \mathcal{U}_0(A)$ by part (iv). Hence, $u = vw^* \in \mathcal{U}_0(A)$.

If A is K_1-injective and $u \in A$ unitary, then $u^*tt^*u = v^*tt^*v \sim_h tt^*$ for $v := ((1-ss^*)+su^*s^*)u$, because $[v] = 0$ in $\mathrm{K}_1(A)$, which implies $v \in \mathcal{U}_0(A)$. □

Proof. The Lemmata 4.2.1 and 4.2.6 are also valid for *real* C^*-algebras E. Some definitions have to be done with some care, see e.g. proof of Part (v,6) or proofs in preliminary Observation (o).

Suppose that 1_E is properly infinite, then there are isometries $t_1, t_2 \in E$ with $t_1^*t_2 = 0$. We can take the isometries $s_1 := t_1$ and $s_2 := t_2t_1$, then $s_1^*s_2 = 0$ and

$$p_{[-1]} := 1-(s_1s_1^* + s_2s_2^*) \geq t_2^2(t_2^2)^*$$

is full and properly infinite with $[p_{[-1]}] = [1]-2[1] = -[1]$ in $\mathrm{K}_0(E)$. Thus here $s_1 := \psi(T_1)$ and $s_2 := \psi(T_2)$ come from from a unital C^*-morphism from $\mathcal{E}_3 := C^*(T_1,T_2,T_3\,;\ T_j^*T_k = \delta_{j,k}1)$ into E.

The more special case is where we can find isometries $t_1, t_2 \in E$ with $t_1t_1^* + t_2t_2^* = 1$ then $[1] = [t_1t_1^*]+[t_2t_2^*] = 2[1]$ in $\mathrm{K}_0(E)$, i.e., $[1]=0$ in $\mathrm{K}_0(E)$, and the $s_1 := t_1, s_2 := t_2$ come from a unital C^*-morphism of $\mathcal{O}_2 := C^*(T_1,T_2\,;\ T_j^*T_k = \delta_{j,k}1,\ T_1T_1^*+T_2T_2^* = 1)$. This is exactly the case where $[1]=0$ in $\mathrm{K}_0(E)$: Then $1-t_2t_2^*$ is a properly infinite and full projection in E with $0 = [1] = [1-t_2t_2^*] \in \mathrm{K}_0(E)$. By the below proved Part (ii), or by [**172**, thm. 1.4], there is an isometry $s_1 \in E$ with $s_1s_1^* + t_2^*t_2 = 1$. Let $s_2 := t_2$ and get $p_{[-1]} = 0$ for this s_1, s_2, that generate copy of $\mathcal{O}_2$.

Recall that *MvN-equivalence of projections* $p, q \in M_n(A)$ means that there is a partial isometry $v \in M_n(A)$ such that $v^*v = p$ and $vv^* = q$. The equivalence definition does not require that A is unital.

Part (i) can be seen from the definitions regarding the arguments in preliminary Part (o) of our proof and Lemmata 4.1.3 and 4.2.1.

Part (ii) is contained essentially in [**172**, thm. 1.4], which says – in our terminology – that the Murray–von-Neumann equivalence classes of full properly infinite projections in a properly infinite unital C^*-algebra E build a group with (generalized) Cuntz addition and that this group is naturally isomorphic to $\mathrm{K}_0(E)$.

If we combine this with the below considered observation (C0) and Remark 4.1.2 then we get the following basic property (Cu) that generalizes [**172**, thm. 1.4] (for simple unital C^*-algebras A) to the case of general C^*-algebras A:

Basic property of full properly infinite projections:

(Cu) Full and properly infinite projections p, q in a C^*-algebra A are Murray–von-Neumann equivalent if and only if $[p] = [q] \in \mathrm{K}_0(A)$. (Here A is not necessarily unital.)

If A contains a full and properly infinite projection $e \in A$, then each element $x \in \mathrm{K}_0(A)$ is the class $[p] = x$ of a properly infinite and full projection $p \in A$ with $p \leq e$.

The observation (Cu) of J. Cuntz is almost equivalent to Part (ii). Our proof uses the Parts (i) and (ii) of the "innocent" abstract Lemma 4.2.3. It shows at first that the sub-semigroup of MvN-equivalence classes of full and properly infinite projections build a group under Cuntz sum and that the natural morphism of this group into $\mathrm{K}_0(A)$ is surjective. Then we compare the defining relations and obtain from Lemma 4.2.3(ii) that this morphism must be a group isomorphism. This proof of observation (Cu) is only slightly different from that of [**172**, thm. 1.4]. It is useful to prove the below considered Observation (o) and Parts (i)–(iii) together.

The below stated basic observation (C0) in the proof of (i,ii,iii) reduces the proof of observation (Cu) to the case of the *unital* properly infinite $E = eAe$, using the natural isomorphism $\mathrm{K}_0(E) \cong \mathrm{K}_0(A)$ of Remark 4.1.2, cf. also Part (v,5).

(o): Let

$$U_c := s_1 s_2^* - s_2 s_1^* + p_{[-1]} = \exp\big((\pi/2)(s_1 s_2^* - s_2 s_1^*)\big)\,. \tag{2.3}$$

Then $U_c \in \mathcal{U}_0(C^*_{\mathbb{R}}(s_1, s_2))$, $U_c^2 = p_{[-1]} - (s_1 s_1^* + s_2 s_2^*)$, U_c has "geodesic" distance

$$\mathrm{cel}(U_c) \leq (\pi/2)\|s_1 s_2^* - s_2 s_1^*\| = \pi/2$$

to 1 inside the metric space $\mathcal{U}_0(E)$, and

$$U_c s_1 = -s_2\,, \quad U_c s_2 = s_1\,, \quad U_c p_{[-1]} = p_{[-1]}\,.$$

Hence, $U_c^*(a \oplus_{s_1,s_2} b) U_c = b \oplus_{s_1,s_2} a$ for $a, b \in E$ and $U_c \in \mathcal{U}_0(E)$ for real or complex C^*-algebras E.

We define a partial unitary Z with $Z^*Z = 1 - p_{[-1]} = ZZ^*$ by

$$Z := s_1^2 s_1^* + s_2 (s_2^*)^2 + (s_1 s_2)(s_2 s_1)^* - s_1 p_{[-1]} s_2^* \in C^*(s_1, s_2) \subseteq E\,.$$

Straight calculation gives $Z\big(a \oplus (b \oplus c)\big) = \big((a \oplus b) \oplus c\big) Z$ for $a, b, c \in E$, and $Z s_2 p_{[-1]} s_2^* = s_1 p_{[-1]} s_1^* Z$.

If $U(s_1) \in \mathcal{U}_0\big(M_2(C^*(s_1, s_2))\big) \subseteq \mathcal{U}_0(M_2(E))$ denotes the Halmos unitary of the isometry s_1 (cf. Remark 4.2.4), then

$$Z = [s_1, s_2]\,\big(U(s_2) \cdot \mathrm{diag}(1, U_c)\big)\,[s_1, s_2]^*\,.$$

Thus $Z \in \mathcal{U}_0\big((1-p_{[-1]})C^*(s_1,s_2)(1-p_{[-1]})\big)$, and the unitary

$$U_d := Z + p_{[-1]} = s_1^2 s_1^* + (s_1 s_2)(s_2 s_1)^* + s_2(s_2^*)^2 - s_1 p_{[-1]} s_2^* + p_{[-1]} \tag{2.4}$$

is in $\mathcal{U}_0(C^*(s_1,s_2)) \subseteq \mathcal{U}_0(E)$, and that U_d "realizes" the distributive law for $\oplus_{s_1,s_2}$ as unitary equivalence via U_d.

By Remark 4.2.4, $\mathrm{cel}(U(s_2)) \leq \pi/2$. If we apply this to the above given decompositions of Z and U_d, then we get that the unitary U_d has "exponential length", i.e., "geodesic" distance

$$\mathrm{cel}(U_d) \leq \mathrm{cel}(U(s_2)) + \mathrm{cel}(U_c) \leq \pi$$

from 1 inside the metric space $\mathcal{U}_0(E)$.

Calculation shows that the unitary equivalence by U_c and U_d includes also the "un-truncated" or "corrected" version $\oplus'$ of $\oplus_{s_1,s_2}$ given by

$$u \oplus' v := s_1 u s_1^* + s_2 v s_2^* + p_{[-1]}$$

on the group of unitary operators or the semi-group of isometries $u, v, w \in E$:

$$U_c^*(u \oplus' v)U_c = v \oplus' u$$

and

$$U_d^*((u \oplus' v) \oplus' w))U_d = u \oplus' (v \oplus' w)\,.$$

This can be seen from $U_c p_{[-1]} = p_{[-1]}$ and $Z s_2 p_{[-1]} s_2^* = s_1 p_{[-1]} s_1^* Z$.

(i,ii,iii): The commutative and associative law for $\oplus = \oplus_{s_1,s_2}$, up to unitary equivalence with a unitary in $\mathcal{U}_0(E)$, follows from Part (o). The other formulae by simple calculations, e.g. $u^*(a \oplus b)u = (u_1^* a u_1) \oplus (u_2^* a u_2)$ for $u := (u_1 \oplus u_2) + p_{[-1]}$, and is in $\mathcal{U}_0(E)$ if $u_1, u_2 \in \mathcal{U}_0(E)$, ...

`Old Lemma form Appendix A, now somewhere above contained:`

Suppose that $p, q \in A$ are full properly infinite projections.

If $[p] = [q]$ in $\mathrm{K}_0(A)$ then there exists $v \in A$ with $v^*v = p$ and $vv^* = q$.

If A contains a full and properly infinite projection p then for each $x \in \mathrm{K}_0(A)$ there exists a full properly infinite projection $q \leq p$ with $x = [q]$.

If $p, r \in A$ are full and properly infinite projections that have the same class $[p] = [q] \in \mathrm{K}_0(A)$ then there exists a partial isometry $z \in A$ with $z^*z = p$ and $zz^* = q$.

The proof of the observation (Cu) of J. Cuntz uses following elementary observation (C0), given below, but the proofs of (Cu), (ii) and (iii) follows not immediately from (C0):

(C0) If A is a (not necessarily unital) C^*-algebra and $e \in A$ is a full and properly infinite projection, then for every $n \in \mathbb{N}$ and every projection $p \in M_n(A)$ there is a projection $p' \in A$ such that p and $p' \oplus 0_{n-1} = \mathrm{diag}(p', 0, \ldots, 0)$ are MvN-equivalent in $M_n(A)$, $p' \leq e$ and $e - p'$ is full and properly infinite in A.

The observation (C0) reduces the proof of observation (Cu) to the case of properly infinite *unital* algebras.

In fact it is formally more general, and is easy to see, that the following holds: If e, p are projections in a C^*-algebra B such that e is properly infinite and p is in the closed ideal $\overline{BeB}$ generated by e, then there exists a partial isometry $z \in B$ with $z^*z = p$ and $zz^* \leq e$. Below we outline this in case $B = M_n(eAe)$.

The *proof of* (C0) goes as follows: $E := eAe$ has a properly infinite unit $1_E := e$, i.e., there are isometries $s_1, s_2 \in E$ with $s_1^* s_2 = 0$. Define isometries $t_k := s_2^{k-1} s_1 \in E$ for $k = 1, 2, \ldots$ with $t_k^* t_j = \delta_{j,k} 1_E$. Let $z_k := t_k \oplus 0_{n-1} = \mathrm{diag}(t_k, 0, \ldots, 0) \in M_n(E) \subseteq M_n(A)$. Then $z_j^* z_k = \delta_{jk}\, \mathrm{diag}(e, 0, \ldots, 0)$.

Since the projection $e \in A$ is full in A and is properly infinite and since the direct sum $A \oplus \{0_{n-1}\} \cong A \otimes p_{11}$ is full in $M_n(A) \cong A \otimes M_n$, the projection $p := \mathrm{diag}(e, 0, \ldots, 0) = e \oplus 0_{n-1}$ is full and properly infinite in $M_n(A)$.

It follows that, for each projection $q \in M_n(A)$ and $\varepsilon \in (0, 1/4]$, there are $m \in \mathbb{N}$ and elements $a_1, \ldots, a_m, b_1, \ldots, b_m \in A$ such that $\| q - \sum_k a_k p b_k \| \leq \varepsilon$. We get $\| q - x^* p y \| \leq \varepsilon$ for $x := \sum_j z_j a_j$ and $y := \sum_k z_k b_k$. It implies the existence of an element $c \in M_n(A)$ with $c^* p c = q$. The projection $r = pcc^*p \leq p = (e, 0, \ldots, 0)$ has form $r = (p'', 0, \ldots, 0)$ for a projection $p'' \leq e$. The projection $p' := s_1 p'' s_1^* \leq e$ has the quoted property that $e - p' \geq s_2 s_2^*$ is full and properly infinite in $E = eAe$ and the given projection $r \in M_n(A)$ is Murray–von-Neumann equivalent to $p' \in E \cong E \oplus 0_{n-1}$ inside $M_n(A)$.

Therefore it suffices to consider only the MvN-equivalence classes $[p]$ of projections $p \in E := eAe$, because each MvN-equivalence class $[q]$ of a projection q in $\bigcup_n M_n(A)$ is identical with the MvN-class $[p]$ of some projection $p \in E$, and we restrict later our considerations to C^*-algebras E with properly infinite unit element.

The projections in E build a commutative semi-group S under Cuntz addition $[p]_{MvN} + [q]_{MvN} := [p \oplus_{s_1,s_2} q]_{MvN}$. See Parts (o) and (i) for the additive and associative law modulo unitary homotopy, i.e., modulo unitary equivalence by unitaries in $\mathcal{U}_0(E)$.

If we consider E as a full corner of $M_n(E)$ by $a \in E \mapsto \mathrm{diag}(a, 0, \ldots, 0)$, then the sum $p \oplus q$ is MvN-equivalent to $p' + q'$ if $p', q' \in M_n(E)$ are projections with $p'q' = 0$, and are MvN-equivalent in $M_n(E)$ to p respectively q. It follows that the natural map $[p]_{MvN} \mapsto [p] \in \mathrm{K}_0(E)$ becomes a semi-group *epimorphism* from the semi-group S of the MvN-equivalence classes of projections $p \in E$ onto $\mathrm{K}_0(E)$.

Since, by definition of K_0, $[p] = [q] \in \mathrm{K}_0(E)$ if and only if there exists $n \in \mathbb{N}$ and a projection $r' \in M_n(E)$ and such that $\mathrm{diag}(p, r')$ and $\mathrm{diag}(q, r')$ are MvN-equivalent in $M_{n+1}(E)$, we can find a projection $r \in E$ that is MvN-equivalent to r' and such that $p \oplus_{s_1,s_2} r$ and $q \oplus_{s_1,s_2} r$ are MvN-equivalent. It follows that the map from the semi-group S of MvN-classes of projections in E into $\mathrm{K}_0(E)$ defines just the same equivalence relations on S as the canonical semi-group morphism from S into its Grothendieck group $\mathrm{Gr}(S)$.

In conclusion, the natural group epimorphism from $\mathrm{Gr}(S)$ onto $\mathrm{K}_0(E)$ is an isomorphism.

By observations (C0), the element $z_0 := [1_E]_{MvN} \in S$ can play the role of z_0 in Lemma 4.2.3(ii) for the semi-group S of MvN-equivalence classes of projections in E with Cuntz addition, because for every $p \in E$, $p \oplus (1-p)$ is MvN-equivalent to 1_E, cf. rules in Part (i), i.e., $[p] + [1-p] = [1] = z_0$ in S. If we let $y_0 := [1 - (1 \oplus 1)] = [p_{[-1]}]$, then $2z_0 + y_0 = z_0$ in S, and $e := z_0 + y_0 = [1 \oplus p_{[-1]}]$ is a dominate zero element of S by Lemma 4.2.3. Thus, the "splitting" projection $1 \oplus p_{[-1]} \oplus 0$ represents the "absorbing" zero element of $e + S \cong \mathrm{Gr}(S)$ via $e + s \mapsto [s]_{\mathrm{Gr}}$ by Lemma 4.2.3. Since $e + e = e$ in S, the natural map from S onto $\mathrm{K}_0(E)$ maps e into the zero element and defines an isomorphism from the subgroup $e + S$ of S onto $\mathrm{K}_0(E)$, because it induces an isomorphism of the Grothendieck group $\mathrm{Gr}(S)$ with $\mathrm{K}_0(E)$ by Lemma 4.2.3(i).

It implies that p and q are MvN-equivalent, if $p, q \in E$ if $[p] = [q]$ in $\mathrm{K}_0(E)$ and are MvN-equivalent to projections in $E \oplus (1 \oplus p_{[-1]})$, i.e., have MvN-class in $S + e$. Since $1 \oplus p_{[-1]} \geq s_1 s_1^*$ is full and properly infinite, each projection that is MvN-equivalent to projections in $E \oplus (1 \oplus p_{[-1]})$ is necessarily full and properly infinite.

The observation (C0) gives that full and properly infinite projections $p \in E$ are MvN-equivalent to projections in $E \oplus (1 \oplus p_{[-1]})$, because there exist a partial isometry $z \in E$ with $z^* z = 1 \oplus p_{[-1]}$ and $zz^* \leq p$, thus p is MvN-equivalent to $(p - zz^*) \oplus (1 \oplus p_{[-1]})$. The projections in $E \oplus (1 \oplus p_{[-1]})$ itself are all *splitting* because its complements majorize $s_2(1 - p_{[-1]})s_2^* + p_{[-1]} \sim_{MvN} 1$. This finishes the proof of observation (Cu), and shows that the elements of $S + e$ can be realized all as MvN-equivalence classes of splitting projections in E.

It is clear that the full and properly infinite projections p are all MvN-equivalent to splitting projections, e.g. take $s_1 p s_1^*$ in the MvN-equivalence class of p.

Sums $p \oplus q$ with full and properly infinite p are again full and properly infinite, and if at least one of $1 - p$ or $1 - q$ is full and properly infinite then $p \oplus q$ becomes a splitting projection.

The observation (Cu) implies that full and properly infinite projections $p, q \in E$ are MvN-equivalent if and only if $[p] = [q]$ in $\mathrm{K}_0(E)$.

If $[p] = [q]$ then also $[1 - p] = [1] - [p] = [1] - [q] = [1 - q]$. If p and q are splitting then $1 - p$ and $1 - q$ are again full and properly infinite. Thus, there exists a partial isometry z with $z^* z = 1 - p$ and $zz^* = 1 - q$. The unitary $u := v + z$ satisfies $up = qu$ if $vv^* = q$ and $v^* v = p$.

If $p, q \in E$ are properly infinite full projections then there exists an isometry $t \in E$ with $tt^* \leq p$. With this isometry it holds: If $v \in E$ is a unitary with $v^* p v = q$

then $u := (tv^*t^* + (1 - tt^*))v$ is a unitary with $0 = [u] \in \mathrm{K}_1(E)$ and $u^*pu = q$, because $tv^*t^* + (1 - tt^*)$ commutes with p.

(iv,a): Let $p, q \in E$ full and properly infinite projections with $[p] = [q] \in \mathrm{K}_0(E)$, and suppose that there exists an isometry $t \in E$ with $t^*(p + q)t = 0$. Then p, q and $r := tpt^*$ are splitting projections and $[p] = [q] = [r]$ in $\mathrm{K}_0(E)$. Since this projections are full and properly infinite, there exist by Part (ii) partial isometries $z_1, z_2 \in \mathcal{U}(E)$ with $z_1^*z_1 = r = z_2^*z_2$ and $z_1z_1^* = p$ and $z_2z_2^* = q$. We get from $t^*(p + q)t = 0$ that $t^*(p + q) = 0$ and $r(p + q) = 0$. Thus $z_k^2 = 0$ for $k = 1, 2$.

The unitary elements

$$u_k := (1 - z_k^*z_k - z_kz_k^*) + (z_k^* - z_k) = \exp((\pi/2)(z_k^* - z_k))\,,$$

are in $\mathcal{U}_0(E)$ and satisfy $u_k^*(z_kz_k^*)u_k = z_k^*z_k = r$ for $k = 1, 2$ by Part (v,6). Hence $u_1^*pu_1 = r = u_2^*qu_2$, and the unitary $u := u_1u_2^*$ with $u^*pu = q$ is in $\mathcal{U}_0(E)$.

(iv,b): Let $p, q \in E$ projections, and define $P := (p \oplus 1) \oplus 0 = s_1^2p(s_1^*)^2 + s_1s_2(s_1s_2)^*$ and $Q := (q \oplus 1) \oplus 0 = s_1^2q(s_1^*)^2 + s_1s_2(s_1s_2)^*$. Then $[p] = [q]$ in $\mathrm{K}_0(E)$, if and only if,

$$[P] = [(p \oplus 1) \oplus 0] = [p] + [1] = [q] + [1] = [(q \oplus 1) \oplus 0] = [Q]\,.$$

The projections P and Q are full and properly infinite because $s_1s_2(s_1s_2)^* \leq P$ and $s_1s_2(s_1s_2)^* \leq Q$. They are also splitting projections and satisfy the assumptions of Part (iv,a), because $s_2^*(P + Q)s_2 = 0$.

Thus, $[p] = [q]$, if and only if, $[P] = [Q]$, if and only if, there exist $u \in \mathcal{U}_0(E)$ with $u^*Pu = Q$.

(v): We show first (v,2) and that $u \in \mathcal{U}(E) \mapsto [u] \in \mathrm{K}_1(E)$ is surjective. Since (v,6) is obvious, this allows to verify (v,1) and (v,4) easily by using (v,3) and (v,6). Therefore we display only the proofs of (v,2), (v,5) and (v,3) in more detail.

(v,2): Recall that $\mathrm{K}_1(E)$ for unital C^*-algebras E can be described as the inductive limit of the discrete groups $\mathcal{U}(M_n(E))/\mathcal{U}_0(M_n(E))$ by the group morphisms

$$u \in \mathcal{U}(M_n(E)) \mapsto u \oplus 1 \in \mathcal{U}(M_{n+1}(E))\,,$$

where on this place $\oplus$ means the *direct* sum (despite that the original definition of the topological $\mathrm{K}_1(B)$ for unital Banach algebras is formally different).

Let $s_1, s_2 \in E$ isometries with $s_1^*s_2 = 0$ (e.g. as above chosen). We define isometries $t_k := s_2^{k-1}s_1 \in E$ for $k = 1, 2, \ldots$.

The t_n satisfy $t_n^*t_m = \delta_{n,m}1$. Let T (more precisely T_n) denote the row $[t_1, t_2, \ldots, t_n, t_n] \in M_{1,n}(E)$. The row T defines a partial isometry in $M_n(E)$ with $T^*T = 1_n$ and $TT^* \leq \mathrm{diag}(1, 0, \ldots, 0)$. We define a C^*-morphism

$$\varphi\colon\ M_n(E) \ni [a_{jk}] \mapsto T[a_{jk}]_{nn}T^* = \sum_{jk} t_ja_{jk}t_k^*$$

from $M_n(E)$ onto e_nEe_n, where

$$e_n := TT^* = t_1t_1^* + \cdots + t_nt_n^* \leq 1\,.$$

The restriction to diagonal elements is given by

$$\varphi\big(\mathrm{diag}(a_1, a_2, \ldots, a_n)\big) \;=\; T_n\;\mathrm{diag}(a_1, a_2, \ldots, a_n)\, T_n^* \;=\; \sum_{1\le j\le n} t_j a_j t_j^*\,.$$

That $u \in \mathcal{U}(E) \mapsto [u] \in \mathrm{K}_1(E)$ is *surjective* follows from the fact that $V \oplus 1_n$ and

$$\mathrm{diag}(\varphi(V) + 1 - \varphi(1_n)\,,\; 1, \ldots, 1) := (\varphi(V) + 1 - \varphi(1_n)) \oplus 1_{2n-1}$$

are unitarily equivalent in $M_{2n}(E)$ for each unitary $V \in M_n(E)$ by the *Halmos* unitary $U(T_n) \in M_2(M_n(E)) \cong M_{2n}(E)$ of the contraction T_n (cf. Remark 4.2.4), i.e., $U(T_n) = [a_{jk}]$ is given by $a_{11} := T_n$ (considered as matrix in $M_n(E)$ with 2-nd to n-th rows equal to zero), $a_{21} := 0$, $a_{22} := a_{11}^*$ and $a_{12} := -(1 - a_{11}a_{11}^*)$. The matrix $U(T_n)$ is a Halmos unitary in $\mathcal{U}_0(M_{2n}(E))$, and

$$U(T_n)(\,V \oplus 1_n\,)U(T_n)^* = a_{11}\, V\, a_{11}^* \;+\; 1_n - a_{11}a_{11}^*$$

The right side of the latter formula is the same as $\mathrm{diag}(\,\varphi(V) + 1 - \varphi(1)\,,\, 1,\, \ldots\,, 1)\,.$ Thus, $[\varphi(V) + 1 - \varphi(1)] = [V]$ in $\mathrm{K}_1(E)$ and the natural map $u \in \mathcal{U}(E) \mapsto [u] \in \mathrm{K}_1(E)$ is *surjective*.

Let $u_0, u_1 \in \mathcal{U}(E)$ and $u \in \mathcal{U}(pEp)$ with $[u_0] = [u_1]$ in $\mathrm{K}_1(E)$.

By (topological) definition of K_1-groups, cf. [**692**, def. 8.1.3], $[u_0] = [u_1]$ in $\mathrm{K}_1(E)$, if and only if, there is $n \in \mathbb{N}$ such that the unitaries $\mathrm{diag}(u_0, 1, \ldots, 1)$ and $\mathrm{diag}(u_1, 1, \ldots, 1)$ are homotopic in $\mathcal{U}(M_n(E))$, i.e., $W := \mathrm{diag}(u_1^* u_0, 1, \ldots, 1) \in \mathcal{U}_0(M_n(E))$ for sufficiently big $n \in \mathbb{N}$. It follows that

$$s_1(u_1^* u_0)s_1^* + (1 - s_1 s_1^*) \;=\; \varphi(W) \;+\; (1 - e_n) \;\in \mathcal{U}_0(E)\,.$$

It gives the desired homotopy in $\mathcal{U}(E)$:

$$(u_1 \oplus 1) + p_{[-1]} = s_1 u_1 s_1^* + (1 - s_1 s_1^*) \sim_h s_1 u_0 s_1^* + (1 - s_1 s_1^*) = (u_0 \oplus 1) + p_{[-1]}\,.$$

(v,5): The difference between the case where p is not full and the here considered case where p is full can be seen in Example 4.2.9.

Let $p \in E$ a projection such that $1 - p$ is full and properly infinite in E and let $u \in \mathcal{U}(pEp)$ a unitary that satisfies $[u + (1 - p)] = 0$ in $\mathrm{K}_1(E)$.

Since $1 - p$ is full and properly infinite, the unit of E must be properly infinite. Thus, there are isometries $s_1, s_2 \in E$ that satisfy the non-degeneracy property (ND) on $p_{[-1]}$.

We define below unitary operators $W, v \in E$ that satisfy

$$(v \oplus_{s_1,s_2} 1) + p_{[-1]} \;=\; s_1 v s_1^* + (1 - s_1 s_1^*) \;=\; W^*(u + (1 - p)W\,.$$

It follows $[(v \oplus 1) + p_{[-1]}] = [u + (1 - p)] = 0$ in $\mathrm{K}_1(E)$. We get $(v \oplus 1) + p_{[-1]} \in \mathcal{U}_0(E)$ by Part (v,2), and can conclude that $u + (1 - p) = W((v \oplus 1) + p_{[-1]})W^* \in \mathcal{U}_0(E)$.

There is an isometry $t \in E$ with $tt^* \le (1-p)$, because $(1-p)$ is full and properly infinite. The projection $r := t(s_2 s_2^* + p_{[-1]})t^*$ is splitting, because $ts_2(ts_2)^* \le r$ and $ts_1(ts_1)^* \le 1 - r$. Obviously, $s_2 s_2^* + p_{[-1]}$ is a splitting projection.

The Weyl–von-Neumann equivalence $r \sim_{WvN} s_2s_2^* + p_{[-1]}$, and the unitary equivalence of splitting projections with same class in $K_0(E)$ – as established in Part (iii) – imply the existence of a unitary $W \in \mathcal{U}(E)$ with $W^*rW = s_2s_2^* + p_{[-1]} = 1 - s_1s_1^*$.

Since $r \leq (1-p)$, the element $e := 1-(p+r) \leq 1-p$ is a projection in E with $p+e = 1-r$ and $u+e$ is a unitary in $(p+e)E(p+e) = (1-r)E(1-r)$.

For every $u \in \mathcal{U}(pEp)$, we can define an element $v \in E$ by

$$v := s_1^*W^*(u+e)Ws_1 = s_1^*W^*(u+(1-p))Ws_1 \,.$$

The element $v \in E$ is unitary, because $u+e \in \mathcal{U}((p+e)E(p+e))$, $Ws_1s_1^* = (1-r)W = (p+e)W$ and $s_1^*W^*Ws_1 = 1$. Then $1-p = e+r$ and

$$(v \oplus 1) + p_{[-1]} = s_1vs_1^* + (1 - s_1s_1^*) = W^*((u+e)+r)W = W^*(u+(1-p))W \,.$$

We consider now the case where the projection $p \in E$ is splitting in E:

If $p \in E$ is a splitting projection, then the inclusion map $\eta\colon pEp \hookrightarrow E$ defines an isomorphism η_* from $K_*(pEp)$ onto $K_*(E)$, because pEp and E are in a natural way stably equivalent: There exists an isometry T in $\mathcal{M}(E \otimes \mathbb{K})$ with $TT^* = p \otimes 1$.

Explicitly the group homomorphisms η_* are given for the classes of splitting projections $e \in pEp$ by $\eta_0([e]) := [e]$ and by $\eta_1([u]) := [u+(1-p)]$ for unitary $u \in \mathcal{U}(pEp)$.

The (generalized) Cuntz addition $\oplus_{s_1,s_2}$ can be chosen such that η_* is compatible with the splitting projection, e.g. such that $s_1s_1^* + s_2s_2^* \leq p$ and and $p - s_1s_1^* - s_2s_2^*$ is a splitting projection in pEp.

This isometries s_1, s_2 can be used to describe the inverse $\theta_* := (\eta_*)^{-1}$ of the η_* on classes $[e] \in K_0(E)$ and $[u] \in K_1(E)$ by $\theta_0([e]) := [s_1es_1^*]$ and $\theta_1([u]) := [s_1us_1^* + (p - s_1s_1^*)]$. Elementary verifications of $\eta_1 \circ \theta_1 = \mathrm{id}$ and $\theta_1 \circ \eta_1 = \mathrm{id}$ follow then from the identities

$$s_1us_1^* + (p - s_1s_1^*) + (1-p) = s_1us_1^* + (1 - s_1s_1^*)$$

and $[u] = [s_1us_1^* + (1 - s_1s_1^*)]$ in $K_1(E)$, and of $[s_1(u+(1-p))s_1^* + (p - s_1s_1^*)] = [u]$ in $K_1(pEp)$. The identities $\eta_0 \circ \theta_0 = \mathrm{id}$ and $\theta_0 \circ \eta_0 = \mathrm{id}$ come from $[s_1es_1^*] = [e]$ for $e \in E$ in $K_0(E)$ and for $e \in pEp$ inside $K_0(pEp)$.

One of the consequences for splitting $p \in E$ and $u \in \mathcal{U}(pEp)$ is:
$[u + (1-p)] = 0$ in $K_1(E)$, if and only if, $[u] = 0$ in $K_1(pEp)$, if and only if, $u + (1-p) \in \mathcal{U}_0(E)$.

(v,3): $(u^* \oplus u) + p_{[-1]} = V^*U_c^*VU_c$, for $V := s_1us_1^* + (1 - s_1s_1) = u \oplus' 1$ and with $U_c \in \mathcal{U}_0(E)$ defined by Equation (2.3) in the proof of Part (o).

(vi): We prove first the result for the special case in sub-part (vi, α), where u commutes with p:
If p is splitting, i.e., if p and $1-p$ are both full and properly infinite projections in

E then there exist isometries $t_1, t_2 \in E$ with $t_1t_1^* \leq p$ and $t_2t_2^* \leq 1-p$. The unitary

$$R := t_1t_2^* - t_2t_1^* + (1 - t_1t_1^* - t_2t_2^*) = \exp((\pi/2)(t_1t_2^* - t_2t_1^*))$$

is in $\mathcal{U}_0(E)$. Obviously $t_1^*R = t_2^*$, $pt_1t_1^* = t_1t_1^*$, $(1-p)t_2t_2^* = t_2t_2^*$ and $R^*t_1t_1^*R = t_2t_2^*$. Thus,

$$R^*pRt_2t_2^* = R^*pt_1t_1^*R = R^*t_1t_1^*R = t_2t_2^*\,.$$

It implies that $R^*(1-p)R\,t_2t_2^* = 0$, $u(1-p)R\,t_2t_2^* = 0$ and that

$$R^*(p + u(1-p))R\,t_2t_2^* = t_2t_2^*$$

Since $(1-p)t_2t_2^* = t_2t_2^*$, we get finally that

$$(up + (1-p))R^*(p + u(1-p))Rt_2t_2^* = t_2t_2^*\,.$$

We let $q := 1 - t_2t_2^*$ and $V := (up + (1-p))R^*(p + u(1-p))R$. Then $1 - q = t_2t_2^*$ is full and properly infinite in E and $V(1-q) = (1-q)$. Hence, there is a unitary $w \in qEq$ such that $w + (1-q) = V$. Since $R \in \mathcal{U}_0(E)$, the unitary V is homotopic in $\mathcal{U}(E)$ to $u = (up + (1-p))(p + u(1-p))$. By assumption, $[u] = 0$ in $\mathrm{K}_1(E)$. It follows $[w + (1-q)] = [V] = [u] = 0$.

We can apply Part (v,5) to $w + (1-q)$ (in place of $u + (1-p)$ of Part (v,5)), because $(1-q) = s_2s_2^*$ is full and properly infinite in E, and $w \in \mathcal{U}(qEq)$ satisfies $[w + (1-q)] = 0$ in $\mathrm{K}_1(E)$. Part (v,5) implies that $V = w + (1-q)$ is in $\mathcal{U}_0(E)$.

Since $u \sim_h V$, it follows that $u \in \mathcal{U}_0(E)$. This proves case (α).

Now suppose, *more generally*, that $u_1, u_2 \in \mathcal{U}(E)$ and a splitting projection $p \in E$ satisfy $\|u_kp - pu_k\| < 1$, for $k = 1, 2$ and that $[u_1] = [u_2] \in \mathrm{K}_1(E)$. Then $q_k := u_kp_ku_k^*$ satisfy $\|q_k - p\| < 1$ for $k = 1, 2$.

By Lemma 4.1.3(v), if $p, q \in E$ are two projections with $\|p - q\| < 1$, then there exists a unitary $v \in \mathcal{U}_0(A)$ with $v^*pv = q$ in the connected component $\mathcal{U}_0(A)$ of 1 in $\mathcal{U}(A)$, where $A := C^*(1, p, q) \subseteq E$.

This applies to the projections p and $q_k := u_kpu_k^*$ $(k = 1, 2)$, and gives $v_1, v_2 \in \mathcal{U}_0(E)$ with $v_kq_kv_k^* = p$. Thus, $v_1u_1pu_1^*v_1^* = v_2u_2pu_2^*v_2^*$ and $u := u_2^*v_2^*v_1u_1$ commutes with $p = t_1t_1^*$. Since $[u_1] = [u_2]$ and $[v_k] = 0$ we get $[u] = [v_1] + [u_1] - [v_2] - [u_2] = 0$.

By the above considered special case (α), we get that $u \in \mathcal{U}_0(E)$. The unitary u is homotopic to $u_2^*u_1$ in $\mathcal{U}(E)$ because $v_2^*v_1 \in \mathcal{U}_0(E)$. Hence, $u_2^*u_1 \in \mathcal{U}_0(E)$ and $u_1 \sim_h u_2$ in $\mathcal{U}(E)$.

(vi,β): Let $t_1, t_2 \in E$ isometries with $\|t_1^*t_2\| < 1$ and $u \in U(E)$ such that $\|t_1^*ut_2\| < 1$ and $[u] = 0 \in \mathrm{K}_1(E)$.

We consider the projection $q := 1 - t_2t_2^*$ and unitarily equivalent properly infinite full projections $p_1 := t_1t_1^*$ and $p_2 := u^*p_1u$. Then p_1 and p_2 are unitarily equivalent and, for $k = 1, 2$,

$$\|(1-q)p_k\| = \|p_kt_2\| \leq \max\big(\|t_1^*t_2\|, \|t_1^*ut_2\|\big) < 1\,.$$

Hence, Lemma 4.1.3(iv) applies and gives skew-adjoint operators $h_k = -h_k^* \in E$ with $\|h_k\| \leq \arcsin \|(1-q)p_k\| < \pi/2$ such that $r_k := \exp(-h_k)p_k \exp(h_k) \leq q$.

The definition of the projections p_k shows that p_1 and p_2 are unitarily equivalent properly infinite and full projections in E. The same follows for the r_k. Moreover the r_k satisfy $t_2^*(r_1 + r_2)t_2 = 0$ because $r_k \leq q = 1 - tt^*$. By Part (iv,a), there exists a unitary $v \in \mathcal{U}_0(E)$ such that $v^* r_1 v = r_2$. It follows that

$$v^* \exp(-h_1)p_1 \exp(h_1)v = v^* r_1 v = r_2 = \exp(-h_2)u^* p_1 u \exp(h_2)\,,$$

i.e., the unitary $w = u \exp(h_2)v^* \exp(-h_1)$ commutes with the projection p_1. The projection $p_1 = \exp(h_1)r_1 \exp(-h_1)$ is splitting, because $p_1 \leq 1 - SS^*$ for the isometry $S := \exp(h_1)t_2$.

The $\mathrm{K}_1(E)$-class $[w]$ of w is zero, because $[u] = 0$ by assumption, $v, \exp(h_k) \in \mathcal{U}_0(E)$ and $[w] = [u] + [\exp(h_1)] - [v] - [\exp(h_2)] = 0$. Thus, Part (vi,α) applies to w and p_1. It proves that $w \in \mathcal{U}_0(E)$, and that $u = w \exp(h_1)v \exp(-h_2)$ is in $\mathcal{U}_0(E)$.

(vii): The observation (Cu), applied to $p := 1 - s_1 s_1^*$ and $q := 1 - t_1 t_1^*$, gives immediately that for two pairs $s_1, s_2 \in E$ and $t_1, t_2 \in E$ of isometries with orthogonal ranges there exist a *unitary* $u \in E$ such that $us_1 = t_1$ and $[u] = 0 \in \mathrm{K}_1(E)$. It can appear that there does not exist any unitary u with $us_1 = t_1$ that satisfies also $us_2 = t_2$. This is e.g. the case if $p_{[-1]}$ and $q_{[-1]}$ are not both zero or are not both properly infinite and full projections.

If $p_{[-1]} = q_{[-1]} = 0$, then $u := t_2 s_2^* + t_1 s_1^*$ is the unique unitary in E with $us_k = t_k$. Therefore, e.g. if $\mathrm{K}_1(E) \neq \{0\}$ and $0 = [1] \in \mathrm{K}_0(E)$, it can happen that $u \in \mathcal{U}(E)$ and $us_k = t_k$ imply $[u] \neq 0$.

But one can always find a unitary v that satisfies $vs_1 = t_1$ and $0 = [u] \in \mathrm{K}_1(E)$ (but not necessarily $vs_2 = t_2$), e.g. let $v := u(1 \oplus_{s_1,s_2} u^*)$ in case $p_{[-1]} = 0$.

In the general case of given pairs of isometries (s_1, s_2) and (t_1, t_2) with orthogonal ranges let $v := t_1 s_1^* + z$ for some partial isometry z with $z^* z = p := 1 - s_1 s_1^*$ and $zz^* = q := 1 - t_1 t_1^*$, existing by Part (ii), because p and q are full and properly infinite. The unitary $u := w^* v$ with $w := (1 - t_2 t_2^*) + t_2 v t_2^*$ is a unitary with $us_1 = t_1$ and $[u] = 0 \in \mathrm{K}_1(E)$.

We can proceed as in the above consideration for the finding of a unitary if $p_{[-1]}$ and $q_{[-1]}$ are both full and properly infinite: Use that $[p_{[-1]}] = -[1_E] = [q_{[-1]}]$ and get from Part (ii) that there is a partial isometry z with $z^* z = p_{[-1]}$ and $zz^* = q_{[-1]}$. Then $v := t_1 s_1^* + t_2 s_2^* + z$ is a unitary with $vs_k = t_k$.

Since $p_{[-1]}$ is full and properly infinite, we get that there exists an isometry $S \in E$ with $SS^* \leq p_{[-1]}$. Then $u := v \cdot \big((1 - SS^*) + Sv^* S\big)$ is a unitary with $us_k = t_k$ and $[u] = 0$ in $\mathrm{K}_1(E)$.

The general observation is the following: Let $s_1, \ldots, s_n$ and $t_1, \ldots, t_n$ isometries in E with $s_j^* s_k = \delta_{jk} 1 = t_j^* t_k$, i.e., the s_k and t_k correspond to unital C^*-morphisms

h_0 and h_1 from $\mathcal{E}_n$ into E. Let $p_{[1-n]} := 1-\sum_{k=1}^n s_k s_k^*$ and $q_{[1-n]} := 1-\sum_{k=1}^n t_k t_k^*$. Clearly $[p_{[1-n]}] = (1-n)[1] = [q_{[1-n]}]$ in $\mathrm{K}_0(E)$.

If $p_{[1-n]} = q_{[1-n]} = 0$ then $u := \sum_{k=1}^n t_k s_k^*$ is the *unique* unitary with $us_k = t_k$ and it can happen that $[u] \neq 0$.

The projections $p_{[1-n]}$ and $q_{[1-n]}$ are MvN-equivalent in E, if and only if, there exists a $u \in \mathcal{U}(E)$ with $us_k = t_k$. This unitary induces a unitary equivalence of $p_{[1-n]}$ and $q_{[1-n]}$ by $up_{[1-n]}u^* = q_{[1-n]}$. In particular, $p_{[1-n]} \sim_{MvN} q_{[1-n]}$.

The latter is always the case if $p_{[1-n]}$ and $q_{[1-n]}$ are both full and properly infinite:

If $p_{[1-n]}$ and $q_{[1-n]}$ are both full and properly infinite, then they are MvN-equivalent by Part (ii), and there exist isometries s_{n+k} $(k = 1, 2, \ldots)$ with $s_{n+k}^* s_{n+\ell} = 0$ for $k \neq \ell$ and $s_{n+k}s_{n+k}^* \leq p_{[1-n]}$.

The unitary $u \in \mathcal{U}(E)$ with $us_k = t_k$ is determined up to multiplication with elements in $G := (1 - p_{[1-n]}) + \mathcal{U}(p_{[1-n]}Ep_{[1-n]})$ from the right side. It is the same as the multiplication with elements in $(1 - q_{[1-n]}) + \mathcal{U}(q_{[1-n]}Eq_{[1-n]})$ from the left side – because $up_{[1-n]} = q_{[1-n]}u$. Since $v := s_{n+1}u^*s_{n+1}^* + (1 - s_{n+1}s_{n+1}^*)$ is in the group G, it follows that uG contains unitaries w with $[w] = 0$ in $\mathrm{K}_1(E)$, e.g. $w := uv$. Our below explained method and Part (vi,β) indicates that it suffices to find an isometry $t \in E$ such that $\|(1 - p_{[1-n]})t\| < 1$ and $\|(1 - p_{[1-n]})u^*t\| < 1$ to show that $uG \cap \mathcal{U}_0(E)$ is not empty.

The consideration of the case $n = 2$ explains the ideas and appearing problems in the general case of *missing* K_1*-injectivity*. We discuss here only the case $n = 2$ in any detail:

The case – where a properly infinite and full projection $r \in E$ with $r \leq p_{[-1]}$ and $r \leq q_{[-1]}$ exists – uses Part (v,5), or likewise Part (vi,α). (Notice that the above given proofs of Parts (v) and (vi) are independent from our considerations given here.)

Suppose that a properly infinite and full projection $r \in E$ exists with $r \leq p_{[-1]}$ and $r \leq q_{[-1]}$. We find an isometry $T \in E$ such that $TT^* \leq r$. Define $s_3 := t_3 := Ts_1$, and the partial isometry $V := t_1s_1^* + t_2s_2^* + t_3s_3^*$. Then $1 - V^*V =: p_{[-2]} = p_{[-1]} - Ts_1s_1^*T$ and $1 - VV^* =: q_{[-2]} = q_{[-1]} - Ts_1s_1^*T$ are full and properly infinite projections, because each of it dominates the range $Ts_2s_2^*T^*$ of the isometry Ts_2 and E is properly infinite. The projections $p_{[-2]}$ and $q_{[-2]}$ are properly infinite and $[p_{[-2]}] = [1] - [V^*V] = [1] - [VV^*] = [q_{[-2]}]$. Thus, there exists a partial isometry Z with $Z^*Z = p_{[-2]}$ and $ZZ^* = q_{[-2]}$. We obtain that

$$U := (T + Z)(1 - Ts_2s_2^*T^* + Ts_2(T + Z)^*s_2^*T^*)$$

satisfies $Us_k = t_k$ $(k = 1, 2, 3)$ and $[U] = 0$ in $\mathrm{K}_1(E)$. Since $s_3 = t_3$, we get $U = W + (1 - P)$ with $P := 1 - Ts_1s_1^*T^* = 1 - s_3s_3^*$ and $W := UP \in \mathcal{U}(PEP)$. The facts that $(1 - P)$ is full and properly infinite and $[W + (1 - P)] = 0$ in $\mathrm{K}_1(E)$ imply that $U = W + (1 - P) \in \mathcal{U}_0(E)$ by Part (v,5) or Part (vi,α). Clearly $Us_k = t_k$ and $Up_{[-1]} = q_{[-1]}U$. □

Example 4.2.9. The difference between the use of splitting or non-splitting properly infinite projection p in the formulation of Lemma 4.2.6(v,5) can be seen from the following example of a strongly purely infinite C^*-algebra E with $\mathcal{U}_0(E) = \mathcal{U}(E)$ and a non-splitting properly infinite projection $p \in E$ that satisfies the first assumption in Lemma 4.2.6(v,5) such that $1-p$ properly infinite and full in E, but $\mathrm{K}_1(pEp) \neq \{0\}$:

Consider $E := \mathcal{M}(\mathcal{P}_\infty \otimes \mathbb{K})$ and $p := 1 \otimes p_{11}$, where $\mathcal{P}_\infty$ denotes here the (up to isomorphisms) unique unital pi-sun algebra in the UCT-class with $\mathrm{K}_0(\mathcal{P}_\infty) = 0$ and $\mathrm{K}_1(\mathcal{P}_\infty) \cong \mathbb{Z}$. Thus, $[u] = 0$ implies in this case $[u + (1-p)] = 0$, but the opposite direction is wrong.

Recall that all properly infinite unital C^*-algebras are K_1-surjective by Lemma 4.2.6(ii). The following Lemma 4.2.10 collects necessary and sufficient conditions for the K_1-injectivity of properly infinite unital C^*-algebras. (But the squizing property of Definition allowes more sufficiant cases for K_1-injectivity.)

Lemma 4.2.10. *Let E a* properly infinite *unital C^*-algebra. Each of the following conditions* (i)–(iv) *is equivalent to the* K_1-injectivity *of E:*

(i) *For every unitary $u \in E$ with $[u] = 0$ in $\mathrm{K}_1(E)$ there exist isometries $t_1, t_2 \in E$ and a unitary $v \in \mathcal{U}_0(E)$ with $\|t_1^* u t_2\| < 1$ and $\|t_1^* v t_2\| < 1$.*

(ii) *For every unitary $u \in E$ with $[u] = 0$ in $\mathrm{K}_0(E)$, there exist isometries $r_1, r_2 \in E$ and a unitary $v \in \mathcal{U}_0(E)$ with $r_1^* v r_2 = 0$ and $r_1^* u r_2 = 0$.*

(iii) *For every isometry $s \in E$ with full and properly infinite $1 - ss^*$ and for every unitary $u \in E$ one can find isometries $t_1, t_2 \in E$ and a unitary $v \in \mathcal{U}_0(E)$ with $ust_1 = vst_2$.*

(iv) *Splitting projections $p, q \in E$ with $[p] = [q] \in \mathrm{K}_0(E)$ are unitarily equivalent by a unitary in $\mathcal{U}_0(E)$.*

(v) *For every isometries s and t with orthogonal ranges (i.e., $s^*t = 0$) and every unitary $u \in \mathcal{U}(E)$ the projections tt^* and u^*tt^*u are homotopic inside the projections of E (denoted by $tt^* \sim_h u^*tt^*u$).*

A sufficient condition for the K_1-injectivity *of E is the following (possibly stronger) property (vi):*

(vi) *For every $u \in \mathcal{U}(E)$ with $0 = [u] \in \mathrm{K}_1(E)$ there exists a splitting projection $p \in E$ with $\|up - pu\| < 1$.*

For example, this is the case for each fixed given $u \in \mathcal{U}(E)$, if there exists a C^*-morphism

$$H_u \colon C^*(u) \otimes \mathcal{O}_\infty \to E^\infty := \ell_\infty(E)/c_0(E)$$

with $H_u(u \otimes 1) = (u, u, \ldots) + c_0(E) \in E^\infty$.

Those C^*-morphisms $H_u \colon C^*(u) \otimes \mathcal{O}_\infty \to E^\infty$ exist for example if E is *strongly* purely infinite, cf. Chapter 3. It is not known if such morphisms H_u exist for all unital purely infinite C^*-algebras E and $u \in \mathcal{U}(E)$. An answer to this question could be interesting for the open question if every purely infinite C^*-algebra is strongly purely infinite. But notice here that all unital p.i. C^*-algebras are K_1-injective because they satisfy the formally stronger "squeezing" property (sq) defined in Definition 4.2.14.

PROOF. The equivalence of each of (i)–(v) with K_1-injectivity:

K_1-injectivity $\Rightarrow$ (iii): Let $s \in E$ an isometry with full and properly infinite $1 - ss^*$ and $u \in E$ unitary. There exists an isometry $t \in E$ with $t^*s = 0$. Let $v := u(tu^*t^* + 1 - tt^*)$ and $t_1 := t_2 := t$. Then $ust_1 = vst_2$ and v is a unitary with $[v] = 0$ in $\mathrm{K}_1(E)$. The K_1-injectivity implies $v \in \mathcal{U}_0(E)$.

(iii) $\Rightarrow$ (ii): Let $u \in \mathcal{U}(E)$ with $[u] = 0$ in $\mathrm{K}_0(E)$. Since 1_E is properly infinite, there exists an isometry $s \in E$ with full and properly infinite $1 - ss^*$. By assumptions of (iii), there exist isometries $t_1, t_2 \in E$ and a unitary $u_0 \in \mathcal{U}_0(E)$ such that $ust_1 = u_0st_2$.

There exists an isometry $t \in E$ with $t^*s = 0$, because $1 - ss^*$ is full and properly infinite by assumptions on s.

The element

$$w := 1 - ss^* - tt^* + st_2s^* + tt_2^*t^* - s(1 - t_2t_2^*)t^* = (1 - ss^* - tt^*) + [s, t]U(t_2)[s, t]^*$$

is a unitary in $\mathcal{U}_0(E)$, because the Halmos unitary $U(t_2)$ is in $\mathcal{U}_0(M_2(E))$, cf. Remark 4.2.4.

Obviously, $ws = st_2$. Since $ust_1 = u_0st_2$, we obtain that $(u_0t)^*(u_0w)st_1 = t^*st_2t_1 = 0$ and $(u_0t)^*u(st_1) = (u_0t)^*u_0st_2 = 0$.

If we take $r_1 := u_0t$, $r_2 := st_1$ and $v := u_0w$ then $v \in \mathcal{U}_0(E)$, and r_1, r_2 are isometries with $r_1^*vr_2 = 0$ and $r_1^*ur_2 = 0$, i.e., the elements v, r_1, r_2 fulfill condition (ii) for the given unitary u with $[u] = 0$.

The implication (ii) $\Rightarrow$ (i) is obvious.

(i) $\Rightarrow$ K_1-injectivity: Let $u \in \mathcal{U}(E)$ with $0 = [u] \in \mathrm{K}_1(E)$ and suppose that (i) holds, i.e., that there exist isometries $t_1, t_2 \in E$ and a unitary $v \in \mathcal{U}_0(E)$ with $\|t_1^*vt_2\| < 1$ and $\|t_1^*ut_2\| < 1$.

We can apply Part (vi,β) of Lemma 4.2.6 to (t_1, vt_2, uv^*) (in place of the triple (t_1, t_2, u) in Part (vi,β) of Lemma 4.2.6), because $[uv^*] = [u] - [v]$ and $[u] = 0$, $v \in \mathcal{U}_0(E)$, and get $uv^* \in \mathcal{U}_0(E)$ and finally $u \in \mathcal{U}_0(E)$. Thus *every* unitary $u \in E$ with $0 = [u] \in \mathrm{K}_1(E)$ is in $\mathcal{U}_0(E)$.

K_1-injectivity $\Rightarrow$(iv): Let $p, q \in E$ splitting projections with $[p] = [q] \in \mathrm{K}_0(E)$. By Part (ii) of Lemma 4.2.6, there exists a unitary $u \in E$ with $u^*pu = q$ and $0 = [u] \in \mathrm{K}_1(E)$. If E is K_1-injective this implies $u \in \mathcal{U}_0(E)$.

(iv)$\Rightarrow$ K_1-injectivity: Let $v \in E$ a unitary with $0 = [v] \in \mathrm{K}_1(E)$. The projection $p := s_1s_1^* \in E$ is splitting, because $s_2s_2^* \leq 1 - p$. Clearly $q := v^*pv$ is also a splitting projection that has same class $[q] = [p]$ in $\mathrm{K}_0(E)$.

By assumption of (iv) there exists a unitary $u \in \mathcal{U}_0(E)$ with $p = u^*qu$. Then vu commutes with the splitting projection $p = s_1 s_1^*$ and $0 = [v] + [u] = [vu]$. The Part (vi,α) of Lemma 4.2.6 shows that $vu \in \mathcal{U}_0(E)$. Thus $v \in \mathcal{U}_0(E)$.

K_1-injectivity $\Rightarrow$(v): Suppose that E is K_1-injective. Let $s, t \in E$ isometries with $t^*s = 0$ and $u \in \mathcal{U}(E)$. Define $v := ((1 - ss^*) + su^*s^*)u$, then $[v] = 0$ in $\mathrm{K}_1(A)$. It implies $v \in \mathcal{U}_0(A)$, because E is K_1-injective. It follows $u^*tt^*u = v^*tt^*v \sim_h tt^*$.

(v)$\Rightarrow$ K_1-injectivity: If $s, t \in E$ are isometries with $s^*t = 0$, then $p := tt^*$ is a splitting projection. Let $u \in \mathcal{U}(A)$ with $0 = [u] \in \mathrm{K}_1(E)$. By assumption of (v), $p \sim_h u^*pu$. Remark 4.1.5 says that there exists $w \in \mathcal{U}_0(A)$ with $p = w^*(u^*pu)w$, i.e., $vp = pv$ for the unitary $v = uw$. We have $[v] = [u] + [w] = 0$, because $[u] = 0 = [w]$. It follows $v \in \mathcal{U}_0(A)$ by Lemma 4.2.6(vi,α). Hence, $u = vw^* \in \mathcal{U}_0(A)$.

This finish the proof of the equivalences of (i)–(v).

(vi)$\Rightarrow$(i): Suppose that for each $u \in \mathcal{U}(E)$ there exists a C^*-morphisms $H_u : C^*(u) \otimes \mathcal{O}_\infty \to E^\infty$ with $H_u(u \otimes 1) = u \in E \subseteq E^\infty$.

Let $u \in \mathcal{U}(E)$ with $[u] = 0$ in $\mathrm{K}_1(E)$ and

$$H_u : C^*(u) \otimes \mathcal{O}_\infty \to E^\infty := \ell_\infty(E)/c_0(E)$$

a C^*-morphism with $H_u(u \otimes 1) = u \in E \subseteq E^\infty$.

Let $s_1, s_2, \ldots$ canonical generators of $\mathcal{O}_\infty$. $H_u(1 \otimes s_k) \subseteq E^\infty$ for $k \in \{1, 2\}$ lift to a sequence of contractions $(s_{k,1}, s_{k,2}, \ldots) \in \ell_\infty(E)$ that satisfy, for $j, k \in \{1, 2\}$, the equations $\lim_n \|s_{j,n}^* s_{k,n} - \delta_{j,k}1\| = 0$ and $\lim_n \|[u, s_{k,n}]\| = 0$.

Replace, for sufficiently big $n \in \mathbb{N}$, the $s_{k,n}$ ($k \in \{1, 2\}$) by its small perturbations $t_{k,n} \in E$ that are isometries and satisfy $\|[u, t_{k,n}]\| < 1/4$ and $\|t_{1,n}^* t_{2,n}\| < 1/4$. If we let $v := 1$, $t_k := t_{k,n}$, then u, v, t_1 and t_2 satisfy the condition in Part (i). Thus, E is K_1-injective if it has the property in Part (v). □

In the following Proposition 4.2.11 the elements $s_1, s_2, \ldots$ denote the canonical generators of $\mathcal{O}_\infty := C^*(s_1, s_2, \ldots\, ;\ s_j^* s_k = \delta_{jk}1)$. Recall that C^*-morphisms $h_0, h_1 : A \to E$ are **homotopic**, if there exists a point-norm continuous path $\xi \in [0, 1] \mapsto H_\xi \in \mathrm{Hom}(A, E)$ of C^*-morphisms with $h_0 = H_0$ and $h_1 = H_1$.

Proposition 4.2.11. *Suppose that E is a C^*-algebra with properly infinite unit element.*

Then, for any unital C^*-morphisms $h_0, h_2 : \mathcal{O}_\infty \to E$, there exists a unitary $u_0 \in \mathcal{U}(E)$ with $u_0 h_2(s_1) = h_0(s_1)$ and $0 = [u_0] \in \mathrm{K}_1(E)$ such that h_0 is homotopic to h_1 in $\mathrm{Hom}(\mathcal{O}_\infty, E)$ with point-norm topology, where we build $h_1 : \mathcal{O}_\infty \to E$ from h_2 by $h_1(s_n) := u_0 h_2(s_n)$ for $n \in \mathbb{N}$.

The algebra E is K_1-injective if and only if any two unital C^*-morphisms from $\mathcal{O}_\infty$ into E are homotopic.

Proof. The unital C^*-morphisms $h_0, h_2 \colon \mathcal{O}_\infty \to E$ are injective because $\mathcal{O}_\infty$ is simple (and purely infinite) by Corollary 2.2.7, cf. also [**169**, thm. 1.13, thm. 3.4] and [**172**, prop. 1.6].

We use this to simplify notations, because we can now suppose that $\mathcal{O}_\infty$ is unitally contained in E (via h_0) by identifying the canonical generators s_n of $\mathcal{O}_\infty$ with its images $h_0(s_n)$, and get a reference copy of $\mathcal{O}_\infty$ inside E. Hence, we can suppose without loss of generality that $\mathcal{O}_\infty \subseteq E$ and that $h_0(s_n) = s_n$, i.e., that h_0 is the identity map of $\mathcal{O}_\infty$.

Let $Z := h_2(s_1)s_1^*$. Then $Zs_1 = h_2(s_1)$, and the projections $Z^*Z = s_1s_1^*$, $ZZ^* = h_2(s_1s_1^*)$, $1-Z^*Z = 1-s_1s_1^*$ and $1-ZZ^* = h_2(1-s_1s_1^*)$ are full and properly infinite projections with $[1-Z^*Z] = [1-ZZ^*]$ in $\mathrm{K}_0(E)$. By Lemma 4.2.6(ii), cf. also [**172**, thm. 1.4], there exists a partial isometry $Y \in E$ with $Y^*Y = 1 - Z^*Z$ and $YY^* = 1 - ZZ^*$. Since $Y^*Z = 0 = ZY^*$, the sum $W := Y + Z$ is a unitary with $Ws_1 = h_2(s_1)$. The element $V := W((1 - s_2s_2^*) + s_2W^*s_2^*)$ is again a unitary with $Vs_1 = h_2(s_1)$, but now with class $[V] = 0$ in $\mathrm{K}_1(E)$.

Let $u_0 := V^*$. It satisfies $[u_0] = 0$ and $u_0h_2(s_1) = s_1 = h_0(s_1)$. We define a new C^*-morphism $h_1 \colon \mathcal{O}_\infty \to E$ by $h_1(s_n) := u_0h_2(s_n)$ for $n = 1, 2, \ldots$. It has the property $h_1(s_1) = s_1$.

The arguments used above (for h_2, Z and construction of V) work also for h_1 in place of h_2 and the partial isometries $Z_n := \sum_{k=1}^n h_1(s_k)s_k^*$:

The Z_n satisfy $P_n := Z_n^*Z_n = \sum_{k=1}^n s_ks_k^*$ and

$$Z_nZ_n^* \;=\; h_1(\sum_{k=1}^n s_ks_k^*) \;=\; h_1(P_n)\,.$$

The full and properly infinite projections $1 - Z_n^*Z_n$ and $1 - Z_nZ_n^* = h_1(1 - Z_n^*Z_n)$ are MvN-equivalent because they have have same $\mathrm{K}_0(E)$-class. Let $Y_n \in E$ a partial isometry with $Y_n^*Y_n = 1 - Z_n^*Z_n$ and $Y_nY_n^* = 1 - Z_nZ_n^*$. The sum $W_n := Y_n + Z_n$ is unitary and the unitary

$$V_n := W_n(1 - s_{n+1}s_{n+1}^* + s_{n+1}W_n^*s_{n+1}^*)$$

satisfies $0 = [V_n] \in \mathrm{K}_1(E)$ and $V_ns_k = h_1(s_k)$ for $k \le n$. In particular, $V_1P_1 = P_1$ and $V_1(1 - s_1s_1^*)$ is a unitary in $\mathcal{U}((1 - s_1s_1^*)E(1 - s_1s_1^*))$. Since $s_1s_1^*$ is a splitting projection and $[V_1] = 0$, this implies by Lemma 4.2.6(v,5) that $V_1(1 - s_1s_1^*)$ has class $[V_1(1 - s_1s_1^*)] = 0$ in $\mathrm{K}_1((1 - s_1s_1^*)E(1 - s_1s_1^*))$, and that $V_1 \in \mathcal{U}_0(E)$.

It follows that there is a continuous path $\lambda \in [0,1] \mapsto V_\lambda \in \mathcal{U}_0(E)$ that connects $V_0 := 1$ and the above defined unitary $V_1 \in \mathcal{U}(E)$.

Similar arguments apply for $n \ge 1$ to the unitary $Q_n := V_n^*V_{n+1}$ and the projection $P_n = Z_n^*Z_n$:

We get that $Q_nP_n = P_n$ and that P_n is splitting. Hence, $[Q_n] = [V_{n+1}] - [V_n] = 0$ in $\mathrm{K}_1(E)$ implies that $[Q_n(1 - P_n)] = 0$ in $\mathrm{K}_1((1 - P_n)E(1 - P_n))$ because $1 - P_n$ is a full projection in E, see Lemma 4.2.6(v,5) with $Q_n(1 - P_n)$ and $1 - P_n$ in place of u and p.

If we let $P_0 := 0$ and $P_1 = s_1 s_1^*$, then by Lemma 4.2.6(v,5),

$$Q_n(1 - P_{n-1}) = Q_n(1 - P_n) + s_n s_n^* \in \mathcal{U}_0((1 - P_{n-1})E(1 - P_{n-1}))\,.$$

We obtain a continuous path $\lambda \in [0,1] \mapsto R_\lambda^{(n)} \in \mathcal{U}((1 - P_{n-1})E(1 - P_{n-1}))$ with $R_0^{(n)} = (1 - P_{n-1})$ and

$$R_1^{n+1} = Q_n(1 - P_n) + s_n s_n^*\,.$$

Notice that $V_{n+1} = V_n Q_n = V_n \cdot (R_1^{(n)} + P_{n-1})$.

We combine the above defined maps $\lambda \in [0,1] \mapsto V_\lambda$ and $n \in \mathbb{N} \mapsto V_n$ to a continuos path $\lambda \in [0,\infty) \mapsto V_\lambda \in \mathcal{U}_0(E)$ for $\lambda \in [n, n+1]$ $(n \geq 1)$ by

$$V_\lambda := V_n \cdot (R_{\lambda - n}^{(n)} + P_{n-1})\,.$$

Since $V_n s_k = h_1(s_k)$ for $k \leq n$ and $P_{n-1} s_k = s_k$ for $k \leq n-1$, it follows that $V_\lambda s_k = h_1(s_k)$ for all $k \leq \lambda - 1$.

The above defined path $\lambda \in [0,\infty) \to V_\lambda \in \mathcal{U}_0(E)$ defines a point-norm continuous path $\xi \in [0,1] \mapsto H_\xi$ in the unital C^*-morphisms from $\mathcal{O}_\infty$ into E by assigning to the generators $s_1, s_2, \ldots \in h_0(\mathcal{O}_\infty)$ and $\xi \in [0,1)$ the values

$$H_\xi(s_n) := V_{(1-\xi)^{-1}\xi} \cdot s_n \;=\; u_\xi \cdot s_n$$

where we let $u_\xi := V_{(1-\xi)^{-1}\xi}$ and $H_1 := h_1$. Then $H_0 = h_0$, and the path is continuous at $\xi = 1$, because

$$\lim_{\xi \to 1} u_\xi s_n = h_1(s_n) \qquad \text{for all } \; n \in \mathbb{N}\,.$$

Moreover, $H_\xi(s_k) = u_\xi s_k = s_k$ if $k + 1 \leq (1 - \xi)^{-1}$ by our construction.

Suppose that E is K_1-injective, i.e., that $[u] = 0 \in \mathrm{K}_1(E)$ implies $u \in \mathcal{U}_0(E)$. Then above considered u_0 is in $\mathcal{U}_0(E)$ and we find a path $\xi \in [1,2] \mapsto u(\xi) \in \mathcal{U}(E)$ with $u(1) = u_0$ and $u(2) = 1$. We can define a point-norm continuous path

$$\xi \in [0,2] \mapsto H_\xi \colon \mathcal{O}_\infty \to E$$

by $H_\xi := h_\xi$ for $\xi \in [0,1]$, and by $H_\xi(s_n) := u(\xi) h_1(s_n)$ for $\xi \in [1,2]$. This path satisfies $H_0 = h_0$ and $H_2 = h_2$.

Suppose that 1_E is properly infinite and that any two unital C^*-morphisms $h_1, h_2 \colon \mathcal{O}_\infty \to E$ are homotopic. Let $u \in \mathcal{U}(E)$ with $0 = [u]$ in $\mathrm{K}_1(E)$.

Since 1 is properly infinite there exist isometries $t_1, t_2 \in E$ with orthogonal ranges, i.e., $t_j^* t_k = \delta_{jk} 1$ for $j, k \in \{1, 2\}$. The sequence $s_n := t_2^{n-1} t_1$ with $t_2^0 := 1$ defines a unital C^*-morphism $H^{(0)}$ from $\mathcal{O}_\infty$ into E, because $s_j^* s_k = \delta_{jk} 1$ for $j, k \in \mathbb{N}$, and $\mathcal{O}_\infty$ is the universal C^*-algebra with this defining relations. Since $\mathcal{O}_\infty$ is simple, cf. Corollary 2.2.7, the C^*-morphisms are injective.

We get another *-monomorphism $H^{(1)}$ from $\mathcal{O}_\infty$ into E that maps the canonical generators $s_1, s_2, \ldots$ of $\mathcal{O}_\infty \cong H^{(0)}(\mathcal{O}_\infty)$ to $H^{(1)}(s_n) := u s_n$ for $n \in \mathbb{N}$.

By assumption there exists a point-norm continuous path $\xi \in [0,1] \mapsto H_\xi$ into the unital C^*-morphisms $H_\xi \colon \mathcal{O}_\infty \to E$, such that $H_k = H^{(k)}$ for $k \in \{0, 1\}$.

Then $p_\xi := H_\xi(s_1 s_1^*)$ is a continuous path in the projections with $p_0 = s_1 s_1^*$ and $p_1 = H^{(1)}(p_0)$. Thus, there exists $V \in \mathcal{U}_0(E)$ with $V^* p_0 V = p_1 = u p_0 u^*$, cf. Lemma 4.1.3(v).

We get $V u p_0 = p_0 V u$ for the splitting projection $p_0 = s_1 s_1^*$. Now $V \in \mathcal{U}_0(E)$ implies that $[Vu] = [u] = 0$ in $\mathrm{K}_1(E)$. It follows that $Vu \in \mathcal{U}_0(E)$ by Part (vi,β) of Lemma 4.2.6. Using again $V \in \mathcal{U}_0(E)$, we obtain $u \in V^* \mathcal{U}_0(E) = \mathcal{U}_0(E)$. □

Remark 4.2.12. The proof of Proposition 4.2.11 shows that two unital C^*-morphisms $h_1, h_2 \colon \mathcal{O}_\infty \to E$ are homotopic if $h_1(s_1) = h_2(s_1)$.

Notice that following Lemma 4.2.13 is not trivial, because it does not require that A is simple.

Lemma 4.2.13. *Let A a purely infinite unital C^*-algebra, let $e, f \in A_+$ with $0 \le f \le e \le 1$ and $S \in A$ an isometry such that $S^* f S$ is contained in the closed ideal $J := I(1-e)$ generated by $(1-e)$.*

Then there exists an isometry $T \in A$ and $\delta \in (0,1]$ that satisfy $\|T^* f T\| = 1 - \delta < 1$.

Proof. The inequality $0 \le (1-e) \le (1-f)$ implies that $I(1-e) \subseteq I(1-f)$. Thus, $S^* f S \in I(1-f)$, and for each $\varepsilon > 0$ there exist $g_1, \ldots, g_n \in A$ such that

$$\|S^* f S - \sum_{k=1}^{n} g_k^* (1-f) g_k\| < \varepsilon$$

Combined with the equation $S^* f S = 1 - S^*(1-f)S$ it shows that 1_A is contained in the closed ideal $I(1-f)$ generated by $1-f$.

If A is purely infinite then this is equivalent to the existence of $d_\varepsilon \in A$ with $\|1 - d_\varepsilon^* (1-f) d_\varepsilon\| < \varepsilon$ for each $\varepsilon \in (0, 1/2)$.

CHECK AGAIN THE ESTIMATES!! :

There exists $\delta \in (0,1)$, – depending on the norm $\|d_{1/4}\|$ –, with

$$\|1 - d_{1/4}^* (1 - \delta - f)_+ d_{1/4}\| < 1/4 .$$

The element $T := C(C^*C)^{-1/2}$ with $C := (1-\delta-f)_+^{1/2} d_{1/4}$ is an isometry in A with $\|T^* f T\| \le 1 - \delta < 1$, because $\|T^* f T\| \le \sup_n \|(1-\delta-f)_+^{1/n} f\|$. □

Definition 4.2.14. We say that a unital C^*-algebra A has the “squeezing” property if A satisfies following **Property (sq)**:

(sq) For each $a \in A$ there exist isometries $r_1, r_2 \in A$ (depending on a) with $\|r_1^* a r_2\| \le 2\|a\|/3$.

It is still not known if C^*-algebras with properly infinite units are K_1-injective, even in case of weakly purely infinite C^*-algebras. Almost all cases where one could prove ([5]) the K_1-injectivity have implicitly to do with the now defined “squeezing” Property (sq) that implies K_1-bijectivity.

[5] – up to August 2018 –

PROPOSITION 4.2.15. *If a unital C^*-algebra A has the "squeezing" Property* (sq) *of Definition 4.2.14 then A is* K_1*-bijective in sense of Definition 4.2.2.*

Following examples (a - c) *of C^*-algebras satisfy Property* (sq)*:*

(a) $\mathcal{E}_n := C^*(s_1, \ldots, s_n\,;\ s_i^* s_j = \delta_{ij} 1)$, *for* $n = 2, \ldots, \infty$.
(b) *each unital purely infinite C^*-algebra A, and*
(c) *the multiplier algebra $A := \mathcal{M}(B)$ of every stable σ-unital C^*-algebra B.*

The class of C^*-algebras $A, A_1, A_2, \ldots$ with Property (sq) *is invariant under following constructions* (i-vii)*:*

(i) *Infinite direct sums* $\ell_\infty(A_1, A_2, \cdots)$,
(ii) *tensor products* $A \otimes^{\max} B$ *with any unital C^*-algebra B,*
(iii) $\mathrm{C_b}(X, A)$ *for locally compact σ-compact Hausdorff spaces X,*
(iv) *quotients A/J, for closed ideals $J \neq A$ of A,*
(v) *inductive limits with unital C^*-morphisms,*
(vi) *fix-point algebras of permutation actions on the n-times tensor product with $n \geq 2$:* $A^{\otimes^n} := A \otimes A \otimes \cdots \otimes A$, *and*
(vii) $B + \varphi(\mathcal{O}_\infty)$, *for every unital C^*-morphism $\varphi\colon \mathcal{O}_\infty \to \mathcal{M}(B)$ if B is a σ-unital C^*-algebra and its multiplier algebra $\mathcal{M}(B)$ has the Property* (sq) *(e.g. if B is stable – by Part (c)).*

In particular it follows:

If a unital C^*-algebra A satisfies Property (sq) *then the asymptotic corona* $\mathrm{C_b}([0,\infty), A)/\,\mathrm{C_0}([0,\infty), A)$ *and the C^*-algebras $E := (A \otimes^{\max} C)/J$, for every unital C^*-algebra C and every closed ideal $J \not\ni 1$ of $A \otimes^{\max} C$, have Property (sq) and are all* K_1*-bijective.*

Stable coronas $\mathrm{Q^s}(B)$ *of σ-unital C^*-algebras B have Property* (sq) *and are* K_1*-bijective.*

Examples (a) and permanence property (v) show that $\mathcal{O}_\infty = \operatorname{indlim}_n \mathcal{E}_n$ *has Property (sq) and is* K_1*-bijective.*

PROOF. We divide the proof into 3 groups.

(1st) shows that unital A with Property (sq) of Definition 4.2.14 contains isometries $s, t \in A$ with $s^*t = 0$ – which implies K_1-surjectivity by Part (v) of Lemma 4.2.6 –, and that Property (sq) implies that A satisfies the necessary and sufficient condition (i) of Lemma 4.2.10 for K_1-bijectivity. Moreover we reformulate Property (sq) in a more applicable form.

(2nd) the Property (sq) has the quoted permanence properties (i-vii), and

(3rd) the under (a,b,c) listed classes of C^*-algebras have Property (sq).

Ad(1st): The Property (sq) implies that A contains two isometries s_1, s_2 with "orthogonal ranges", i.e., with $s_1^* s_2 = 0$. Indeed, for $a := 1$ exist by Property (sq) isometries $r_1, r_2 \in A$ with $\|r_1^* r_2\| \leq 2/3$. Let $p := r_1 r_1^*$ and $q := 1 - r_2 r_2^*$. The projections p, q satisfy $\|p(1-q)\| = \|r_1^* r_2\| \leq 2/3$. By Lemma 4.1.3(iv) there exists a unitary $w \in \mathcal{U}_0(A)$ with $p \leq wqw^* = 1 - (wr_2)(wr_2)^*$, i.e., $r_1^*(wr_2) = 0$. Thus, $s_1^* s_2 = 0$ for the isometries $s_1 := r_1$ and $s_2 := wr_2$, and A has a properly infinite unit element. It implies that A is K_1-surjective by Lemma 4.2.6(v).

We derive a stronger and more flexible formulation of Property (sq):
If there exists $\delta_0 \in (0,1)$ with the property that, for each $a \in A$, there exist isometries $r_1, r_2 \in A$ – depending on a – with $\|r_1^* a r_2\| \leq (1-\delta_0) \cdot \|a\|$, then we can replace a by $r_1^* a r_2$ and get isometries $t_1, t_2 \in A$ – depending on $r_1^* a r_2$ – with $\|(r_1 t_1)^* a (r_2 t_2)\| \leq \|a\| \cdot (1-\delta_0)^2$.

Repeats of this argument show that the Property (sq) is equivalent to the property that for each element $a \in A$ and given $\varepsilon > 0$ there exists isometries $r_1, r_2 \in A$ with $\|r_1^* a r_2\| < \varepsilon$.

If we replace in Definition 4.2.14 the element a by $s_1^* a s_2$ with isometries $s_1, s_2 \in A$ with orthogonal ranges, i.e., $s_j^* s_k = \delta_{jk} 1$, then we find isometries $r_1, r_2 \in A$ with $\|r_1^*(s_1^* a s_2) r_2\| < \varepsilon$. The element $t_1 := s_1 r_1$ and $t_2 := s_2 r_2$ are *isometries* in A that satisfy

$$\|t_1^* a t_2\| < \varepsilon, \quad \text{and} \quad t_j^* t_k = \delta_{jk} 1\,. \tag{2.5}$$

It implies immediately that A fulfills the sufficient condition for K_1-injectivity in Lemma 4.2.10(i) with $v := 1$ for each $u \in \mathcal{U}(A)$. Indeed, take $a := u$ and $t_k := r_k$ ($k \in \{1,2\}$) for some isometries $r_1, r_2 \in A$ with $\|r_1^* a r_2\| < 1/2$ and $r_1^* r_2 = 0$.

Induction over n in Inequality (2.5) shows that, for any finite subset $F = \{a_1, \ldots, a_n\} \subset A$ and $\varepsilon > 0$, there exist isometries $r_1, r_2 \in A$ with $\|r_1^* x r_2\| < \varepsilon$ for all $x \in F$, and $r_1^* r_2 = 0$.

The induction step from n to $n+1$ uses that isometries $s, t \in A$ exist with $\|s^*(r_1^* a_{n+1} r_2) t\| < \varepsilon$. Then $(r_1 s)^*(r_2 t) = 0$ and $\|(r_1 s)^* a_k (r_2 t)\| < \varepsilon$ for $k = 1, \ldots, n$.

Ad(2nd): C^*-algebras A with the above derived formally stronger property, – but that is equivalent to Property (sq) –, have the permanence properties (i-vi):

(i): If $A_1, A_2, \ldots$ are unital C^*-algebras with Property (sq), then the algebra $\ell_\infty(A_1, A_2, \cdots)$ of bounded sequences $a := (a_1, a_2, \ldots)$ with $a_k \in A_k$ is a unital C^*-algebra. If $\varepsilon > 0$ is given then we find isometries $j \in \{1,2\}$, $r_{k,j} \in A_k$ such that $\|r_{n,1}^* a_n r_{n,2}\| < \varepsilon/2$. The $r_j := (r_{1,j}, r_{2,j}, \ldots)$ are isometries in $\ell_\infty(A_1, A_2, \ldots)$ and satisfy $\|r_1^* a r_2\| < \varepsilon$.

(ii): If A has Property (sq) and B is a unital C^*-algebra, then the tensor product $A \otimes^{\max} B$ has Property (sq).

Indeed, let $c \in A \otimes^{\max} B$ and $\varepsilon > 0$. There exist $n \in \mathbb{N}$, $a_1, \ldots, a_n \in A$ and $b_1, \ldots, b_n \in B$ with $\|b_k\| \leq 1$ such that in $A \otimes^{\max} B$ holds

$$\|\, c - (a_1 \otimes b_1 + \ldots + a_n \otimes b_n)\,\| \,<\, \varepsilon/2\,.$$

By the (2nd) observation there exist isometries $t_1, t_2 \in A$ with $t_1^* t_2 = 0$ and $\|t_1^* a_k t_2\| < \varepsilon/2n$ for $k = 1, \ldots, n$. Then $r_\ell := t_\ell \otimes 1 \in A \otimes^{\max} B$ ($\ell = 1,2$) are isometries that satisfy $\|r_1^* c r_2\| < \varepsilon$.

Induction shows that moreover for every finite sequence $c_1, \ldots, c_n \in A \otimes^{\max} B$ and $\varepsilon > 0$ there exists isometries $t_1, t_2 \in A$ with $t_1^* t_2 = 0$ that satisfy the inequalities

$$\|(t_1^* \otimes 1) c_k (t_2 \otimes 1)\| < \varepsilon \qquad \text{for } \ 1 \leq k \leq n\,.$$

(iii): Suppose that A is unital and has property (sq), and that X is a locally compact σ-compact Hausdorff space. The σ-compactness of X is equivalent to the property that $\mathrm{C}_0(X)_+$ contains a function $x \mapsto e(x) \in [0,1]$ that defines a strictly positive element e of the C^*-algebra $\mathrm{C}_0(X)$ with $\|e\| = 1$. We fix such a function $e(x)$.

Let $X \ni x \mapsto a(x) \in A$ a continuous map with $\|a(x)\| \leq 1$ for all $x \in X$. We show the existence of isometries $S, T \in \mathrm{C_b}(X, A)$ with $T^* S = 0$, and

$$\|T(x)^* a(x) S(x)\| \leq e(x)/2 \qquad \text{for all } \ x \in X\,.$$

In particular, $\|T^* a S\| \leq 1/2$ and $T^* a S \in \mathrm{C}_0(X, A)$.

We consider A as the C^*-subalgebra of $\mathrm{C_b}(X, A)$ consisting of constant A-valued functions from X to A. The subsets

$$K_n := e^{-1}[2^{-n}, 1] = \{x \in X\,;\ e(x) \geq 2^{-n}\}$$

build an increasing family of compact "reference" subsets of X with the properties:

$$K_{n-1} \subseteq K_n^\circ \quad \text{and} \quad \bigcup_n K_n = X\,,$$

that follow from

$$K_{n-1} = e^{-1}([2^{-(n-1)}, 1]) \subseteq e^{-1}\big((2^{-n}, 1]\big) \subseteq K_n^\circ \subseteq K_n = e^{-1}([2^{-n}, 1])\,.$$

The arguments need some care because we can not suppose that the interior of $e^{-1}(2^{-n})$ is empty, – different to the case e.g. of the function $f_0(\tau) := \tau$ on $(0,1]$ – in place of e for $(0,1]$ in place of X.

We use the functions $h_n \in \mathrm{C}_0(0,1]_+$ considered in Section 22 of Appendix A to build a suitable decomposition of $1 \in \mathrm{C_b}(X, A)$ inside $\mathrm{C_b}(X)_+$:

The increasing functions $h_n \in \mathrm{C}_0(0,1]_+$ are given by

$$h_n(\tau) := \min\big(1, \max(2^n \tau - 1, 0)\big)\,, \quad \text{for } \ \tau \in [0,1]\,,\ n = 0, 1, \ldots\,.$$

The set $(2^{-n}, 1]$ is the open support of h_n, contained in $h_{n+1}^{-1}(1) = [2^{-n}, 1]$. Thus, $h_n h_{n+1} = h_n$ and the non-negative function $h_{n+1} - h_n$ has support in the open interval $(2^{-(n+1)}, 2^{-(n-1)})$. It implies that the below used functions $\psi_n := (h_n - h_{n-1})^{1/2}$ (applied to the values $e(x)$ of e) are well-defined and have the property that $\psi_n \psi_m = 0$ for $|n - m| > 1$. Notice that $h_0 := 0\,,\ h_1 = (2f_0 - 1)_+\,, \ldots$, and in general $h_n = (2^n f_0 - 1)_+ - (2^{n-1} f_0 - 1)_+$ in the algebra $\mathrm{C}_0(0,1]$ and for $n \in \mathbb{N}$.

It follows that for each $\gamma \in (0,1]$ only finitely many functions $h_n - h_{n-1}$ have support in $[\gamma, 1]$. In particular, $\sum_{n \geq 1} (h_n - h_{n-1})$ converges on each interval $[\gamma, 1]$ uniformly to 1. Notice that

$$(h_n \circ e)^{-1}(0,1] = e^{-1}(h_n^{-1}(0,1]) = e^{-1}\big((2^{-n}, 1]\big) \subseteq K_n^\circ \subseteq K_n\,.$$

It shows that $(h_{n+1} \circ e)(x) = 1$ if and only if $x \in e^{-1}([2^{-n}, 1]) = K_n$. The support of $h_n \circ e$ is contained in the interior K_n° of K_n because $h_{n+1}h_n = h_n$.

Hence, the open support of the non-negative function $h_n(e(x)) - h_{n-1}(e(x))$ is contained in $V_n := K_n^\circ \setminus K_{n-2}$. It says that the support of $(h_n \circ e) - (h_{n-1} \circ e)$ is an open subset of X that is contained in the open subset V_n of X. Obviously V_n is contained in the closed subset $F_n := K_n \setminus K_{n-2}^\circ$ of X. Summing up, the functions $\varphi_n(x) := \big(h_n(e(x)) - h_{n-1}(e(x))\big)^{1/2} := \psi_n(e(x))$ with $\psi_n := (h_n - h_{n-1})^{1/2}$ for $n = 1, 2, \dots$ earn from the $h_n - h_{n-1} \geq 0$ the properties (I), (II) and (III):

(I) $\varphi_n \varphi_m = 0$ if $|n - m| > 1$,

(II) The open supports $U_n := \varphi_n^{-1}((0, 1])$ of φ_n are contained in the open subsets $V_n := K_n^\circ \setminus K_{n-2}$. And V_n is contained in the closed subset $F_n := K_n \setminus (K_{n-2}^\circ)$.

(III) $\sum_{n=1}^\infty \varphi_n(x)^2$ converges on each compact subset Y of X uniformly to 1. More precisely: There exists $\nu(Y) \in \mathbb{N}$ such that $\varphi_n | Y = 0$ for all $n > \nu(Y)$.

Parts (II) of this property list shows that $\sum_n \varphi_n(x) a_n$ is a well-defined element in $\mathrm{C_b}(X, A)$ of norm ≤ 2 if $a_1, a_2, \ldots \in A$ is an arbitrary sequence of contractions.

We define isometries $S, T \in \mathrm{C_b}(X, A)$ by the sums

$$S(x) := \sum_{n=1}^{\infty} \varphi_n(x) s_n \quad \text{and} \quad T(x) := \sum_{n=1}^{\infty} \varphi_n(x) t_n\,,$$

Here s_n, t_n are the below constructed isometries in A with mutually orthogonal ranges, i.e., with $s_m^* t_n = 0$ and $s_m^* s_n = \delta_{m,n} 1 = s_m^* s_n$ for all $m, n \in \mathbb{N}$. The in this way defined S and T are always in $\mathrm{C_b}(X, A)$, and satisfy $S^*S = 1 = T^*T$, $S^*T = 0$.

We complete the proof by an inductive selection of isometries $s_n, t_n \in A$ with above orthogonality properties and such that the corresponding isometries T and S satisfy

$$\|T(x)^* a(x) S(x)\| \leq 4^{-n} \qquad \text{for all} \quad x \in K_n^\circ \setminus K_{n-2}\,.$$

This implies $\|T(x)^* a(x) S(x)\| \leq e(x)/2$ for all $x \in X$ because $e(x) \in [2^{-n}, 4 \cdot 2^{-n})$ on $K_n \setminus K_{n-2}$.

In the (1st) step it was shown that A has a properly infinite unit if A has Property (sq). Let $r_1, r_2 \in A$ isometries in A with $r_1^* r_2 = 0$, and let $y_n := r_1^n r_2$ and $z_n := r_2^n r_1$. Then $y_m^* y_n = \delta_{m,n} 1 = z_m^* z_n$ and $y_m^* z_n = 0$ for all $m, n \in \mathbb{N}$.

We define by induction sequences of isometries $(g_1, g_2, \ldots)$ and $(h_1, h_2, \ldots)$ with $g_n, h_n \in A$, and build from them and from y_n, z_n new sequences $(s_1, s_2, \ldots)$ and $(t_1, t_2, \ldots)$ of isometries in A with the desired property by the following rules:

(α) $s_1 := r_1 r_2 \cdot g_1$ and $t_1 := r_2 r_1 \cdot h_1$,

(β) $s_{n+1} := r_1 s_n g_{n+1}$ and $t_{n+1} := r_2 t_n h_{n+1}$.

Then $s_1 = y_1 g_1$, $s_2 = y_2 g_1 g_2$, $s_n = y_n g_1 \cdot \ldots \cdot g_n$ and $t_n = z_n h_1 \cdot \ldots \cdot h_n$. To get the desired estimate we have to require that the isometries $g_n, h_n \in A$ satisfy the following inequalities, where $a_n := a|K_n$. We must consider also the overlap for the $x \in X$ with $\varphi_n(x)\varphi_{n+1}(x) \neq 0$.

It implies that we must find in each step pairs of isometries (g_1, h_1), respectively (g_{n+1}, h_{n+1}), in A that fulfill the three inequalities $\|h_1^* c_{1,k} g_1\| < 4^{-1}$ $(k = 1, 2, 3)$ for given elements $c_{1,1}, c_{1,2}, c_{1,3} \in \mathrm{C}(K_2, A)$, respectively $\|h_{n+1}^* c_{n,k} g_{n+1}\| < 4^{-1}$ for – in induction process new defined – given elements $c_{n,1}, c_{n,2}, c_{n,3} \in \mathrm{C}(K_{n+2}, A)$.

In our case here we have to take in $\mathrm{C}(K_2, A)$ the 3 elements

$$c_{1,1} := r_1^* r_2^* a_2 r_1 r_2 \,, \quad c_{1,2} := r_1^* (r_2^*)^2 a_2 r_1 r_2 \quad \text{and} \quad c_{1,3} := r_1^* r_2^* a_2 (r_1)^2 r_2 \,.$$

In the induction step we have to consider in $\mathrm{C}(K_{n+2}, A)$ the elements

$$c_{n,1} := t_n^* r_2^* a_{n+2} r_1 s_n \,, \quad c_{n,2} := t_n^* (r_2^*)^2 a_{n+2} r_1 s_n \quad \text{and} \quad c_{n,3} := t_n^* r_2^* a_{n+2} (r_1)^2 s_n \,.$$

If A has Property (sq) and $B := \mathrm{C}(K)$ for a compact space K then the proof of Part (2nd,ii) shows moreover that – for $c_1, \ldots, c_n \in \mathrm{C}(K, A)$ and $\varepsilon > 0$ – there exist isometries $s, t \in A \subseteq \mathrm{C}(K, A)$ with $t^* s = 0$ and $\|t^* c_k s\| < \varepsilon$ for $k = 1, \ldots, n$.

This implies the existence of the desired $g_{n+1}, h_{n+1} \in A$:
Simply put here $\varepsilon := 4^{-n}$ and take for c_1, c_2 and c_3 the above considered elements in $\mathrm{C}(K_{n+2}, A)$. Then we can take $g_{n+1} := s$ and $h_{n+1} := t$. This finishes the proof of the existence of the proposed isometries g_{n+1} and h_{n+1} in A, that define together with r_1, r_2 the desired new isometries s_{n+1} and t_{n+1} in A by composition rules (α) and (β).

(iv): If A is unital and has property (sq) and $J \neq A$ is a closed ideal of A, then A/J is unital. Let $b \in A/J$ and $\varepsilon > 0$. There exists $a \in A$ with $\pi_J(a) = b$ and isometries $r_1, r_2 \in A$ with $\|r_1^* a r_2\| < \varepsilon$. The isometries $t_j := \pi_J(r_j) \in A/J$ satisfy $\|t_1^* b t_2\| < \varepsilon$.

(v): If A is the inductive limit of a directed net of unital morphisms between C^*-algebras, then A has the "local" property that for each contraction $a \in A$ and $\nu \in (0, 1/4)$ there exists a unital C^*-algebra B with property (sq), an element $b \in B$ with $\|b\| \leq 1$, isometries $r_1, r_2 \in B$ that satisfy $r_1^* r_2 = 0$ and $\|r_1^* b r_2\| \leq \nu$, and a unital C^*-morphism $\psi \colon B \to A$ with $\|\psi(b) - a\| < \nu$. Then $t_1 := \psi(s_1)$ and $t_2 := \psi(s_2)$ are isometries in A with orthogonal ranges that satisfy $\|t_1^* a t_2\| \leq 2\nu < 1/2$.

(vi): Suppose that the unital C^*-algebra A has property (sq), and let $\phi \colon A^{\otimes^n} \to A^{\otimes^n}$ a permutation *-automorphism that is defined via

$$\phi(a_1 \otimes a_2 \otimes \cdots \otimes a_n) := a_{\pi(1)} \otimes a_{\pi(2)} \otimes \cdots \otimes a_{\pi(n)}$$

by a permutation π of $\{1, \ldots, n\}$.

As we have seen in (1st) Part and Part (ii) that for every $b \in A^{\otimes^n}$ and $\varepsilon > 0$ there exist isometries $t_1, t_2 \in A$ such that $t_1^* t_2 = 0$ and

$$\| \, (t_1^* \otimes 1 \otimes \cdots \otimes 1) b (t_2 \otimes 1 \otimes \cdots \otimes 1) \, \| \, < \, \varepsilon \,.$$

Thus $s_k := t_k \otimes t_k \otimes \cdots \otimes t_k$, $k \in \{1, 2\}$ are isometries with $\phi(s_k) = s_k$, $s_1^* s_2 = 0$ and $\| s_1^* b s_2 \| < \varepsilon$. The s_1 and s_2 are contained in the fix-point algebra of all actions of permutation automorphisms of $A^{\otimes^n}$.

(vii): The C^*-algebra $\mathcal{M}(B)$ has a properly infinite 1, i.e., contains isometries $S, T \in \mathcal{M}(B)$ with $T^* S = 0$, and $\mathcal{M}(B)$ is K_1-bijective by (1st) Part. For each $b \in B$ and $\varepsilon \in (0, 1)$ there exists isometries $r_1, r_2 \in \mathcal{M}(B)$ with $r_2^* r_1 = 0$ and $\| r_2^* b r_1 \| < \varepsilon$ by proof of (1st) Part. We may suppose here that $1 - r_1 r_1^* - r_2 r_2^*$ is a full and properly infinite projection, otherwise replace r_2 by $r_2 r_1$.

Let $\varphi \colon \mathcal{O}_\infty \to \mathcal{M}(B)$ a unital C^*-morphism, $X \in B + \varphi(\mathcal{O}_\infty)$ and $\varepsilon \in (0, 1/8)$.

Then $X = c + \varphi(d)$ with $c \in B$ and $d \in \mathcal{O}_\infty$. $\mathcal{O}_\infty$ has Property (sq) because it is the inductive limit of the $\mathcal{E}_n$ in Part (a) and Part (v) applies (or use Part (b) because $\mathcal{O}_\infty$ is purely infinite by Corollary 2.2.7). If follows that there exists isometries $t_1, t_2 \in \mathcal{O}_\infty$ with $t_2^* t_1 = 0$ and $\| t_2^* d t_1 \| < \varepsilon$. Here $1 - (t_1 t_1^* + t_2 t_2^*)$ is a full and properly infinite projection ([6]). Define $b := \varphi(t_2)^* d \varphi(t_1) \in B$. Then $\| (\varphi(t_2) S_2)^* X (\varphi(t_1) S_1) \| < \varepsilon + \| S_2^* b S_1 \|$ for all isometries $S_1, S_2 \in \mathcal{M}(B)$. The Property (sq) of $\mathcal{M}(B)$ implies that we find isometries $S_1, S_2 \in \mathcal{M}(B)$ with $\| S_2^* b S_1 \| < \varepsilon$ and $S_2^* S_1 = 0$. Here we can replace S_2 by $S_2 S_1$ to make sure that $1 - S_1 S_1^* - S_2 S_2^*$ is full and properly infinite. Then we find a unitary $v \in \mathcal{U}(\mathcal{M}(B))$ with $v \varphi(t_1) = S_1$, $v \varphi(t_2) = S_2$ and $[v] = 0 \in \mathrm{K}_1(\mathcal{M}(B))$. The Property (sq) of $\mathcal{M}(B)$ causes the K_1-injectivity of $\mathcal{M}(B)$, by (1st) Part. Thus, $v \in \mathcal{U}_0(\mathcal{M}(B))$ and there exist $f_1, \ldots, f_n \in \mathcal{M}(B)$ with $f_k^* = -f_k$ and $v = \exp(f_1) \cdot \ldots \cdot \exp(f_n)$. Let $\{e_j\} \subset B_+$ $(j \in \mathbb{N})$ a quasi-central approximate unit in B, build e.g. by functional calculus from a strictly positive contraction in B_+. The unitaries $U_j := \exp(e_j f_1 e_j) \cdot \ldots \cdot \exp(e_j f_n e_j))$ are in $1_{\mathcal{M}(B)} + B$ and $\lim_{j \to \infty} \| U_j^* x U_j - v^x v \| = 0$ for each $x \in B$. Thus, there exists $U \in \mathcal{U}(B + \mathbb{C} \cdot 1) \cap (1 + B)$ with $\| U^* b U - v^* b v \| < \varepsilon$. We get $\| (U \varphi(t_1))^* b (U \varphi(t_2)) \| \leq 2\varepsilon$. Then $T_k := \varphi(t_k) U \varphi(t_k)$ $(k = 1, 2)$ are isometries in $B + \varphi(\mathcal{O}_\infty)$ with $\| T_2^* X T_1 \| < 3\varepsilon < 1/2$.

(Ad 3rd) Some algebras with Property (sq):

The argument at the beginning of the proof of (1st) shows also that is suffices to require for all elements a in a dense subset X of A that there exists a constant $\gamma \in (0, 1)$ such that for each $a \in X$ there exist isometries r_1, r_2 (depending from a) with $\| r_1^* a r_2 \| < \gamma \| a \|$, e.g. we could start with the property that there exist for each $a \in X$ isometries $r_1, r_2 \in A$ with $3 \| r_1^* a r_2 \| \leq 2 \| a \|$.

(a): $\mathcal{E}_n := C^*(s_1, \ldots, s_n \, ; \, s_i^* s_j = \delta_{ij})$, $n = 2, \ldots, \infty$, satisfy Property (sq):

Indeed, let $w := k_1 k_2 \ldots k_p$, $v := \ell_1 \ell_2 \ldots \ell_q$, “words” of length $p, q \in \mathbb{N}$ with “letters” $k_j, \ell_i \in \{1, \ldots, n\}$ from the “alphabet” $\{1, \ldots, n\}$. Define $T_0 := 1$ and an isometry by the product

$$T_p(w) := s_{k_1} s_{k_2} \cdot \ldots \cdot s_{k_p} \, .$$

[6] Use here that $[1] = 1$ by $\mathrm{K}_0(\mathcal{O}_\infty) \cong \mathbb{Z}$, or simply replace t_2 by $t_2 t_1$ to make sure that $1 - t_1 t_1^* - t_2 t_2^*$ is full and properly infinite.

It is easy to see that the linear span of the element 1 and of the "elementary" products $T_q(w)$, $T_q(w)^*$ and $T_q(w)(T_r(v)^*)$ is dense in the C^*-algebra $\mathcal{E}_n$ (in both of real or complex case), because the product $T_q(v)^*T_p(w)$ is equal to 1 if $v = w$, is equal to zero if there exists $g \leq r := \min(p, q)$ with $k_g \neq \ell_g$, is equal to $T_{(p-q)}(u_1)$ if $q < p$ and $w = vu_1$ and is equal to $T_{(q-p)}(u_2)^*$ if $p < q$ and $v = wu_2$.

We denote by G one of this elementary products or let $G = 1$. A sort of "length" $L(G)$ is defined by $L(1) := 0$, $L(T_q) := q$, $L((T_q)^*) := q$ and $L(T_q \cdot (T_r)^*) := q + r$. Clearly, $s_k^*T_p(w) = \delta_{k,k_1}T_{p-1}(v)$ for all $k = 1, \ldots, n$ with word $v := k_2k_3 \ldots k_n$ for $w = k_1k_2 \ldots k_n$.

Let $G = T_p(w)T_q(v)^*$ with $w = k_1 \ldots k_p$, $v = \ell_1 \ldots \ell_q$ $(p, q \geq 1)$, then, $L(s_k^*Gs_\ell) = L(G) - 2$ if and only if $k_1 = k$ *and* $\ell_1 = \ell$, otherwise only $s_k^*Gs_\ell = 0$ can happen.

In case $G = T_p(w)$, $w = k_1 \ldots k_p$, we get $s_k^*Gs_\ell \neq 0$ if and only if $k = k_1$ and then $L(s_k^*Gs_\ell) = L(G)$, because then $G = T_p(u)$ with $u = k_2 \ldots k_p\ell$. Since $L(G^*) = L(G)$ the same holds for $G = T_p(w)^*$ with the role of k and ℓ interchanged.

Therefore, one can find, for each linear combination $C = \alpha_0 1 + \sum_{j=1}^{m} \alpha_j G_j$ (with scalars α_j), an index $1 \leq j_0 \leq m$ and suitable $k, \ell \in \{1, \ldots, n\}$ such that $k \neq \ell$, $s_k^*G_{j_0}s_\ell = 0$ for at least one $j_0 \in \{1, \ldots, m\}$ and $L(s_k^*G_js_\ell) \leq L(G_j)$ for $j \neq j_0$. Thus $s_k^*Cs_\ell = \sum_{j\neq 0, j\neq j_0} \alpha_j s_k^*G_js_\ell$ with elementary products $s_k^*G_js_\ell$ (it can be equal to 1).

Iteration – say m-times – of this operation leads to words w and v in the alphabet $\{1, \ldots, n\}$ such that for the isometries $T_m(w)$ and $T_m(v)$ holds $T_m(w)^*T_m(v) = 0$ and $T_m(w)^*CT_m(v) = 0$. It says that $\mathcal{E}_n$ has Property (sq).

(b): The proof for purely infinite unital C^*-algebras is much more engaged than the proof for strongly purely infinite unital C^*-algebras. The latter class contains all *simple* unital purely infinite C^*-algebras by Proposition 2.2.1(v).

The question whether or not pure infiniteness implies the – for our considerations important – strong pure infiniteness is still unsolved (June 2017).

Let us give first, for the readers convenience, the obvious and easy proof for strongly purely infinite C^*-algebras. This algebras have the "matrix diagonalization" property, cf. Definition 2.16.3 and Proposition 2.16.4:

If $a \in A$ is a contraction then we can build the positive 2×2-matrix $b = [b_{jk}] \in M_2(A)_+$ with diagonal entries $b_{11} := 1 =: b_{22}$ and $b_{21}^* := b_{12} := a$. By the matrix diagonalization property of A there exists a diagonal matrix $D := \mathrm{diag}(d_1, d_2)$ with $\|D^*bD - 1_2\| < 1/4$, i.e., $\|d_1^*ad_2\| < 1/4$ and $\|d_j^*d_j - 1\| < 1/4$ for $j = 1, 2$. Thus, the positive elements $d_j^*d_j$ are invertible with spectrum $\mathrm{Spec}(d_j^*d_j) \subseteq (3/4, 5/4)$ and $s_j := d_j(d_j^*d_j)^{-1/2}$ are isometries with $\|s_1^*as_2\| \leq (1/4)(4/3) = 1/3$.

The different and more engaged proof of Part (b) for the general case of purely infinite unital C^*-algebras A goes as follows:

Since $1 \in A$ is properly infinite for purely infinite A there exists isometries $S_1, S_2 \in A$ with orthogonal ranges, i.e., $S_j^* S_k = \delta_{jk} 1$:

The isometries $T_k := S_2^k S_1 \in A$ satisfy $T_k^* T_\ell = \delta_{jk} 1$, and $C^*(T_1, T_2, \dots) \subset A$ is a copy $\mathcal{O}_\infty$ in A.

Let $a \in A$ an element of norm $\|a\| = 1$. We are going to show that there exist isometries $s, t \in A$ such that $\|t^* a s\| < 1$:

If $\|T_2^* a T_1\| < 1$, then we can take $s := T_1$ and $t := T_2$. If $\|T_2^* a T_1\| = 1$, then we consider (from now on) the closed ideal $J := I(1 - T_1^* a^* T_2 T_2^* a T_1)$ of A generated by $1 - T_1^* a^* T_2 T_2^* a T_1 \in A_+$:

If 1_A is contained in J, then Lemma 4.2.13 applies with $e := f := T_1^* a^* T_2 T_2^* a T_1$ and $S := 1$, and implies that there exists an isometry $T \in A$ and $\delta \in (0, 1]$ with $\|T^* f T\| = 1 - \delta < 1$. Thus, $\|T_2^* a (T_1 T)\| = (1 - \delta)^{1/2} < 1$, and we can take $s := T_1 T$ and $t := T_2$.

If 1_A is not contained in J, then $\pi_J(T_1^* a^* T_2 T_2^* a T_1) = 1$. Thus $\pi_J(T_2^* a T_1)$ is an isometry in A/J. Then $\pi_J(T_2^* a T_1 T_3) = \pi_J(T_2^* a T_1) \pi_J(T_3)$ is again an isometry in A/J. The contraction $Z := T_2^* a T_1 T_2 \in A$ satisfies $\pi_J(Z^*) \pi_J(T_2^* a T_1 T_3) = 0$ and $\pi_J(Z^* Z) = 1$.

We define a closed left ideal of A by

$$L := \; \{ \, b \in A \, ; \; b \cdot T_2^* a T_1 T_3 \in J \, \} \, .$$

It contains Z^* and all elements of J, i.e., $J \cup \{Z^*\} \subseteq L$.

Let K denote the closed ideal of A that is generated by the hereditary C^*-subalgebra $D := L^* \cap L$. Then $L^* \cdot L \subseteq D$, and D contains J and the contraction ZZ^*. It follows that the closed ideal K of A contains J and $Z^*(ZZ^*)Z$. The equation $\pi_J(Z^*) \pi_J(ZZ^*) \pi_J(Z) = \pi_J(1)$ shows that $1 - Z^*(ZZ^*)Z \in J$. Hence, $1 \in K$ and $K = A$.

The C^*-algebra A and its full hereditary C^*-subalgebra D are purely infinite, and the ideal generated by D contains 1_A. It implies the existence of elements $g \in A$ and $d \in D_+$ such that $g^* d g = 1$.

The isometry $V := d^{1/2} g \in A$ satisfies $V^* \in L$ because $VV^* \in D$. Thus, $V^* T_2^* a T_1 T_3 \in J$ by definitions of L and $D = L^* \cap L$.

The positive contractions $f := T_1^* a^* T_2 V V^* T_2^* a T_1$, $e := T_1^* a^* T_2 T_2^* a T_1$ and isometry $S := T_3$ satisfy the assumptions of Lemma 4.2.13, i.e., $0 \leq f \leq e$ and $S^* f S \in I(1 - e) = J$.

By Lemma 4.2.13 there exists an isometry $T \in A$ with $\|T^* f T\| < 1$. Thus, $\|V^* T_2^* a T_1 T\| = \|T^* f T\|^{1/2} < 1$. It says that the isometries $s := T_1 T$ and $t := T_2 V$ satisfy $\|t^* a s\| < 1$.

We have seen above that for each unital purely infinite A and $a \in A$ with $\|a\| = 1$ there exists isometries $s, t \in A$ such that $\|t^* a s\| < 1$ and $t^* s = 0$. This argument does *not* give immediately a fixed general constant $\gamma_0 \in (0, 1)$ with the property that we for every $a \in A$ there exist isometries $s, t \in A$ (depending on a) with $\|t^*as\| \leq (1-\gamma_0) \cdot \|a\|$. So that the iteration argument in the (1st) Part of the proof does not apply here.

But we can give an indirect argument that proves that for each $a \in A$ and $\varepsilon > 0$ there are isometries $s, t \in A$ (depending on a and ε) with $\|t^*as\| < \varepsilon$:

Define for $a \in A$ the number

$$\gamma(a) := \inf\{ \|t_2^* a t_1\| \,;\; t_1, t_2 \in A\,,\; t_j^* t_k = \delta_{j,k} 1\,, \}\,.$$

Obviously $0 \leq \gamma(a) \leq \|a\|$ and $\gamma(\xi a) = |\xi| \cdot \gamma(a)$. We show that $\gamma(a) = 0$ for all $a \in A$:

Suppose − to derive a contradiction − that $\gamma(a) > 0$ for some $a \in A$ with $\|a\| = 1$. Then we can find sequences $t_{k,1}, t_{k,2}, \ldots, t_{k,n}, \ldots \in A$ ($k \in \{1, 2\}$) with $t_{j,n}^* t_{k,n} = \delta_{j,k} 1$ and $\lim_n \|t_{2,n}^* a t_{1,n}\| = \gamma(a)$. Let

$$b_n := \|t_{2,n}^* a t_{1,n}\|^{-1} t_{2,n}^* a t_{1,n}\,.$$

Then $b := (b_1, b_2, \ldots)$ is a contraction in $\ell_\infty(A)$ that has the property that for every isometries $S, T \in \ell_\infty(A)$ holds $\|T^* b S\| = 1$.

It is easy to see that C^*-algebra $\ell_\infty(A)$ is again purely infinite if A is purely infinite in sense of Definition 1.2.1, cf. the permanence properties of purely infinite C^*-algebras listed in Proposition 2.5.19. Hence, our above "individual" squeezing result is also true for elements $b \in \ell_\infty(A)$.

But this general fact contradicts the existence of a contraction $b \in \ell_\infty(A)$ with the property that $\|T^* b S\| \geq 1$ for all isometries $S, T \in \ell_\infty(A)$.

It follows that the above defined number $\gamma(a) \in [0, \|a\|]$ is zero for all $a \in A$ if A is a unital purely infinite C^*-algebra. In particular, we find then for each $a \in A$ isometries $s, t \in A$ with $3\|t^*as\| \leq 2$.

– (c): Let B a stable σ-unital C^*-algebra and $A := \mathcal{M}(B)$. By Lemma A.23.1, for every separable C^*-subalgebra $C \subset \mathcal{M}(B)$ there exist isometries $S, T \in \mathcal{M}(B)$ with the property that $T^*CS \subseteq B$ and $T^*S = 0$.

By Remark 5.1.1(8) we find a sequence of isometries $s_k \in \mathcal{M}(B)$ with the property that $\sum_k s_k s_k^*$ converges strictly to 1 with respect of the strict topology on $\mathcal{M}(B)$. If we select suitable s_{k_n} from the sequence $s_1, s_2, \ldots$ then we can manage that $T_n := T s_{k_n}$ and $T_n := T s_{k_n}$ satisfy $\lim_n \|T_n^* c S_n\| = 0$ and $T_n^* S_n = 0$ for all $c \in C$. Thus, $A := \mathcal{M}(B)$ has Property (sq). □

Now we turn to the generalization of K_1-injectivity and K_1-surjectivity to the case of non-unital σ-unital C^*-algebras:

Definition 4.2.16. If A is a *not necessarily unital* C^*-algebra, then we can consider the natural **unitization** $\widetilde{A} := A + \mathbb{C}1 \subseteq \mathcal{M}(A)$ of A, and then use the definitions of K_1-surjectivity and K_1-injectivity for $\widetilde{A}$ in place of E in Definition 4.2.2, where we notice that $\mathrm{K}_1(\widetilde{A}) = \mathrm{K}_1(A)$ and each unitary $u \in A + \mathbb{C}1$ is homotopic in $\mathcal{U}(\widetilde{A})$ to a unitary $v \in \mathcal{U}(\widetilde{A}) \cap (1+A)$. Notice that our definition of $\widetilde{A}$ entails that $\widetilde{A} = A$ if A is unital.

I.e., A is K_1**-surjective** (respectively is K_1**-injective**) if the natural map

$$u = 1 + a \in \mathcal{U}(\widetilde{A}) \mapsto [u] \in \mathrm{K}_1(A)$$

from $(1+A) \cap \mathcal{U}(A + \mathbb{C} \cdot 1)$ to $\mathrm{K}_1(A)$ is surjective (respectively has kernel equal to $(1+A) \cap \mathcal{U}_0(\widetilde{A})$).

The C^*-algebra A is K_1**-bijective** if A is K_1-surjective and K_1-injective.

Following Remark 4.2.17 lists some sufficient criteria for K_1-surjectivity and K_1-injectivity of some special non-unital C^*-algebras. It will be used for our "constructive" version of K_*-theory and the study of Cuntz semi-groups of C^*-morphisms.

Remark 4.2.17. C^*-algebras A with the property that the unit element of $\mathcal{M}(A)$ is properly infinite appear often in our considerations.

Suppose that A is a σ-unital non-unital C^*-algebra. The multiplier algebra $\mathcal{M}(A)$ has a properly infinite unit, if and only if, there exists a unital C^*-morphism $\mathcal{O}_\infty \to \mathcal{M}(A)$, and this is the case if and only if A is isomorphic to an ideal of some C^*-algebra E with properly infinite unit.

The class of C^*-algebras A with properly infinite $1 \in \mathcal{M}(A)$ is invariant under passage to non-zero ideals and non-zero quotients.

If $\mathcal{M}(A)$ has a properly infinite unit, then A is K_1*-surjective* in the sense of Definition 4.2.16.

If the multiplier algebra $\mathcal{M}(A)$ has a properly infinite unit, then the algebra A is K_1*-injective* in the sense of Definition 4.2.16, if and only if, $A + \mathcal{O}_\infty \subseteq \mathcal{M}(A)$ is a K_1-injective C^*-algebra.

Every σ-unital stable C^*-algebra A is K_1-bijective, because $\mathcal{M}(A)$ has the "squeezing" Property (sq), and this property carries over to $A + \psi(\mathcal{O}_\infty)$ for every unital C^*-morphism $\psi \colon \mathcal{O}_\infty \to \mathcal{M}(A)$, cf. Parts (c) and (vii) of Proposition 4.2.15.

Details for Remark 4.2.17. Let E a C^*-algebra, J a closed ideal of E and $\psi \colon J \to A$ an isomorphism from J onto A. Then $\mathcal{M}(\psi)$ is an isomorphism from $\mathcal{M}(J)$ onto $\mathcal{M}(A)$ and there exists a unital C^*-morphism $\varphi \colon E \to \mathcal{M}(A)$. If the unit of E is properly infinite then the unit $1_{\mathcal{M}(A)} = \varphi(1_E)$ of $\mathcal{M}(A)$ is properly infinite. Conversely, if $1_{\mathcal{M}(A)}$ is properly infinite in $\mathcal{M}(A)$, then one can take $E := \mathcal{M}(A)$ and $J = A$.

If A is a non-zero ideal of a C^*-algebra E with properly infinite unit 1_E then every closed ideal $\{0\} \neq J$ of A is a closed ideal E. If $J \neq A$, then A/J is a non-zero closed ideal of E/J and E/J has again a properly infinite unit.

If B is unital and $\mathcal{O}_\infty \subseteq \mathcal{M}(B) = B$, then $B = 1 + B$ is K_1*-surjective*, by Lemma 4.2.6(v).

If A is non-unital and $1 \in \mathcal{M}(A)$ is properly infinite, then there is copy of $\mathcal{O}_\infty$ unitally contained in $\mathcal{M}(A)$ with $\mathcal{O}_\infty \cap A = \{0\}$. With this copy there are natural isomorphisms $\mathrm{K}_1(A) = \mathrm{K}_1(A+\mathbb{C}\cdot 1) \cong \mathrm{K}_1(A+\mathcal{O}_\infty)$, and $\mathcal{U}(A+\mathbb{C}\cdot 1)/\mathcal{U}_0(A+\mathbb{C}\cdot 1) \cong \mathcal{U}(A+\mathcal{O}_\infty)/\mathcal{U}_0(A+\mathcal{O}_\infty)$ and $\big((A+1)\cap\mathcal{U}(A+\mathbb{C}\cdot 1)\big)/\big((A+1)\cap\mathcal{U}_0(A+\mathbb{C}\cdot 1)\big) \cong \mathcal{U}(A+\mathbb{C}\cdot 1)/\mathcal{U}_0(A+\mathbb{C}\cdot 1)$.

The proposed K_1-injectivity of $\mathcal{M}(A)$ implies that unital C^*-morphisms $\varphi_1, \varphi_2 \colon \mathcal{O}_\infty \to \mathcal{M}(A)$ are point-norm homotopic, cf. Proposition 4.2.11 i.e., there is a norm-continuous path of unitaries $u(\xi) \in \mathcal{U}(\mathcal{M}(A))$ $\xi \in [0,\infty)$ with $u(1) = 1$ and $\lim_{\xi\to\infty} u(\xi)\varphi_1(s_n) = \varphi_2(s_n)$ for all $n \in \mathbb{N}$. Such unitaries can be in strict topology approximated by products of of exponentials with exponents $-x^* = x \in A$. That shows that the interaction with elements in A can be done by correction with products by $u_1, \ldots, u_n \in (A+1)\cap\mathcal{U}_0(A+\mathbb{C}\cdot 1)$. This gives hope for over carry of Property (sq).

If A is stable and σ-unital, then the multiplier algebra $\mathcal{M}(A)$ has Property (sq) and $\mathrm{K}_*(\mathcal{M}(A)) = 0$, which implies $\mathcal{U}(\mathcal{M}(A)) = \mathcal{U}_0(\mathcal{M}(A))$ by K_1-bijectivity.

If A is *not* unital, but $1_{\mathcal{M}(A)}$ is properly infinite in $\mathcal{M}(A)$, then $A + \mathcal{O}_\infty \subset \mathcal{M}(A)$ is unital and K_1-surjective and the inclusion $A + \mathbb{C}\cdot 1 \hookrightarrow A + \mathcal{O}_\infty$ defines a natural isomorphism $\mathrm{K}_1(A) = \mathrm{K}_1(A+\mathbb{C}\cdot 1) \cong \mathrm{K}_1(A+\mathcal{O}_\infty)$ that coincides with the isomorphism $\mathrm{K}_1(A) \cong \mathrm{K}_1(A+\mathcal{O}_\infty)$ given by splitting of the 6-term exact K_*-sequence for the (right-)split exact sequence $0 \to A \to A+\mathcal{O}_\infty \to \mathcal{O}_\infty \to 0$, because $A \cap \mathcal{O}_\infty = \{0\}$ if A is not unital, and $\mathrm{K}_1(\mathcal{O}_\infty) = \mathrm{K}_1(\mathbb{C}) = 0$.

Since $A+\mathcal{O}_\infty$ is K_1-surjective by Lemma 4.2.6(v), for each $x \in \mathrm{K}_1(A+\mathcal{O}_\infty) \cong \mathrm{K}_1(A+\mathbb{C}\cdot 1)$ there is a unitary $u = a+v \in \mathcal{U}(A+\mathcal{O}_\infty)$ with $a \in A$ and $v \in \mathcal{U}(\mathcal{O}_\infty)$ such that $x = [u] = [v]+[v^*a+1]$. But $\mathcal{U}(\mathcal{O}_\infty) = \mathcal{U}_0(\mathcal{O}_\infty) \subset \mathcal{U}_0(A+\mathcal{O}_\infty)$ by [**172**, cor. 3.12], cf. also Section 1 of Appendix A. Thus $[v] = [1] = 0 \in \mathrm{K}_1(A+\mathcal{O}_\infty)$ and $x = [v^*a+1] \in \mathrm{K}_1(A+\mathcal{O}_\infty) \cong \mathrm{K}_1(A+\mathbb{C}\cdot 1)$ is the class of the unitary $v^*a+1 \in A+1$. This establishes the K_1-*surjectivity* of A, i.e., shows the surjectivity of the map

$$u := a+1 \in \mathcal{U}(A+\mathbb{C}\cdot 1)\cap(A+1) \mapsto [u] \in \mathrm{K}_1(A)\,.$$

Suppose that $A+\mathcal{O}_\infty$ ($\subseteq \mathcal{M}(A)$) is K_1-*injective.* If $0 = [a+1] \in \mathrm{K}_1(A)$ for $a+1 \in \mathcal{U}(A+\mathbb{C}\cdot 1)$, then $0 = [a+1] \in \mathrm{K}_1(A+\mathcal{O}_\infty)$ and $a+1 \in \mathcal{U}_0(A+\mathcal{O}_\infty)$. Let $\pi \colon A+\mathcal{O}_\infty \to \mathcal{O}_\infty$ the natural *-epimorphism $\pi(a+b) = b$ for $a \in A$ and $b \in \mathcal{O}_\infty$.

By the proposed K_1-injectivity of $A+\mathcal{O}_\infty$, there exist a continuous path $\xi \in [0,1] \mapsto v(\xi) \in \mathcal{U}(A+\mathcal{O}_\infty)$ such that $v(0) = 1$ and $v(1) = a+1$. Then $u(\xi) := \pi(v(\xi)^*)\cdot v(\xi)$ is a continuous path in $\mathcal{U}(A+\mathbb{C}\cdot 1)\cap(A+1)$ with $u(0) = 1$ and $u(1) = a+1$, i.e., $a+1 \in \mathcal{U}_0(A+\mathbb{C}\cdot 1)$. Thus, $A+\mathbb{C}\cdot 1$ is K_1-injective.

Now suppose conversely that $A+\mathbb{C}\cdot 1$ is K_1-injective and $u = a+v \in \mathcal{U}(A+\mathcal{O}_\infty)$ satisfies $0 = [u] \in \mathrm{K}_1(A+\mathcal{O}_\infty)$. Notice $\pi(u) = v \in \mathcal{U}_0(\mathcal{O}_\infty) = \mathcal{U}(\mathcal{O}_\infty)$. Then $\pi(u^*)u = v^*a+1$ satisfies $0 = [v^*a+1] \in \mathrm{K}_1(A+\mathbb{C}\cdot 1) \cong \mathrm{K}_1(A+\mathcal{O}_\infty)$. Thus, $v^*a+1 \in \mathcal{U}_0(A+\mathbb{C}1) \subset \mathcal{U}_0(A+\mathcal{O}_\infty)$ and $u = v\cdot(v^*a+1) \in \mathcal{U}_0(A+\mathcal{O}_\infty)$.

Every σ-unital stable C^*-algebra A is K_1-bijective:

If A is stable, then there is a non-degenerate C^*-morphism $\psi\colon \mathbb{K} \to \mathcal{M}(A)$ with $\psi(\mathbb{K}) \cap A = \{0\}$. It extends to a strictly continuous unital *-monomorphism $\mathcal{M}(\psi)\colon \mathcal{L}(\ell_2) \cong \mathcal{M}(\mathbb{K}) \to \mathcal{M}(A)$. Let $T_1, T_2, \ldots \in \mathcal{L}(\ell_2)$ isometries such that $\sum_n T_n T_n^*$ converge to id_{ℓ_2} in $\mathcal{L}(\ell_2)$ with respect to the *strong operator topology. Then $s_n := \mathcal{M}(\psi)(T_n)$ have the property that $\sum_n s_n s_n^*$ converges strictly to 1 in $\mathcal{M}(A)$.

If $\mathcal{O}_\infty = C^*(s_1, s_2, \ldots) \subseteq \mathcal{M}(A)$ is a copy of $\mathcal{O}_\infty$ with the additional property that $\sum_n s_n s_n^*$ converges strictly to 1 in $\mathcal{M}(A)$, then $A + \mathcal{O}_\infty \subseteq \mathcal{M}(A)$ satisfies the squeezing condition (sq) of Definition 4.2.14 and is K_1-injective by Proposition 4.2.15 :

Indeed, let $a + X \in A + \mathcal{O}_\infty$ with $a \in A$ and $X \in \mathcal{O}_\infty$, and $\varepsilon > 0$. We find $s_{n_k} \in \mathcal{O}_\infty$ with $\|s_{n_k}^* a s_{n_{k+1}}\| < \varepsilon/2$, by strict convergence to $1_{\mathcal{M}(A)}$ of $\sum s_n^* s_n$. Proposition 4.2.15(a,iii) provide isometries $S, T \in \mathcal{O}_\infty$ that satisfy

$$\|S^*(s_{n_k}^* X s_{n_{k+1}})T\| < \varepsilon/2\,.$$

The isometries $(s_{n_k}S, s_{n_{k+1}}T)$ are ε-squeezing for $a + X$.

Thus if $\psi\colon \mathcal{O}_\infty \to \mathcal{M}(A)$ is a unital C^*-morphism with the additional property that $\sum_n s_n s_n^*$ converges strictly to 1 in $\mathcal{M}(A)$, then $A+\psi(\mathcal{O}_\infty)$ has the "squeezing" Property (sq) of Definition 4.2.14. It implies by Proposition 4.2.15 that $A+\psi(\mathcal{O}_\infty)$ is K_1-bijective.

If $\varphi\colon \mathcal{O}_\infty \to \mathcal{M}(A)$ is any unital C^*-morphism with the property that there exists a unitary $u \in \mathcal{M}(A$ such that $u^*\varphi(b)u - \psi(b) \in A$ for all $b \in \mathcal{O}_\infty$, then the C^*-subalgebra $A + \varphi(\mathcal{O}_\infty) \subseteq \mathcal{M}(A)$ satisfies again the "squeezing" Property (sq) of Definition 4.2.14 and is therefore K_1-bijective. □

Notice here that the proof of Proposition 4.2.15(vii) shows that $A+\varphi_1(\mathcal{O}_\infty)$ has Property (sq), if and only if, $A + \varphi_2(\mathcal{O}_\infty)$ has Property (sq) under the assumption that $\mathcal{M}(A)$ is K_1-injective.

If $\varphi\colon \mathcal{O}_\infty \to \mathcal{M}(A)$ is any unital C^*-morphism then the C^*-subalgebra $A + \varphi(\mathcal{O}_\infty) \subseteq \mathcal{M}(A)$ satisfies again the "squeezing" Property (sq) of Definition 4.2.14.

REMARK 4.2.18. Let A be a σ-unital non-unital C^*-algebra such that $\mathcal{M}(A)$ is K_1-injective, as e.g. in case where A is stable, and let $\varphi_k\colon \mathcal{O}_\infty \to \mathcal{M}(A)$, $k \in \{1, 2\}$, unital C^*-morphisms.

(i) $A + \varphi_1(\mathcal{O}_\infty)$ has Property (sq), if and only if, $A + \varphi_2(\mathcal{O}_\infty)$ has Property (sq).
(ii) If $\varphi\colon \mathcal{O}_\infty \to \mathcal{M}(A)$ is any unital C^*-morphism then the C^*-subalgebra $A + \varphi(\mathcal{O}_\infty) \subseteq \mathcal{M}(A)$ satisfies again the "squeezing" Property (sq) of Definition 4.2.14.

DETAILS FOR REMARK 4.2.18. Then φ_1 and φ_2 are homotopic by Proposition 4.2.11.

(i): Is true and provable, because arguments in the proof of Proposition 4.2.15(vii) apply here.

(ii): It follows from Proposition 4.2.15(vii), because $\mathcal{M}(A)$ satisfies the "squeezing" Property (sq) of Definition 4.2.14 if A is σ-unital and stable. □

It would be useful for the above considerations if the following Conjectures 4.2.19 can be verified. Are there similar results for $\mathcal{O}_2$ in place of $\mathcal{O}_\infty$?

Conjecture 4.2.19. *Let A a separable* stable *C^*-algebra and $\varphi_k\colon \mathcal{O}_\infty \to \mathcal{M}(A)$ $(k = 1, 2)$ unital C^*-morphisms.*

(C. 1) *The C^*-subalgebras $A + \varphi_1(\mathcal{O}_\infty)$ and $A + \varphi_2(\mathcal{O}_\infty)$ are isomorphic.*
(C. 2) *There exist a unitary $U \in \mathcal{M}(A)$ such that $U^*\varphi_1(b)U - \varphi_2(b) \in A$ for all $b \in \mathcal{O}_\infty$.*
(C. 3) *The C^*-morphisms $\varphi_1, \varphi_2\colon \mathcal{O}_\infty \to \mathcal{M}(A)$ are approximately unitary equivalent by a sequence of unitaries $u_1, u_2, \ldots \in \mathcal{M}(A)$ with the additional property $u_k^*\varphi_2(b)u_k - \varphi_1(b) \in A$ for all $b \in \mathcal{O}_\infty$.*

Clearly (C. 3) *implies* (C. 2)*, and* (C. 2) *implies* (C. 1)*.*

Is (C. 1) *also true for non-stable σ-unital non-unital separable A if it is true for all stable separable A?*

The following lemma explains the equivalence of rather different looking defining relations that are used for definitions of Ext-groups or KK-groups (in particular that here in this book versus those given by other authors).

Lemma 4.2.20. *Suppose that E is unital, D is a* full *hereditary C^*-subalgebra of E, and that A is a unital C^*-subalgebra of E such that D is an ideal of A.*

(o) *There are isomorphisms*

$$\mathrm{K}_*(A/D) \cong \mathrm{kernel}(\mathrm{K}_*(A) \to \mathrm{K}_*(E))\,,$$

which split the 6-term exact sequence into split exact sequences

$$0 \to \mathrm{K}_*(D) \to \mathrm{K}_*(A) \to \mathrm{K}_*(A/D) \to 0\,.$$

(i) *Let p_1 and p_2 projections in A, such that $p_2 - p_1 \in D$ and $[p_1]_E = [p_2]_E$ in $\mathrm{K}_0(E)$. Then $[p_1]_A = [p_2]_A$ in $\mathrm{K}_0(A)$.*
(ii) *Let u_1 and u_2 unitaries in A, such that $u_2 - u_1 \in D$ and $[u_1]_E = [u_2]_E$ in $\mathrm{K}_1(E)$. Then $[u_1]_A = [u_2]_A$ in $\mathrm{K}_1(A)$.*
(iii) *If A is K_1-surjective, then A/D is K_1-surjective.*

The equations $[p_1]_A = [p_2]_A$ in (i), or $[u_1]_A = [u_2]_A$ in (ii), can fail if $D \triangleleft A$ is not hereditary in E or is hereditary in E but is not full in E.

Give example!

This obstruction plays a role for the classifications of non-stable and non-unital extensions, or unital extensions that do not dominate a unital "zero" extension. See the ????

`Give example for the latter !! Gabe's remarks ???`

Is A/D K_1-bijective if A and E (hence D ??) are K_1-bijective?

Proof. (o): The inclusion maps $\eta_D\colon D \hookrightarrow A$ and $\eta_A\colon A \hookrightarrow E$ define group homomorphisms $[\eta_D]_*\colon \mathrm{K}_*(D) \to \mathrm{K}_*(A)$ and $[\eta_A]_*\colon \mathrm{K}_*(A) \to \mathrm{K}_*(E)$. The composition $\alpha := \eta_A \circ \eta_D\colon d \in D \mapsto d \in E$ of this homomorphisms defines isomorphisms $[\alpha]_* = [\eta_A]_* \circ [\eta_D]_*$ from $\mathrm{K}_*(D)$ onto $\mathrm{K}_*(E)$, because D is full and hereditary in E.

It follows that $[\eta_D]_*$ must be *injective* and that $[\eta_A]_*$ is a surjective group homomorphism from $\mathrm{K}_*(A)$ onto $\mathrm{K}_*(E)$. Thus, the boundary maps

$$\partial\colon\ \mathrm{K}_{(*+1) \bmod 2}(A/D) \to \mathrm{K}_*(D)$$

of the natural 6-term exact sequence must be trivial, i.e.,

$$0 \to \mathrm{K}_*(D) \to \mathrm{K}_*(A) \to \mathrm{K}_*(A/D) \to 0$$

are exact sequences with group morphisms $[\eta_D]_*$ and $[\pi_D]_*\colon \mathrm{K}_*(A) \to \mathrm{K}_*(A/D)$ defined by the quotient map $\pi_D\colon A \to A/D$.

In particular, the maps $[\pi_D]_*$ are epimorphisms with kernels $[\eta_D]_*(\mathrm{K}_*(D))$.

Natural "splitting" epimorphisms from $\mathrm{K}_*(A)$ onto $\mathrm{K}_*(D)$ can be defined by

$$\beta_* := [\alpha]_*^{-1} \circ [\eta_A]_*\colon\ \mathrm{K}_*(A) \to \mathrm{K}_*(D)\,.$$

We define a group endomorphisms $\gamma_*\colon\ \mathrm{K}_*(A) \to \mathrm{K}_*(A)$ with $(\gamma_*)^2 = \gamma_*$ by

$$\gamma_* := [\mathrm{id}_A]_* - [\eta_D]_* \circ \beta_*\,.$$

The endomorphism γ_* maps $\mathrm{K}_*(A)$ onto the kernel of $[\eta_A]_*\colon\ \mathrm{K}_*(A) \to \mathrm{K}_*(E)$. The "orthogonal" idempotent group endomorphism $[\mathrm{id}_A]_* - \gamma_* = [\eta_D]_* \circ [\alpha]_*^{-1} \circ [\eta_A]_*$ of $\mathrm{K}_*(A)$ maps $\mathrm{K}_*(A)$ onto $[\eta_D]_*(\mathrm{K}_*(D))$.

The restriction of $[\pi_D]_*$ onto the kernel $\gamma_*(\mathrm{K}_*(A))$ of $[\eta_A]_*\colon\ \mathrm{K}_*(A) \to \mathrm{K}_*(E)$ defines an isomorphism $[\pi_D]_* \circ \gamma_*$ from the kernel of $[\eta_A]_*\colon\ \mathrm{K}_*(A) \to \mathrm{K}_*(E)$ onto $\mathrm{K}_*(A/D)$.

Thus, the kernel of $[\eta_A]_*\colon\ \mathrm{K}_*(A) \to \mathrm{K}_*(E)$ is isomorphic to $\mathrm{K}_*(A/D)$ in a natural way by $[\pi_D]_* \circ \gamma_*$.

We get in particular that

$$[\eta_A]_* \oplus [\pi_D]_*\colon\ \mathrm{K}_*(A) \to \mathrm{K}_*(E) \oplus \mathrm{K}_*(A/D)$$

are group isomorphisms from $\mathrm{K}_*(A)$ onto $\mathrm{K}_*(E) \oplus \mathrm{K}_*(A/D)$ that realize the splitting of $\mathrm{K}_*(D) \to \mathrm{K}_*(A) \to \mathrm{K}_*(A/D)$.

(i,ii): Let $p_1, p_2 \in A$ projections (respectively $u_1, u_2 \in \mathcal{U}(A)$). Consider $x_0 := [p_2] - [p_1] \in \mathrm{K}_0(A)$ (respectively $x_1 := [u_2] - [u_1] \in \mathrm{K}_1(A)$).

If $p_2 - p_1 \in D$ (respectively $u_2 - u_1 \in D$) then $[\pi_D]_*(x_*) = 0$. If $[p_1]_E = [p_2]_E$ in $\mathrm{K}_0(E)$ (respectively $[u_1]_E = [u_2]_E$ in $\mathrm{K}_1(E)$), then $[\eta_A]_*(x_*) = 0$ in $\mathrm{K}_*(E)$. Above we have seen that $[\eta_A]_* \oplus [\pi_D]_*$ is faithful on $\mathrm{K}_*(A)$. Thus, the assumptions of Parts (ii) or (iii) imply that $x_* = 0$ in $\mathrm{K}_*(A)$.

(iii): If $u \in \mathcal{U}(A) \mapsto [u] \in \mathrm{K}_1(A)$ and $[\pi_D]_1 \colon \mathrm{K}_1(A) \to \mathrm{K}_1(A/D)$ are surjective, then for each $x \in \mathrm{K}_1(A/D)$ there exist $u \in \mathcal{U}(A)$ with $x = [\pi_D]_1([u]) = [\pi_D(u)]$. Thus, Part (iii) follows from $\pi_D(\mathcal{U}(A)) \subseteq \mathcal{U}(A/D)$. □

3. Addition of C^*-morphisms

We apply the above definition of $\oplus_{s_1,s_2}$ to C^*-morphisms and completely positive maps, and study later associated commutative semigroups and the corresponding Grothendieck groups. Throughout this section we consider two C^*-algebras D and E such that E is unital and contains a copy of $\mathcal{O}_2$ unitally.

Definition 4.3.1. Let $h_1, h_2 \colon D \to E$ be two C^*-morphisms (or completely positive maps) and let s_1, s_2 be generators of a unital copy of $\mathcal{O}_2$ in E. Then the **Cuntz addition** of h_1 and h_2 (with respect to s_1, s_2) is defined by:

$$(h_1 \oplus_{s_1,s_2} h_2)(b) := s_1 h_1(b) s_1^* + s_2 h_2(b) s_2^*, \quad \forall\, b \in D\,.$$

Two C^*-morphisms $h, k \colon D \to E$ are said to be **unitarily equivalent** (notation: $[h] = [k]$) if there exists a unitary u in E such that $k(b) = u^* h(b) u$ for all $b \in D$ (notation: $k = u^* h(\cdot) u$).

Sometimes one has to consider only unitary equivalences $k = u^* h(\cdot) u$ with unitaries u in a subgroup $\mathcal{G}$ of the unitary group $\mathcal{U}(E)$ of E, where $\mathcal{G}$ often contains the connected component $\mathcal{U}_0(E)$ of the unit element 1_E in $\mathcal{U}(E)$ (notation: $h \approx_{\mathcal{G}} k$). We write $h \approx k$ or $[h]_\approx = [k]_\approx$ if here $\mathcal{G} := \mathcal{U}_0(E)$, i.e.,

$$h \approx k \quad \Leftrightarrow \quad k \in [h]_\approx \quad \Leftrightarrow \quad \exists\, u \in \mathcal{U}_0(E) \text{ with } k = u^* h(\cdot) u\,.$$

Cuntz addition defines the structure of a commutative semigroup on the set $[\mathrm{Hom}(D, E)]$ of unitary equivalence classes of C^*-morphisms from D into E, by setting

$$[h_1] + [h_2] := [h_1 \oplus_{s_1,s_2} h_2]$$

for arbitrary choice of generators $\{s_1, s_2\}$ of $\mathcal{O}_2$ in E. The correctness of this definition can be verified using the following Proposition 4.3.2.

It shows *moreover* that the more refined addition

$$[h_1]_{\mathcal{G}} + [h_2]_{\mathcal{G}} := [h_1 \oplus_{s_1,s_2} h_2]_{\mathcal{G}}$$

is well-defined if $\mathcal{U}_0(E) \subseteq \mathcal{G} \subseteq \mathcal{U}(E)$ and defines the structure of a commutative semigroup on the set of all equivalence classes $[h]_{\mathcal{G}}$. We write $[\mathrm{Hom}(D, E)]_\approx$ in case $\mathcal{G} = \mathcal{U}_0(E)$.

PROPOSITION 4.3.2. *Let $h_i \colon D \to E$, $i = 1,2,3$ be C^*-morphisms and let $\{s_1, s_2\}$ and $\{t_1, t_2\}$ be canonical generators of copies of $\mathcal{O}_2$ in E. The Cuntz-addition $[h_1] + [h_2] := n[h_1 \oplus_{s_1,s_1} h_2]$ on unitary equivalence* classes *$[h]$ of C^*-morphisms $h \colon D \to E$ is well-defined, independent from the chosen canonical generators s_1, s_2 of $\mathcal{O}_2 \subseteq E$, commutative and associative:*

(i) ($\oplus$ is well-defined) *For any unitary operators v and w in E,*

$$vh_1v^* \oplus_{s_1,s_2} wh_2w^* = u(h_1 \oplus_{s_1,s_2} h_2)u^*,$$

where $u := s_1vs_1^* + s_2ws_2^*$ is a unitary operator in E.

(ii) (Consistency)

$$u^*((h_1 \oplus_{s_1,s_2} h_2)(b))u = (h_1 \oplus_{t_1,t_2} h_2)(b), \quad b \in D,$$

where $u := s_1t_1^* + s_2t_2^*$ is a unitary operator in E;

(iii) (Commutativity)

$$U_c(h_1 \oplus_{s_1,s_2} h_2)U_c^* = h_2 \oplus_{s_1,s_2} h_1,$$

where $U_c := s_2s_1^* - s_1s_2^*$ is a unitary operator in the connected component $\mathcal{U}_0(E)$ of 1_E in $\mathcal{U}(E)$;

(iv) (Associativity)

$$U_d(h_1 \oplus (h_2 \oplus h_3))U_d^* = (h_1 \oplus h_2) \oplus h_3,$$

where $\oplus$ means $\oplus_{s_1,s_2}$ and $U_d := s_1^2s_1^* + s_2(s_2^*)^2 + s_1s_2(s_2s_1)^*$ is in $\mathcal{U}_0(E)$.

PROOF. Each of Parts (i)–(iv) can be seen by straight calculation – compare introductory remarks in the

proof of Lemma 4.2.6 and the

proofs of Parts (o) and (vii) of Lemma 4.2.6. The unitaries U_c and U_d are in $\mathcal{U}_0(C^*(s_1, s_2))$, cf. proof of Part (o) of Lemma 4.2.6. □

The observation that $U_c, U_d \in \mathcal{U}_0(C^*(s_1, s_2))$ follows also from the less elementary observation that $\mathcal{U}(\mathcal{O}_2) = \mathcal{U}_0(\mathcal{O}_2)$, cf. [**172**, thm. 1.9, thm. 3.7] in case of complex C^*-algebras. It is possible to show it also for the "real" version $(\mathcal{O}_2)_\mathbb{R}$ of $\mathcal{O}_2$ that each "orthogonal" operator in $(\mathcal{O}_2)_\mathbb{R}$ is inside the orthogonal operators connected to 1 by a continuous path, but the proofs of [**172**, thms. 1.9, 3.7] have to be modified slightly, cf. Section 1 of Appendix A. We say this here because it implies that some parts of our results remain valid in the case of real C^*-algebras.

DEFINITION 4.3.3. Let $h_1, h_2 \colon D \to E$ be C^*-morphisms. Then h_1 will be said to n-**dominate** h_2 if there exist $a_1, \ldots, a_n$ in E such that $a_1^*a_1 + \ldots + a_n^*a_n = 1$ and $h_2(b) = a_1^*h_1(b)a_1 + \ldots + a_n^*h_1(b)a_n$ for all $b \in D$. We shall say that h_1 **dominates** h_2 if h_1 1-dominates h_2, i.e., if $h_2(b) = s^*h_1(b)s$, $b \in D$, for some isometry s in E.

Note that for unital D a non-unital h_1 can dominate a unital h_2. But a unital h_1 can not dominate a non-unital h_2 by (iii) of the following Lemma 4.3.4.

LEMMA 4.3.4. *Suppose that $h_1\colon D \to E$ is a C^*-morphism, that $s, t \in E$ are isometries and that $g \in E$ is a contraction. Define completely positive contractions $h_2, h_3, T\colon D \to E$ by $h_2 := s^* h_1(\cdot)s$, $h_3 := t^* h_1(\cdot)t$ and $T := g^* h_1(\cdot)g$.*

(i) *The c.p. map $T\colon D \to E$ is a C^*-morphism if and only if $gg^* \in h_1(D)' \cap E$* and $(gg^* - gg^*gg^*)h_1(D) = \{0\}$.
Moreover, $T = h_1$ if and only if $g \in h_1(D)' \cap E$ and $(1 - g^*g)h_1(D) = \{0\}$.
In particular, h_2 is a C^*-morphism if and only if $ss^* \in h_1(D)' \cap E$. It holds $h_2 = h_1$ if and only if $s \in h_1(D)' \cap E$.

(ii) *If h_2 is a C^*-morphism, then h_3 is unitarily equivalent to h_2, if and only if, tt^* is Murray–von Neumann equivalent to ss^* in $h_1(D)' \cap E$.*
Moreover, $h_2 = h_3$ if and only if $ts^* \in h_1(D)' \cap E$.

(iii) *h_2 is unital if h_1 is unital.*

(iv) *h_1 dominates zero if and only if there is an isometry $v \in E$ which range vv^* orthogonal to the image of h_1, i.e., $vv^*h_1(D) = 0$.*

(v) *Suppose that there exists a unital C^*-morphism from $\mathcal{O}_2$ into E that is given by isometries $s_1, s_2 \in E$ as canonical generators, that $h_1 \oplus_{s_1,s_2} h_1 = r^* h_1(\cdot) r$ for an isometry $r \in E$, and that $h_2 := s^* h_1(\cdot)s$ and $h_3 := t^* h_1(\cdot)t$. Then $h_2 \oplus_{s_1,s_2} h_3 = q^* h_1(\cdot) q$ for the isometry $q := r(s \oplus_{s_1,s_2} t)$.*

PROOF. (i): Let $g \in E$ with $\|g\| \leq 1$ and $a^* = a \in E$ (likewise $a = h_1(d)$ for some $d^* = d \in D$).

Clearly, $g^*agg^*bg = g^*abg$ and $g^*bgg^*ag = g^*bag$ for all $b \in E$, if gg^* commutes with a and if $x = 0$ for $x := g^*(1 - gg^*)a$. That means $gg^*a = agg^*$ and $0 = x^*x = (gg^* - gg^*gg^*)a(gg^*a) = 0$.

Conversely, if $g^*a^2g = g^*agg^*ag$, then $(1 - gg^*)^{1/2}ag = 0$. It implies $gg^*a = gg^*agg^* = agg^*$, because $a^* = a$ and $(1 - gg^*)agg^* = 0$. It follows that gg^* commutes with a and $(gg^* - gg^*gg^*)a = 0$.

Hence, $gg^* \in h_1(D)' \cap E$ and $(gg^* - gg^*gg^*)h_1(D) = \{0\}$, if and only if, the map $T := g^*h_1(\cdot)g$ from D into E satisfies $T(dc) = T(d)T(c)$ for all $d^* = d, c \in D$, i.e., if and only if T is a C^*-morphism.

If $g^*ag = a$ and $g^*a^2g = a^2$, then $0 \leq (ag - ga)^*(ag - ga) = -a(1 - g^*g)a \leq 0$. Thus, $ga = ag$ and $(1 - g^*g)a = 0$ for all $a^* = a \in h_0(D)$ if $h_1 = g^*h_1(\cdot)g =: T$. The converse is obvious.

If g is an isometry $g = s$ then only the necessary and sufficient condition $ss^* \in h_0(D)' \cap E$ remains, and the condition $s \in h_0(D)' \cap E$ for the case $h_0 = h_2$.

(ii): If $u \in E$ is a unitary in E with $u^*h_2(\cdot)u = h_3(\cdot)$, then $v = sut^*$ is a partial isometry in E with $vv^* = ss^*$, $v^*v = tt^*$ and $v^*h_1(\cdot)v = tt^*h_1(\cdot)tt^* = tt^*h_1(\cdot)$. Thus $h_1(b)v = ss^*h_1(b)v = vv^*h_1(b)v = vtt^*h_1(b) = vh_1(b)$ for every $b \in D$.

Conversely, if there is a partial isometry $v \in h_1(D)' \cap E$ with $vv^* = ss^*$ and $v^*v = tt^*$, then $u = s^*vt$ is a unitary in E such that $u^*h_2(\cdot)u = h_3$.

(iii): $s^*h_1(1)s = s^*s = 1$.

(iv): Suppose that h_1 dominates zero. Then there is an isometry $v \in E$ with $v^* h_1(a) v = 0$ for all $a \in D$. Thus $vv^* h_1(a)(vv^* h_1(a))^* = 0$ for all $a \in D$. Conversely, $v^* h_1(a) v = v^*(vv^* h_1(a)) v = 0$ if $v \in E$ is an isometry with range orthogonal to $h_1(D)$.

(v): by straight calculation. □

PROPOSITION 4.3.5. *Let D and E be C^*-algebras and suppose that E contains a copy of $\mathcal{O}_2 = C^*(s_1, s_2)$ unitally. Let $h_i \colon D \to E$, $i = 1, 2$ be C^*-morphisms.*

- (i) *If h_1 dominates h_2 and $h_2(D)' \cap E$ contains a copy of $\mathcal{O}_2$ unitally, then $h_1 \oplus h_2$ and h_1 are unitarily equivalent.*
- (ii) *If h_1 n-dominates h_2 and $h_1(D)' \cap E$ contains two isometries with orthogonal range, then h_1 dominates h_2.*
- (iii) *$[h_1] + [h_1] = [h_1]$ if and only if $h_1(D)' \cap E$ contains a copy of $\mathcal{O}_2$ unitally.*
- (iv) *h_1 dominates $h_1 \oplus h_1$ if and only if $h_1(D)' \cap E$ contains a copy of $\mathcal{O}_\infty$ unitally.*

  For every non-zero projection p in this copy of $\mathcal{O}_\infty$ in $h_1(D)' \cap E$ with $[p] = 0$ in $\mathrm{K}_0(\mathcal{O}_\infty)$ there exists an isometry $s \in E$ with $ss^* = p$. The c.p. map $h_0 := s^* h_1(\cdot) s$ is a C^*-morphism from D into E with $[h_0] + [h_0] = [h_0]$, and h_0 dominates h_1.
- (v) *If there is a contraction $f \in E$ such that $h_1 \oplus h_1 = f^* h_1(\cdot) f$, then there exists a C^*-morphism k from $D \otimes \mathcal{O}_\infty$ into E such that $h_1 = k((\cdot) \otimes 1)$.*

The copies of $\mathcal{O}_2$ considered in the assumptions and in Parts (i) and (iii), or the copies of $\mathcal{O}_\infty$ appearing in Parts (ii), (iv) and (v) can be different, are even not necessarily homotopic. In the situation of Part (v) it can happen that there is no copy of $\mathcal{O}_\infty$ unitally contained in E itself that commutes with the elements of $h_1(D)$.

PROOF. (i): Suppose $h_2(\cdot) = t^* h_1(\cdot) t$, for $t \in E$ with $t^* t = 1$. Then tt^* commutes with the images of h_1 by Lemma 4.3.4(i). If $r_1, r_2 \in h_2(D)' \cap E$ are isometrics with $r_1 r_1^* + r_2 r_2^* = 1$, then $t_1 := (1 - tt^*) + t r_1 t^*$ and $t_2 := t r_2$ are isometries that satisfy $t_1 t_1^* + t_2 t_2^* = 1$. Thus, $V := t_1 r_1^* + t_2 r_2^*$ is a unitary. The unitary V realizes the unitary equivalence $V(h_1 \oplus_{r_1, r_2} h_2) V^* = h_1 \oplus_{t_1, t_2} h_2$. Then $t h_2(\cdot) t^* = t(t^* h_1(\cdot) t) t^* = tt^* h_1(\cdot)$ implies $h_1 \oplus_{t_1, t_2} h_2 = h_1$ because

$$(1 - tt^*) h_1(\cdot) + t r_1 h_2(\cdot) r_1^* t^* + t r_2 h_2(\cdot) r_2^* t^* = (1 - tt^*) h_1(\cdot) + t h_2(\cdot) t^* = h_1 .$$

The unitary equivalence of h_1 and $h_1 \oplus_{s_1, s_2} h_2$ with the before given isometries s_1, s_2 can be realized by $u^* h_1(\cdot) u = h_1 \oplus_{s_1, s_2} h_2$ where $u := s_1 t_1^* + s_2 t_2^*$. This unitary u can be replaced here by any unitary $v_0 \cdot u \cdot (v_1 \oplus_{s_1, s_2} v_2)$ with unitaries $v_0, v_1 \in h_1(D)' \cap E$ and $v_2 \in h_2(D)' \cap E$.

(ii): By assumption, there are isometries $t_1, t_2 \in h_1(D)' \cap E$ satisfying $t_1^* t_2 = 0$. The isometries $s_j := t_2^j t_1$, $j = 1, \ldots, n$, are in $h_1(D)' \cap E$ and satisfy $s_i^* s_j = \delta_{ij}$, $1 \le i, j \le n$. Now suppose $h_2 = \sum_{j=1}^n a_j^* h_1(\cdot) a_j$, with $a_j \in E$ and $\sum a_j^* a_j = 1$.

Then, by taking $b := \sum_j s_j a_j$, we have

$$h_2 = \sum a_j^* h_1(\cdot) a_j = \sum\nolimits_{i,k} a_i^* s_i^* h_1(\cdot) s_k a_k = b^* h_1(\cdot) b.$$

Moreover,

$$b^* b = \sum\nolimits_{i,k} a_i^* s_i^* s_k a_k = \sum a_j^* a_j = 1.$$

(iii): By definition $[h_1] + [h_1] = [h_1]$ means that there is a unitary $u \in E$ such that $u^* h_1(\cdot) u = s_1 h_1(\cdot) s_1^* + s_2 h_1(\cdot) s_2^*$ for isometries $s_1, s_2 \in E$ which are the canonical generators of a copy of $\mathcal{O}_2$. Then $t_i := u s_i$, $i = 1, 2$, are generators of $\mathcal{O}_2$ in $h_1(D)' \cap E$, because, for $a \in D$ and $i \in \{1, 2\}$,

$$h_1(a) t_i \;=\; t_1 h_1(a) t_1^* t_i + t_2 h_1(a) t_2^* t_i \;=\; t_i h(a)\,.$$

Conversely, $h_1 \oplus_{t_1,t_2} h_1 = h_1$ if $t_1, t_2 \in h_1(D)' \cap E$ are isometries and generators of a copy of $\mathcal{O}_2$. Now apply Proposition 4.3.2(i).

(iv): If h_1 dominates $h_1 \oplus h_1$, then there is an isometry $t \in E$ such that $t^* h_1(\cdot) t = s_1 h_1(\cdot) s_1^* + s_2 h_1(\cdot) s_2^*$. The elements $t_i := t s_i$, $i = 1, 2$, are isometries with orthogonal ranges such that $h_1 = t_i^* h_1(\cdot) t_i$ for $i = 1, 2$. We get $t_1, t_2 \in h(D)' \cap E$ by Lemma 4.3.4(i). Thus $C^*(t_1, t_2)$ is unitally contained in $h_1(D)' \cap E$ and contains the copy $C^*(t_2^n t_1\,;\, n = 1, 2, \ldots)$ of $\mathcal{O}_\infty$ unitally.

Conversely, suppose that $h_1(D)' \cap E$ contains a copy of $\mathcal{O}_\infty$ unitally. Then there are isometries t_1 and t_2 in $h_1(D)' \cap E$ with orthogonal ranges. The element $t := t_1 s_1^* + t_2 s_2^* \in E$ is an isometry and satisfies $t^* h_1(\cdot) t = s_1 h_1(\cdot) s_1^* + s_2 h_1(\cdot) s_2^*$.

Suppose that $p \neq 0$ is a projection in a given copy of $\mathcal{O}_\infty \subseteq h_1(D)' \cap E$ with $[p] = 0$ in $\mathrm{K}_0(\mathcal{O}_\infty)$ and $1_E \in \mathcal{O}_\infty$, e.g. $p = 1 - (t_2 t_1)(t_2 t_1)^*$ if $\mathcal{O}_\infty \cong C^*(t_2^n t_1\,;\, n = 1, 2, \ldots) \subseteq E$. It implies that also $[p] = 0$ in $\mathrm{K}_0(E)$ and that p is properly infinite in $\mathcal{O}_\infty$ and E, because $\mathcal{O}_\infty$ is simple and purely infinite by Corollary 2.2.7, (cf. also [**169**, thm. 3.4]).

Thus, by Lemma 4.2.6(ii), p is Murray–von-Neumann equivalent to 1 in E, i.e., there exists an isometry $s \in E$ with $ss^* = p$. The map $h_0 := s^* h_1(\cdot) s$ is a C^*-morphism from D into E, because $p = ss^*$ commutes with $h_1(D)$. The commutant $h_0(D)' \cap E$ of $h_0(D)$ contains $s^* p \mathcal{O}_\infty p s$ unitally, and $s^* p \mathcal{O}_\infty p s$ is isomorphic to $p \mathcal{O}_\infty p$. By [**172**], $\mathcal{O}_\infty$ is a simple purely infinite C^*-algebra. It follows for non-zero projections $p \in \mathcal{O}_\infty$ with $[p] = 0$ in $\mathrm{K}_0(\mathcal{O}_\infty)$ that the hereditary C^*-subalgebra $p \mathcal{O}_\infty p$ of $\mathcal{O}_\infty$ (with unit p) contains a copy of $\mathcal{O}_2$ unitally. Thus $[h_0] + [h_0] = [h_0]$ by Part (iii).

The C^*-morphism h_0 dominates h_1, because there exists an isometry $t \in \mathcal{O}_\infty \subseteq h_1(D)' \cap E$ with $tt^* \leq p = ss^*$. Then $ss^* t = t$, $s^* t$ is an isometry in E, $h_1 = t^* h_1(\cdot) t$ and $t^* s h_0(\cdot) s^* t = t^* s s^* h_1(\cdot) s s^* t$.

(v): Let $\{s_1, s_2\}$ denote the canonical generators of the given copy of $\mathcal{O}_2$ in E. We define C^*-subalgebras $C, N \subseteq E$ by

$$N := \mathrm{Ann}(h_1(D)) := \{\, e \in E\,;\; h_1(D) e \,\cup\, e h_1(D) \,= \{0\}\,\}$$

and by $C := h_1(D)' \cap E$. Then N is an ideal of C and C/N is a *unital* C^*-algebra. It is not difficult to see that there exists a unique C^*-morphism $\lambda\colon D \otimes^{\max} C/N \to E$ with the property

$$\lambda(d \otimes (g + N)) = dg \quad \text{for all } d \in D \text{ and all } g \in C\,.$$

If $f^* h_1(\cdot) f = h_1 \oplus_{s_1,s_2} h_1$ for a contraction $f \in E$, then the elements fs_1 and fs_2 are in C and $t_j := fs_j + N$ $(j = 1,2)$ are isometries in C/N with $t_1^* t_2 = 0$, i.e., $h_1(a) fs_k = fs_k h_1(a)$, $(1 - s_k^* f^* f s_k) h_1(a) = 0$ for $a \in D$ for $k = 1,2$, and $s_1^* f^* f s_1 + s_2^* f^* f s_2 = f^* f \oplus f^* f \leq 1$. The latter is obvious, and the first two equations follow from $s_k^* f h_1(\cdot) f s_k = h_1$ by Lemma 4.3.4(i).

The isometries $T_n := t_2^n t_1$ for $n \in \mathbb{N}$ build a sequence of isometries in C/N with $T_n^* T_m = 0$ for $m \neq n$. Thus, there is a unital *-monomorphism $\gamma\colon \mathcal{O}_\infty \to C/N$. Then $k := \lambda \circ (\mathrm{id}_D \otimes \gamma)$ is a C^*-morphism from $D \otimes \mathcal{O}_\infty$ into E with $k(d \otimes 1) = h_1(d)$ for $d \in D$. □

The Cuntz addition $[h] + [k]$ of unitary equivalence classes of morphisms $h, k\colon D \to E$ is far away from the sum of linear maps, e.g. $[h] + [0] \neq [h]$ if h is unital.

If we consider the zero-absorbing maps $h \oplus 0$ then the following proposition gives additional later useful sufficient conditions on domination and unitary equivalence by unitaries in $\mathcal{U}_0(E)$. Here $\mathcal{U}_0(E)$ denotes the connected component of 1_E in the group $\mathcal{U}(E)$ of unitaries in E with operator-norm topology.

PROPOSITION 4.3.6. *Suppose that E is unital and contains a copy of $\mathcal{O}_2$ unitally with canonical generators s_1, $s_2 \in \mathcal{O}_2 \subseteq E$. Let $h_1\colon D \to E$ be a C^*-morphism and $h_2\colon D \to E$ a contractive linear map.*

(i) *h_1 dominates zero, if and only if, $[h_1] + [0] = [h_1]$.*
This is the case, if and only if, there exists $u \in \mathcal{U}(E)$ such that $t_1 := us_1$, $t_2 := us_2$ and u satisfy $t_1 h_1(a) = h_1(a) = h_1(a) t_1$, $h_1(a) t_2 = 0$ for $a \in D$.
The unitary u can be taken such that $[u] = 0 \in \mathrm{K}_1(E)$ in addition.

(ii) *If h_1 dominates zero and $x \in E$ is a contraction, then the element $s := t_1 x + t_2 (1 - x^* x)^{1/2}$ – with t_1, t_2 as in* Part(i) *– is an isometry in E that satisfies $h_1(\cdot) x = h_1(\cdot) s$ and $x^* h_1(\cdot) = s^* h_1(\cdot)$.*
In particular, $s^* h_1(\cdot) s = h_2$ for an isometry $s \in E$ if h_1 dominates zero and $x^* h_1(\cdot) x = h_2$ for some contraction $x \in E$.

(iii) *Suppose that*
 (α) *h_1 dominates zero,*
 (β) *the inclusion map $C^*(h_2(D)) \hookrightarrow E$ dominates zero,* and
 (γ) *there are contractions $x, y \in E$ such that $h_2(\cdot) = x^* h_1(\cdot) y$ and $x x^* h_1(\cdot) y y^* = h_1$, i.e., also $x h_2(\cdot) y^* = h_1$.*

Then there exist $U, V \in \mathcal{U}(E)$ such that $h_2(\cdot) = U^* h_1(\cdot) V$.
If, moreover, $x = 1$, then one can find U and V such that $U = 1$.

In particular, h_1 is unitarily equivalent to h_2, if h_1 and h_2 dominate both zero and there exists $x \in E$ with $\|x\| \leq 1$, $x^* h_1(\cdot)x = h_2$ and $xh_2(\cdot)x^* = h_1$.

(iv) *Suppose that h_1 dominates zero and that h_2 is unitarily equivalent to h_1 in E.*

(a) *There exists $v \in \mathcal{U}(E)$ with $h_2 = v^* h_1(\cdot)v$ and $[v] = 0$ in $\mathrm{K}_1(E)$.*

(b) *If E is K_1-injective, then there is a unitary $v \in \mathcal{U}_0(E)$ with $h_2 = v^* h_1(\cdot)v$.*

(c) *If there exists an isometry $r \in E$ with $r^*(h_1(a) + h_2(a))r = 0$ for all $a \in D$, then there exists $v \in \mathcal{U}_0(E)$ with $h_2 = v^* h_1(\cdot)v$.*

(d) *If E has moreover the property that for every unitary $u \in E$ and every isometry $t \in E$ there are isometries $r, s \in E$ and $w \in \mathcal{U}_0(E)$ with $utr = wts$ then there is $v \in \mathcal{U}_0(E)$ with $h_2 = v^* h_1(\cdot)v$.*

(v) *If $R \in E$ is an isometry with $R^* h_1(\cdot)R = 0$ and $p \in E$ is a projection with $pR = 0$, then the $u \in \mathcal{U}(E)$ in* Part(i) *can be chosen such that $0 = [u] \in \mathrm{K}_1(E)$ and $t_1 = us_1$ satisfies $t_1 h_1(a) = h_1(a) = h_1(a)t_1$ for $a \in D$ and $pt_1 = p = t_1 p$.*

Proof. (i): If h_1 dominates zero, then $[h_1]+[0] = [h_1]$ by Proposition 4.3.5(i), because the copy of $\mathcal{O}_2$ in E commutes with the zero morphism $0(a) := 0$.

Conversely, if $[h_1] + [0] = [h_1]$, then, by definition of Cuntz Addition, there is a unitary $v \in E$ with $vs_1 h_1(\cdot)s_1^* v^* = h_1$. Then $r_j := vs_j$ $(j = 1, 2)$ are isometries with $r_1 h_1(\cdot)r_1^* = h_1$ and $r_1 r_1^* + r_2 r_2^* = 1$. In particular, $h_1(\cdot)r_2 = 0$, i.e., h_1 dominates zero. It follows $h_1(\cdot)r_1 r_1^* = h_1(\cdot)$ and $h_1(D)r_2 E r_2^* = \{0\}$.

Let $q_2 := r_2 r_1$ and $q_1 := r_1 r_1^* + r_2 r_1 r_2^*$, then q_1 and q_2 are isometries in E with $q_1 q_1^* + q_2 q_2^* = 1$, $h_1(\cdot)q_2 = 0$ and $q_1 h_1(\cdot) = h_1(\cdot) = h_1(\cdot)q_1$. The unitary $v := q_1 s_1^* + q_2 s_2^* \in \mathcal{U}(E)$ satisfies $vs_j = q_j$. Let $w := q_1 q_1^* + q_2 v^* q_2^*$, $u := wv$, $t_1 := us_1 = q_1$ and $t_2 := us_2 = q_2 v^*$. Then u, t_1, t_2 have the desired properties, because $h_1(\cdot)q_2 = 0$ and $[u] = [w] + [v] = [1] + [v^*] + [v] = [1] = 0$ in $\mathrm{K}_1(E)$.

(ii): Obviously $s := t_1 x + t_2(1 - x^* x)^{1/2}$ is an isometry and $h_1(\cdot)s = h_1(\cdot)t_1 x = h_1(\cdot)x$ by Part (i).

If $h_2 = x^* h_1(\cdot)x$ then $h_2 = s^* h_1(\cdot)s$, because $x^* h_1(a) = (h_1(a^*)x)^*$ and $D^2 = D$.

(iii): Let $a \in D_+$, $d_1 := xx^*$, $d_2 := yy^*$ and $b := h_1(a)$.

Then $b \geq 0$, $0 \leq d_i \leq 1$ $(i = 1, 2)$ and $d_1 b^{1/n} d_2 = b^{1/n}$ $(n = 1, 2, \ldots)$. This implies $d_1 p d_2 = p$ for the support p of b in E^{**}, because p is the weak limit of $b^{1/n}$.

Thus $pd_1 pd_2 p = p$. Since $0 \leq d_i \leq 1$, we get $pd_i p = p$, $p(1 - d_i)p = 0$, $(1 - d_i)^{1/2} p = 0 = p(1 - d_i)^{1/2}$, and $(1 - d_1)^{1/2} b = 0 = b(1 - d_2)^{1/2}$, because $pb = b = bp$. for $i = 1, 2$. That means

$$(1 - d_1)^{1/2} h_1(\cdot) = 0 = h_1(\cdot)(1 - d_2)^{1/2}.$$

Let $k\colon C^*(h_2(D)) \to E$ the inclusion map. By Part (i) there exist isometries $\tau_1, \tau_2 \in E$ such that $1 = \tau_1\tau_1^* + \tau_2\tau_2^*$, $k(\cdot)\tau_1 = \tau_1 k(\cdot) = k(\cdot)$ and $k(\cdot)\tau_2 = 0$. Let $t_1, t_2 \in E$ for h_1 as in (i). It follows from Part (i) and from the above equations for d_1, d_2 and h_1 that

$$U := t_1 x \tau_1^* - t_2 x^* \tau_2^* + t_1(1-d_1)^{1/2}\tau_2^* + t_2(1-x^*x)^{1/2}\tau_1^*$$

and

$$V := t_1 y \tau_1^* - t_2 y^* \tau_2^* + t_1(1-d_2)^{1/2}\tau_2^* + t_2(1-y^*y)^{1/2}\tau_1^*$$

are unitaries in E with

$$U^*h_1(\cdot)V = \tau_1(x^*h_1(\cdot)y)\tau_1^* = \tau_1 h_2(\cdot)\tau_1^* = h_2.$$

If $x = 1$, then, with $a := c^{1/2}$ for $c \in D_+$,

$$U^*h_1(c)U = h_2(a)(h_2(a)^*) = h_1(a)d_2h_1(a) = h_1(a^2) = h_1(c).$$

Thus, U commutes with the elements of $h_1(D)$, and $h_2(\cdot) = h_1(\cdot)U^*V$.

Suppose that h_1 and h_2 both dominate zero and that there is a contraction $x \in E$ with $x^*h_1(\cdot)x = h_2$ and $xh_2(\cdot)x^* = h_1$. Then there is an isometry $t \in E$ with $t^*h_2(\cdot)t = 0$, i.e., $h_2(D) = \mathrm{span}(h_2(D_+))$ is contained $(1-tt^*)E(1-tt^*)$. Thus, $t^*bt = 0$ for all $b \in C^*(h_2(D))$, and the above construction of U and V works for x and $y := x$. It gives $d_2 = d_1$ and $V = U$. Hence, $h_2 = U^*h_1(\cdot)U$.

(iv): Let $U \in \mathcal{U}(E)$ with $U^*h_1(\cdot)U = h_2$. In particular, $[h_2] = [h_1] = [h_1] + [0] = [h_2] + [0]$, i.e., h_2 dominates zero.

(iv,a): Let $t_1, t_2 \in E$ the isometries with the properties given in (i), then $V := (1 \oplus_{t_1,t_2} U^*)U$ is unitary and satisfies $V^*h_1(\cdot)V = U^*h_1(\cdot)U = h_2\,.$ $[V] = [1] + [U^*] + [U] = 0$ in $\mathrm{K}_1(E)$, cf. Lemma 4.2.6(v,1).

(iv,b): If $\mathcal{U}_0(E)$ is the kernel of $\mathcal{U}(E) \to \mathrm{K}_1(E)$ (i.e., if E is K_1-injective) then $V \in \mathcal{U}_0(E)$ for the V as in Part (iv, a).

(iv,c): Suppose that there is an isometry $r \in E$ with $r^*(h_1(a) + h_2(a))r = 0$ for all $a \in D$. Then $h_k(D) \subseteq (1-rr^*)E(1-rr^*)$ for $k = 1, 2$. We consider the C^*-subalgebra $F := C^*(h_1(D) + h_2(D)) \subseteq E$ generated by

$$h_1(D) + h_2(D) \subseteq (1-rr^*)E(1-rr^*)\,.$$

The inclusion morphism $f \in F \mapsto f \in E$ dominates zero, because $r^*Fr = 0$. By Part (i) there are canonical generators t_1, t_2 of a copy of $\mathcal{O}_2$ in E such that $t_1 f = f = f t_1$ and $f t_2 = 0 = t_2^* f$ for $f \in F$. Let $V = t_1 U t_1^* + t_2 U^* t_2^*$. Then V is in $\mathcal{U}_0(E)$ by Lemma 4.2.6(v,3), and $V^*h_1(\cdot)V = t_1U^*h_1(\cdot)Ut_1^* = t_1h_2(\cdot)t_1^* = h_2\,.$

(iv,d): The property in Part (iv,d) implies that $\mathcal{U}_0(E)$ is the kernel of $\mathcal{U}(E) \ni u \mapsto [u] \in \mathrm{K}_1(E)$, cf. Lemma 4.2.10(iii). Thus Part (iv, b) applies.

(v): Since $pR = 0$ and $R^*h_1(D)R = \{0\}$, the C^*-subalgebra $F := C^*(h_1(D), p) \subseteq E$ is contained in $(1-RR^*)E(1-RR^*)$. The identity map $f \in F \mapsto f \in E$ dominates zero because $R^*fR = 0$ for all $f \in (1-RR^*)E(1-RR^*)$.

Application of Part (i) to (F, id_F) – in place of (D, h_1) – gives that there is a unitary $u \in \mathcal{U}(E)$ with $0 = [u] \in \mathrm{K}_0(E)$ and $t_1 f = f = f t_1$ for $t_1 := us_1$ and $f \in F$. In particular $t_1 p = p = pt_1$ and $t_1 h_1(a) = h_1(a) = h_1(a)t_1$ for $a \in D$. □

COROLLARY 4.3.7. *Suppose that A and E are unital C^*-algebras, $h_1, h_2 \colon A \to E$, unital C^*-morphisms, and that unital C^*-morphisms $\psi_1, \psi_2 \colon \mathcal{O}_2 \to E$ exist with $\psi_k(\mathcal{O}_2) \in h_k(A)' \cap E$ for $k = 1, 2$.*

If h_1 and h_2 one-step dominate each other, i.e., if there exist contractions $S, T \in E$ with $h_2 := S^* h_1(\cdot) S$ and $h_1 := T^* h_2(\cdot) T$, then h_1 and h_2 are unitary equivalent in E.

PROOF. By Proposition 4.3.5(i), h_1 is unitarily equivalent to $h_1 \oplus h_2$ and h_2 is unitarily equivalent to $h_2 \oplus h_1$.

The symmetry $T := s_2 s_1^* + s_1 s_2^*$ satisfies $T^*(h_1 \oplus_{s_1,s_2} h_2)T = h_2 \oplus_{s_1,s_2} h_1$. □

COROLLARY 4.3.8. *Two unital C^*-morphisms $h_0, h_1 \colon \mathcal{O}_2 \to E$ are approximately unitary equivalent.*

They are homotopic if and only if the unitary $u := h_1(s_1)h_0(s_1^*) + h_1(s_2)h_0(s_2^*)$ is in $\mathcal{U}_0(E)$.

PROOF. In fact h_1 and h_2 are unitary equivalent in $E_\infty := \ell_\infty(E)/c_0(E)$ if we use here the later in Chapter 5 proven result that $\mathcal{O}_2 \otimes \mathcal{O}_2$ is unitally contained in $\mathcal{O}_2$, (or could use here that $\mathcal{O}_2 \cong \mathcal{O}_2 \otimes \mathcal{O}_2$ by the later proven Corollary F(iii)), and that this unital imbedding $\psi \colon \mathcal{O}_2 \otimes \mathcal{O}_2 \to \mathcal{O}_2$ has the property that $a \mapsto \psi(a \otimes 1)$ is approximately unitarily equivalent to the identity map of $\mathcal{O}_2$ by the approximate innerness of $\delta_2 \colon \mathcal{O}_2 \to \mathcal{O}_2$. gives the ψ (In fact, the morphisms $\delta_2 \colon \mathcal{O}_2 \to \mathcal{O}_2$ and $a \mapsto \psi(a \otimes 1)$ are moreover unitarily homotopic to the identity map of $\mathcal{O}_2$.) This and the nuclearity of $\mathcal{O}_2$ ensures that that any two unital C^*-morphisms from $\mathcal{O}_2$ into E_∞ 1-step dominate each other. Hence Corollary 4.3.7 applies to $h_1, h_2 \colon \mathcal{O}_2 \to E_\infty$.

The homotopy of h_1 and h_2 with $h_1(s_k) = u(1)h_0(s_k)$ for a continuous map $[0,1] \ni t \mapsto u(t) \in \mathcal{U}(A)$ with $u(0) = 1$ is given by $h_t \colon \mathcal{O}_2 \to \mathcal{U}(A)$ with $h_t(s_k) := u(t)s_k$. □

REMARK 4.3.9. If $h_0, h_1 \colon \mathcal{O}_2 \to E$ are homotopic, then one can show that they are moreover "unitarily homotopic", cf. Corollary 4.6.4, i.e., are unitary equivalent in $\mathrm{C_b}([0,\infty), E)/\mathrm{C}_0([0,\infty), E)$. (It does not imply that, conversely, h_0 and h_1 itself are unitarily equivalent or are homotopic in E.)

4. Groups defined by absorbing C^*-morphisms

Suppose that $h_0 \colon D \to E$ is a C^*-morphism such that $h_0(D)' \cap E$ contains $\mathcal{O}_2$ unitally. Proposition 4.3.5(iii) says that this is equivalent to the existence of a unital C^*-morphism from $\mathcal{O}_2$ into E and the equation $[h_0] + [h_0] = [h_0]$.

DEFINITION 4.4.1. We define then the semigroup

$$S(h_0\,;\, D, E) := \{\, [h]\,;\;\, h \in \mathrm{Hom}(D, E)\,,\;\, h \text{ is dominated by } h_0 \,\}$$

and

$$G(h_0\,;\,D,E) := \{\,[h]+[h_0]\,;\ [h]\in S(h_0\,;\,D,E)\,\}\,.$$

Notice that $G(h_0\,;\,D,E) = [h_0] + S(h_0\,;\,D,E)\ \subseteq S(h_0\,;\,D,E)\,.$

Due to the terminology used in the abstract Lemma 4.2.3, we call sometimes the morphisms $h \in \operatorname{Hom}(D,E)$ with the property $[h] \in G(h_0\,;\,D,E)$ the **absorbing** morphisms in the class of those morphisms $k \in \operatorname{Hom}(D,E)$, that are dominated by h_0 .

G. Kasparov has introduced a similar notion of absorption in his early paper [**405**] on Ext-groups. By Proposition 4.3.5(i), a unitary equivalence class $[h] \in S(h_0\,;\,D,E)$ is in $G(h_0\,;\,D,E)$ if and only if h dominates h_0.

The definitions, the above listed properties and Remark 3.1.2(iii) together immediately imply the following consequences of "$[k] \in S(h_0\,;\,D,E)$":

(i) $k(D) \subseteq J$ if $[k] \in S(h_0\,;\,D,E)$, $h_0(D) \subseteq J$ and J is an ideal of E.
(ii) k is nuclear if $[k] \in S(h_0\,;\,D,E)$ and h_0 is nuclear.

More general, it is obvious that $k \in \mathcal{C}$ if $h_0 \in \mathcal{C}$ for some matrix operator-convex cone $\mathcal{C} \subseteq \operatorname{CP}(D,E)$. This applies in particular to the m.o.c. cone $\mathcal{C}(h_0)$ that is generated by h_0.

PROPOSITION 4.4.2. *Suppose that E contains a copy of $\mathcal{O}_2$ unitally and $h_0\colon D \to E$ is a C^*-morphism with $[h_0] + [h_0] = [h_0]$.*

(i) *$S(h_0\,;\,D,E)$ is a commutative semigroup under Cuntz addition of unitary equivalence classes, and*
(ii) *$G(h_0\,;\,D,E)$ is a subgroup of $S(h_0\,;\,D,E)$, and $[h] \to [h] + [h_0]$ is a semigroup epimorphism from $S(h_0\,;\,D,E)$ onto $G(h_0\,;\,D,E)$. It identifies $G(h_0\,;\,D,E)$ naturally with the Grothendieck group of $S(h_0\,;\,D,E)$, in the sense that every semi-group morphism $\varphi\colon S(h_0\,;\,D,E) \to \Gamma$ into a group Γ satisfies $\varphi([h]) = \varphi([h]+[h_0])$ for all $[h] \in S(h_0\,;\,D,E)$.*

PROOF. Let $s_1, s_2 \in h_0(D)' \cap E$ isometries with $s_1s_1^* + s_2s_2^* = 1$, as given by Proposition 4.3.5(iii).

(i): If h_1 is dominated by h_0 then the same property holds for every map in the unitary equivalence class $[h_1]$. Suppose that $[h_1]$ and $[h_2]$ are in $S(h_0; D, E)$. Then $[h_1]+[h_2] \in S(h_0\,;\,D,E)$, because $h_1 \oplus_{s_1,s_2} h_2$ is dominated by h_0, cf. Lemma 4.3.4(v). The semigroup structure follows now from Proposition 4.3.2(i).

(ii): Since $[h_0]+[h_0] = [h_0]$, the subset $G(h_0\,;\,D,E)$ is a subgroup of the semigroup $S(h_0\,;\,D,E)$, and $[h_0]$ is the neutral element (zero element) of $G(h_0\,;\,D,E)$. The inverse element of $[h]$ in $G(h_0\,;\,D,E)$ can be detected as follows: Since $h \in S(h_0\,;\,D,E)$, there is an isometry $t \in E$ with $h = t^*h_0t$. Then $p = tt^*$ is a projection in $h_0(D)' \cap E$ by Lemma 4.3.4(i), and $(1-p)t = 0 = t^*(1-p)$. Hence,

$$k := (1-p)h_0(\cdot) + th_0(\cdot)t^*$$

is a C^*-morphism. The morphism h_0 dominates k by Proposition 4.3.5(ii) because h_0 2-dominates k.

Now it is easy to verify that $k \oplus_{s_1,s_2} h = u^* h_0(\cdot) u$, where $\{s_1, s_2\}$ are generators of $\mathcal{O}_2$ in $h_0(D)' \cap E$, and u is the unitary operator $s_1 t s_2^* + s_1(1-p)s_1^* + s_2 t^* s_1^*$. Then $[(h \oplus h_0) \oplus (k \oplus h_0)] = [h_0 \oplus h_0 \oplus h_0] = [h_0]$. Hence $[k \oplus h_0]$ is the inverse of $[h \oplus h_0]$ in $G(h_0\,;\,D, E)$. This shows that Lemma 4.2.3 applies to the semigroup $S(h_0\,;\,D, E)$ and $G(h_0\,;\,D, E) = [h_0] + S(h_0\,;\,D, E)$. □

The following Proposition 4.4.3 identifies $G(h_0\,;\,D, E)$ with a subgroup of the K_0 group $\mathrm{K}_0(h_0(D)' \cap E)$ and gives the later used characterizations of the elements of this subgroup, and it describes the K_*-theoretic picture of our $\mathrm{Ext}(\mathcal{C};\,\cdot,\cdot)$- and $\mathrm{R}(\mathcal{C};\,\cdot,\cdot)$-groups studied in Chapters 5 and 7. Here the Cuntz addition $\oplus$ in Parts (ii) and (iii) has to be defined with help of the canonical generators of a fixed copy of $\mathcal{O}_2$ that is unitally contained in $h_0(D)' \cap E$.

PROPOSITION 4.4.3. *Let $h_0 \colon D \to E$ a C^*-morphism, such that $h_0(D)' \cap E$ contains a copy of $\mathcal{O}_2$ unitally, and let p and p' projections in $h_0(D)' \cap E$.*

(i) *The group $G(h_0\,;\,D, E)$ is naturally isomorphic to the kernel of the natural K_*-theory map*

$$i_0 \colon \mathrm{K}_0(h_0(D)' \cap E) \to \mathrm{K}_0(E),$$

where $i_0 := \mathrm{K}_0(i)$ for the inclusion map $i \colon h_0(D)' \cap E \hookrightarrow E$.

(ii) *The element $[p] \in \mathrm{K}_0(h_0(D)' \cap E)$ is in the kernel of i_0, if and only if, there is a unitary v in the connected component $\mathcal{U}_0(E)$ of 1_E in $\mathcal{U}(E)$ such that $v^*(p \oplus 1 \oplus 0)v = 1 \oplus 0$.*

The equation $[p] = [p']$ holds in $\mathrm{K}_0(h_0(D)' \cap E)$, if and only if, there is a unitary $u \in \mathcal{U}_0(h_0(D)' \cap E)$ such that $u^*(p \oplus 1 \oplus 0)u = p' \oplus 1 \oplus 0$.

(iii) *If h_0 dominates zero, then projections p and p' in $h_0(D)' \cap E$ define the same element of $\mathrm{K}_0(h_0(D)' \cap E)$, if and only if, $[p] = [p']$ in $\mathrm{K}_0(E)$ and there is a unitary $u \in h_0(D)' \cap E$ such that $\Delta := (p' \oplus 1 \oplus 0) - u^*(p \oplus 1 \oplus 0)u$ is in the (two-sided) annihilator of $h_0(D)$, i.e., $h_0(a)\Delta = 0$ for all $a \in D$.*

PROOF. We let $C := h_0(D)' \cap E$ and define the Cuntz addition $\oplus$ by isometries $s_1, s_2 \in C$ with $s_1 s_1^* + s_2 s_2^* = 1_E$, i.e., $\oplus = \oplus_{s_1,s_2}$.

(i): A C^*-morphism $h \colon D \to E$ has unitary equivalence class $[h]$ in $S(h_0\,;\,D, E)$ if and only if there is an isometry $t \in E$ with $h = t^* h_0(\cdot) t$ (cf. Definition 4.3.3). Then $tt^* \in C$ by Lemma 4.3.4(i). If $s \in E$ is an other isometry with $s^* h_0(\cdot) s = h$, then $z = ts^*$ is a partial isometry in C by Lemma 4.3.4(ii). We have $tt^* = zz^*$ and $z^* z = ss^*$, i.e., tt^* and ss^* are Murray–von-Neumann equivalent in C. Let $k \colon D \to E$ a C^*-morphism in the unitary equivalence class $[h]$ of h. Then there is a unitary $u \in E$ with $k = u^* h(\cdot) u = u^* t^* h_0(\cdot) t u$. Thus k is a C^*-morphism that is dominated by h_0, and $[k] = [h]$. Note that $(tu)(tu)^* = tt^*$.

It follows that the map θ from $S(h_0\,;\,D, E)$ into $\mathrm{K}_0(C)$, defined by

$$\theta([h]) := [tt^*] \in \mathrm{K}_0(C)$$

for $h = t^*h_0(\cdot)t$, with $t^*t = 1$ is well-defined, because $[s^*h_0(\cdot)s] = [t^*h_0(\cdot)t] = [h]$ implies that the projections tt^* and ss^* are Murray–von Neumann equivalent in C.

By Lemma 4.3.4(v), $h_1 \oplus h_2 = r^*h_0(\cdot)r$ with $r = t_1 \oplus t_2$ where $h_i(\cdot) = t_i^*h_0(\cdot)t_i$ for $i = 1, 2$. Thus, $\theta([h_1] + [h_2]) = [t_1t_1^* \oplus t_2t_2^*] \in \mathrm{K}_0(C)$. This is the same as $[t_1t_1^*] + [t_2t_2^*] = \theta([h_1]) + \theta([h_2])$ by Lemma 4.2.6(i). In particular $\theta([h_0]) = 0$, because $2\theta([h_0]) = \theta([h_0])$. Since $\mathrm{K}_0(C)$ is a group, $[h] + [h_0] \mapsto \theta([h])$ is a well-defined group homomorphism from $G(h_0\,; D, E)$ into $\mathrm{K}_0(C)$.

As $1_E \in \mathcal{O}_2 \subseteq E$, we get for $h = t^*h_0(\cdot)t$ with $t^*t = 1$,

$$[0]_E = [1]_E = [t^*t]_E = [tt^*]_E \in \mathrm{K}_0(E),$$

so that θ maps $S(h_0\,; D, E)$ into the kernel of i_0.

Let $h_1 = s^*h_0(\cdot)s$, $h_2 = t^*h_0(\cdot)t$ and $\theta([h_1]) = \theta([h_2])$, i.e., $[ss^*] = [tt^*]$ in $\mathrm{K}_0(C)$. The projections $1 \oplus ss^*$ $(= (1 \oplus s)(1 \oplus s)^*)$ and $1 \oplus tt^*$ are full and properly infinite in C, thus are MvN-equivalent in C by Lemma 4.2.6(ii). But this means that $h_0 \oplus h_1$ and $h_0 \oplus h_2$ are unitarily equivalent, by Lemma 4.3.4(ii). Thus $[h_1] + [h_0] = [h_2] + [h_0]$ if $\theta([h_1]) = \theta([h_2])$, and $\theta | G(h_0\,; D, E)$ is a *monomorphism*.

Now let $x \in \mathrm{K}_0(C)$ with $i_0(x) = 0$. Since C is properly infinite, it follows from Lemma 4.2.6(iii), that there exists a projection $p \in C$, and isometries $s, t \in C \subseteq E$, such that $x = [p]$, $ss^* \leq p$ and $tt^* \leq 1 - p$. Then $i_0(x) = [p] = 0 = [1]$ in $\mathrm{K}_0(E)$, and, by Lemma 4.2.6(ii), there is $r \in E$ with $rr^* = p \in C$ and $r^*r = 1$. The completely positive map $h := r^*h_0(\cdot)r$ is a C^*-morphism from D into E by Lemma 4.3.4(i) and h_0 dominates h, i.e., $[h] \in S(h_0\,; D, E)$. Moreover, $\theta([h] + [h_0]) = \theta([h]) = [rr^*] = [p] = x$. Hence, $[h] + [h_0] \mapsto \theta([h])$ is a group *isomorphism* from $G(h_0\,; D, E)$ *onto* $\ker(i_0) \subseteq \mathrm{K}_0(C)$.

(ii): Recall that $1 \oplus 0 = s_1s_1^*$ is unitarily equivalent to $1 \oplus 1 \oplus 0$ by a unitary in $\mathcal{U}(\mathcal{O}_2) = \mathcal{U}_0(\mathcal{O}_2)$, cf. Proposition 4.3.2. Thus, (ii) is a special case of Lemma 4.2.6(iv,b) (with C in place of E for the equation $[p] = [p'] \in \mathrm{K}_0(C)$).

(iii): Let p, p' are projections in C. If $[p] = [p']$ in $\mathrm{K}_0(C)$, then $[p] = [p']$ in $\mathrm{K}_0(E)$ and, by (ii), there is a unitary $u \in C$ with $u^*(p \oplus 1 \oplus 0)u = p' \oplus 1 \oplus 0$.

Conversely, suppose that $[p] = [p']$ in $\mathrm{K}_0(E)$ and that there is a unitary $u \in C$ such that $\Delta := (p' \oplus 1 \oplus 0) - u^*(p \oplus 1 \oplus 0)u$ satisfies $\Delta \cdot h_0(D) = \{0\}$.

Let $p_1 := u^*(p \oplus 1 \oplus 0)u$ and $p_2 := p' \oplus 1 \oplus 0$. Then $[p_1] = [p] + [1] + [0] = [p]$ and $[p_2] = [p']$ as well in $\mathrm{K}_0(C)$ as in $\mathrm{K}_0(E)$. Therefore, p_1 and p_2 are projections in C with $[p_1] = [p_2]$ in $\mathrm{K}_0(E)$ and $p_2 - p_1 \in N$, where $N \subseteq E$ denotes the (two-sided) annihilator of $h_0(D)$ in E.

The two-sided annihilator N of $h_0(D)$ is a hereditary C^*-subalgebra of E and is an ideal of $C = h_0(D)' \cap E$. The hereditary C^*-subalgebra N of E is *full* in E, because h_0 dominates zero by assumptions of Part (iii), i.e., there is an isometry $t \in E$ with $tt^* \in N$. By Lemma 4.2.20(i), we get $[p_1] = [p_2] \in \mathrm{K}_0(C)$ from $p_2 - p_1 \in N$ and $[p_1] = [p_2] \in \mathrm{K}_0(E)$. □

REVISE HISTORIC REMARKS:

The assumptions in the following Theorem 4.4.6 are the same as of Lemma [**442**, lem. 3.8], but with assumption [**442**, lem. 3.8(vi)] removed, because it can be derived from the other assumptions, cf. Lemma 4.4.7(vii). An old outline of the proof of Lemma [**442**, lem. 3.8] – displayed in beamer presentations – incorrectly claimed that the natural surjective group homomorphism $\varphi\colon G(h_0\,;\,D,E) \to G(H_0\,;\,D,E)$ is always *injective*. This is still unknown, and Professor Claire Anantharaman-Delaroche mentioned her concerns about the injectivity claim for the natural group homomorphism φ to the author (likely around 1996). And she suggested that the homotopy invariance of the "unsuspended" but stable $\mathcal{E}$-theory (respectively the slightly different $\mathcal{O}_2$-unital $\mathcal{E}$-theory in the approach of N. Ch. Phillips) should show the equivalence to KK-theory.

It turns out that the Grothendieck groups of some kinds of unsuspended but stable $\mathcal{E}$-theories are homotopy invariant, but that gives not a proof for the coincidence with the related sort of KK-theories if equipped with certain additional "equivariant" behavior.

At the actual state we have two different proofs of the homotopy invariance of the continuous Rørdam groups $\mathrm{R}(\mathcal{C}\,;\,A,B)$ that are defined in Chapter 7 for stable separable A and B and non-degenerate m.o.c. cone $\mathcal{C} := \mathcal{C}(h_0)$, – which is in this special case isomorphic to the below considered group $G(h_0\,;\,D,E)$:

One way is to prove first independently that the groups $\mathrm{R}(\mathcal{C}\,;A,B)$ are homotopy invariant itself by a generalization and modification of the ideas of N.Ch. Phillips in his proof of the homotopy invariance of the generalized unsuspended E-theory for pi-sun algebras in [**627**].

See Section **??** concerning a similar but more general sort of stable, but unsuspended, E-semigroups and an outline of the homotopy invariance of its Grothendieck group. It is not clear if one can use a "controlled" homotopy invariance of $\mathrm{R}(\mathcal{C}\,;\,A,B)$ to establish the injectivity of the natural epimorphism $\varphi\colon G(h_0\,;\,D,E) \to G(H_0\,;\,D,E)$, in the special case where naturally $\mathrm{R}(\mathcal{C}\,;\,A,B) = G(h_0\,;\,D,E)$ with $D := A \otimes \mathbb{K}$, $E := \mathcal{M}(\mathrm{C}_0(\mathbb{R},B))/\,\mathrm{C}_0(\mathbb{R},B)$ and

$$h_0\colon D \to B \subset J := \mathrm{C}_\mathrm{b}(\mathbb{R}_+,B)/\,\mathrm{C}_0(\mathbb{R}_+,B) \subset E\,,$$

a generating homomorphism for the given m.o.c. cone $\mathcal{C} \subset \mathrm{CP}(A,B)$, cf. Chp. 7. Notice that $G(h_0\,;\,D,E)$ is in this particular case the same as $\mathrm{Ext}(\mathcal{C}\,;\,A,SB) \cong \mathrm{KK}(\mathcal{C}\,;\,A,B)$.

```
Until now:
We have only that (DC) is valid for our special applications,
that (DC) implies functorial equivalence of R(C;.,.) with KK(C;.,.).
The injectivity criteria of the following Theorem 4.4.6
and arguments in Chapters 7,
8 and 9 show that the injectivity of the
group epimorphism φ implies also homotopy invariance of R(C; A,B).
```

An ''independent proof'' from the natural isomorphism
between $\mathrm{R}(\mathcal{C}\,;\,A,B[0,1])$ and $\mathrm{R}(\mathcal{C}\,;\,A,B)$
to the injectivity of φ is not found or written up!!!
So far, until now.
An isomorphism $\mathrm{R}(\mathrm{CP}_{\mathrm{nuc}}\,;A,B[0,1])\cong\mathrm{R}(\mathrm{CP}_{\mathrm{nuc}}\,;A,B))$
was shown first by N.Ch. Phillips in [627] (for A and B in Cuntz standard form?).
Then he used the characterization of N. Higson [364].
We do not know if we can also go this way
but the *general problem* is that it is not known if $U(0)=1$ and

$$U^*(k\oplus H_0)(a)U-H_0(a)\in \mathrm{C}_0([0,\infty),B)\ \text{ for all } a\in A$$

always implies that $h_0\otimes k$ and h_0
are asymptotical homotopic,
i.e., if there exists $g_{s,t}\in S(h_0;\,A,B)$ with
$s,t\in[0,1]\times[0,\infty)$ point-norm continuous
and $g_{0,t}=h_0\oplus k$ and $g_{1,t}=h_0$.

We generalize in Section **??** an idea of N.Ch. Phillips that shows that the *Grothendieck* groups of certain semigroups of asymptotic morphisms are homotopy invariant, in a way that covers also the case of our (!) more general types of Rørdam groups.

But we underline that in our special case the injectivity criteria (DC) of Theorem 4.4.6 follows from the homotopy invariance of $\mathrm{KK}(\mathcal{C}\,;\,A,B)$, where it is very important that this holds for *arbitrary* m.o.c. cones. It allows a precise explanation for the sketched and a bit imprecise arguments outlined at the end of the Preprint [**434**], cf. also [**442**].

We describe in Theorem 4.4.6 the hypothetical elements in the kernel of the homomorphism φ, and give an applicable sufficient criteria (DC) for the injectivity of φ.

We show in Section 3 of Chapter 9 that in the later used special case of the canonical surjection $\mathrm{R}(\mathcal{C}\,;\,A,B)\to\mathrm{Ext}(\mathcal{C}\,;\,A,\,SB)\cong\mathrm{KK}(\mathcal{C}\,;\,A,B)$ the decomposition condition (DC) of Theorem 4.4.6 is a consequence of

$$\mathrm{KK}(\mathcal{C}(0,1]\,;\,A;\mathrm{C}_0((0,1],B))=0\,,$$

i.e., the homotopy invariance of $\mathrm{KK}(\mathcal{C}\,,A,B)$ allows to proof for our applications the property (DC) that implies finally the needed bijectivity.

([7]).

It shows that the homotopy invariance of the Kasparov groups alone imply that of $\mathcal{C}$-related Rørdam groups and KK-groups are isomorphic. As claimed in the appendix of the Preprint [**434**], there not really proved.

[7] The author regrets for his remarks “Es ist ein Gradeaus-Beweis.” below [**442**, lem. 3.8], and ”... should be able to work out the details” in the appendix of [**434**].

We need for the description of the *kernel* of the group homomorphism $\varphi\colon G(h_0\,; D,E) \to G(H_0\,; D,E)$ in the following Theorem 4.4.6 and in Lemma 4.4.15, some basic notations and definitions of algebraic nature:

DEFINITION 4.4.4. Let $A \subseteq E$ a C^*-subalgebra, $I \triangleleft E$ an closed ideal of E, $C := A' \cap E$ the commutant (or "centralizer") of A in E, and define by

$$\mathrm{Ann}(A) := \mathrm{Ann}(A,E) := \{\, e \in E\,;\ eA \cup Ae = \{0\}\,\}\,. \tag{4.1}$$

the *annihilator* of A in E. We consider following C^*-subalgebras of E:

$$\mathrm{Der}(A,I) := \{\, e \in E\,;\ ea - ae \in I,\ \forall\, a \in A\,\} \;=\; \pi_I^{-1}\big(\,\pi_I(A)' \cap (E/I)\,\big)\,, \tag{4.2}$$

$$\mathcal{N}(A,I) := \{\, e \in E\,;\ ea, ae \in I,\ \forall\, a \in A\,\} \;=\; \pi_I^{-1}\big(\,\mathrm{Ann}(\pi_I(A), E/I)\,\big)\,. \tag{4.3}$$

Compare Remarks 6.1.2 for further details on $\mathrm{Ann}(\,\cdot\,)$ and $\mathcal{N}(\,\cdot\,,\,\cdot\,)$. Notice that $C = \mathrm{Der}(A,\{0\}) \subseteq \mathrm{Der}(A,I)$ and that $\mathcal{N}(A,I)$ is a closed ideal of $\mathrm{Der}(A,I)$.

DEFINITION 4.4.5. We define a discrete abelian group $\Gamma\big(A,I,E\big)$ by

$$\Gamma\big(A,I,E\big) := \mathrm{K}_1\big(\mathrm{Der}(A,I)\big)\,/\,\mu\big(\mathrm{K}_1(C)\big) \tag{4.4}$$

where the group morphism $\mu := [\eta]_1\colon \mathrm{K}_1(C) \to \mathrm{K}_1(\mathrm{Der}(A,I))$ comes from the inclusion map $\eta\colon C \hookrightarrow \mathrm{Der}(A,I)\,$.

The formulation "later specified" used in Parts (iii) and (iv) of the following Theorem means that different possible choices of the (non-unital) C^*-subalgebra $F \subseteq C$ with the properties in Part (iii) and of isometries $s_0, t_0 \in E$ with the properties in Part (iv) are *not* uniquely determined, but have to exist and can be be chosen/adjusted such that they interplay in the manner that is described in Parts (iii,iv). Their existence with the required interplay is a property of the system $(J \subseteq E, \beta, h_0, H_0)\,$.

THEOREM 4.4.6. *Suppose that $h_0\colon D \to E$ and $H_0\colon D \to E$ are *-monomorphisms, where D is a separable C^*-algebra and E is a unital C^*-algebra. Further let J be a closed ideal of E and β a *-automorphism of E, such that $h_0(D) \subseteq J$, $\beta^2 = \mathrm{id}$, $\beta H_0 = H_0$ and $\beta(J) \cap J = 0$.*

We require that E, J, D, H_0, h_0, and β satisfy the following assumptions (i)-(vi)*, with $C := H_0(D)' \cap E$.*

- (i) *The algebra $h_0(D)' \cap H_0(D)' \cap E \subseteq C$ contains β-invariant isometries s, t with $ss^* + tt^* = 1$.*
- (ii) *If H_0 dominates $k\colon D \to E$, then there exists a unitary $u \in E$ such that $u^*(k \oplus H_0)(a)u - H_0(a) \in J$ for all $a \in D$.*
- (iii) *There exists a (later specified) C^*-subalgebra $F \subseteq C$ with following properties:*
  - (a) *$F \cdot H_0(D) \subseteq J + \beta(J)$,*
  - (b) *$\beta(F) = F$, and*
  - (c) *for every $f \in J + \beta(J)$ and every projection $q \in F$, there is a projection $p \in F$ with $pf = fp = f$, $q \le p$ and $q \neq p$.*

(iv) *There are (later specified) β-invariant isometries $s_0, t_0 \in E$ that interplay with F, C, H_0 and h_0 in the following manner*

$$p_0 := s_0 s_0^* \in F\,, \ \ t_0 \in C\,, \ \ s_0 s_0^* + t_0 t_0^* = 1$$

and

$$s_0^* H_0(a) s_0 = h_0(a) + \beta(h_0(a)) \quad \textit{for all } a \in D\,.$$

(v) *Every non-zero projection in F is unitarily equivalent to p_0 by a unitary in $1 + F$.*

(vi) *There exists a unitary u_1 in $J' \cap E$ such that $u_1 \beta h_0(\cdot) s s^* = t t^* \beta h_0(\cdot) u_1$.*

If assumptions (i)-(vi) *are satisfied, then $h_0 \oplus H_0$ is unitarily equivalent to H_0 and the mapping $\varphi\colon [k] + [h_0] \mapsto [k] + [H_0]$ is a (well-defined) group epimorphism from $G(h_0\,;\, D, E)$ onto $G(H_0\,;\, D, E)$.*

The kernel *of this epimorphism is naturally isomorphic to $\Gamma(H_0(D), J, E)$.*

The natural group epimorphism $\varphi\colon [k] + [h_0] \mapsto [k] + [H_0]$ from $G(h_0\,;\, D, E)$ onto $G(H_0\,;\, D, E)$ is injective, *if and only if, E, J, β, D, and H_0 satisfy the following* decomposition condition (DC)*:*

(DC) *For each $u \in \mathcal{U}_0(E) \cap \mathrm{Der}(H_0(D), J)$ there exists $v \in \mathcal{U}(C)$ such that*

$$v(u \oplus_{s,t} 1) \in \mathcal{N}(H_0(D), J + \beta(J)) + \mathbb{C} \cdot 1\,.$$

The condition (DC) *is equivalent to the following (formally weaker) property* (wDC)*:*

(wDC) *If $u \in \mathcal{U}_0(E) \cap \mathrm{Der}(H_0(D), J)$ and $k \in S(h_0\,;\, D, E)$ satisfy*

$$(k + \beta h_0) \oplus_{s_0,t_0} H_0 = u^* H_0(\cdot) u\,,$$

then

$$[k] + [h_0] = [h_0]\,.$$

`Compare below with above concerning` R(...) `to` KK(...).

The group homomorphism $G(h_0\,;\, D, E) \;\to\; G(H_0\,;\, D, E)$ is a "minimal" abstract version of the natural group epimorphism from the generalized Rørdam groups $\mathrm{R}(\mathcal{C}\,;\, D, B)$, cf. Chapter 7, to the $\mathcal{C}$-equivariant extension groups $\mathrm{Ext}(\mathcal{C}(\mathbb{R});\, D, SB) \cong \mathrm{KK}(\mathcal{C};\, D, B)$ introduced in Chapter 5 and compared with KK-groups in Chapter 8.

The criteria (wDC) shows that the injectivity of this group epimorphism is `equivalent ???`
to a suitable version of homotopy invariance for the groups $\mathrm{R}(\mathcal{C}\,;\, D, B)$.

`Not proved until now !!! Imprecise idea exists?`

The Rørdam groups are unsuspended – but stable – versions of, from a cone $\mathcal{C}$ depending, E-theory groups. The definition of $\mathrm{R}(\mathcal{C}\,;\, D, B)$ is entirely algebraic and does not require any sort of homotopy invariance in its formulation, even not implicitly.

`A cited condition (vwDC) is not defined somewhere!!!`
In fact we show that a below given formally weaker condition (vwDC) implies that $\Gamma(H_0(D), J, E) = 0$.

We have used in the formulation of Parts (iii) and (iv) in Theorem 4.4.6 the terminus "specified", that should say the following (together with Part (v)): We demand that our "given" natural system $(E, J, D, H_0, h_0, \beta)$ has the property that F, s_0 and t_0 exist with the properties listed in Parts (iii). But then we fix one of the possible systems (F, s_0, t_0) and add it to the structure given by $(E, J, D, H_0, h_0, \beta)$ simply for further references in the proof. The additional (F, s_0, t_0) are not uniquely determined by $(E, J, D, H_0, h_0, \beta)$. The F in most of our applications satisfies in addition that $\mathrm{K}_1(F) = 0$, that can not be derived from the assumptions of Theorem 4.4.6.

The difference to Part (v) is that this is an additional requirement on F, and we need from Part (vi) only that such u_0 *exists* in later proofs it not necessary to use always the same u_0 with the in (vi) quoted property.

The Parts (i)–(v) of following Lemma 4.4.7 are not obvious because $[\varphi] = [\varphi + 0] \neq [\varphi] + [0] = [\varphi \oplus 0]$ for C^*-morphisms φ that do *not* dominate zero. The used isometry s_0 and $p_0 := s_0 s_0^*$ are given by assumption (iv) of Theorem 4.4.6.

Recall that $C := H_0(D)' \cap E$ in Theorem 4.4.6.

LEMMA 4.4.7. *The assumptions* (i)–(vi) *on* h_0 *and* H_0 *in Theorem 4.4.6 imply the following properties* (i)-(xii)*:*

(i) *Let B_j, $j = 1, 2$, separable C^*-algebras, $k_j \colon B_j \to J \subseteq E$ C^*-morphisms, and use $u_1 \in \mathcal{U}(E)$ from assumption (vi) in Theorem 4.4.6. Then, for all $b \in B_1$, $c \in B_2$ and $d \in D$,*

$$u_1\big((k_1(b) + \beta h_0(d)) \oplus_{s,t} k_2(c)\big)u_1^* = k_1(b) \oplus_{s,t} (k_2(c) + \beta h_0(d)) .$$

In particular, for all C^*-morphisms $k_1, k_2 \colon D \to J \subseteq E$,

$$[k_1 + \beta h_0] + [k_2] = [k_1] + [k_2 + \beta h_0] .$$

For each σ-unital C^*-algebra B and C^*-morphism $k \colon B \to J + \beta J$ holds $[k] = [k] + [0]$. Moreover, for every isometry $T \in E$ there exists a unitary $u \in \mathcal{U}_0(E)$ such that $k(b)u = k(b)T^*$ for all $b \in B$. In particular, $u^* k(\cdot) u = T k(\cdot) T^*$.

Special cases are $[k_1 + \beta k_3] = [k_1 + \beta k_3] + [0]$, for all C^*-morphisms $k_1, k_3 \colon D \to J \subseteq E$, and – with $k_2 := 0$, $k_3 := h_0$ –,

$$[k_1 + \beta h_0] = [k_1 + \beta h_0] + [0] = [k_1] + [\beta h_0] .$$

(ii) $[h_0] + [\beta h_0] = [h_0 + \beta h_0] = [h_0 + \beta h_0] + [h_0] = [h_0 + \beta h_0] + [0]$.

(iii) $[H_0] + [h_0 + \beta h_0] = [H_0]$.

(iv) $[H_0] + [h_0] = [H_0] = [H_0] + [\beta h_0]$.

(v) *Each of H_0, $h_0 + \beta h_0$, βh_0 and h_0 dominates zero.*

(vi) *There exist isometries* $s_1, t_1 \in E$ *with* $s_1 s_1^* + t_1 t_1^* = 1$, $p_0 t_1 = p_0 = t_1 p_0$ *and* $t_1 H_0(\cdot) = H_0(\cdot) = H_0(\cdot) t_1$. *In particular,* $t_1 \in C$, $s_1 s_1^* \leq 1 - p_0$, $s_1 s_1^* H_0(\cdot) = 0$ *and* $s_1 s_1^* E s_1 s_1^* = s_1 E s_1^* \subseteq \mathrm{Ann}(H_0(D), E) \subseteq C$.

(vii) *If* $[h] \in S(H_0\,; D, E)$ *and* $h(D) \subseteq J + \beta J$, *then* h *has a unique decomposition* $h = k_1 + \beta k_2$ *with* C^**-morphisms* $k_1, k_2 \colon D \to J$ *that satisfy* $[k_1], [k_2] \in S(h_0\,; D, E)$.

In particular, $[k] \in S(h_0\,; D, E)$ *if* $[k + \beta h_0] \in S(H_0\,; D, E)$ *and* $k(D) \subseteq J$.

If $x \in E$ *is a contraction, such that* $(1 - xx^*) H_0(D) x = \{0\}$ *and* $x^* H_0(D) x \subset J + \beta J$, *then there are unique* $k_1, k_2 \in S(h_0\,; D, E)$ *with* $k_1 + \beta k_2 = x^* H_0(\cdot) x$.

This applies to projections $x := P \in C$ *with* $H_0(D) P \subseteq J + \beta J$.

(viii) *Let* B *a* σ*-unital* C^**-algebra and* $k_1, k_2 \colon B \to J$ C^**-morphisms. Then* $[k_1] = [k_2]$, *if and only if, there exists a unitary* $u \in \mathcal{U}_0(\beta h_0(D)' \cap E)$ *with* $\beta h_0(d) u = \beta h_0(d)$ *for all* $d \in D$ *and and* $k_2(b) = u^* k_1(b) u$ *for all* $b \in B$.

In particular, then $u \in \mathcal{U}_0(E)$ *and* $\beta(u) \in h_0(D)' \cap E$.

If $B := D$ *then* $[k_1 + \beta h_0] = [k_2 + \beta h_0]$ *implies* $[k_1] = [k_2]$.

If B *is a* σ*-unital* C^**-algebra,* $k \colon B \to J$ *a* C^**-morphism and* $T \in E$ *is an isometry, then there exists* $u \in \mathcal{U}_0(\beta h_0(D)' \cap E)$ *that satisfies* $u^* k(\cdot) u = T k(\cdot) T^*$ *and* $\beta h_0(d) u = \beta h_0(d)$ *for all* $d \in D$.

(ix) *Let* $q_1, q_2 \in F$ *denote non-zero* commuting *projections in* F. *Then there exists a unitary* $u \in (F + 1) \cap \mathcal{U}_0(F + \mathbb{C} \cdot 1) \subseteq C$ *with* $u^* q_1 u = q_2$.

For every separable subset $X \subseteq J + \beta J$ *there exists a projection* $p \in F$ *and an isometry* $R \in C$ *with* $pR = 0$ *and* $pxp = x$ *for all* $x \in X$.

For each isometry $V \in E$ *(or unitary* V*) there exists* $U \in \mathcal{U}_0(E)$ *with* $xV^* = xU$ *for all* $x \in X$.

(x) *There exist isometries* $s_2, s_3 \in E$ *that satisfy*

$$s_2^* H_0(\cdot) s_2 = h_0 \ , \quad s_3^* H_0(\cdot) s_3 = \beta h_0 \ , \quad \text{and} \quad s_2 s_2^* + s_3 s_3^* = p_0 \, .$$

The projection $p_2 := s_2 s_2^*$ *is in* C, *and and* p_2, s_2 *and* s_3 *satisfy* $s_2 h_0 s_2^* = p_2 H_0(\cdot) = s_0 h_0 s_0^*$ *and*

$$s_3 \beta h_0 s_3^* = (p_0 - p_2) H_0(\cdot) = s_0 \beta h_0 s_0^* = \beta(s_0 h_0 s_0^*) \, .$$

In particular, $p_2 H_0(D) \subseteq J$ *and* $(p_0 - p_2) H_0(D) \subseteq \beta J$.

If $s, t \in C$ *are the isometries in Theorem 4.4.6(i), then the partial isometries* $s_2 s s_2^*$, $s_2 t s_2^*$, $s_3 s s_3^*$, $s_3 t s_3^*$, $s_0 s s_0^*$ *and* $s_0 t s_0^*$ *are in* C.

In particular, the projections $p_2 = s_2 s_2^*$, $p_0 - p_2 = s_3 s_3^*$ *and* p_0 *are properly infinite in* C, *satisfy* $0 = [p_2] \in \mathrm{K}_0(p_2 C p_2)$,

??? $0 = [p_0 - p_2] \in \mathrm{K}_0((p_0 - p_2) C (p_0 - p_2))$ *??? or* $= 0$ *in* $\mathrm{K}_0(p_0 C p_0)$ *???*

and $[p_0] = 0$ *in* $\mathrm{K}_0(p_0 C p_0)$.

There exists an isometry $t_2 \in C$ *with* $t_2 t_2^* = 1 - p_2$ *and unitary elements* $u, v \in \mathcal{U}(C)$ *such that*

$$u^* p_2 u = p_2 + t_2 p_2 t_2^* \qquad \text{and} \qquad v^* p_2 v = p_2 \oplus_{s,t} p_2 \, .$$

The elements $s_0^* s_2,\, s_0^* s_3 \in E$ *are isometries with* $(s_2^* s_0)(s_0^* s_3) = 0$.

If B *is a* σ*-unital* C^**-algebra and* $h\colon B \to J$ *a* C^**-morphism then there exists* $u_h \in \mathcal{U}_0((\beta h_0)(D)' \cap E)$ *such that* $\beta h_0(\cdot) u_h = \beta h_0$ *and* $e h(b) u_h = e h(b) s_2^* s_0$ *for all* $b \in B$ *and* $e \in E$.

(xi) *For every non-zero projection* $p \in F$ *there exists properly infinite projections* $q, r \in C$ *with* $q + r = p$, $qr = 0$, $q \in \mathcal{N}(H_0(D), J)$ *and* $r \in \mathcal{N}(H_0(D), \beta J)$. *Each decomposition* $p = q + r$ *of this kind satisfies* $[qH_0(\cdot)] = [h_0]$ *and* $[rH_0(\cdot)] = [\beta h_0]$.

(xii) *If* $p \in F$ *is a projection with* $p \geq p_0$ *and* $p \neq p_0$, *then there exist* $V \in \mathcal{U}(C)$ *and* $W \in \mathcal{U}_0(E)$ *such that* $W^*(h_0 + \beta h_0) W = p_0 H_0(\cdot)$, $V p_0 = p_0 = p_0 V$ *and*

$$V^*(p - p_0) H_0(\cdot) V = t_0 W^*(h_0 + \beta h_0) W t_0^* .$$

Proof. We give a pre-information in Point (o) and prove Part (ix) before the other Parts of Lemma 4.4.7.

(o): Assumptions (iii) and (iv) of Theorem 4.4.6 together imply $p_0 H_0(d) = s_0 h_0(d) s_0^* + s_0 \beta h_0(d) s_0^*$ and $t_0 H_0(d) t_0^* = (1 - p_0) H_0(d)$ for $d \in D$. Thus

$$H_0 = (h_0 + \beta h_0) \oplus_{s_0, t_0} H_0 .$$

(ix): Let $q_1, q_2 \in F$ non-zero *commuting* projections. We show the existence of $u \in \mathcal{U}_0(F + \mathbb{C} \cdot 1) \cap (1 + F)$ with $u^* q_1 u = q_2$:
If $q_1, q_2 \in F$ are projections with $q_1 q_2 = q_2 q_1$, then

$$q_j \leq q_3 := (q_1 + q_2) - (q_1 q_2) \in F \quad \text{for } j \in \{1, 2\} ,$$

and q_3 is a projection. The unitaries in $(1 + F) \cap \mathcal{U}_0(F + \mathbb{C} \cdot 1)$ build a group. Thus, it suffices to consider the special cases where $0 \neq q_1 \leq q_2$:

By assumption (iii) of Theorem 4.4.6 with $f = 0$, there is a projection $p \in F \subseteq C := H_0(D)' \cap E$ such that $p \geq q_2$ and $p \neq q_2$.

Any non-zero projection $q \in F$ is unitary equivalent to p_0 by a unitary $w \in 1 + F$ by assumption (v) of Theorem 4.4.6. Thus, there are unitaries $w_k, w \in 1 + F$, $k \in \{1, 2\}$, with $w_k^* p_0 w_k = q_k$ and $w^* p_0 w = p - q_2$. The partial isometries $v_k := w_k^* p_0 w \in F$, satisfy $v_k v_k^* = q_k$, $v_k^* v_k = p - q_2$ and $v_k^2 = 0$. It follows that $q_k + (p - q_2) = v_k v_k^* + v_k^* v_k$ and

$$U_k := v_k^* + v_k + (1 - v_k v_k^* + v_k^* v_k)$$

are selfadjoint unitaries in $\mathcal{U}_0(F + \mathbb{C} \cdot 1)$ with $U_k q_k = (p - q_2) U_k$ for $k = 1, 2$. Hence, $u^* q_2 u = q_1$ and $u \in (F + 1) \cap \mathcal{U}_0(F + \mathbb{C} \cdot 1)$ for $u := U_2^* U_1$.

(If E is a real C^*-algebra E then we can take here $u := V_2^* V_1$ with unitaries

$$V_k := \exp((\pi/2)(v_k^* - v_k)) = v_k^* - v_k + (1 - v_k v_k^* - v_k^* v_k)$$

because also $V_k q_k = (p - q_2) V_k$.)

Let $p \in F$ is a projection with $p \geq p_0$. We show the existence of isometries $R, T \in C$, that satisfy $pR = 0$, $pT = Tp = p$ and $TT^* + SS^* = 1$ for $S := Rs_0 \in E$ (not necessarily in C):

Let $u \in \mathcal{U}_0(F + \mathbb{C} \cdot 1) \subseteq \mathcal{U}_0(C)$ with $u^* p_0 u = p \geq p_0$.

If $p := p_0$, then we can take the isometries $R_0, T_0 \in C$ and $S_0 \in E$ defined by $R_0 := t_0$, $T_0 := p_0 + t_0^2 t_0^*$ and $S_0 := R_0 s_0 = t_0 s_0$.

The assumptions $s_0 s_0^* = p_0$, $s_0 s_0^* + t_0 t_0^* = 1$, $p_0 \in F \subseteq C$, $t_0 \in C$ in parts (iii,iv) of Theorem 4.4.6, show that $S_0 \in E$ and $R_0, T_0 \in C$ are isometries with $R_0 R_0^* = 1 - p_0$, $p_0 R_0 = 0$, $p_0 S_0 = 0$, and $T_0 T_0^* + S_0 S_0^* = 1$.

It follows that $R := u^* R_0$, $S := Rs_0 = u^* S_0$ and $T := u^* T_0 u$ have the desired properties with respect to $p = u^* p_0 u$.

For every separable subset $X \subseteq J + \beta J$ there exists a projection $p \in F$ and an isometry $R \in C$ with $pxp = x$ and $xR = 0$ for all $x \in X$:

Let $A := C^*(X) \subseteq J + \beta J$ the separable C^*-subalgebra generated by X and $f \in A_+$ a strictly positive contraction for A. By assumptions (iii,c) and (iv) of Theorem 4.4.6 there exists a projection $p \in F$ with $pf = f = fp$ and $p \geq p_0 = s_0 s_0^* \in F$. Since fAf is dense in A, we get $pxp = x$ for all $x \in X \subseteq A$.

Let $p \in F$ with $p \geq p_0$ and $pxp = x$ for all $x \in X$.

There exists $u \in \mathcal{U}_0(C)$ with $u^* p_0 u = p$ as shown above. The isometry $R = u^* t_0$ is in C and satisfies $pR = 0$. It follows that $xR = xpR = 0$ for all $x \in X$.

Let $X \subseteq J + \beta J$ a separable subset, and $V \in E$ an isometry. We show the existence of $U \in \mathcal{U}_0(E)$ with $xV^* = xU$ for all $x \in X$:

If we replace the above considered separable subset $X \subseteq J + \beta J$ by the separable subset $XV^* \cup X \subseteq J + \beta J$, then the above observations lead to a projection $p \in F$ with $p \geq p_0$, $xp = x$ and $xV^* p = xV^*$ for all $x \in X$.

Take a unitary $u \in \mathcal{U}_0(F + \mathbb{C} \cdot 1) \cap (1 + F)$ with $u^* p_0 u = p$. Let $R := u^* t_0$, $S := Rs_0$ and $T := p + Rt_0 R^*$ as above considered with $pS = 0$, $pT = p = Tp$ and $SS^* + TT^* = 1$.

Thus, for $x \in X$, $xS = xpS = 0$, $xT = xpT = xp = x$ and

$$xV^* T^* = xV^* pT^* = xV^* p = xV^* .$$

It implies that $xTV^* T^* = xV^*$ and $xSe = 0$ for all $x \in X$ and $e \in E$. We define $U \in E$ by

$$U := TV^* T^* + SVS^* + S(1 - VV^*)T^* .$$

Since $xS = 0$ we get

$$xU = xTV^* T = xV^* \quad \text{for all } x \in X .$$

It remains to prove that $U \in \mathcal{U}_0(E)$:

The operator $Z := [T, S] \in M_{1,2}(E) \subset M_2(E)$ satisfies $ZZ^* = 1$ and $Z^*Z = 1_2 := \mathrm{diag}(1, 1)$, i.e.,

$$\psi\colon a \in M_2(E) \mapsto ZaZ^* \in E$$

is a *-algebra isomorphism ψ from $M_2(E)$ onto E. Obviously, the above defined unitary $U \in \mathcal{U}(E)$ is the image $U = \psi(U(V^*))$ of the *Halmos unitary* $U(V^*) \in M_2(E)$ built from the contraction V^*, as defined in Remark 4.2.4. The Halmos unitaries are all in $\mathcal{U}_0(M_2(E))$. Hence, $U = \psi(U(V^*)) \in \mathcal{U}_0(E)$.

(i): Let $k_j\colon B_j \to J$ C^*-morphisms of C^*-algebras B_j, $j \in \{1, 2, 3, 4\}$. The property $\beta(J) \cap J = \{0\}$ shows that the linear maps $(a, b) \mapsto k_i(b) + \beta k_j(c)$ from $B_i \oplus B_j$ into $J + \beta J$ are C^*-morphisms.

If $B_j := B$ for $j \in \{1, 2, 3, 4\}$ then this implies that the linear maps $b \in B \mapsto k_j(b) + \beta k_{j+2}(b)$ $(j \in \{1, 2\})$ are C^*-morphism form B into $J + \beta J$. The equality $[k_1 + \beta k_3] = [k_2 + \beta k_4]$ in $[\mathrm{Hom}(B, J + \beta J)]$ implies $[k_1] = [k_2]$ and $[k_3] = [k_4]$, because there exists a unitary $u \in E$ that satisfies for $v := \beta(u)$ and all $b \in B$ that

$$J \ni (u^*k_1(b)u - k_2(b)) = -\beta(vk_3(b)v^* - k_4(b)) \in \beta J\,,$$

which implies that $u^*k_1(\cdot)u = k_2$ and $v^*k_3(\cdot)v = k_4$ by assumption $J \cap \beta J = \{0\}$ of Theorem 4.4.6.

In particular $k_j + \beta h_0$ for $j = 1, 2$ are C^*-morphisms from D into $J + \beta J$ if $B_1 := B_2 := D$ and $k_3 := h_0$, because $h_0(D) \subseteq J$.

If we use the Cuntz sum $\oplus_{s,t}$ with s, t in Theorem 4.4.6(i), then

$$u_1\big((e + \beta h_0(d)) \oplus_{s,t} f\big)u_1^* = e \oplus_{s,t} (f + \beta h_0(d)) \quad \text{for all } d \in D,\ e, f \in J\,, \tag{4.5}$$

where $u_1 \in \mathcal{U}(E)$ comes from assumption (vi) of Theorem 4.4.6. We use here that $u_1 \in \mathcal{U}(J' \cap E)$ by assumption 4.4.6(vi), that $\beta(s) = s$ and $\beta(t) = t$ are in $h_0(D)' \cap E$ by assumption (i) of Theorem 4.4.6, and that – therefore – assumption 4.4.6(vi) implies moreover

$$u_1 s\beta h_0(\cdot)s^*u_1^* = t\beta h_0(\cdot)t^*\,. \tag{4.6}$$

Equation (4.5) says that $(k_1(b) + \beta h_0(d)) \oplus_{s,t} k_2(c)$ is unitarily equivalent to $k_1(b) \oplus_{s,t} (\beta h_0(d) + k_2(c))$ by the unitary u_1 for all $b \in B_1$, $c \in B_2$ and $d \in D$.

If $B_1 = B_2 = D$ we get especially

$$[k_1 + \beta h_0] + [k_2] = [k_1] + [k_2 + \beta h_0]\,.$$

An other special case is $k_2 := 0$, $k_1 := k$ and $B_1 := B$ for σ-unital C^*-algebras B and C^*-morphisms $k\colon B \to J$. We get that the C^*-morphisms $(b, d) \mapsto (k(b) + \beta h_0(d)) \oplus_{s,t} 0$ and $(b, d) \mapsto k(b) \oplus_{s,t} \beta h_0(d)$ are unitary equivalent.

It implies $[k + \beta h_0] + [0] = [k] + [\beta h_0]$ for $k\colon D \to J$.

Let B any σ-unital C^*-algebra, $k\colon B \to J + \beta J$ a C^*-morphism and $T \in E$ an isometry. There exists a strictly positive contraction $b_0 \in B_+$ for B if B is σ-unital.

If we apply the above proven Part (ix) to the subset $X := \{k(b_0)\}$ of $J + \beta J$, then we see that there exists $u \in \mathcal{U}_0(E)$ with $k(b)T^* = k(b)u$ for all $b \in Bb_0$. We get

$k(b)T = k(b)u$ for all $b \in B = \overline{Bb_0}$. Thus $Tk(b^*a)T^* = u^*k(b^*a)u$ for all $a, b \in B$. It yields $Tk(\cdot)T^* = u^*k(\cdot)u$, because both sides are bounded linear maps and the linear span of $B^* \cdot B$ is dense in B (actually $B \cdot B = B$ by [**616**, prop. 1.4.5]).

If we take $T := s \in C$ with s from assumption (i) of Theorem 4.4.6, then we get $[k] + [0] = [k \oplus_{s,t} 0] = [Tk(\cdot)T^*]$ and $[sk(\cdot)s^*] = [k]$.

(ii): We get $[h_0] + [\beta h_0] = [h_0 + \beta h_0] + [0] = [h_0 + \beta h_0]$, if we let $k_1 := h_0$, $k_2 := 0$ and $k_3 := h_0$ in Part (i). By Theorem 4.4.6(i), $s, t \in h_0(D)' \cap E$ and $ss^* + tt^* = 1$. It implies that $[h_0] + [h_0] = [h_0]$. We obtain:

$$[h_0 + \beta h_0] + [h_0] = [h_0] + [\beta h_0] + [h_0] = [h_0] + [\beta h_0]\,.$$

(iii): Info (o) shows that $[H_0] = [h_0 + \beta h_0] + [H_0]$ as elements of $S(H_0\,;\,D, E)$.

(iv): $[H_0] + [h_0] = [H_0] + [h_0 + \beta h_0] + [h_0] = [H_0] + [h_0 + \beta h_0] = [H_0]$ in $S(H_0\,;\,D, E)$, by Parts (iii) and (ii).

$[H_0] + [\beta h_0] = [H_0] + [h_0] + [\beta h_0] = [H_0] + [h_0 + \beta h_0] = [H_0]$ by Parts (ii, iii).

(v): By Part (i), with $k_3 := h_0$ and $k_1 = 0$, we get $[\beta h_0] = [\beta h_0] + [0]$, and, with $k_3 := 0$ and $k_1 = h_0$, $[h_0] = [h_0] + [0]$, i.e., that each of βh_0 and h_0 dominate zero. Part (ii) implies that $h_0 + \beta h_0$ dominates zero. This and Part (iv) together imply that H_0 dominates zero, i.e., that $[H_0] = [H_0] + [0]$.

(vi): By Proposition 4.3.6(v), it suffices to show that there exists an isometry $R \in E$ with $p_0 R = 0$ and $R^* H_0(\cdot) R = 0$.

Part (v), – i.e., $[H_0] = [0] + [H_0]$ by Proposition 4.3.5(i) –, and assumptions (i,iv) of Theorem 4.4.6 imply the existence of a unitary $u \in E$ with

$$u^* H_0(\cdot) u \;=\; 0 \oplus_{s_0, t_0} H_0(\cdot) \;=\; t_0 H_0(\cdot) t_0^* = (1 - p_0) H_0(\cdot)\,.$$

Let $R := t_0 u s_0$. Then $R^*R = 1$, $p_0 R = 0$ and $t_0^* H_0(\cdot) R = H_0(\cdot) u s_0$, because s_0 and t_0 are isometries with $p_0 = s_0 s_0^*$, $s_0^* t_0 = 0$ and $t_0 \in C$ – by assumptions (iv) in Theorem 4.4.6. It follows for $a \in D$ that

$$R^* H_0(a) R = s_0^* u^* H_0(a) u s_0 = s_0^* t_0 H_0(a) t_0^* s_0 = 0\,.$$

(vii): If $[h] \in S(H_0\,;\,D, E)$ then there exists an isometry $T \in E$ with $h = T^* H_0(\cdot) T$ by definition of $S(H_0\,;\,D, E)$.

If $h(D) \subseteq J + \beta J$, then the bounded linear map $\lambda(d) := H_0(d)T$ $(d \in D)$ maps D into $J + \beta J$. The C^*-subalgebra $A = C^*(\lambda(D))$ of $J + \beta J$ generated by the image $\lambda(D)$ of the separable D by the linear contraction λ is separable. Let $f \in A_+$ a strictly positive contraction. By assumptions (iii) and (iv) of Theorem 4.4.6, there is a projection $p \in F \subseteq C := H_0(D)' \cap E$ such that $pf = f$ and $p \geq p_0$. In particular $T^* p H_0(d) T = T^* H_0(d) T = h(a)$ for $d \in D$. The above proven Part (ix) provides a unitary $u \in (F + 1) \cap \mathcal{U}_0(F + \mathbb{C} \cdot 1) \subseteq \mathcal{U}_0(C)$ with $upu^* = p_0$. It follows that $h = T_0^* p_0 H_0(\cdot) T_0$ for the isometry $T_0 := uT$. Let $k_1 := T_0^* s_0 h_0(\cdot) s_0^* T_0$ and $k_2 := \beta(T_0)^* s_0 h_0(\cdot) s_0^* \beta(T_0)$. Then $k_j(D) \subseteq J$ for $j = 1, 2$ and k_1, k_2 are

C^*-morphisms from D into J with $h = k_1 + \beta k_2$, because $p_0 H_0 = s_0(h_0 + \beta h_0)s_0^*$, $h_0(D) \subseteq J$, $\beta(s_0) = s_0$ and $J \cap \beta J = \{0\}$.

By Part (v), h_0 dominates zero, i.e., $[h_0] = [0] + [h_0]$ and there exists a unitary $v \in E$ such that such that $v^* h_0(\cdot) v = s_0 h_0(\cdot) s_0^*$. Then $T_1 := vT_0 = vuT$ and $T_2 := v\beta(T_0)$ are isometries in E such that $h = k_1 + \beta k_2$ for $k_j := T_j^* h_0(\cdot) T_j$ $(j = 1, 2)$. In particular, $[k_1], [k_2] \in S(h_0\,;\, D, E)$.

The property $J \cdot \beta(J) = J \cap \beta(J) = \{0\}$ of J in Theorem 4.4.6 implies that arbitrary maps $k_1, k_2 \colon B \to J$ of any C^*-algebra B must be automatically C^*-morphisms if $h := k_1 + \beta k_2$ is a C^*-morphism and that $k_1 + \beta k_2$ is the unique decomposition of h as sum $h = k_1 + \beta k_2$ by maps $k_1, k_2 \colon B \to J$.

Thus, $h = k_1 + \beta k_2$ with $[k_1], [k_2] \in S(h_0\,;\, D, E)$ is the unique decomposition of $h := T^* H_0(\cdot) T$ with $h(D) \subseteq J + \beta J$.

The C^*-morphism H_0 dominates zero by Part (v). Hence Proposition 4.3.6(ii) applies and gives that $[h] \in S(H_0\,;\, D, E)$ for $h := x^* H_0(\cdot) x$ if $x \in E$ is a contraction with $(1 - xx^*) H_0(D) x = \{0\}$.

It happens in particular for all projections $x := P \in C$.

If, in addition, $x^* H_0(D) x \subset J + \beta J$, then above arguments show that $h = k_1 + \beta k_2$ for unique $k_1, k_2 \colon D \to J$, that satisfy $[k_1], [k_2] \in S(h_0\,;\, D, E)$.

(viii): Let $k, \ell \colon B \to J + \beta J$ C^*-morphisms with $[k] = [\ell]$ for a σ-unital C^*-algebra B, i.e., suppose that there exists $V \in \mathcal{U}(E)$ with $V k(\cdot) V^* = \ell(\cdot)$.

If we apply the before proven Part (ix) to $X := \{k(b_0)\}$ then we get $u \in \mathcal{U}_0(E)$ with $k(b)V^* = k(b)u$ for all $b \in B$, as in the proof of Part (i). Thus $u^* k(\cdot) u = V k(\cdot) V^* = \ell(\cdot)$.

This shows that if B is σ-unital and $k_1, k_2 \colon B \to J$ satisfy $[k_1] = [k_2]$ then there exists a (norm-) continuous path $\xi \in [0,1] \mapsto U_\xi \in \mathcal{U}(E)$ with $U_0 = 1$ and $U_1^* k_1(\cdot) U_1 = k_2$.

Let $b_0 \in B$ a strictly positive contraction in B, and let A_0 denote the *separable* C^*-subalgebra of $J + \beta J$ generated by $\beta h_0(D)$ and by the elements $k_1(b_0) U_\xi \in J$ for $n \in \mathbb{N}$ and $\xi \in [0,1]$. Notice that $A_0 = (A_0 \cap J) + \beta h_0(D)$, because $J \cap \beta J = \{0\}$. Let a_0 a strictly positive contraction of $A_0 \cap J$ and d_0 a strictly positive contraction of D. It follows that the C^*-subalgebra A of $J + \beta J$ generated by $\beta h_0(D)$ and $k_1(b) U_\xi \in J$ for $b \in B$ and $\xi \in [0,1]$ is σ-unital with strictly positive contraction $a_0 + \beta h_0(d_0)$, because again $A = (A \cap J) + \beta h_0(D)$, $A_0 \subset A$, and each $k_1(b) U_\xi$ is contained in the closed left-ideal generated by $k_1(b_0) U_\xi$, i.e., $a_0 \in A \cap J \subseteq J \cdot a_0$.

If we let $h \colon A \to J + \beta J$ denote the identity map on the σ-unital C^*-algebra A, then Part (i) applies to A and h. The Part (i) shows that there exists a unitary $W \in \mathcal{U}_0(E)$ with $aW^* = as^*$ for all $a \in A$, where we consider the isometries $s, t \in E$ from assumption (i) of Theorem 4.4.6. It implies $Wa = sa$ and $WaW^* = sas^*$ for $a \in A$, because $A = A \cdot A$ as set.

Equation (4.5) yields

$$(u_1W)(e+\beta h_0(d))(u_1W)^* = ses^* + t\beta h_0(d)t^* \quad \text{for all } d\in D, e\in A\cap J\,. \quad (4.7)$$

In particular, $t\beta h_0(\cdot)t^*(u_1W) = u_1W\beta h_0(\cdot)$. Equation (4.7) holds more generally for all $d\in D$ and all $b\in J$ with the property that $WbW^* = sbs^*$.

We define a norm-continuous group-morphism $\lambda_W\colon \mathcal{U}(E)\to\mathcal{U}(E)$ by

$$\lambda_W(U) := W^*u_1^*(U\oplus_{s,t}1)u_1W \quad \text{for } U\in\mathcal{U}(E)\,.$$

Clearly $\lambda_W(U^*) = \lambda_W(U)^*$. Straight calculation shows that $\lambda_W(U)\cdot\beta h_0(d) = \beta h_0(d)$ for $d\in D$ and all $U\in\mathcal{U}(E)$. The property $u_1\in J'\cap E$ implies that $\lambda_W(U^*)a\lambda_W(U) = U^*aU$ if $a\in J$ and $U\in\mathcal{U}(E)$ satisfy that $WaW^* = sas^*$ and $WU^*aUW^* = sU^*aUs^*$.

By our above construction of $A = (A\cap J) + \beta h_0(D)$ we get a norm-continuous path $\xi\in[0,1]\mapsto V_\xi\in\mathcal{U}(E)$ with $V_0 = 1$, $V_\xi^*k_1(\cdot)V_\xi = U_\xi^*k_1(\cdot)U_\xi$ and

$$V_\xi\cdot\beta h_0(\cdot) = h_0(\cdot) = \beta h_0(\cdot)\cdot V_\xi$$

if we define V_ξ by

$$V_\xi := \lambda_W(U_\xi)\,.$$

In particular, $V_\xi\in\beta h_0(D)'\cap E$ for each $\xi\in[0,1]$, because $\beta h_0(d)V_\xi = \beta h_0(d)$ for all $d\in D$. Thus, $u := V_1\in\mathcal{U}_0(\beta h_0(D)'\cap E)$ satisfies $u^*k_1(b)u = k_2(b)$ for $b\in B$ and $u\beta h_0(d) = h_0(d) = \beta h_0(d)u$.

If $k\colon B\to J$ is a C^*-morphism, B is separable and $T\in E$ an isometry then there exists a unitary $v\in\mathcal{U}_0(E)$ with $v^*k(\cdot)v = Tk(\cdot)T^*$ by Part (i) (proven via Part (ix)).

If we apply above observations to $k_1 := k$ and $k_2 := Tk(\cdot)T^*$ with $k_2 = v^*k_1(\cdot)v$, then we obtain the existence of a unitary $u\in\mathcal{U}_0(\beta(h_0(D))'\cap E)$ that satisfies $\beta h_0(\cdot)u = \beta h_0$ and $u^*k(\cdot)u = Tk(\cdot)T^*$.

(x): Recall that $s_0^*H_0(\cdot)s_0 = h_0 + \beta h_0$. By Part (ii), $[h_0+\beta h_0] = [h_0] + [\beta h_0]$. Thus, there is a unitary $V\in\mathcal{U}(E)$ such that

$$V(h_0+\beta h_0)V^* = sh_0s^* + t\beta h_0t^*\,,$$

where the isometries s,t come from Theorem 4.4.6(i,vi). If we apply the assumption (i) of Theorem 4.4.6 to $k := h_0+\beta h_0$ and $T := V$, we get some $u\in\mathcal{U}_0(E)$ with

$$u^*s_0^*H_0(\cdot)s_0u = sh_0s^* + t\beta h_0t^*\,.$$

Thus, $s_2 := s_0us$ and $s_3 := s_0ut$ are isometries in E that satisfy $s_2s_2^*+s_3s_3^* = p_0$, $s_2^*H_0(\cdot)s_2 = h_0$ and $s_3^*H_0(\cdot)s_3 = \beta h_0$.

By Lemma 4.3.4(i), the equation $s_2^*H_0(\cdot)s_2 = h_0$ implies that $p_2 := s_2s_2^*\in C$ and $p_0 - p_2 = s_3s_3^*\in C$ because $p_0\in F\subseteq C$ by Theorem 4.4.6(iv,iii).

Since $p_0, p_2\in C$, we get $p_2H_0(a) = s_2h_0(a)s_2^*\in J$, and $(p_0-p_2)H_0(a) = s_3\beta h_0(a)s_3^*\in\beta J$ for $a\in D$.

To compare e.g. $s_2h_0s_2^*$ with $s_0h_0s_0^*$, we define linear maps $L_1, L_2 \colon D \to E$ by

$$L_1(a) := (p_2H_0(a)) - s_0h_0(a)s_0^* \quad \text{and} \quad L_2(a) := ((p_0-p_2)H_0(a)) - s_0\beta h_0(a)s_0^*\,.$$

Then $L_1 + L_2 = 0$, i.e., $L_1(a) = -L_2(a)$ for $a \in D$, $L_1(D) \subseteq J$ and $L_2(D) \subseteq \beta J$.

The orthogonality $J \cdot \beta J = J \cap \beta J = \{0\}$ yields $L_1(a) = 0$ and $L_2(a) = 0$ for $a \in D$. Thus, $p_2H_0(\cdot) = s_0h_0s_0^*$ and $(p_0 - p_2)H_0(\cdot) = s_0(\beta h_0)s_0^*$, i.e., $s_2h_0s_2^* = s_0h_0s_0^*$ and $s_3(\beta h_0)s_3^* = s_0(\beta h_0)s_0^*$.

We let $G_1 := h_0(D)' \cap E$ and $G_2 := \beta G_1$, then $s_0G_js_0^* \subseteq C$ for $j = 1, 2$, $s_2G_1s_2^* \subseteq C$ and $s_3G_2s_3^* \subseteq C$ as the following calculations show:

The elements $p_0 = s_0s_0^*$, $p_2 := s_2s_2^*$ and $p_0 - p_2 := s_3s_3^*$ are in C, i.e., commute with the elements of $H_0(D)$. The definitions of s_0, s_2 and s_3 give us that

$$s_0^*H_0s_0 = h_0 + \beta h_0\,, \quad s_2^*H_0s_2 = h_0 \quad \text{and} \quad s_3^*H_0s_3 = \beta h_0\,.$$

Thus,

$$H_0s_0 = s_0(h_0 + \beta h_0)\,, \quad H_0s_2 = s_2h_0\,, \quad \text{and} \quad H_0s_3 = s_3\beta h_0\,.$$

It implies also

$$(h_0 + \beta h_0)s_0^* = s_0^*H_0\,, \quad h_0s_2^* = s_2^*H_0\,, \quad \text{and} \quad \beta h_0s_3^* = s_3^*H_0\,.$$

Let $x \in G_1$, $d \in D$, then

$$H_0(d)s_2xs_2^* = s_2h_0(d)xs_2^* = s_2xh_0(d)s_2^* = s_2xs_2^*H_0(d)\,.$$

The verifications of $s_3G_2s_3^* \subseteq C$ and $s_0G_js_0^* \subseteq C$ $(j = 1, 2)$ are similar.

The isometries $s, t \in E$ commute element-wise with $h_0(D) \cup H_0(D)$ and are β-invariant by Theorem 4.4.6(i), and since $t_0 \in C$ by Theorem 4.4.6(iv), the partial isometries $s_2ss_2^*$, $s_2ts_2^*$, $s_3ss_3^*$, $s_3ts_3^*$, $s_0ss_0^*$, $s_0ts_0^*$, $t_0st_0^*$ and $t_0tt_0^*$. are all in C.

It shows that the projections $p_2 = s_2s_2^* \leq p_0$, $p_0 - p_2$ and p_0 are properly infinite in p_2Cp_2, $(p_0 - p_2)C(p_0 - p_2)$ and p_0Cp_0 and there (!) $[p_2] = 0$, $[p_0 - p_2] = 0$ and $[p_0] = 0$, i.e., this hereditary C^*-subalgebras of C contain copies of $\mathcal{O}_2$ unital.

Since $1 - p_2 \geq 1 - p_0 = t_0t_0^*$ and $p_2, t_0 \in C$ it follows that $1 - p_2$, $1 - p_0$ and $1 = 1_C$ are full and properly infinite projections in C with same class in $\mathrm{K}_0(C)$. Thus, by Lemma 4.2.6(ii), there exists an isometry $t_2 \in C$ with $t_2t_2^* = 1 - p_2$.

There exist $u_2, v_2 \in \mathcal{U}(C)$ such that

$$u_2^*p_2u_2 = p_2 + t_2p_2t_2^* \qquad \text{and} \qquad v_2^*p_2v_2 = p_2 \oplus_{s,t} p_2\,.$$

This happens because p_2 is properly infinite with $[p_2] = 0$ in $\mathrm{K}_0(p_2Cp_2)$, because the projections $p_2 + t_2p_2t_2^*$ and $p_2 \oplus_{s,t} p_2$ are in the ideal of C generated by p_2, and the complementary projections $1 - p_2$, $1 - (p_2 + t_2p_2t_2^*)$ and $1 - (p_2 \oplus_{s,t} p_2)$ are respectively the ranges of the isometries t_2, t_2^2 and $t_2 \oplus t_2$.

The Murray–von-Neumann equivalences

$$q_0 := p_0 + t_0p_0t_0^* \sim p_0 \sim p_0 \oplus_{s,t} p_0 =: r_0$$

and

$$q_2 := p_2 + t_2 p_2 t_2^* \sim p_2 \sim p_2 \oplus_{s,t} p_2 =: r_2$$

can be given in C explicitly by the partial isometries $z_0 := s_0 s s_0^* + s_0 t s_0^* t_0^*$, and $z_2 := s_2 s s_2^* + s_2 t s_2^* t_2^*$, respectively by $y_0 := (s_0 \oplus_{s,t} s_0) s_0^*$ and $y_2 := (s_2 \oplus_{s,t} s_2) s_2^*$. Thus, below listed unitary elements $u_0, u_2, v_0, v_2 \in \mathcal{U}(C)$ satisfy $u_0 q_0 = p_0 u_0$, $u_2 q_2 = p_2 u_2$, $v_0 p_0 = r_0 v_0$ and $v_2 p_2 = r_2 v_2$.

$$u_0 := s_0 s s_0^* + s_0 t s_0^* t_0^* + t_0 (t_0^*)^2 \,, \tag{4.8}$$

$$u_2 := s_2 s s_2^* + s_2 t s_2^* t_2^* + t_2 (t_2^*)^2 \,, \tag{4.9}$$

$$v_0 := s s_0 s^* s_0^* + t s_0 t^* s_0^* + s t_0 s^* t_0^* + t t_0 t^* t_0^* \,, \tag{4.10}$$

$$v_2 := s s_2 s^* s_2^* + t s_2 t^* s_2^* + s t_2 s^* t_2^* + t t_2 t^* t_2^* \,. \tag{4.11}$$

The MvN-equivalences can be seen also from

$$\begin{aligned} p_0 &= (1 \oplus_{s,t} 1) \oplus_{s_0,t_0} 0 \,, \\ p_0 + t_0 p_0 t_0^* &= 1 \oplus_{s_0,t_0} (1 \oplus_{s_0,t_0} 0) \\ p_0 \oplus_{s,t} p_0 &= (1 \oplus_{s_0,t_0} 0) \oplus_{s,t} (1 \oplus_{s_0,t_0} 0) \,, \end{aligned}$$

because the below given Lemma 4.4.8 recognizes that u_0, u_2 v_0 and v_2 conjugate the used iterations of Cuntz addition.

The elements $S := s_0^* s_2$ and $T := s_0^* s_3$ are isometries in E with $S^* T = 0$, because s_2 and s_3 are isometries with $s_2 s_2^* + s_3 s_3^* = p_0 = s_0 s_0^*$.

If B is σ-unital and $h\colon B \to J$ is a C^*-morphism then there exists a unitary $U \in \mathcal{U}_0(\beta h_0(D)' \cap E)$ with $U^* k(\cdot) U = S k(\cdot) S^*$ and $\beta h_0(d) U = h_0(d)$ for $d \in D$ by Part (viii). Take $u_h := U$.

(xi): By assumption (v) of Theorem 4.4.6, there exists a unitary $u \in 1 + F \subseteq C$ such that $u^* p_0 u = p$. Let $q := u^* p_2 u$ and $r := u^* (p_0 - p_2) u$ with $p_0 \geq p_2 \in C$ the projection from Part (x).

Since $F \subseteq C$ and $p_0, p_2 \in C$, also $q, r \in C$ and $q + r = p$.

The projections satisfy $q \in \mathcal{N}(H_0(D), J)$ and $r \in \mathcal{N}(H_0(D), \beta J)$, because $u \in C$ and $p_2 H_0(\cdot) = s_0 h_0 s_0^* \in J$ and $(p_0 - p_2) H_0(\cdot) = \beta(s_0 h_0 s_0^*) \in J$.

More generally, suppose that are given a non-zero projection $p \in F$ and projections $p, r \in C$ with $p = q + r$ with $q H_0(D) \subseteq J$ and $r H_0(D) \subseteq \beta J$.

By assumption 4.4.6(v), there exists $u \in \mathcal{U}(1 + F) \subseteq C$ with $u^* p_0 u = p$. Let $p_3 := u q u^* \in C$. Then $p_3 H_0(a) = u(q H_0(a)) u^* \in J$ and $(p_0 - p_3) H_0(a) \in \beta J$ for $a \in D$.

Thus, $[p_3 H_0(\cdot)] = [q H_0(\cdot)]$ and $[(p_0 - p_3) H_0(\cdot)] = [r H_0(\cdot)]$.

The same calculation as in proof of Part (x) with p_2 replaced by p_3 shows that $p_3 H_0(\cdot) = s_0 h_0 s_0^*$ and $(p_0 - p_3) H_0(\cdot) = s_0 \beta h_0 s_0$. Thus $[q H_0(\cdot)] = [h_0] + [0] = [h_0]$ and $[r H_0(\cdot)] = [\beta h_0] + [0] = [\beta h_0]$ by Part (i).

(xii): Let $p \in F$ a projection with $p \geq p_0$ and $p \neq p_0$, where $p_0 = s_0 s_0^*$ for the isometries s_0, t_0 in assumption (iv) of Theorem 4.4.6 with $p_0 \in F$, $t_0 \in C$ and $t_0 t_0^* = 1 - p_0$.

If we let $B := D$, $k := h_0 + \beta h_0$ and $T := s_0$ in Part (i), we get a unitary $W \in \mathcal{U}_0(E)$ with

$$W^*(h_0 + \beta h_0)W = s_0(h_0 + \beta h_0)s_0^* = p_0 H_0(\cdot)\,.$$

The elements t_0, p_0 and $p - p_0$ are in C. Thus, the proof of Part (xii) reduces to to the construction of $V \in \mathcal{U}(C)$ that satisfies

$$p_0 V = p_0 = V p_0 \quad \text{and} \quad V^*(p - p_0)V = t_0 p_0 t_0^* \tag{4.12}$$

Since p_0, $p - p_0$ and p are non-zero commuting projections in F, we find by Part (ix) unitaries

$$V_1, V_2 \in \mathcal{U}_0(F + \mathbb{C} \cdot 1) \subseteq \mathcal{U}_0(C)$$

with $V_1^* p_0 V_1 = p - p_0$ and $V_2^* p_0 V_2 = p$, and define $V \in E$ by

$$V := p_0 + V_1^* p_0 t_0^* + V_2^*(1 - p_0)t_0^*\,.$$

Straight calculation shows that V is unitary and fulfills Equations (4.12). The unitary V is in C because p_0, t_0, V_1 and V_2 are in C. □

Proof of Theorem 4.4.6 (Part 1: φ is surjective).
The C^*-morphism H_0 dominates h_0 by the equation $[h_0] + [H_0] = [H_0]$ in Lemma 4.4.7(iv). Thus

$$S(h_0\,;\, D, E) \subseteq S(H_0\,;\, D, E)\,,$$

and $[k] + [h_0] = [h] + [h_0]$ implies $[k] + [H_0] = [h] + [H_0]$. Since $[h_0] = [h_0] + [h_0]$ and $[H_0] = [H_0] + [H_0]$, the mapping

$$\varphi \colon [k] + [h_0] \mapsto [k] + [H_0]$$

is well-defined and additive, i.e., is a group homomorphism from $G(h_0\,;\, D, E) = S(h_0\,;\, D, E) + [h_0]$ into $G(H_0\,;\, D, E) = S(H_0\,;\, D, E) + [H_0]$. It is useful to consider $G(h_0\,;\, D, E)$ and $G(H_0\,;\, D, E)$ as subgroups of the big commutative semigroup $[\mathrm{Hom}(D, E)]$ of all unitary equivalence classes of C^*-morphisms from D into E with Cuntz addition, as introduced below Definition 4.3.1. This kind of subgroups of $[\mathrm{Hom}(D, E)]$ have natural morphism that are considered in parts (iii) and (iv) of the Lemma 4.2.3 in more generality on semi-groups.

We show that the group homomorphism φ is *surjective*:
Let $[g] \in S(H_0\,;\, D, E)$. By assumption (ii) of Theorem 4.4.6, there exists a unitary $u \in E$ with

$$T(a) := u^*(g(a) \oplus_{s_0, t_0} H_0(a))u - H_0(a) \in J \qquad \text{for all } \; a \in D\,.$$

We use here the isometries s_0, t_0 from assumption (iv) of Theorem 4.4.6 to realize the Cuntz sum $\oplus := \oplus_{s_0,t_0}$, simply to make calculations more transparent. Compare Proposition 4.3.2(ii) for the change of u if one takes another realization of $\oplus$ by other copies of $\mathcal{O}_2$ in E.

The image $T(D)$ of the linear map T generates a separable C^*-subalgebra $B \subseteq J$, because D is separable. Let $f \in J$ be a strictly positive element of B.

By assumption 4.4.6(iii), there exists a non-zero projection $p \in F \subseteq C$ with $pf = fp = f$. It follows that $(1-p)c = c(1-p) = 0$ for every $c \in B$, and that p commutes element-wise with $H_0(D)$. In particular, $(1-p)T(\cdot) = 0 = T(\cdot)(1-p)$, i.e., $pT(a) = T(a) = T(a)p$ for all $a \in D$.

Since $F \cdot H_0(D) \subseteq J + \beta J$ and $F \subseteq C$ by assumption (iii) of Theorem 4.4.6, we get for $a \in D$ that

$$pu^*(g(a) \oplus_{s_0,t_0} H_0(a))u = pT(a) + pH_0(a) \in J + \beta J\,,$$

$$pu^*(g(a) \oplus_{s_0,t_0} H_0(a))u = u^*(g(a) \oplus_{s_0,t_0} H_0(a))up$$

and

$$(1-p)u^*(g \oplus_{s_0,t_0} H_0)u = (1-p)H_0\,.$$

Let s_0, t_0 the isometries from Theorem 4.4.6(iv) with $t_0 \in C := H_0(D)' \cap E$ and $s_0 s_0^* = p_0 = 1 - t_0 t_0^*$ with $p_0 \in F \subseteq C$. By assumption (v) of Theorem 4.4.6, there is a unitary $v \in 1 + F \subseteq C$ with $v^* p v = p_0$.

We get $pv = vp_0$ and that $W := uvs_0$ is an isometry in E such that the projection $WW^* = uvp_0v^*u^* = upu^*$ commutes element-wise with $(g \oplus_{s_0,t_0} H_0)(D)$.

It implies that $p_0 = s_0 s_0^*$ commutes element-wise with the image of $(uv)^*\,(g \oplus_{s_0,t_0} H_0)\,uv$.

We define a C^*-morphism $h \colon D \to J + \beta J$ by

$$h := W^*(g \oplus H_0)W = s_0^*(uv)^*\,(g \oplus_{s_0,t_0} H_0)\,uvs_0\,.$$

The commutation properties of $p_0 = s_0 s_0^*$ implies that

$$s_0 h(\cdot) s_0^* = p_0(uv)^*\,(g \oplus_{s_0,t_0} H_0)\,uv = v^*(pV(\cdot) + pH(\cdot))v^*\,.$$

The equations

$$(1-p_0)(uv)^*\,(g \oplus_{s_0,t_0} H_0)\,uv = v^*(1-p)(T(\cdot) + H_0(\cdot))v = (1-p_0)H_0(\cdot) = t_0 H_0(\cdot) t_0^*$$

and

$$s_0 h(\cdot) s_0^* = p_0(uv)^*\,(g \oplus_{s_0,t_0} H_0)\,uv\,,$$

together lead to

$$v(h \oplus_{s_0,t_0} H_0)v^* = u^*(g \oplus_{s_0,t_0} H_0)u\,.$$

If we use that $s_0 s_0^* = p_0 \in F \subseteq C$, $t_0 \in C$ and $s_0 s_0^* + t_0 t_0^* = 1$ by assumptions (iii) and (iv) of Theorem 4.4.6, we get

$$t_0 H_0(\cdot) t_0^* = (1-p_0)H_0(\cdot) == (1-p_0)(uv)^*(g \oplus H_0)uv$$

and

$$h \oplus_{s_0,t_0} H_0 = s_0 h(\cdot) s_0^* + (1-p_0) H_0(\cdot) = (uv)^* (g \oplus_{s_0,t_0} H_0) uv \,.$$

Thus,

$$[h] + [H_0] = [g] + [H_0] \in S(H_0\,;\, D, E)\,.$$

It says that H_0 dominates $h \oplus_{s_0,t_0} H_0$ by Definition 4.4.1. (Compare also Definition 4.3.3, Lemma 4.3.4(iv) and Proposition 4.3.6.)

The equation $h = s_0^*(h \oplus_{s_0,t_0} H_0)s_0$ shows that H_0 dominates also h, i.e., $[h] \in S(H_0\,;\, D, E)$.

Since $v \in F + 1 \subseteq C$ is unitary, we get that $v^* H_0(\cdot) v = H_0$, and, by definition of T and v, that $p_0 v^* T(a) v = v^* T(a) v \in J$ for $a \in D$. It implies

$$s_0 h(a) s_0^* - p_0 H_0(a) = p_0\big((vu^*(g(a) \oplus_{s_1,t_1} H_0(a))uv) - H_0(a)\big) = p_0 v^* T(a) v\,.$$

By assumption 4.4.6(iv), $s_0^* H_0(a) s_0 = h_0(a) + \beta h_0(a)$ and $s_0^* s_0 = 1$. Thus,

$$h(a) - h_0(a) - \beta(h_0(a)) = s_0^* v^* T(a) v s_0 \in J \qquad \text{for } a \in D\,.$$

Since $h_0(D) \subseteq J$ it follows that $h(D) \subseteq J + \beta(J)$ and $h = k + \beta h_0$ for a unique C^*-morphism $k\colon D \to J$, because $h_0(D) \subseteq J$ and $J \cap \beta(J) = \{0\}$.

Now $[h] = [k + \beta h_0] \in S(H_0\,;\, D, E)$ and $h(D) \subseteq J + \beta J$ implies that the homomorphism h_0 dominates k by Lemma 4.4.7(vii), i.e., $[k] \in S(h_0\,;\, D, E)$.

By Lemma 4.4.7(iii,i,iv),

$$[k] + [H_0] = [k] + [h_0 + \beta h_0] + [H_0] = [h] + [h_0] + [H_0] = [h] + [H_0]\,.$$

It follows $[k] + [H_0] = [h] + [H_0] = [g] + [H_0]$. Thus, the group morphism

$$\varphi\colon [k] + [h_0] \in G(h_0\,;\, D, E) \mapsto [k] + [H_0] \in G(H_0\,;\, D, E)$$

is *surjective*. □

We start here the collection of observations that will be used in the proof of the necessity and sufficiency of the Condition (DC) for the *injectivity* of the natural epimorphism from $G(h_0\,;\, D, E)$ onto $G(H_0\,;\, D, E)$. It is essentially a detailed study of its possibly existing kernel.

LEMMA 4.4.8. *Let* (s,t) *and* (s_0, t_0) *the isometries from assumptions* (i) *respectively* (iv) *of Theorem* 4.4.6 *and* (s_2, t_2) *the isometries in Lemma* 4.4.7(x)*.*

The elements u_0*,* u_2*,* v_0 *and* v_2 *– as defined by equations* (4.8)*,* (4.9)*,* (4.10) *and* (4.11) *in the proof of Lemma* 4.4.7(x) *– are in* $\mathcal{U}(C)$ *and have the properties that, for* $a, b, c, d \in E$ *and* $k \in \{0, 1\}$*,*

$$u_k^*\big((a \oplus_{s,t} b) \oplus_{s_k,t_k} c\big)u_k = a \oplus_{s_k,t_k} (b \oplus_{s_k,t_k} c)\,,$$

and

$$v_k^*\big((a \oplus_{s_k,t_k} c) \oplus_{s,t} (b \oplus_{s_k,t_k} d)\big)v_k = (a \oplus_{s,t} b) \oplus_{s_k,t_k} (c \oplus_{s,t} d)\,.$$

In particular, for all C^**-morphisms* $k, \ell\colon D \to J$ *and* $h := k + \beta\ell$*,*

$$u_0^*\big((h \oplus_{s,t} (h_0 + \beta h_0)) \oplus_{s_0,t_0} H_0\big)u_0 = h \oplus_{s_0,t_0} H_0\,,$$

$$u_2^*\big((k \oplus_{s,t} h_0) \oplus_{s_2,t_2} H_0\big)u_2 = k \oplus_{s_2,t_2} H_0\,,$$

and

$$v_0^*\big(((k+\beta h_0) \oplus_{s_0,t_0} H_0) \oplus_{s,t} ((\ell+\beta h_0) \oplus_{s_0,t_0} H_0)\big)v_0 = ((k \oplus_{s,t} \ell)+\beta h_0) \oplus_{s_0,t_0} H_0\,.$$

Proof. The elements u_0, u_2, v_0 and v_1 of E are in C because $s,t \in C$ by assumption (i) of Theorem 4.4.6, t_0, t_2, $s_0 s s_0^*$, $s_0 t s_0^*$, $s_2 s s_2^*$ and $s_2 t s_2^*$ are in C by assumption (iv) of Theorem 4.4.6 and Lemma 4.4.7(x).

Straight calculation shows that u_k and v_k are unitary for $k \in \{0,2\}$ and have the quoted transformation properties.

Use $(h_0+\beta h_0) \oplus_{s_0,t_0} H_0 = H_0$ and $h_0 \oplus_{s_2,t_2} H_0 = H_0$ in the last equations. □

Lemma 4.4.9. *Let $A := H_0(D)$, $U \in \mathcal{U}\big(\mathcal{N}(A, J+\beta J)+\mathbb{C}\cdot 1\big)$ and $q^*q = q \in F$. There exists a projection $p \in F$ with $p \geq q$, $p \neq q$ and*

$$U^*(H_0(\cdot)p)U = U^*H_0(\cdot)Up\,, \tag{4.13}$$

$$U^*(H_0(\cdot)(1-p))U = H_0(\cdot)(1-p)\,. \tag{4.14}$$

More generally we find for each separable subset $X \subseteq \mathcal{N}(A, J+\beta J)$ and each projection $q \in F$ a projection $p \in F$ with $p \geq q$ and $p \neq q$ and $H_0(\cdot)x = H_0(\cdot)pxp$ for all $x \in X$.

Proof. Multiplying U by suitable $\xi \in \mathbb{C}$ we may suppose that $U = 1+y$ with $y \in \mathcal{N}(A, J+\beta J))$.

More generally, let $\mathcal{Y}$ a separable C^*-subalgebra of $\mathcal{N}(A, J+\beta J))$. Then the separable subset $X := (A\cdot\mathcal{Y}) \cup (\mathcal{Y}\cdot A)$ of $J+\beta J$, generates a separable C^*-subalgebra B of $J+\beta J$.

Let $f \in B_+ \in \beta(J)+J$ a strictly positive contraction for B. By assumption (iii,c) of Theorem 4.4.6 there exists a projection $p \in F$ with $f = pfp$, $p \geq q$ and $p \neq q$. Thus $pb = b = bp$ for all $b \in B$. In particular, $(1-p)B = \{0\} = B(1-p)$.

Since $A = H_0(D)$ and $p \in F \subseteq C$, it follows all $y \in \mathcal{Y}$ that $H_0(\cdot)py = H_0(\cdot)y = H_0(\cdot)yp$, $pyH_0(\cdot) = yH_0(\cdot) = ypH_0(\cdot)$ and $(1-p)H_0(\cdot)y = 0 = H_0(\cdot)y(1-p)$. $H_0(\cdot)y = H_0(\cdot)pyp$

If we let $U := 1+y$ then we get $H_0(\cdot)pU = H_0(\cdot)Up$ and

$$H_0(\cdot)(1-p)U = (1-p)H_0(\cdot)U = (1-p)H_0(\cdot)\,.$$

In particular, $U^*pH_0(\cdot)U = U^*H_0(\cdot)Up$.

Notice that $(1-p)^2 = 1-p \in C$. It implies for all $c,b \in D$ that

$$U^*H_0(c^*b)(1-p)U = ((1-p)H_0(c)U)^*(1-p)H_0(b)U = H_0(c^*b)(1-p)\,.$$

□

Lemma 4.4.10. *Let $A := H_0(D)$. The maps*

$$\lambda_0\colon \mathcal{U}(\beta h_0(D)' \cap E) \ni u \mapsto s_0 u s_0^* + (1-p_0) \in \mathcal{U}(E)$$

and

$$\lambda_2 \colon \mathcal{U}(E) \ni u \mapsto \; s_2 u s_2^* + (1-p_2) \in \mathcal{U}(E)$$

are norm-continuous group morphisms into $\mathcal{U}(\mathrm{Der}(A,J)) \cap (p_0 E p_0 + (1-p_0))$.

If moreover $\beta h_0(\cdot) u = \beta h_0$, *then* $1 - \lambda_0(u) \in \mathcal{N}(A,J) \cap p_0 E p_0$.

For each $u \in \mathcal{U}(E)$, $1 - \lambda_2(u) \in p_2 \mathcal{N}(A,J) p_2 = p_2 E p_2 \subseteq \mathcal{N}(A,J)$.

For every σ*-unital hereditary* C^**-subalgebra* B *of* J *there exists a unitary* $w_B \in \mathcal{U}_0(\beta h_0(D)' \cap E)$ *that satisfies* $\beta h_0(\cdot) w_B = \beta h_0$ *and*

$$b w_B = b s_2^* s_0 \quad \text{for all } b \in B .$$

In particular, for each C^**-morphism* $k \colon D \to J$ *with* $k(D) \subseteq B$ *and the unitary* $W := w_B \oplus_{s_0,t_0} 1 \in \mathcal{U}_0(\mathrm{Der}(A,J))$ *holds* $(1-W) \in \mathcal{N}(A,J) \cap p_0 E p_0$ *and*

$$\big((k + \beta h_0) \oplus_{s_0,t_0} H_0\big) W = W \big(k \oplus_{s_2,t_2} H_0\big) .$$

Proof. Recall that $s_0(\beta h_0)s_0^* = (p_0 - p_2)H_0 = s_3(\beta h_0)s_3^*$ and $(1-p_2)H_0 = t_2 H_0 t_2^*$ by Lemma 4.4.7(x). By assumption (iv) of Theorem 4.4.6, $t_0 \in C$ and $t_0 t_0^* = 1 - p_0$. We obtain

$$s_0(\beta h_0)s_0^* + t_0 H_0 t_0^* = t_2 H_0 t_2^* = (1-p_2)H_0 .$$

It follows that

$$\lambda_0(u) := s_0 u s_0^* + (1-p_0) \in p_0 E p_0 + (1-p_0)$$

is a unitary in E.

The $\lambda_0(u)$ commute elementwise with $s_0 \beta h_0(D) s_0^* \cup (1-p_0)H_0(D)$ if $u \in \mathcal{U}(\beta h_0(D)' \cap E)$.

In particular, $\lambda_0(u)$ commutes with the elements of $(1-p_2)H_0(D)$ if $u \in \mathcal{U}(\beta h_0(D)' \cap E)$. It follows that $\lambda_0(u) - 1 \in \mathrm{Der}(A,J) \cap p_0 E p_0$

If u satisfies moreover that $\beta h_0(\cdot) \cdot u = \beta h_0$ then $(1-\lambda_0(u))H_0(\cdot)(1-p_2) = 0$ and $(1-\lambda_0(u)^*)H_0(\cdot)(1-p_2) = 0$. It implies

$$1 - \lambda_0(u) \in \mathcal{N}(A,J) ,$$

because $H_0(D)p_2 = s_2 h_0(D) s_2^* \subseteq p_2 J p_2$.

The element $1 - \lambda_2(u)$ is in $p_2 \mathcal{N}(A,J) p_2$ for *every* $u \in \mathcal{U}(E)$ because $p_2 = s_2 s_2^* \in \mathcal{N}(A,J)$ implies $s_2 E s_2^* = p_2 \mathcal{N}(A,J) p_2$.

If only $u \in \mathcal{U}(\beta h_0(D)' \cap E)$ we see at least that the unitaries $1 - \lambda_0(u)$ and $1 - \lambda_2(u)$ are in $\mathrm{Der}(A,J) \cap p_0 E p_0$, because they commute with the elements in $(1-p_2)H_0(D)$ and $p_2 H_0 = s_2 h_0 s_2^*$ takes values in J.

The map λ_0 satisfies $\lambda_0(1) = 1$ and is a norm-continuous group homomorphism from $\mathcal{U}(\beta h_0(D)' \cap E)$ into the intersection of $\mathcal{U}(\mathrm{Der}(A,J))$ with $p_0 E p_0 + (1-p_0)$. In particular, λ_0 maps $\mathcal{U}_0(\beta h_0(D)' \cap E)$ into the intersection of $\mathcal{U}_0(\mathrm{Der}(A,J))$ and $p_0 \mathcal{U}_0(E) p_0 + (1-p_0)$.

Since $p_2 H_0 = s_2 h_0 s_2^*$ has image in J we get that $p_2 E p_2 = s_2 E s_2^* \subset \mathcal{N}(A,J) \subseteq \mathrm{Der}(A,J)$, and that λ_2 maps $\mathcal{U}(E)$ into the unitaries of $p_2 E p_2 + (1-p_2)$. Thus, $\lambda_2(\mathcal{U}_0(E))$ is contained in $\mathcal{U}_0(\mathcal{N}(A,J) + \mathbb{C}\cdot 1) \subseteq \mathcal{U}_0(\mathrm{Der}(A,J))$.

Notice that $p_2 E p_2 + (p_0 - p_2) \subset p_0 E p_0$.

Let B a σ-unital hereditary C^*-subalgebra of J, and $h\colon B \hookrightarrow J$ the inclusion map $h(b) = b$.

By Lemma 4.4.7(x), there exists a unitary $u_h \in \mathcal{U}_0(\beta h_0(D)' \cap E)$ with $u_h \beta h_0(\cdot) = \beta h_0 = \beta h_0(\cdot) u_h$ and $b u_h = h(b) u_h = h(b) s_2^* s_0 = b s_2^* s_0$ for $b \in B$. Thus $u_h^* b u_h = s_0^* s_2 b s_2^* s_0$ for $b \in B$, and we get that $w_B := u_h$ has the claimed additional properties, i.e., $b w_B = b s_2^* s_0$ for $b \in B$, $w_B \in \mathcal{U}_0(\beta h_0(D)' \cap E)$ and $\beta h_0(\cdot) w_B = \beta h_0$. Then $W := \lambda_0(w_B) \in \mathcal{U}_0(\mathrm{Der}(A,J))$, $(1-W) \in \mathcal{N}(A,J) \cap p_0 E p_0$ and $(k \oplus_{s_2,t_2} H_0) W = W (k \oplus_{s_0,t_0} H_0)$ for each $k\colon D \to J$ with $k(D) \subseteq B$:

By definition of w_B, we have $b w_B = b s_2^* s_0$ for $b \in B$ and $w_B \in \mathcal{U}_0(\beta h_0(D)' \cap E)$ and $\beta h_0(\cdot) w_B = \beta h_0$.

Let $W := \lambda_0(w_B) = w_B \oplus_{s_0,t_0} 1$. Then $W \in \mathcal{U}_0(\mathrm{Der}(A,J))$, $(1-W) \in \mathcal{N}(A,J) \cap p_0 E p_0$ and

$$s_0^*(b \oplus_{s_0,t_0} 0) W = b s_0^* s_0 w_B s_0^* = b w_B s_0^* = b s_2^* s_0 s_0^* = b s_2^*$$

for $b \in B$, because $s_0 s_0^* = p_0$ and $s_2 s_2^* \leq p_0$ by Lemma 4.4.7(x).

We combine this with

$$p_0 \cdot (b_j \oplus_{s_0,t_0} 0) = b_j \oplus_{s_0,t_0} 0\,,$$

for $j \in \{1,2\}$, and obtain for $b := b_2^* b_1$ that

$$W^*(b \oplus_{s_0,t_0} 0) W = b \oplus_{s_2,t_2} 0\,.$$

Since $\lambda_0(w_B)(D)$ commutes element-wise with elements in the image of the map $s_0 \beta h_0 s_0^* + t_0 H_0 t_0^* = t_2 H_0 t_2^*$, we get for C^*-morphisms $k\colon D \to E$ with the property $k(D) \subseteq B \subseteq J$ that $W(k \oplus_{s_2,t_2} H_0) = \big((k + \beta h_0) \oplus_{s_0,t_0} H_0\big) W$. □

LEMMA 4.4.11. *Let $A := H_0(D)$ and $u \in \mathcal{U}(\mathrm{Der}(A, J + \beta J))$.*

There exist $v \in \mathcal{U}_0(F + \mathbb{C}\cdot 1) \subseteq \mathcal{U}_0(C)$ and C^*-morphisms $k_1, k_2\colon D \to J$ with $(1-v) \in F \subset C \cap \mathcal{N}(A, J+\beta J)$, $[k_1], [k_2] \in S(h_0\,;\, D, J)$ and

$$(k_1 + \beta k_2) \oplus_{s_0,t_0} H_0 = v u^* H_0(\cdot) u v^*\,.$$

If moreover $u \in \mathcal{U}(\mathrm{Der}(A,J))$, then necessarily $k_2 = h_0$, and there exists $W \in \mathcal{U}_0(\mathrm{Der}(A,J))$ such that $(1-W) \in \mathcal{N}(A,J) \cap p_0 E p_0$ and

$$k_1 \oplus_{s_2,t_2} H_0 = W^*\big((k_1 + \beta h_0) \oplus_{s_0,t_0} H_0\big) W = W^* v u^* H_0(\cdot) u v^* W\,.$$

PROOF. Let $u \in \mathcal{U}(\mathrm{Der}(A, J + \beta J))$. The image of the corresponding H_0-derivation

$$\delta_u \colon d \in D \mapsto u H_0(d) - H_0(d) u$$

is contained in a separable C^*-subalgebra $B \subset J + \beta J$. Let $f \in B$ a strictly positive contraction in B.

By assumptions (iii) of Theorem 4.4.6, there exists a projection $p \in F \subset C$ with $p \geq p_0$, $pf = f$ and $p \neq p_0$. It follows that $pb = b = bp$ for all $b \in B$.

In particular, $u^*\delta_u(d) = u^*\delta_u(d)p$ for $d \in D$. It implies for $d \in D$ that

$$u^*H_0(d)up = H_0(d)p - u^*(uH_0(d) - H_0(d)u) \in J + \beta J$$

because $u \in \mathrm{Der}(A, J + \beta J)$, $F \cdot H_0(D) \subset J + \beta J$ and $F \subseteq C$ by assumptions (iii) of Theorem 4.4.6.

Moreover, $(1-p)\delta_u(d) = 0$ and $\delta_u(d)(1-p) = 0$ imply $(1-p)uH_0(d) = (1-p)H_0(d)u$, and $uH_0(d)(1-p) = H_0(d)u(1-p)$.

Thus, $H_0(d)(1-p) = u^*H_0(d)u(1-p)$ and $u^*H_0(d)up \in J + \beta J$ for all $d \in D$. It follows that $1-p$ and p commute with the elements of $u^*H_0(D)u$ and that

$$k\colon D \ni d \mapsto u^*H_0(d)up$$

is a C^*-morphism from D into $J + \beta J$.

Part (ix) of Lemma 4.4.7 provides a unitary $v \in (1 + F) \cap \mathcal{U}_0(F + \mathbb{C} \cdot 1)$ with $vpv^* = p_0$.

Since $F \subset C$ by assumption (iii) of Theorem 4.4.6, we get that

$$t_0H_0(d)t_0^* = H_0(d)(1-p_0) = (uv^*)^*H_0(d)uv^*(1-p_0)\,.$$

In particular, $1-p_0$ and p_0 commute element-wise with $(uv^*)^*H_0(D)uv^*$. Recall that $pv^* = v^*p_0$. We use that $p_0 = s_0s_0^*$ by assumption (iv) of Theorem 4.4.6 and define a C^*-morphism $h\colon D \to E$ by

$$h(d) := s_0^*(uv^*)^*H_0(d)uv^*s_0 = (v^*s_0)^*k(d)(v^*s_0)\,.$$

Then $h(D) \subseteq J + \beta J$ and

$$h \oplus_{s_0,t_0} H_0 = (uv^*)^*H_0(\cdot)uv^*\,.$$

Hence, $h = T^*H_0(\cdot)T$ for the isometry $T := uv^*s_0$ and $[h] \in S(H_0\,; D, E)$.

Moreover, $h(D) \subseteq J + \beta J$ because $k(D) \subseteq J + \beta J$. Thus Lemma 4.4.7(vii) applies to h and shows that there are unique C^*-morphisms $k_1, k_2\colon D \to J$ with $[k_1], [k_2] \in S(h_0\,; D, E)$ and $h = k_1 + \beta k_2$.

Finally, we obtain that

$$(k_1 + \beta k_2) \oplus_{s_0,t_0} H_0 = v(u^*H_0(\cdot)u)v^*\,.$$

Suppose now that $u \in \mathcal{U}(\mathrm{Der}(A, J))$. Then, $uv^* \in \mathcal{U}(\mathrm{Der}(A, J))$ for $v \in \mathcal{U}(C)$, because $C \subseteq \mathrm{Der}(A, J)$, and, for $d \in D$ holds

$$s_0\big(k_1(d) - h_0(d) + \beta(k_2(d) - h_0(d))\big)s_0^* = v^*u^*H_0(d)uv - H_0(d)\,, \tag{4.15}$$

because $0 \oplus_{s_0,t_0} H_0 = (1-p_0)H_0(\cdot)$ and $p_0H_0 = s_0(h_0 + \beta h_0)s_0^*$.

The element $s_0(k_1(d) - h_0(d))s_0^*$ and the right side of Equation (4.15) are in J, but the element $s_0\beta(k_2(d) - h_0(d))s_0^*$ is in βJ for all $d \in D$. Thus, $k_2 = h_0$ by the assumption $J \cap \beta J = \{0\}$ in Theorem 4.4.6.

Suppose now that $k_2 = h_0$. By Lemma 4.4.10 there exists $W \in \mathcal{U}_0(\mathrm{Der}(A, J))$ such that $W \in p_0 E p_0 + (1 - p_0)$ and

$$W(k_1 \oplus_{s_2,t_2} H_0) = ((k_1 + \beta h_0) \oplus_{s_0,t_0} H_0)W\,.$$

Hence, $k_1 \oplus_{s_2,t_2} H_0 = W^* v u^* H_0(\cdot) u v^* W$. □

We do not suppose that $k_1, k_2 \in S(h_0\,;\, D, E)$ in the following lemma.

Lemma 4.4.12. *Let $A := H_0(D)$ and $k_1, k_2 \colon D \to J$ C^*-morphisms – not necessarily in $S(H_0\,;\, D, E)$. The following are equivalent:*

(i) $[k_1] + [h_0] = [k_2] + [h_0]$ *in the semi-group* $[\mathrm{Hom}(D, J)]$.

(ii) *There exists* $U_0 \in \mathcal{U}\big(\mathcal{N}(A, J + \beta J) + \mathbb{C} \cdot 1\big)$ *such that*

$$\big((k_1 + \beta h_0) \oplus_{s_0,t_0} H_0\big)U_0 = U_0\big((k_2 + \beta h_0) \oplus_{s_0,t_0} H_0\big)\,. \tag{4.16}$$

(iii) *There exists* $U_1 \in \mathcal{U}\big(\mathcal{N}(A, J) + \mathbb{C} \cdot 1\big)$ *such that* $U_1 \in \mathcal{U}_0\big(\mathrm{Der}(A, J)\big)$ *and*

$$\big((k_1 + \beta h_0) \oplus_{s_0,t_0} H_0\big)U_1 = U_1\big((k_2 + \beta h_0) \oplus_{s_0,t_0} H_0\big)\,. \tag{4.17}$$

(iv) *There exists* $U_2 \in \mathcal{U}_0\big(\mathcal{N}(A, J) + \mathbb{C} \cdot 1\big)$ *such that*

$$(k_1 \oplus_{s_2,t_2} H_0)U_2 = U_2(k_2 \oplus_{s_2,t_2} H_0)\,. \tag{4.18}$$

In particular, a C^*-morphism $k \colon D \to E$ satisfies $[k] + [h_0] = [h_0]$ in $[\mathrm{Hom}(D, E)]$, if and only if, $k(D) \subseteq J$ and there exists $u \in \mathcal{U}\big(\mathcal{N}(A, J + \beta J) + \mathbb{C} \cdot 1\big)$ and $v \in \mathcal{U}(C)$ such that

$$(k + \beta h_0) \oplus_{s_0,t_0} H_0 = v u^* H_0(\cdot) u v^*\,.$$

If $[k_0] + [h_0] = [h_0]$ then there exists $U_3 \in \mathcal{U}_0\big(\mathrm{Der}(A, J)\big)$ with $(1 - U_3) \in \mathcal{N}(A, J)$ and

$$(k + \beta h_0) \oplus_{s_0,t_0} H_0 = U_3^* H_0(\cdot) U_3\,.$$

Proof. Let $A := H_0(D)$. Part (iii) implies Part (ii) with $U_0 := U_1$ because $\mathcal{N}(A, J) \subseteq \mathcal{N}(A, J + \beta J)$.

(iv)⇒(iii): If we apply Lemma 4.4.10 to the separable C^*-subalgebra B of J that is generated by $k_1(D) \cup k_2(D)$, then we get a unitary $W \in \mathcal{U}_0(\mathrm{Der}(A, J))$ such that for $i \in \{0, 1\}$ holds

$$\big((k_i + \beta h_0) \oplus_{s_0,t_0} H_0\big)W = W\big(k_i \oplus_{s_2,t_2} H_0\big)\,.$$

Let $U_1 := W U_2 W^*$. The C^*-algebra $\mathcal{N}(A, J)$ is a closed ideal of the C^*-subalgebra $\mathrm{Der}(A, J) \subset E$ with $1_E \in \mathrm{Der}(A, J)$. It implies that $\mathcal{U}_0\big(\mathcal{N}(A, J) + \mathbb{C} \cdot 1\big)$ is a normal subgroup of $\mathcal{U}\big(\mathrm{Der}(A, J)\big)$. Thus $U_2 \in \mathcal{U}_0\big(\mathcal{N}(A, J) + \mathbb{C} \cdot 1\big)$. This implies together with $W \in \mathcal{U}\big(\mathrm{Der}(A, J)\big)$ that $U_1 \in \mathcal{U}_0\big(\mathcal{N}(A, J) + \mathbb{C} \cdot 1\big)$.

Straight calculation shows that U_1 fulfills the equation (4.17).

(ii)⇒(i): Suppose that $U_0 \in \mathcal{U}\big(\mathcal{N}(H_0(D), J + \beta J) + \mathbb{C} \cdot 1\big)$ satisfies Equation (4.16).

By Lemma 4.4.9 with $U := U_0$ and $q := p_0$, there exists a projection $p \in F$ with $p \geq p_0$ and $p \neq p_0$ such that $U_0^*\big(H_0(\cdot)(1-p)\big)U_0 = H_0(\cdot)(1-p)$. If we use that $t_0 H_0 t_0^* = (1-p_0)H_0$ we get:

$$U_0^*\big(s_0(k_1+\beta h_0)s_0^* + (p-p_0)H_0(\cdot)\big)U_0 = s_0(k_2+\beta h_0)s_0^* + (p-p_0)H_0(\cdot)$$

By Part (xii) of Lemma 4.4.7 there exists unitaries $V \in \mathcal{U}(C)$ and $W \in \mathcal{U}_0(E)$ such that $W^*(h_0+\beta h_0)W = p_0 H_0$, $Vp_0 = p_0 = p_0 V$ and

$$V^*(p-p_0)H_0 V = t_0 W^*(h_0+\beta h_0)W t_0^*\,.$$

We define a unitaries

$$V_0 := s_0 s^* + t_0 W^* t^* \quad \text{and} \quad V_1 := V_0^* V^* U_0 V V_0\,.$$

Straight calculation, using assumptions (i) of Theorem 4.4.6, shows that

$$V_1^*\big((k_1 \oplus_{s,t} h_0) + \beta(h_0)\big)V_1 = (k_2 \oplus_{s,t} h_0) + \beta(h_0)\,.$$

If we use that $J \cdot \beta J = \{0\}$ then we get finally

$$V_1^*(k_1 \oplus_{s,t} h_0)V_1 = (k_2 \oplus_{s,t} h_0)\,,$$

that yields $[k_1]+[h_0] = [k_2]+[h_0]$.

(i)⇒(iv): Suppose that $[k_1]+[h_0] = [k_2]+[h_0]$. Let $h_i := k_i \oplus_{s,t} h_0$ for $i \in \{1,2\}$. Then $[h_1] = [h_2]$ in $[\mathrm{Hom}(D,J)]$ and there exists $v \in \mathcal{U}(E)$ with $v^* h_1 v = h_2$.

Since $h_i(D) \subseteq J$, we can find even a unitary $u \in \mathcal{U}_0(E)$ with $u^* h_1 u = h_2$ by Lemma 4.4.7(viii). We define a unitary $W := u \oplus_{s_2,t_2} 1$ in $s_2\mathcal{U}_0(E)s_2^* + (1-p_2)$. Then $1-W \in \mathcal{N}(A,J)$ and W is contained in $\mathcal{U}_0(\mathcal{N}(A,J)+\mathbb{C}\cdot 1) \subset \mathcal{U}_0(\mathrm{Der}(A,J))$, because $p_2 H_0(\cdot) = s_2 h_0 s_2^*$ by Lemma 4.4.7(x) and because $x^* H_0(D) \subset J$ implies $xEx^* \subseteq \mathcal{N}(A,J)$. Obviously, $W^*(h_1 \oplus_{s_2,t_2} H_0)W = h_2 \oplus_{s_2,t_2} H_0$.

By Lemma 4.4.8, the element $u_2 := s_2 s s_2^* + s_2 t s_2^* t_2^* + t_2(t_2^2)^*$ from equation (4.9) is in $\mathcal{U}(C)$ and satisfies

$$\big((a \oplus_{s,t} b) \oplus_{s_2,t_2} c)\big)u_2 = u_2\big(a \oplus_{s_2,t_2} (b \oplus_{s_2,t_2} c)\big) \quad \text{for} \quad a,b,c \in E\,.$$

Part (x) of Lemma 4.4.7 shows that $h_0 \oplus_{s_2,t_2} H_0 = p_2 H_0 + (1-p_2)H_0 = H_0$. Thus, $k_i \oplus_{s_2,t_2} H_0 = u_2^*(h_i \oplus_{s_2,t_2} H_0)u_2$ for $i \in \{1,2\}$, and with $U_2 := u_2^* W u_2$ we get

$$U_2^*(k_1 \oplus_{s_2,t_2} H_0)U_2 = k_2 \oplus_{s_2,t_2} H_0\,.$$

The algebra $\mathcal{N}(A,J)$ is an ideal of $\mathrm{Der}(A,J)$. This implies that the group $\mathcal{U}_0(\mathcal{N}(A,J)+\mathbb{C}\cdot 1)$ is a normal subgroup of $\mathcal{U}(\mathrm{Der}(A,J))$ that is contained in $\mathcal{U}_0(\mathrm{Der}(A,J))$.

If we use that W is contained in $\mathcal{U}_0(\mathcal{N}(A,J)+\mathbb{C}\cdot 1)$ and $C \subseteq \mathrm{Der}(A,J)$ then we can see that the above defined U_2 is an element of $\mathcal{U}_0(\mathcal{N}(A,J)+\mathbb{C}\cdot 1)$.

Moreover $(1-W)H_0(\cdot)(1-p_2) = 0$ implies that also $(1-W^*)H_0(\cdot)(1-p_2) = 0$, and thus $(1-W) \in \mathcal{N}(A,J)$. It follows $(1-U_2) \in \mathcal{N}(A,J)$.

Finally we consider the special case $k_1 := k$ and $k_2 := h_0$:

If a C^*-morphism $k\colon D \to E$ satisfies $[k] + [h_0] = [h_0]$ in $[\mathrm{Hom}(D, E)]$, then there exists $V \in \mathcal{U}(E)$ with $k \oplus_{s,t} h_0 = V^* h_0(\cdot)V$. Thus $k = T^* h_0(\cdot)T$ for the isometry $T := Vs$, i.e., $[k] \in S(h_0\,;\, D, E)$ and $k(D) \subseteq J$.

Recall that $[h_0] = [h_0] + [h_0]$ and $H_0 = (h_0 + \beta h_0) \oplus_{s_0,t_0} H_0$ by assumptions (i,iv) of Theorem 4.4.6.

Therefore, the equivalence of Parts (i), (ii) and (iii) shows that $[k] + [h_0] = [h_0]$ is equivalent to $k(D) \subseteq J$ and the existence of $U_0 \in \mathcal{U}\big(\mathcal{N}(A, J + \beta J) + \mathbb{C} \cdot 1\big)$, respectively of $U_1 \in \mathcal{U}\big(\mathcal{N}(A, J) + \mathbb{C} \cdot 1\big)$ with $U_1 \in \mathcal{U}_0\big(\mathrm{Der}(A, J)\big)$, such that, for $j \in \{0, 1\}$:

$$(k + \beta h_0) \oplus_{s_0,t_0} H_0 = U_j^* H_0 U_j\,.$$

(Notice that necessarily $U_0^* U_1 \in C$.)

We find $\xi \in \mathbb{C}$ with $|\xi| = 1$ such that $1 - \xi U_1 \mathcal{N}(A, J)$ and can replace U_1 by ξU_1 in Part (iii).

If $u \in \mathcal{U}\big(\mathcal{N}(A, J + \beta J) + \mathbb{C} \cdot 1\big)$ and $v \in \mathcal{U}(C)$ are given such that

$$(k + \beta h_0) \oplus_{s_0,t_0} H_0 = vu^* H_0(\cdot)uv^*\,,$$

then we can take $U_0 := vuv^*$ to satisfy Formula (4.16) in Part (ii). □

Next Lemma 4.4.13 true? To be checked: ??

But it could work with kind of "stabilization"?

Lemma 4.4.13. *Let $A := H_0(D) \subseteq E$, $C := A' \cap E$ and $I := J + \beta J$ as in Theorem 4.4.6.*

For each separable C^*-subalgebra $B \subseteq \mathcal{N}(A, I) \subset \mathrm{Der}(A, I)$ there exist $u \in (F + 1) \cap \mathcal{U}_0(F + \mathbb{C} \cdot 1) \subseteq \mathcal{U}_0(C)$ and an isometry $T \in E$ such that

$$u^* bu - s_0 T^* bT s_0^* \in \mathrm{Ann}(A, E) \quad \textit{for all } b \in B\,.$$

In particular, for each contraction $e \in 1 + \mathcal{N}(A, I)$ with $1 - e^* e \in \mathrm{Ann}(A)$ and $1 - ee^* \in \mathrm{Ann}(A)$ there exists a unitary in $u \in \mathcal{N}(A, I) + 1$ with $u - e \in \mathrm{Ann}(A)$.

We do not know if this also holds with $I := J \triangleleft E$ (replacing $J + \beta J$) and $u^* bu - s_2 T^* bT s_2^* \in \mathrm{Ann}(A, E)$ for $b \in B$ (in place of the known weak conclusion $u^* bu - s_0 T^* bT s_0^* \in \mathrm{Ann}(A, E)$).

Is it used or needed somewhere?

It needs certainly a more elaborate proof if it is true.

Proof. In other words, we have to show that for each separable C^*-subalgebra $B \subseteq E$ with the property $B \cdot H_0(D) \subseteq I := J + \beta J$ there exists an isometry $T \in E$ and a unitary $u \in 1 + F$ with $u \in \mathcal{U}_0(F + \mathbb{C} \cdot 1)$ such that $(u^* bu - s_0 T^* bT s_0^*) \cdot H_0(D) = \{0\}$ for every $b \in B$.

Let $B \subseteq \mathcal{N}(A, I)$ a separable C^*-subalgebra and $b_0 \in B$ a strictly positive contraction in B.

Then let $e \in G_+ \subseteq I_+$ a strictly positive contraction for the separable C^*-subalgebra G of I generated by $B \cdot A$ (recall $A := H_0(D)$).

Notice that the linear span of all elements in $(BA)^n$, $(AB)^n$, $A(BA)^n = (ABBA)^n$ and $B(AB)^n = (BAAB)^n$ for $n = 1, 2, \ldots$ is dense in G. It follows that $BG \cup GB \subseteq G$ and $AG \cup GA \subseteq G$, i.e., that $A \cup B \subset \mathcal{N}(G, E)$.

The elements $x := b_1 a_1 + a_2 b_2$ with $a_1, a_2 \in A$ and $b_1, b_2 \in B$ build a set of generators of G, that is invariant under involution.

`Check next:`

$b_0 x, a_0 x \in G$ for $b_0 \in B$ and the linear span

$AB \cup BA \cup AB^2A \cup BA^2B \cup (AB)^n \cup (BA)^n \cup A(BA)^n$ generates $C^*(A \cup B)$????

Let $f_n \in I_+$ a sequence of positive contractions such that $f_n f_{n+1} = f_n$, $\lim_n f_n e = e = \lim_n e f_n$, $\lim_n \|(1 - f_n)b(1 - f_n)a\| = 0$, $\lim_n \|[b, f_n]\| = 0$ and $\lim_n \|[a, f_n]\| = 0$ for $b \in B$ and $a \in A$

????

Let $g := \sum_n 2^{-n} f_n$. There exists a projection $p \in F \subseteq C$ with $p \geq p_0$ and $p \neq p_0$ such that $pg = g = gp$ by assumption (iii,c) of Theorem 4.4.6.

(And there exist projections $q, r \in E$, but not in F, with $p = q + r$ and $q, \beta(r) \in \mathcal{N}(A, J)$ by Lemma 4.4.7(xi).)

`Write below new proof`
`fitting to above!!`

If $BA \subseteq J$, then $e, f_n, g \in J$ and

??? $rg, gr \in \operatorname{Ann}(A, E)$,

because $Ar = 0 = rA$ and $rgA = 0$??? Using an with respect to $C^*(A, r)$ approximately central approximate unit $(c_\tau) \in J_+$ of J, we get $c_\tau g \to g$ ...

Thus, $(1 - p)BA = \{0\}$ and $BA(1 - p) = B(1 - p)A = \{0\}$. It follows also that $AB(1 - p) = \{0\}$ and $A(1 - p)B = \{0\}$. Thus $(b - pbp) \in \operatorname{Ann}(A)$ for all $b \in B$, because $b - pbp = b(1 - p) + (1 - p)bp$.

Moreover $pb^*(1 - p)cp \in \operatorname{Ann}(A)$ for all $b, c \in B$, because $(pb^*(1 - p)cp)^* = (pc^*(1 - p)bp)$ and $(pb^*(1 - p)cp)^*(pb^*(1 - p)cp)A = \{0\}$. We get $pBp \subseteq \mathcal{N}(A, I)$ because $p \in C \subseteq \operatorname{Der}(A, I)$ and $\mathcal{N}(A, I)$ is an ideal of $\operatorname{Der}(A, I)$.

There exists $u \in (1 + F) \cap \mathcal{U}_0(F + \mathbb{C} \cdot 1)$ with $u^* p u = p_0$.

Let $\gamma_0(b) := p_0 u^* b u p_0$. Then $u^* \gamma_0(b) u = pbp$.

Is $b - qbq = (b - up_2 u^* b u p_2 u^*) H_0(d) = 0$ for all $b \in B$? Likely not! More general open:

`Is there in case` $I = J$ `a decomposition`
$u^* b u - s_2 \gamma(b) s_2^* \in \operatorname{Ann}(A, E)$???

Let $T := us_0$ and $\gamma(b) := T^*bT$. Then $pbp = us_0\gamma(b)s_0^*u^*$. Thus $u^*bu - s_0\gamma(b)s_0^* \in \mathrm{Ann}(A)$ for all $b \in B$.

$H_0(d)T = us_0s_0^*H_0(d)s_0 = us_0(h_0(d) + \beta h_0(d))$.

There exist $u \in (F+1) \cap \mathcal{U}_0(F + \mathbb{C}\cdot 1) \subseteq \mathcal{U}_0(C)$ and an isometry $T \in E$ such that, for all $b \in B$, $u^*bu - s_2T^*bTs_2^* \in \mathrm{Ann}(A)$ in case $I = J$ (respectively $u^*bu - s_0T^*bTs_0^* \in \mathrm{Ann}(A)$ in case $I = J + \beta J$):

To be filled in

There exists an isometry $T \in E$ with $T^*H_0(\cdot)T = 0$ and $TT^* + p_0 \leq 1$:

By Lemma 4.4.7(vi), there exists an isometry $s_1 \in E$ with $s_1s_1^* \leq 1 - p_0$ and $s_1s_1^*H_0(\cdot) = 0$. Thus $T := s_1$ is as desired. (One could also use directly $T := R$ for R in the proof of Lemma 4.4.7(vi).)

To be filled in. Check. ?? The "naive" definition should be the following definition:

Let $U(e)$ the Halmos unitary of e defined in Remark 4.2.4 and $s_1, t_1 \in E$ the isometries from Lemma 4.4.7(vi), and define

$$u := [t_1, s_1]U(e)[t_1, s_1]^* = t_1et_1^* + s_1e^*s_1^* - t_1(1 - ee^*)^{1/2}s_1^* + s_1(1 - e^*e)^{1/2}t_1^*$$

Then $s_1e^*s_1^*, t_1(1 - ee^*)^{1/2}s_1^*, s_1(1 - e^*e)^{1/2}t_1^* \in \mathrm{Ann}(A)$ and $t_1a = a = at_1 = t_1^*a$ for all $a \in A$.

Thus $ua = t_1et_1^*a = t_1ea$ and $au = aet_1^*$ for $a \in A$. Need modification of s_1, t_1 such that $t_1ea = ea$ for $a \in A$ and $aet_1^* = ae$ for $a \in A$.

Notice that $ea - ae = g$ is contained in a separable C^*-subalgebra G of I, $t_1ea = t_1(g + ae) = t_1g + ae = ea + (t_1 - 1)g$. $aet_1^* = (t_1ea)^* = ((t_1 - 1)g)^* + ae$ for suitable $g \in G$

Thus we have to find a unitary V in $C := A' \cap E$ such that $s_1^*Vg = 0$ for all $g \in G$. Then still $V^*s_1s_1^*V \leq 1 - p_0$ and $V^*s_1s_1^*Va = V^*s_1s_1^*aV = 0$ for $a \in A$. We can rename V^*s_1 by R and use it to construct a suitable correction of s_1, t_1:

To find $V \in F$, we take $q \in F$ with $q \geq p_0$, $q \neq p_0$ and $qg = g = gq$ for all $g \in G$ (is possible by Parts (iii,iv) of Theorem 4.4.6). Then s_1V has the property $V^*s_1s_1^*V \leq (1 - q) = V^*(1 - p_0)V \leq (1 - p_0)$.

Let $R := V^*s_1$. Then $R^*A = \{0\}$ and $R^*G = \{0\}$ for $V \in \mathcal{U}_0(F)$ with $V^*p_0V = q$ as defined above. Since E is properly infinite there exists isometries S, T with $SS^* \leq RR^*$, $SS^* + TT^* = 1$ and $Ta = a = aT = aT^*$, $Tg = g = gT = gT^*$ for $a \in A$ and $g \in G$.

Now define $u := [T, S]U(e)[T, S]^*$. Then we get that $(e - u)A = \{0\} = A(e - u)$.

A construction of u in the special case that $e := s_2fs_2^* + 1 - p_2$ in case $I = J$ (respectively $e := s_0fs_0^* + 1 - p_0$ in case $I = J + \beta J$) where $f \in E$ is a contraction such that $2p_2 - s_2f^*fs_2^* - s_2ff^*s_2^* \in \mathrm{Ann}(A, E)$ (respectively $2p_0 - s_0f^*fs_0^* - s_0ff^*s_0^* \in \mathrm{Ann}(A, E)$).

Let $Z := [s_2, T, 1 - p_2 - TT^*] \in M_{1,3}(E)$ if $I = J$ (respectively let $Z := [s_0, T, 1 - p_0 - TT^*]$ if $I = J + \beta J$) and $U(f) \in M_2(E)$ the Halmos unitary of f as defined in Remark 4.2.4.

Then $ZZ^* = 1$ and $u := Z(U(f) \oplus 1)Z^*$ is a unitary that satisfies $u \in \mathcal{N}(A, I) + 1$ and $u - e \in \mathrm{Ann}(A, E)$. □

REMARK 4.4.14. Let $A := H_0(D)$, $I := J + \beta J$ and $u \in \mathcal{U}(\mathrm{Der}(A, I))$. By Lemma 4.4.11 there exist $v \in \mathcal{U}(C)$ and a C^*-morphism $k \colon D \to I$, i.e., $k = k_1 + \beta k_2$ with C^*-morphisms $k_1, k_2 \colon D \to J$, that satisfy

$$k \oplus_{s_0,t_0} H_0 = v^* u^* H_0(\cdot) u v \, .$$

The following are equivalent:

(i) $[k] + [h_0 + \beta h_0] = [h_0 + \beta h_0]$.
(ii) There are $w_1, w_2 \in \mathcal{U}(C)$ such that $1 - w_1 u w_2 \in \mathcal{N}(A, I)$.
(iii) There exist $w \in \mathcal{U}(C)$ such that $wuv \in \mathcal{U}_0(\mathcal{N}(A, I) + \mathbb{C} \cdot 1)$.

PROOF. The proof of the equivalences in Parts (i)–(iii) of Remark 4.4.14 is similar to the proof of Lemma 4.4.12 with $\oplus_{s_2,t_2}$ and $V := u_2$ replaced by $\oplus_{s_0,t_0}$ and $V := u_0$ in Lemma 4.4.8 and in proof of Lemma 4.4.7(x). □

Let C, $\mathrm{Ann}(A, E)$, $\mathrm{Der}(A, I)$, $\mathcal{N}(A, I)$, $\mu \colon \mathrm{K}_1(C) \to \mathrm{K}_1(\mathrm{Der}(A, I))$ and $\Gamma\big(A, I, E\big)$ as introduced in Definitions 4.4.4 and 4.4.5.

Notice that $\mathrm{Der}(A, I_0) \subseteq \mathrm{Der}(A, I)$ if $I_0 \subseteq I$ for an ideal $I_0 \lhd E$. In particular, $C := A' \cap E = \mathrm{Der}(A, \{0\}) \subseteq \mathrm{Der}(A, I)$.

Recall that $\mathcal{N}(A, I)$ is an ideal of $\mathrm{Der}(A, I)$ and that $\mathcal{N}(A, I_0) \subseteq \mathcal{N}(A, I)$ if $I_0 \subseteq I$. In particular, $\mathrm{Ann}(A, E) := \mathcal{N}(A, \{0\}) \subseteq C \cap \mathcal{N}(A, I)$.

We use below the group morphisms

$$\mu \colon \mathrm{K}_1(C) \to \mathrm{K}_1(\mathrm{Der}(A, I)) \quad \text{and} \quad \mu' \colon \mathrm{K}_1(\mathcal{N}(A, I)) \to \mathrm{K}_1(\mathrm{Der}(A, I))$$

given by the inclusion maps $C \hookrightarrow \mathrm{Der}(A, I)$ and $\mathcal{N}(A, I) \hookrightarrow \mathrm{Der}(A, I)$. Recall that

$$\Gamma(A, J, E) := \mathrm{K}_1(\mathrm{Der}(A, J)) / \mu(\mathrm{K}_1(C)) \, .$$

LEMMA 4.4.15. *Let $A := H_0(D)$, $C := A' \cap E$ and $I := J + \beta J$ (respectively $I := J$). Let $\mathrm{Ann}(A, E) := \mathcal{N}(A, \{0\})$, $\mathrm{Der}(A, I)$ and $\mathcal{N}(A, I)$ as in Definition 4.4.4.*

(i) *$\mathcal{N}(A, I)$ is a closed ideal of $\mathrm{Der}(A, I)$ and a full hereditary C^*-subalgebra of E. It holds*

$$\mathrm{Der}(A, I) = C + \mathcal{N}(A, I) \, .$$

In particular there is a natural isomorphism

$$C / (C \cap \mathcal{N}(A, I)) \;\cong\; \mathrm{Der}(A, I) / \mathcal{N}(A, I) \, ,$$

(ii) *The annihilator* $\mathrm{Ann}(A,E)$ *of* A *in* E *is a closed ideal of* C *and is a full hereditary* C^**-subalgebra of* E.

It satisfies

$$\mathrm{Ann}(A,E) = \mathcal{N}(A,J)\cap\beta(\mathcal{N}(A,J)) \subseteq \mathcal{N}(A,I)\,.$$

In particular, the quotient maps $\pi\colon C \to C/\mathrm{Ann}(A,E)$ *and* $\mathrm{Der}(A,I)\to C/(C\cap\mathcal{N}(A,I))$ *induce surjective maps on the* K_**-groups, e.g.* $[\pi]_1(\mathrm{K}_1(C)) = \mathrm{K}_1(C/\mathrm{Ann}(A,E))$ *:*

For every contraction $c\in C$ *with* $1-c^*c, 1-cc^*\in\mathrm{Ann}(A,E)$ *there exists a unitary* $u\in C$ *such that*

$$1-u(c\oplus_{s,t}1)\in\mathrm{Ann}(A,E)\,.$$

(iii) *The* C^**-algebras* $\mathrm{Der}(A,I)$, C, $\mathcal{N}(A,I)+\mathbb{C}\cdot 1$ *and all its non-zero quotients and unifications of closed non-zero ideals are* K_1*-surjective* C^**-algebras.*

(iv) $\mathcal{U}(\mathcal{N}(A,I)+\mathbb{C}\cdot 1)$ *is a closed* normal *subgroup of* $\mathcal{U}(\mathrm{Der}(A,I))$ *and* $\mathcal{U}(C)$ *is a closed subgroup of* $\mathcal{U}(\mathrm{Der}(A,I))$ *.*

(v) *Let* $\mathcal{G}(I)$ *denote the set* $\mathcal{U}(C)\cdot\mathcal{U}(\mathcal{N}(A,I)+\mathbb{C}\cdot 1)$ *of products* $u\cdot v$ *with* $u\in\mathcal{U}(C)$ *and* $v\in\mathcal{U}(\mathcal{N}(A,I)+\mathbb{C}\cdot 1)$ *.*

The set $\mathcal{G}(I)$ *is an* open subgroup *of* $\mathcal{U}(\mathrm{Der}(A,I))$ *that satisfies*

$$\mathcal{G}(I)\oplus_{s,t}1\subseteq\mathcal{G}(I)\,.$$

In particular, $\mathcal{U}_0(\mathrm{Der}(A,I))\subseteq\mathcal{G}(I)$ *.*

(vi) *For each* $u\in\mathcal{U}(E)$ *there exists a unitary* $v\in 1+\mathrm{Ann}(A,E)\subset C$ *such that* $[v\cdot u]=0$ *in* $\mathrm{K}_1(E)$.

For each unitary in $u\in\mathcal{U}(\mathcal{N}(A,J+\beta J)+\mathbb{C}\cdot 1)$ *with the* additional *property* $u\in\mathrm{Der}(A,J)$ *there exists unitaries* $v,w\in\mathcal{U}(C)$ *such that*

$$v\,u\,w\in\mathcal{U}_0(\mathcal{N}(A,J)+\mathbb{C}\cdot 1)\subseteq\mathcal{U}_0(\mathrm{Der}(A,J))\,.$$

In particular, the image $\mu'(\mathrm{K}_1(\mathcal{N}(A,J)))\subseteq\mathrm{K}_1(\mathrm{Der}(A,J))$ *of* $\mathrm{K}_1(\mathcal{N}(A,J))$ *is contained in the image* $\mu(\mathrm{K}_1(C))$ *in* $\mathrm{K}_1(\mathrm{Der}(A,J))$, *and the mapping*

$$\mathcal{G}(J)\ni u\mapsto[u]\in\mathrm{K}_1(\mathrm{Der}(A,J))$$

maps $\mathcal{G}(J)$ onto $\mu(\mathrm{K}_1(C))\subseteq\mathrm{K}_1(\mathrm{Der}(A,J))$.

(vii) *The natural group morphisms* $\mathrm{K}_1(C)\to\mathrm{K}_1(C/\mathrm{Ann}(A,E))$ *and*

$$\mathrm{K}_1\big(\mathrm{Der}(A,I)\big)\to\mathrm{K}_1\big(\mathrm{Der}(A,I)/\mathcal{N}(A,I)\big)$$

are surjective.

(viii) *The natural group epimorphism* $\varphi\colon[k]+[h_0]\mapsto[k]+[H_0]$ *from* $G(h_0\,;\,D,E)$ *onto* $G(H_0\,;\,D,E)$ *is injective, if and only if, the natural group morphism*

$$\mathrm{K}_1(C/\mathrm{Ann}(A,E))\to\mathrm{K}_1\big(C/(C\cap\mathcal{N}(A,J))\big)$$

is surjective.

(ix) *This map* $\varphi\colon[k]+[h_0]\mapsto[k]+[H_0]$ *is injective, if and only if,*

$$u\oplus_{s,t}1\in\mathcal{G}(J)\quad\textit{for all}\;\; u\in\mathcal{U}(\mathrm{Der}(A,I))\cap\mathcal{U}_0(E)\,. \tag{4.19}$$

(x) *A sufficient condition for the injectivity of* φ *is that the natural group morphism*

$$\mathcal{U}\big(C/\operatorname{Ann}(A,E)\big) \to \mathcal{U}\big(C/(C\cap\mathcal{N}(A,I))\big)$$

contains $1\oplus\mathcal{U}\big(C/(C\cap\mathcal{N}(A,I))\big)$ *in its image.*

PROOF. Recall that $A := H_0(D)$, and that we let alternatively $I := J$ or $I := J+\beta J$ to avoid repeats. We need sometimes additional considerations for the case $I := J$.

(i): Clearly, $\operatorname{Der}(A,I) = \pi_I^{-1}\big(\pi_I(A)'\cap(E/I)\big)$. Thus, $\operatorname{Der}(A,I)$ is a C^*-subalgebra of E and

$$C := A'\cap E = \operatorname{Der}(A,\{0\}) \subseteq \operatorname{Der}(A,I)\,.$$

In the same way $\mathcal{N}(A,I) = \pi_I^{-1}(\operatorname{Ann}(\pi_I(A),E/I))$, where $\operatorname{Ann}(\pi_I(A),E/I)$ means the two-sided annihilators in E/I of the elements of $\pi_I(A)$.

Since $\operatorname{Ann}(\pi_I(A),E/I)$ is a closed ideal of $\pi_I(A)'\cap(E/I)$, the C^*-algebra $\mathcal{N}(A,I)$ is a closed ideal of $\operatorname{Der}(A,I)$.

In particular, $C+\mathcal{N}(A,I)$ is a C^*-subalgebra of $\operatorname{Der}(A,I)$ in general for all closed ideals I of E.

Let $e\in E_+$ with $eH_0(d)-H_0(d)e \in I := J+\beta J$ for all $d\in D$, i.e., $e\in \operatorname{Der}(A,I)$. Since D is separable, the image $T(D)$ of $T(d) := eH_0(d)-H_0(d)e$ is contained in a separable C^*-subalgebra B of $J+\beta J$. Let $f\in B_+$ a strictly positive contraction for B. By assumption (iii) of Theorem 4.4.6, there is a projection $p\in F$ with $pf = f = fp$, $p_0\le p$ and $p_0\ne p$.

Since $F\subseteq C$ by assumption (iii) of Theorem 4.4.6, it follows for $d\in D$ that

$$0 = (1-p)T(d) = (1-p)eH_0(d) - H_0(d)(1-p)e \quad\text{and}\quad 0 = T(d)(1-p)\,.$$

Thus, $(1-p)e, pe(1-p)\in C$ and $e-pep = (1-p)e+pe(1-p)\in C$. By assumptions (iii,v) of Theorem 4.4.6, $pH_0(D) = H_0(D)p\subset J+\beta J$. Thus, $pep\in\mathcal{N}(H_0(D),J+\beta J)$.

It also shows that $\operatorname{Der}(A,I) = C+\mathcal{N}(A,I)$ in the case where $I = J+\beta J$:

We can use that $\operatorname{Der}(A,J)\subset\operatorname{Der}(A,J+\beta J)$ in the case where $I = J$:

If $e\in\operatorname{Der}(A,J)_+$, then $e\in\operatorname{Der}(A,J+\beta J)$ and there exists a projection $p\in F$ with $e-pep\in C$ by our above considerations. Since $C = \operatorname{Der}(A,\{0\})\subset\operatorname{Der}(A,J)$ and $F\subseteq\mathcal{N}(A,J+\beta J)$ it follows that

$$pep = e-(e-pep)\in\operatorname{Der}(A,J)\cap\mathcal{N}(A,J+\beta J)\,.$$

It turns out that the latter implies that pep is in $\mathcal{N}(A,J)$:

By Part (xi) of Lemma 4.4.7 there exist projections $q,r\in C$ with the properties $p = q+r$, $[qH_0(\cdot)] = [h_0]$ and $[rH_0(\cdot)] = [\beta h_0]$. In particular $q\in C\cap\mathcal{N}(A,J)$ and $r\in C\cap\mathcal{N}(A,\beta J)$.

For $d \in D$ holds $rH_0(d) = H_0(d)r \in \beta J$. Thus,

$$\beta(J) \ni rerH_0(d) - H_0(d)rer = r(eH_0(d) - H_0(d)e)r \in J\,.$$

Since $J \cap \beta J = \{0\}$ it follows that $rer \in C$. Hence, $pep - rer \in \mathrm{Der}(A, J)$ and

$$e - (pep - rer) = (e - pep) + rer \in C\,.$$

We show that the element $pep - rer = qer + req + qeq$ is in $\mathcal{N}(A, J)$, and get that $e \in C + \mathcal{N}(A, J)$:

Since $q, r \in C$, we get e.g. from $qerH_0(d) - H_0(d)qer = q(eH_0(d) - H_0(d)e)r$ and $e \in \mathrm{Der}(A, J)_+$ that $qer, req, rer \in \mathrm{Der}(A, J)$. It follows from $J \cap \beta J = \{0\}$, $H_0(d)r \in \beta J$, $qH_0(d) \in J$ and $reqH_0(d) - H_0(d)req \in J$ that necessarily $H_0(d)req = 0$ for all $d \in D$. Since $(qer)^* = req \in \mathrm{Der}(A, J)$ it follows $qerH_0(d) = 0$ for all $d \in D$.

$(re + qe)(qH_0(d)) \in J$ and $qer\, H_0(d) = 0$ imply $(qer + req + qeq)H_0(d) \in J$.

Since $pep - rer$ is self-adjoint it follows that $pep - rer \in \mathcal{N}(A, J)$.

Summing up we get $e = x + y$ with $x = (e + rer) - (pep) \in C$ and $y = pep - rer \in \mathcal{N}(A, J)$.

Thus, $\mathrm{Der}(A, I)_+ \subseteq C + \mathcal{N}(A, I)$. Since $C + \mathcal{N}(A, I)$ is a C^*-subalgebra of the C^*-algebra $\mathrm{Der}(A, I)$ it follows $\mathrm{Der}(A, I) = C + \mathcal{N}(A, I)$ for $A := H_0(D)$ and $I := J + \beta J$ (respectively $A := H_0(D)$ and $I := J$).

The ideal $C \cap \mathcal{N}(A, I)$ of C is the kernel of the restriction to C of the epimorphism $\mathrm{Der}(A, I) \to \mathrm{Der}(A, I)/\mathcal{N}(A, I)$. Since $\mathrm{Der}(A, I) = C + \mathcal{N}(A, I)$, this quotient map defines an isomorphism

$$\mathrm{Der}(A, I)/\mathcal{N}(A, I) \cong C/(C \cap \mathcal{N}(A, I))\,.$$

(ii): The (two-sided) annihilator $\mathrm{Ann}(A, E)$ is a closed ideal of C, because

$$c_1ec_2a = c_1eac_2 = 0 \quad \text{and} \quad ac_1ec_2 = c_1aec_2 = 0$$

if $e \in \mathrm{Ann}(A, E)$, $a \in A$ and $c_1, c_2 \in C$.

The C^*-subalgebra $\mathrm{Ann}(A, E)$ is *hereditary* in E, because $e_1Ee_2 \subseteq \mathrm{Ann}(A, E)$ if $e_1, e_2 \in \mathrm{Ann}(A, E)$.

If $e \in \mathrm{Ann}(A, E)$, i.e., if $ea = 0 = ae$ for all $a \in A \subseteq E$, then $e \in \mathcal{N}(A, J) \subseteq \mathcal{N}(A, I)$ and $e \in C = A' \cap E$. Thus $\mathrm{Ann}(A, E)$

Since $\beta H_0 = H_0$, it follows $\beta A = A$ and $\beta(\mathrm{Ann}(A, E)) = \mathrm{Ann}(A, E)$.

Thus, $\mathrm{Ann}(A, E) \subseteq \mathcal{N}(A, J) \cap \beta\mathcal{N}(A, J)$.

We get $\beta\mathcal{N}(A, J) = \mathcal{N}(A, \beta J)$ from $\beta(A) = A$.

If $e \in E$ satisfies $eH_0(D) \subseteq J$ and $eH_0(D) \subseteq \beta J$, then $eH_0(D) \subseteq J \cap \beta J = \{0\}$.

Thus, $\mathcal{N}(A, J) \cap \beta\mathcal{N}(A, J) = \mathrm{Ann}(A, E)$.

The *-monomorphism H_0 dominates zero by Lemma 4.4.7(vi), i.e., there exists an isometry $s_1 \in E$ with $s_1^* H_0(\cdot) s_1 = \{0\}$. It implies that $s_1 s_1^* \in \mathrm{Ann}(A, E)$ if $A := H_0(D)$, i.e., $\mathrm{Ann}(A, E)$ is full in E.

(iii): The unital algebra $C := A' \cap E \subseteq \mathrm{Der}(A, I)$ contains the isometries s, t with orthogonal ranges by assumption (i) of Theorem 4.4.6, and $\mathcal{N}(A, I)$ is a non-zero ideal of $\mathrm{Der}(A, I)$ by Part (i).

All non-zero quotients of C and of $\mathrm{Der}(A, I)$ and all (unitization of) non-zero ideals of this quotients are K_1-surjective by Remark 4.2.17.

(iv): The groups $\mathcal{U}(\mathcal{N}(A, I) + \mathbb{C} \cdot 1)$ and $\mathcal{U}(C)$ are norm-closed subgroups of $\mathcal{U}(\mathrm{Der}(A, I))$, because unitary groups of C^*-algebras are norm-closed.

The group $\mathcal{U}(\mathcal{N}(A, I) + \mathbb{C} \cdot 1)$ is normal in $\mathcal{U}(\mathrm{Der}(A, I))$ because $\mathcal{N}(A, I)$ is an ideal of $\mathrm{Der}(A, I) = C + \mathcal{N}(A, I)$.

(v): The set $\mathcal{G}(I)$ of products $\mathcal{U}(C) \cdot \mathcal{U}(\mathcal{N}(A, I) + \mathbb{C} \cdot 1)$ is a subgroup of $\mathcal{U}(\mathrm{Der}(A, I))$ because $\mathcal{U}(\mathcal{N}(A, I) + \mathbb{C} \cdot 1)$ is a normal subgroup of $\mathcal{U}(\mathrm{Der}(A, I))$ by Part (iv).

If $u \in \mathcal{U}_0(\mathrm{Der}(A, I))$ then u is a product of exponentials, i.e., there exist $t_m \in \mathrm{Der}(A, I)$ $(m = 1, \cdots, n)$ such that $t_m^* = -t_m$ and $u = \exp(t_1) \cdot \ldots \cdot \exp(t_n)$. We find $c_m \in C$ $(m = 1, \ldots, n)$ with $c_m^* = -c_m$ and $t_m - c_m \in \mathcal{N}(A, I)$, because $\mathrm{Der}(A, I) = C + \mathcal{N}(A, I)$ by Part (i). If we define $v \in \mathcal{U}_0(C)$ by $v := \exp(c_1) \cdot \ldots \cdot \exp(c_n)$, then $v^* u \in 1 + \mathcal{N}(A, I)$, because $\mathcal{U}(\mathcal{N}(A, I) + \mathbb{C} \cdot 1)$ is a normal subgroup of $\mathcal{U}(\mathrm{Der}(A, I))$ and $\exp(-c_m) \exp(t_m) \in 1 + \mathcal{N}(A, I)$ for $m = 1, \ldots, n$.

It follows that $\mathcal{G}(I)$ is an *open* subgroup of $\mathcal{U}(\mathrm{Der}(A, I))$.

Recall that every open subgroup G_2 of a topological group G_1 is also closed in G_1, because G_2 is the complement in G_1 of the union of open sets $G_2 \cdot g$ with $g \in G_1 \setminus G_2$.

If $u, v \in \mathcal{U}(C)$ then $u \oplus_{s,t} v = sus^* + tvt^* \in \mathcal{U}(C)$ because $s, t \in C$.

If $w \in \mathcal{U}(\mathcal{N}(A, I) + \mathbb{C} \cdot 1)$ then $w = (\xi 1) \cdot (e + 1)$ for some $\xi \in \mathbb{C}$ with $|\xi| = 1$ and $e \in \mathcal{N}(A, I)$.

The unitary $s^* w s + tt^* = (\xi \cdot ss^* + tt^*)(ses^* + 1)$ is in $\mathcal{G}(I)$, because $\xi \cdot ss^* + tt^* \in \mathcal{U}_0(C)$ and $ses^* \in \mathcal{N}(A, I)$.

Thus $\mathcal{G}(I) \oplus_{s,t} 1 \subseteq \mathcal{G}(I)$.

(vi): By Lemma 4.4.7(vi) there exist isometries $s_1, t_1 \in E$ with $s_1 s_1^* + t_1 t_1^* = 1$ and s_1 satisfies $s_1^* A = \{0\} = A s_1$. It implies that $s_1 \, E \, s_1^* \subseteq \mathrm{Ann}(A, E)$. If $u \in \mathcal{U}(E)$ then $[u] = [u \oplus' 1] = [(1 - s_1 s_1^*) + s_1 u s_1^*]$ in $\mathrm{K}_1(E)$ by Lemma 4.2.6(v,2).

Thus $v := (1 - s_1 s_1^*) + s_1 u^* s_1^*$ is a unitary in $1 + \mathrm{Ann}(A, E)$ with $[vu] = 0$ in $\mathrm{K}_1(E)$.

Remaining TEXT:

For each unitary in $u \in \mathcal{U}(\mathcal{N}(A,I) + \mathbb{C}\cdot 1)$ with the additional property $u \in \mathrm{Der}(A,J)$ there exists unitaries $v, w \in \mathcal{U}(C)$ such that

$$v\,u\,w \in \mathcal{U}_0(\mathcal{N}(A,J) + \mathbb{C}\cdot 1) \subseteq \mathcal{U}_0(\mathrm{Der}(A,J))\,.$$

In particular, the image $\mu'(\mathrm{K}_1(\mathcal{N}(A,J))) \subseteq \mathrm{K}_1(\mathrm{Der}(A,J))$ of $\mathrm{K}_1(\mathcal{N}(A,J))$ is contained in the image $\mu(\mathrm{K}_1(C))$ in $\mathrm{K}_1(\mathrm{Der}(A,J))$, and the mapping

$$\mathcal{G}(J) \ni u \mapsto [u] \in \mathrm{K}_1(\mathrm{Der}(A,J))$$

maps $\mathcal{G}(J)$ *onto* $\mu(\mathrm{K}_1(C)) \subseteq \mathrm{K}_1(\mathrm{Der}(A,J))$.

(vi): `New approach:`

Next to PROOF of a Lemma ??:

Let $u \in \mathcal{U}(\mathcal{N}(A,I)+\mathbb{C}\cdot 1)$. Then $u \in \mathrm{Der}(A,I)$ and by Lemma 4.4.11 there exist $k\colon D \to I$ and $v \in \mathcal{U}(C)$ such that

$$k \oplus_{s_0,t_0} H_0 = v^*u^*H_0(\cdot)uv\,,$$

where $k = k_1 + \beta k_2$ for C^*-morphisms $k_1, k_2\colon D \to J$. Moreover, $k_2 = h_0$ in case $I = J$.

Lemma 4.4.8 (in case $I = J$) and Remark 4.4.14 (in case $I = J + \beta J$) show that $v^*uv \in \mathcal{U}(\mathcal{N}(A,I)+\mathbb{C}\cdot 1)$ implies that $[k]+[h_0+\beta h_0] = [h_0+\beta h_0]$ (which is equivalent to $[k_1]+[h_0] = [h_0]$ in case $I = J$), that this is equivalent to the existence of a unitary $U \in \mathcal{U}_0(\mathcal{N}(A,I)+\mathbb{C}\cdot 1)$ with

$$k \oplus_{s_0,t_0} H_0 = U^*H_0(\cdot)U\,.$$

It follows that $w := uv \cdot U^* \in \mathcal{U}(C)$, and $w^*uv = U^* \in \mathcal{U}_0(\mathcal{N}(A,I)+\mathbb{C}\cdot 1)$.

(vii): Clearly $\mathrm{Ann}(A,E)$ is a closed ideal of C and is a hereditary C^*-subalgebra $\mathrm{Ann}(A,E)$ of E. It is full in E because there exist an isometry $s_1 \in E$ with $s_1^*H_0(\cdot)s_1 = 0$ by Lemma 4.4.7(vi).

Since $\mathcal{N}(A,I) = \pi_J^{-1}(\mathrm{Ann}(\pi_J(A), E/J))$, it is a hereditary C^*-subalgebra of E that contains $\mathrm{Ann}(A,E)$. Thus $\mathcal{N}(A,I)$ is full in E. By Part (i), $\mathcal{N}(A,I)$ is a closed ideal of $\mathrm{Der}(A,I)$ that is hereditary and full in E.

Since $\mathrm{Ann}(A,E)$ is a closed ideal of C and $\mathcal{N}(A,E)$ is a closed ideal of $\mathrm{Der}(A,E)$, and both are full and hereditary in E, Part (vii) follows from Lemma 4.2.20(o).

END Proofs (i)-(vii).

TEXT OF GENERAL CONCLUSIONS:

Finally, the K_*-theory 6-term exact sequence

$$0 \to (C \cap \mathcal{N}(A,I)) \to C \to C/(C\cap\mathcal{N}(A,I)) \to 0\,.$$

shows that the group morhism $\mathrm{K}_1(C) \to \mathrm{K}_1(C/(C\cap\mathcal{N}(A,I)))$ is surjective, if and only if, $\mathrm{K}_0(C\cap\mathcal{N}(A,I))) \to \mathrm{K}_0(C)$ is injective.

The latter is related to the injectivity of $\varphi\colon [k]+[h_0] \mapsto [k]+[H_0]$.

???????

END TEXT

BEGIN TEXT OF GENERAL Conclusion:

The group morphism $\varphi\colon [k]+[h_0] \mapsto [k]+[H_0]$ is injective, if and only if, the natural group morphism

$$\mathrm{K}_1\big(C/\mathrm{Ann}(A,E)\big) \to \mathrm{K}_1\big(C/(C\cap\mathcal{N}(A,I))\big)$$

is surjective.

This is the case if and only if $u \oplus_{s,t} 1 \in \mathcal{G}$ for all $u \in \mathcal{U}(\mathrm{Der}(A,I))$.

A *sufficient* condition for the latter is that the natural group morphism

$$\mathcal{U}(C/\operatorname{Ann}(A,E)) \to \mathcal{U}(C/(C\cap\mathcal{N}(A,I)))$$

is surjective.

Notice that $\operatorname{Ann}(A,E) \subseteq C\cap\mathcal{N}(A,I)$ are ideals of C and that $\operatorname{Ann}(A,I)$ is a full hereditary C^*-subalgebra of E. By Lemma 4.2.20, $\mathrm{K}_*(C/\operatorname{Ann}(A,I))$ is natural isomorphic to the kernel of $\mathrm{K}_*(C) \to \mathrm{K}_*(E)$, and the natural sequences

$$\mathrm{K}_*(\operatorname{Ann}(A,I)) \to \mathrm{K}_*(C) \to \mathrm{K}_*(C/\operatorname{Ann}(A,I))$$

are split-exact sequences.

Recall that $G(H_0\,;\,D,E)$ (respectively $G(h_0\,;\,D,E)$) is isomorphic to the kernel of $\mathrm{K}_0(C)\to\mathrm{K}_0(E)$ (respectively of $\mathrm{K}_0(h_0(D)'\cap E)\to\mathrm{K}_0(E)$).

□

PROOF OF THEOREM 4.4.6 (PART 2: KERNEL OF φ IN $G(h_0,D,E)$).

Let $\mathcal{A}$ (temporary) denote the set of $k\in\operatorname{Hom}(D,E)$ with $k(D)\subseteq J$ and the property that $k\oplus H_0$ is unitary equivalent to H_0 by a unitary in E, i.e., with $[k]+[H_0]=[H_0]$ in $[\operatorname{Hom}(D,E)]_u$. Recall that $[k]+[H_0]$ is the unitary equivalence class of $k\oplus H_0$ in the elements in $\operatorname{Hom}(D,E)$, which is independent from the chosen isometries $S,T\in E$ with $SS^*+TT^*=1$ for the sum $\oplus := \oplus_{S,T}$.

If $k\in\operatorname{Hom}(D,E)$ is in $\mathcal{A}$, i.e., $k(D)\subseteq J$ and and $[k]+[H_0]=[H_0]$, then k satisfies

- (1a) $[k]\in S(h_0\,;\,D,E)$, (by Lemma 4.4.7(vii)), and
- (1b) $[k]+[h_0]$ is in the kernel of $\varphi\colon G(h_0\,;\,D,E)\to G(H_0\,;\,D,E)$. (Because $([k]+[h_0])+[H_0]=[k]+([h_0]+[H_0])=[k]+[H_0]$ by Lemma 4.4.7(iv).)
- (2) $[k+\beta h_0]+[H_0]=[H_0]$. (Because $[k+\beta h_0]=[k]+[\beta h_0]$ for $k\in\operatorname{Hom}(D,E)$ with $k(D)\subseteq J$ and $[\beta h_0]+[H_0]=[H_0]$ by Lemma 4.4.7(i, iv).)

Conversely properties (1a) and (1b) or properties (1a) and (2) imply for $k\in\operatorname{Hom}(D,E)$ that $k\in\mathcal{A}$.

Indeed: (1a) implies $k(D)=T^*h_0(D)T\in J$ for some isometry $T\in E$ and $\varphi([k]+[h_0])=[H_0]$ says by definition of φ that $([k]+[h_0])+[H_0]=[H_0]$, i.e., that $[k]+[H_0]=[k]+([h_0]+[H_0])=([k]+[h_0])+[H_0]=[H_0]$ by Lemma 4.4.7(iv).

Thus, the set of unitary equivalence classes $[k]\in[\operatorname{Hom}(D,E)]$ of the elements $k\in\mathcal{A}$ is identical with the set of elements $[k]$ in the semi-group $S(h_0\,;\,D,E)$ that satisfy $\varphi([k]+[h_0])=[H_0]$.

The set $\mathcal{A}$ contains h_0 by Lemma 4.4.7(iv). If $k\in\mathcal{A}$ and $[h]=[k]$ then $h\in\mathcal{A}$ (here $[\cdot]$ denotes the unitary equivalence classes of elements of $\operatorname{Hom}(D,E)$). If $k_1,k_2\in\mathcal{A}$ then $k_1\oplus k_2\in\mathcal{A}$.

This is because [??????] =?.

Let $k \in \mathrm{Hom}(D,J) \subset \mathrm{Hom}(D,E)$, then

$$[k] + [H_0] = [H_0] \quad \Leftrightarrow \quad [k + \beta h_0] + [H_0] = [H_0]\,,$$

because, by Lemma 4.4.7(iv,i,iii),

$$[k + \beta h_0] + [H_0] = [k + \beta h_0] + [0] + [H_0] = [k] + [\beta h_0] + [H_0] = [k] + [H_0]\,.$$

Thus, if we take s_0 and t_0 as in assumption (iv) of Theorem 4.4.6, then $[H_0] = [k] + [H_0]$ becomes equivalent to $[H_0] = [(k + \beta h_0) \oplus_{s_0,t_0} H_0]$, i.e., is equivalent to the existence $u \in \mathcal{U}(E)$ that satisfies following *equation*:

$$s_0(k(\cdot) + \beta h_0(\cdot))s_0^* + (1 - p_0)H_0(\cdot) = (k + \beta h_0) \oplus_{s_0,t_0} H_0 = u^* H_0(\cdot)u\,. \tag{4.20}$$

The equation shows that $u \in \mathrm{Der}(H_0(D), J)$ and that the unitary u is determined by k in the right side of the equation up to multiplications Vu by unitaries $V \in \mathcal{U}(C)$.

We can also use the isometries s_2, t_2 of Lemma 4.4.7(x) and get directly $v \in \mathcal{U}(E)$ with

$$k \oplus_{s_2,t_2} H_0 = v^* H_0(\cdot)v \tag{4.21}$$

This unitary v is again in $\mathrm{Der}(H_0(D), J)$ and is determined by the left side, i.e., by k, only up to multiplications Uv with $U \in \mathcal{U}(C)$.

By Lemma 4.4.10 there exists a unitary $W \in \mathcal{U}_0(\mathrm{Der}(H_0(D), J)) \cap (p_0Ep_0 + (1 - p_0))$ with $((k + \beta h_0) \oplus_{s_0,t_0} H_0)W = W(k \oplus_{s_2,t_2} H_0)$.

It follows that $W^*u^*H_0(\cdot)uW = v^*H_0(\cdot)v$, i.e., $\mathcal{U}(C)uW = \mathcal{U}(C)v$. In particular, $\mu(\mathrm{K}_1(C)) + [u] = \mu(\mathrm{K}_1(C)) + [v]$ in $\mathrm{K}_1(\mathrm{Der}(H_0(D), J))$, because $[W] = 0$ in $\mathrm{K}_1\big(\mathrm{Der}(H_0(D), J)\big)$.

Recall here, that we have defined $\mu\colon \mathrm{K}_1(C) \to \mathrm{K}_1\big(\mathrm{Der}(H_0(D), J)\big)$ by the natural *-monomorphism $C \hookrightarrow \mathrm{Der}(H_0(D), J)$.

The above considerations show that the class of the unitaries u and v in Equations (4.20) and (4.21) define for $k \in \mathcal{A}$ the same class

$$\gamma_0(k) := [u] + \mu(\mathrm{K}_1(C)) = [v] + \mu(\mathrm{K}_1(C)) \tag{4.22}$$

in $\mathrm{K}_1(\mathrm{Der}(H_0(D), J))/\mu(\mathrm{K}_1(C))$.

We get that that $\gamma_0(h_0) = \mu(\mathrm{K}_1(C))$, because $s_0(h_0 + \beta h_0)s_0^* = p_0 H_0$ and $t_0 H_0 t_0^* = (1 - p_0)H_0$ by Assumptions (iii) and (iv) of Theorem 4.4.6.

If we use the definition of the unitary v in Equation (4.21) then we obtain that $\gamma_0(k) = \gamma_0(U^*kU)$ for all unitaries $U \in E$:
Indeed, the property $k(D) \subseteq J$ implies that there exists a unitary $V \in \mathcal{U}_0(E)$ with $U^*k(\cdot)U = V^*k(\cdot)V$, cf. Lemma **??**(????).

Let $v \in \mathcal{U}(\mathrm{Der}(H_0(D), J)$ as in Equation (4.21) and $W := v(V \oplus_{s_2,t_2} 1)$ then

$$(U^*k(\cdot)U) \oplus_{s_2,t_2} H_0 = W^* H_0(\cdot) W\,.$$

It implies that $\mathcal{U}(C)W = \mathcal{U}(C)v(V \oplus_{s_2,t_2} 1)$. The unitary $V \oplus_{s_2,t_2} 1$ is in $s_2\mathcal{U}_0(E)s_2^* + t_2t_2^*$. The group $s_2\mathcal{U}_0(E)s_2^* + t_2t_2^*$ is contained in the connected component of $\mathcal{U}(\mathrm{Ann}(H_0(D), J) + \mathbb{C}1) \subseteq \mathcal{U}(\mathrm{Der}(H_0(D), J))$.

It implies $[W] = [v] \in \mathcal{U}(\mathrm{Der}(H_0(D), J))$ and $\gamma_0(U^*k(\cdot)U) = \gamma_0(k)$, by the defining equation (4.22) of γ_0.

It follows that there is a unique mapping γ from the set $[\mathcal{A}]$ of elements $[k] \in S(h_0\,;\, D, E)$ with the property that $[k] + [h_0]$ is in the kernel of

$$S(h_0\,;\, D, E) \to G(h_0\,;\, D, E) \to G(H_0\,;\, D, E)$$

to $\mathrm{K}_1\big(\mathrm{Der}(H_0(D), J)\big)/\mu\big(\mathrm{K}_1(C)\big)$, such that γ satisfies $\gamma_0(k) = \gamma([k])$ for $k \in \mathcal{A}$ and $\gamma([h_0]) = \mu(\mathrm{K}_1(C))$.

We show now that γ **is additive:**
Let $k_1, k_2 \in \mathcal{A}$ and take $u_1, u_2 \in \mathcal{U}(\mathrm{Der}(H_0(D), J))$ with $k_j \oplus_{s_2,t_2} H_0 = u_j^* H_0 u_j$ for $j \in \{1, 2\}$.

By Lemma 4.4.8, if (s_2, t_2) are the isometries in Lemma 4.4.7(x) and the unitary $v_2 \in C$ is defined by Equation (4.11) given in proof of Lemma 4.4.7(x), then for $a, b, c, d \in E$ holds:

$$v_2^*\big((a \oplus_{s_2,t_2} c) \oplus_{s,t} (b \oplus_{s_2,t_2} d)\big)v_2 = (a \oplus_{s,t} b) \oplus_{s_2,t_2} (c \oplus_{s,t} d)\,.$$

If we let $a := k_1(d)$, $b := k_2(d)$, $c = d := H_0(d)$ then we get for $k_j \oplus_{s_2,t_2} H_0 = u_j^* H_0 u_j$ and the unitary $U := (u_1 \oplus_{s,t} u_2) \cdot v_2$ the equation

$$U^* H_0 U = v_2^*\big((u_1^* H_0 u_1) \oplus_{s,t} (u_2^* H_0 u_2)\big)v_2 = (k_1 \oplus_{s,t} k_2) \oplus_{s_2,t_2} H_0\,.$$

It follows that $\gamma_0(k_1 \oplus_{s,t} k_2) = \mu(\mathrm{K}_1(C)) + [U]$ Since $[U] = [u_1] + [u_2] + [v_2]$ and $v_2 \in C$, it follows that

$$\gamma_0(k_1 \oplus_{s,t} k_2) = \gamma_0(k_1) + \gamma_0(k_2)$$

in $\mathrm{K}_1(\mathrm{Der}(H_0(D)), J)/\mu(\mathrm{K}_1(C)) =: \Gamma\big(H_0(D), J, E\big)$.

Thus, γ_0 is additive with respect to Cuntz addition on $\mathcal{A}$ with $\gamma_0(h_0) = \mu(\mathrm{K}_1(C))$ and defines an additive map γ_1 from the sub-semigroup of those elements $[k]$ of $S(h_0\,;\, D, E)$ with $[k] + [h_0]$ in the kernel of φ.

`NEXT steps:`

Step (next 1):

`TEXT:`

`Let` $k \in \mathcal{A}$ `then` $\gamma_0(k) = \mu(\mathrm{K}_1(C))$
`if and only if` $[k] + [h_0] = [h_0]$:

It shows that $\gamma_1([k]) = \mu(\mathrm{K}_1(C))$ and $k \oplus_{s_2,t_2} H_0 = u^* H_0 u$ if and only if $[u] \in \mu(\mathrm{K}_1(C))$.

Notice that $[\mathcal{A}] + [h_0]$ is a subgroup of $G(h_0\,;\, D, E)$ and is identical with the kernel of φ.

It will be shown below that $k \in \mathcal{A}$ and $\gamma_0(k) = 0$ together imply that $[k]+[h_0] = [h_0]$. It follows that $\gamma_1|[\mathcal{A}] + [h_0]$ "restricted" to the kernel of φ in $G(h_0\,;\, D, E)$ is faithful on the kernel $\varphi^{-1}([H_0])$ of φ.

The neutral element "0" of $\mathrm{K}_1(\mathrm{Der}(H_0(D), J))/\mu(\mathrm{K}_1(C))$ is $\gamma_0(h_0) = \mu(\mathrm{K}_1(C))$ and the invariance under unitary equivalence that $[k] + [h_0] = [h_0]$ implies

$$\gamma_0(k) = \gamma_1([k]) = \mu(\mathrm{K}_1(C)) \,.$$

Suppose that $k \in \mathcal{A}$ and $\gamma_0(k) = \mu(\mathrm{K}_1(C))$. It follows that there exists $v \in \mathcal{U}(C)$ and $w \in \mathcal{U}_0(\mathrm{Der}(H_0(D), J))$ with $(v \oplus s, t1)w = (u \oplus_{s,t} 1)$ (cf. Lemma 4.2.6(v,2)).

Each $w \in \mathcal{U}_0(\mathrm{Der}(H_0(D), J))$ decomposes by Lemma 4.4.15(v) into a product $w = w_1 w_2$ with $w_1 \in \mathcal{U}(C)$ and $w_2 \in \mathcal{U}(\mathbb{C}\cdot 1 + \mathcal{N}(H_0(D), J))$.

`Is it not` $\mathcal{U}(\mathbb{C}1 + \mathcal{N}(H_0(D), J))$ `???`

It follows that $(k \oplus_{s,t} h_0) \oplus_{s_2,t_2} H_0 = w_2^* H_0 w_2$.

This causes by Lemma **??** that $[k \oplus h_0] = [h_0]$ provided that in addition ???????

Step (next 2): γ_1 is surjective:

(a) $\mathrm{Der}(H_0(D), J)$ and C are K_1-surjective.

i.e., For $x \in \mathrm{K}_1(\mathrm{Der}(H_0(D), J))$ exists $u \in \mathcal{U}(\mathrm{Der}(H_0(D), J))$ with $x = [u]$.

compare next with places above!

We define for $k \in \mathcal{A}$ a class $\mathcal{U}(k) = \mathcal{U}(C)u \subset \mathcal{U}(\mathrm{Der}(H_0(D), J))$ of $\mathcal{U}(C)\backslash\mathcal{U}(\mathrm{Der}(H_0(D), J))$ by $u \in \mathcal{U}(k)$ if and only if u satisfies Equation (4.20).

If $k \in \mathcal{A}$, then the set $\mathcal{U}(k) \subseteq \mathcal{U}(\mathrm{Der}(H_0(D), J))$ is an element of the right homogenous space

$$\mathcal{U}(C)\backslash\mathcal{U}(\mathrm{Der}(H_0(D), J))$$

given by right multiplication of elements of $\mathcal{U}(\mathrm{Der}(H_0(D), J))$ by elements of $\mathcal{U}(C) \subseteq \mathcal{U}(\mathrm{Der}(H_0(D), J))$.

Clearly, the unitary u in Equation (**??**) is determined by k only up to multiplications vu with $v \in \mathcal{U}(C)$. We denote this subset of $\mathcal{U}(E)$ by

$$\mathcal{U}(k) := \mathcal{U}(C)u$$

if a C^*-morphism $k\colon D \to J$ satisfies $[k] + [H_0] = [H_0]$. Thus, $\mathcal{U}(k) = \mathcal{U}(C) \cdot \mathcal{U}(k)$.

$\mathcal{U}(k) \subseteq \mathcal{U}(\mathrm{Der}(H(D), J))$:

The elements of $\mathcal{U}(k)$ are contained in $\mathrm{Der}(H(D), J)$, because

$$p_0 H(\cdot) = s_0(h_0 + \beta h_0)s_0^* \,,$$

by assumption 4.4.6(iv), and this together with Equation (**??**) implies

$$H_0(a)u - uH_0(a) = us_0(k(a) - h_0(a))s_0^* \in J \quad \text{for all } \ a \in D \,.$$

Thus $u \in \mathrm{Der}(H_0(D), J)$. Since $C \subseteq \mathrm{Der}(H_0(D), J)$ it follows that

$$\mathcal{U}(C)u =: \mathcal{U}(k) \subseteq \mathcal{U}(\mathrm{Der}(H_0(D), J))$$

The class

$$\mathcal{U}(k) \in \mathcal{U}(C) \setminus \mathcal{U}(\mathrm{Der}(H_0(D), J))$$

defines a class

$$\gamma_0(k) := [u] + \mu(\mathrm{K}_0(C)) \in \Gamma := \Gamma(H_0(D), J, E) := \mathrm{K}_0(\mathrm{Der}(H_0(D), J))/\mu(\mathrm{K}_0(C))\,.$$

`Next steps:`

(next 1)

$\gamma_0(k_1) = \gamma_0(k_2)$ if $[k_1] = [k_2]$, i.e., $\gamma_0(k)$ is invariant under unitary equivalence.

Let $w \in \mathcal{U}(E)$ with $w^* k_2(\cdot) w = k_1$.

If $[k_1] = [k_2]$ then there exists by Lemma 4.4.7(viii) a unitary $w \in \mathcal{U}_0(\beta h_0(D)' \cap E)$ such $k_1 + \beta h_0 = w^*(k_2 + \beta h_0) w$.

Let $\xi \in [0,1] \mapsto w(\xi) \in \mathcal{U}(\beta h_0(D)' \cap E)$ a continuous path with $w(0) = 1$ and $w(1) = w$. The continuous path

$$v(\xi) := s_0 w(\xi) s_0^* + t_0 t_0^* \in \mathcal{U}(E)$$

satisfies $v(\xi) = 1$ and for $d \in D$ that

$$v(\xi) H_0(d) - H_0(d) v(\xi) = s_0(w(\xi) h_0(d) - h_0(d) w(\xi)) s_0^* \in J\,,$$

i.e., $v(\xi) \in \mathrm{Der}(H_0(D), J)$. It follows that $v(1) \in \mathcal{U}_0(\mathrm{Der}(H_0(D), J))$. Thus, $[v(1)] = 0$ in $\mathrm{K}_1(\mathrm{Der}(H_0(D), J))$ and

$$\gamma_0(k_2) = \gamma_0(k_1) + (\mu(\mathrm{K}_1(C)) + [v(1)]) = \gamma_0(k_1)\,.$$

Notice that $w \in \mathcal{U}_0(E)$ also implies that $v \in \mathcal{U}_0\big(\mathcal{N}(H_0(D), J + \beta J) + \mathbb{C} \cdot 1\big)$.

An *alternative proof* of the equivalence of γ_0 with respect to unitary equivalence can be given directly by Lemma 4.4.7(i):

The equality $[k_1] = [k_2]$ yields by ???????????

Consequence of the invariance:

We can define

$$\gamma_1([k]) := \gamma_0(k)$$

for a representative $k \in \mathrm{Hom}(D, J)$ of the class $[k] \in S(h_0\,;\, D, E)$.

(next 2)

$\gamma_1([k_1] + [k_2]) = \gamma_1([k_1]) + \gamma_1([k_2])$, i.e., the mapping

$\gamma_1 \colon S(h_0\,;\, D, E) \to \Gamma := \Gamma(H_0(D), J, E) := \mathrm{K}_1(\mathrm{Der}(H_0(D), J))/\mu(\mathrm{K}_1(C))$

is an additive map from the semi-group $S(h_0\,;\, D, E)$ into the group Γ.

Use Lemma 4.4.8 and that $s = \beta(s), t = \beta(t) \in (h_0(D) \cup H_0(D))' \cap E$ by assumptions of Theorem 4.4.6, both cases of definitions with $\oplus_{s_0,t_0}$ or with $\oplus_{s_2,t_2}$.

(next 3)

$\mathcal{U}(h_0) = \mathcal{U}(C)$, i.e., $\gamma_1([h_0]) = \gamma_0(h_0) = 0$.

In particular, $\gamma_1([k]+[h_0]) = \gamma_1([k])$ for all $k\colon D\to J$ with $[k]+[H_0]=[H_0]$.

Thus, $\gamma([k]) := \gamma_1([k])$ defines a group homomorphism from the kernel $\varphi^{-1}([H_0]) \subseteq G(h_0\,;D,E)$ of $\varphi\colon G(h_0\,;D,E) \to G(H_0\,;D,E)$ into $\Gamma := \Gamma(H_0(D),J,E)$.

(next 4)

The homomorphism γ is surjective:

For every $x\in \mathrm{K}_1(\mathrm{Der}(H_0(D),J))$ there exists $u\in \mathcal{U}(\mathrm{Der}(H_0(D),J))$ with $[u]=x$, because $C\subseteq \mathrm{Der}(H_0(D),J)$ is properly infinite and this implies that $\mathrm{Der}(H_0(D),J)$ (respectively C) is K_1-surjective by Lemma 4.2.6(v).

It suffices to find $k\colon D\to J$, $v\in\mathcal{U}(C)$ and $w\in\mathcal{U}_0(\mathrm{Der}(H_0(D),J))$ with

$$(k+\beta h_0)\oplus_{s_0,t_0} H_0 = w^*v^*u^*H_0(\cdot)uvw\,.$$

Give Ref's for next blue!!

In fact, there exists $v\in\mathcal{U}_0(F+\mathbb{C}\cdot 1)\cap(1+F)$ such that $uv\in\mathcal{U}(k)$ for some C^*-morphism $k\colon D\to J$ with $[k]+[H_0]=[H_0]$.

Thus, $[uv]=[u]+[v]=[u]$ in $\mathrm{K}_1(\mathrm{Der}(H_0(D),J))$, and $\gamma([k]+[h_0]) = \mu(\mathrm{K}_1(C))+[u]$ in Γ. It shows that γ is surjective.

(next 5)

If $k\colon D\to J$ is a C^*-morphism, $y\in\mathcal{N}(J+\beta J)$, $1+y\in\mathcal{U}(E)$ and

$$s_0(k+\beta h_0)s_0^* + (1-p_0)H_0(\cdot) = (1+y^*)H_0(\cdot)(1+y)\,,$$

then $[k]+[h_0]=[h_0]$:

Indeed, by Lemma 4.4.9 there exists a projection $p\in F$ with $p\geq p_0$, $p\neq p_0$ and

$$(1+y^*)(1-p)H_0(\cdot)(1+y) = (1-p)H_0(\cdot)\,,$$

because it implies that

$$(1+y^*)pH_0(\cdot)(1+y) = s_0(k+\beta h_0)s_0^* + (p-p_0)H_0(\cdot)\,.$$

By Part (xii) of Lemma 4.4.7, there exists a unitary $V\in C$ and $u_2\in\mathcal{U}_0(E)$ with $up_0=p_0=p_0u$ and

$$V^*(p-p_0)H_0(\cdot)V = t_0u_2^*(h_0+\beta h_0)u_2t_0^*\,.$$

It follows for $W:=V(p_0+t_0u_2^*t_0^*)$ that

$$(k+\beta h_0)\oplus_{s_0,t_0}(h_0+\beta h_0) = W^*(1+y^*)pH_0(\cdot)(1+y)W\,.$$

By part (ix) of Lemma 4.4.7 there exists a unitary $u_3\in\mathcal{U}_0(F+\mathbb{C}\cdot 1)\subset C$ with $u_3^*pu_3=p_0=s_0s_0^*$ and, by assumption (iv) of Theorem 4.4.6, $p_0H_0(\cdot)=s_0(h_0+\beta h_0)s_0^*$. We obtain with the unitary $U:=u_3(1+y)W\in\mathcal{U}(E)$ that

$$(k+\beta h_0)\oplus_{s_0,t_0}(h_0+\beta h_0) = U^*\big((h_0+\beta h_0)\oplus_{s_0,t_0}0\big)U\,.$$

If we use now that $J\cap\beta J=0$ and $h_0(D)\cup k(D)\subset J$ then we get

$$k \oplus_{s_0,t_0} h_0 = U^*\big((h_0 \oplus_{s_0,t_0} 0)\big)U\,,$$

which is up to multiplication of U by unitaries in $(s_0 h_0(D) s_0^*)' \cap E$ equivalent to $[k] + [h_0] = [h_0] + [0]$. But we know from Part (ii) of Lemma 4.4.7 that $[h_0] = [h_0] + [0]$.

(next 6)

The kernel of γ is $\{[h_0]\}$:

If $\gamma([k]) = \mu(\mathrm{K}_1(C))$, and $u \in \mathcal{U}(k) \subseteq \mathrm{Der}(H_0(D), J)$, then there exist $V \in \mathcal{U}(C)$ and $W \in \mathcal{U}_0(\mathrm{Der}(H_0(D), J))$ such that $u \oplus_{S,T} 1 = VW$.

`Definition of` S, T `??`

It follows that

$$((k \oplus_{s,t} h_0) + \beta h_0) \oplus_{s_0,t_0} H_0 = (u \oplus_{S,T} 1)^* H_0(\cdot)(u \oplus_{S,T} 1) = W^* H_0(\cdot) W\,.$$

By Lemma 4.4.15(iv ????) ????, $W = V_1 W_1$ with $V_1 \in C$ and $W_1 = y + 1 \in \mathcal{U}(\mathcal{N}(H_0(D), J) + \mathbb{C}\cdot 1)$ with $y \in \mathcal{N}(H_0(D), J)$. Thus, for $W_1 := y + 1$,

$$s_0((k \oplus_{s,t} h_0) + \beta h_0) s_0^* + (1 - p_0) H_0(\cdot) = W_1^* H_0(\cdot) W_1\,.$$

Since

$$C = H_0(D)' \cap E = \mathrm{Der}(H_0(D), \{0\}) \subseteq \mathrm{Der}(H_0(D), J)\,,$$

we can define for $k \in \mathrm{Hom}(D, J)$ with $[k] \in S(h_0\,; D, E)$ in the kernel of φ an element $\mathcal{U}(k)$ of the (right-sided) homogenous space $\mathcal{U}(C)\backslash\mathcal{U}(\mathrm{Der}(H_0(D), J))$ by

$$\mathcal{U}(k) := \{vu\,;\ v \in \mathcal{U}(C)\,\}$$

where is u some unitary satisfying Equation (**??**).

Obvious examples are $\mathcal{U}(h_0) = \mathcal{U}(C)$ and $\mathcal{U}(0) = \mathcal{U}(C)u_\aleph$, where $u_\aleph := s_1 s_0^* + t_1 t_0^*$ with the isometries s_1, t_1 of Lemma 4.4.7(vi).

If $[k] = [k']$, then $[k + \beta h_0] = [k' + \beta h_0]$ by Lemma 4.4.7(viii), and the unitary equivalence can be realized by a unitary $w \in \mathcal{U}_0(E)$ with $w^*(k + \beta h_0)w = k' + \beta h_0$.

It implies that

$$\mathcal{U}(k') = \mathcal{U}(k) \cdot (w \oplus_{s_0,t_0} 1)\,.$$

Notice that $w \oplus_{s_0,t_0} 1$ is a unitary in $1 + \mathcal{N}(H_0(D), J)$ and is in $\mathcal{U}_0(\mathcal{N}(H_0(D), J) + \mathbb{C}\cdot 1)$. In particular, $\mathcal{U}(k)$ and $\mathcal{U}(k')$ are contained in the same two-sided class of

$$\mathcal{U}(C)\backslash\mathcal{U}(\mathrm{Der}(H_0(D), J))/\mathcal{U}_0(\mathcal{N}(H_0(D), J) + \mathbb{C}\cdot 1)\,.$$

It follows that $\mathcal{U}(k) \subseteq \mathcal{U}(C)\cdot\mathcal{U}(\mathcal{N}(H_0(D), J))$ if $[k] = [h_0]$.

The isometries s_1, t_1 of Lemma 4.4.7(vi) satisfy $p_0 t_1 = t_1 p_0 = p_0$, $t_1 \in C$, $H_0(\cdot)s_1 = 0$, $s_1^* H_0(\cdot) = 0$, $H_0(\cdot)t_1 = H_0$, and $t_1^* H_0(\cdot) = H_0$. It yields $t_1 a t_1^* = a$ for all $a \in s_0 E s_0^*$, and $t_1(1 - p_0)H_0(\cdot)t_1^* = (1 - p_0)H_0(\cdot)$.

Let $u \in \mathcal{U}(E)$, then

$$u_1 := u^* \oplus_{s_1,t_1} u := s_1 u^* s_1^* + t_1 u t_1^* \tag{4.23}$$

has the properties

$$u_1^* H_0(\cdot) u_1 = t_1 u^* H_0(\cdot) u t_1^* \qquad \text{and} \quad u_1 \in \mathcal{U}_0(E)\,.$$

The above equations together imply for $u \in \mathcal{U}(k) \subseteq \mathcal{U}(E)$ in Equation (**??**), that the unitary $u_1 \in \mathcal{U}_0(E)$ defined by (4.23) again satisfies Equation (**??**):

$$(k + \beta h_0) \oplus_{s_0,t_0} H_0 = u_1^* H_0(\cdot) u_1\,.$$

It follows that $u_1 \in \mathcal{U}(k) \cap \mathcal{U}_0(E) \neq \emptyset$ if $[k] \in S(h_0\,;\, D, E)$ and $[k] + [H_0] = [H_0]$.

We seek for an estimate of the set $\mathcal{U}(k_1 \oplus_{s,t} k_2) \subseteq \mathcal{U}(\mathrm{Der}(H_0(D), J))$ for $k_j \colon D \to E$ with $[k_j] \in S(h_0\,;\, D, E)$ and $[k_j] + [H_0] = [H_0]$, $j = 1, 2$.

New generators S, T of $\mathcal{O}_2$ come from the generators (s, t) and (s_0, t_0) in Theorem 4.4.6(i,iv) by

$$S := s_0 s s_0^* + t_0 s t_0^* \quad \text{and} \quad T := s_0 t s_0^* + t_0 t t_0^* \tag{4.24}$$

Then $S, T \in C$: use $\beta(s) = s$, $\beta(t) = t$, $s, t \in h_0(D)' \cap H_0(D)' \cap E$,

$SH_0 = S s_0 (h_0 + \beta h_0) s_0^* + S t_0 H_0 t_0^* = s_0 (s h_0 + s \beta h_0) s_0^* + t_0 s H_0 t_0^* = s_0 (h_0 s + (\beta h_0) s) s_0^* + t_0 H_0 s t_0^* = H_0 S$. Similarly, $TH_0 = H_0 T$.

Since $S s_0 = s_0 s$, $T s_0 = s_0 t$, $S p_0 = p_0 S$, $T p_0 = p_0 T$ and

$$(\beta h_0) \oplus_{s,t} (\beta h_0) = \beta(h_0 \oplus_{s,t} h_0) = \beta h_0\,,$$

we get for $k_1, k_2 \colon D \to J$ that

$$\big((k_1 + \beta h_0) \oplus_{s_0,t_0} H_0\big) \oplus_{S,T} \big((k_2 + \beta h_0) \oplus_{s_0,t_0} H_0\big) \;=\; \big((k_1 \oplus_{s,t} k_2) + \beta h_0\big) \oplus_{s_0,t_0} H_0\,.$$

If $k_1, k_2 \in S(h_0\,;\, D, E)$ with $[k] + [H_0] = [H_0]$ and $[k'] + [H_0] = [H_0]$, then for $k_3 := k_1 \oplus_{s,t} k_2$ holds $[k_3] = [k_1] + [k_2]$ and $[k_3] + [H_0] = [H_0]$.

The class $\mathcal{U}(k_3)$ is given by

$$\mathcal{U}(k_1 \oplus_{s,t} k_2) = \mathcal{U}(C) \cdot (\mathcal{U}(k_1) \oplus_{S,T} \mathcal{U}(k_2))\,,$$

because, for $u_1 \in \mathcal{U}(k_1)$ and $u_2 \in \mathcal{U}(k_2)$

$$\big(k_1 \oplus_{s,t} k_2) + \beta h_0\big) \oplus_{s_0,t_0} H_0 = (u_1 \oplus_{S,T} u_2)^* H_0(\cdot)(u_1 \oplus_{S,T} u_2)\,.$$

It follows that

$$\mathcal{U}(k \oplus_{s,t} h_0) = \mathcal{U}(C) \cdot (\mathcal{U}(k) \oplus_{S,T} 1)\,,$$

and, if $[k] + [h_0] = [k'] + [h_0]$, that there is a unitary $u_0 \in \mathcal{U}_0(E)$ with

$$u_0^*(k \oplus_{s,t} h_0) + \beta h_0) u_0 = k' \oplus_{s,t} h_0) + \beta h_0,$$

i.e., then

$$\mathcal{U}(k' \oplus_{s,t} h_0) = \mathcal{U}(C) \cdot (\mathcal{U}(k) \oplus_{S,T} 1) \cdot (u_0 \oplus_{s_0,t_0} 1)\,.$$

Since

$$u_0 \oplus_{s_0,t_0} 1 \in \mathcal{U}_0(E) \oplus_{s_0,t_0} 1 \subseteq \mathcal{U}_0(\mathcal{N}(H_0(D), J) + \mathbb{C} \cdot 1)\,,$$

this implies in particular

$$\mathcal{U}(k' \oplus_{s,t} h_0) \subseteq \mathcal{U}(C) \cdot (\mathcal{U}(k) \oplus_{S,T} 1) \cdot \mathcal{U}_0(\mathcal{N}(H_0(D), J) + \mathbb{C} \cdot 1)\,.$$

We show below that the weaker condition

$$\mathcal{U}(k') \subseteq \mathcal{U}(C) \cdot (\mathcal{U}(k) \oplus_{S,T} 1) \cdot \mathcal{U}_0(\mathcal{N}(H_0(D), J + \beta J) + \mathbb{C} \cdot 1)\,,$$

implies conversely that

$$[k] + [h_0] = [k'] + [h_0]\,.$$

It follows the equivalence of

$$[k] + [h_0] = [h_0] = [h_0] + [h_0]$$

and

$$\mathcal{U}(k) \subseteq \mathcal{U}(C) \cdot \mathcal{U}_0(\mathcal{N}(H_0(D), J + \beta J) + \mathbb{C} \cdot 1)\,.$$

If we let ????????, then we can find a unitary $u \in E$ that satisfies Equation (**??**) with the additional condition

$$1 \oplus_{S,T} u \in \mathcal{U}_0(E)\,.$$

`Next also mentioned above ?`

Let $(k + \beta h_0) \oplus_{s_0,t_0} H_0 = u^* H_0(\cdot) u$. Since $p_0 H_0(\cdot) = s_0(h_0(\cdot) + \beta h_0(\cdot)) s_0^*$ by assumption (iv) of Theorem 4.4.6, we get that

$$u^* H_0(a) u - H_0(a) = s_0(k(a) - h_0(a)) s_0^* \in J \quad \text{for all} \quad a \in D\,.$$

It follows that $u \in \mathcal{U}(\mathrm{Der}(H_0(D), J))$, $u(1-p_0) \in C$ and $up_0u^* H_0(D) \subseteq J + \beta J$.

Since $1 - up_0u^* = u(1-p_0)^2 u^* \in C$, the map

$$a \in D \mapsto up_0u^* H_0(a)$$

is a C^*-morphism from D into $J + \beta(J)$, because $p_0 u^* H_0(a) u - p_0 H_0(a) \in J$ and $p_0 H_0(a) \in J + \beta(J)$ for all $a \in D$.

Let $(k + \beta h_0) \oplus_{s_0,t_0} H_0 = u^* H_0(\cdot) u$. It implies $u \in \mathrm{Der}(H_0(D), J)$.

We get (see above)

$$((k \oplus_{s,t} h_0)?????\beta h_0) \oplus_{s_0,t_0} H_0 = U^* H_0(\cdot) U$$

with $U := u \oplus_{S,T} 1$.

Suppose now more generally that $u \in \mathrm{Der}(H_0(D), J + \beta J)$ is given with the additional property and $u \oplus_{s,t} 1 = wv$ with unitaries $w \in C$ and $v = 1 + x$ with $x \in \mathcal{N}(H_0(D), J + \beta J)$.

Let $W := sS^* + tT^*$. Since $s, t, S, T \in C$ it follows that $W \in C$ and $u \oplus_{S,T} 1 = W^*(u \oplus_{s,t} 1) W$.

We get $u \oplus_{S,T} 1 = W^* w W \cdot W^* v W$, and $W^* v W = 1 + y$ with $W^* w W \in C$ and $y = W^* x W \in \mathcal{N}(H_0(D), J + \beta J)$.

Thus, $U^* H_0(a) U = (1 + y^*) H_0(a) (1 + y)$. Since $H_0(D) y \subseteq J + \beta J$ and D is separable, there is a separable C^*-subalgebra $B \subseteq J + \beta J$ that contains $H_0(D) y$. Let $f \in B_+$ is a strictly positive contraction B. By assumptions (iii), (iv) and (v) of

Theorem 4.4.6 there exists a projection $q \in F \subseteq C$ with $qf = f$, $q \geq p_0$ and $q \neq p_0$. It follows that $qH_0(a)y = H_0(a)y = H_0(a)yq$. Thus $qH_0(a)(1+y) = H_0(a)(1+y)q$ and $qU^*H_0(a)U = (W^*vW)^*qH_0(a)W^*vW$.

Since $q = p_0 + r$ with $r = q - p_0 = q(1-p_0) \leq t_0t_0^*$, $r \in E$, it follows for

???????

that

$$s_0((k \oplus_{s,t} h_0) + \beta h_0)s_0^* + rH_0(\cdot) = (W^*vW)^*qH_0(a)W^*vW\,.$$

There are unitaries $u_1, u_2 \in 1 + F$ such that $u_1ru_1^* = p_0$ and $u_2qu_2^* = p_0$. We get $rH_0(\cdot) = u_1^*p_0H_0(\cdot)u_1$ and $qH_0(\cdot) = u_2^*p_0H_0(\cdot)u_2$. Since $p_0H_0(\cdot) = s_0(h_0+\beta h_0)s_0^* = (h_0 + \beta h_0) \oplus_{s_0,t_0} 0$ and $J \cdot \beta J = 0 = J \cap \beta J$, we obtain for the summands with values in J that

$$s_0(k \oplus_{s,t} h_0)s_0^* + u_1^*s_0h_0(\cdot)s_0^*u_1 = (W^*vW)^*u_2^*s_0h_0(a)s_0^*u_2W^*vW\,,$$

with $p_0u_1^*s_0 = 0$. Can define $V_1 \in \mathcal{U}(E)$ such that

$$t_1V_1^*s_0h_0(\cdot)s_0^*V_1t_1^* = u_1^*s_0h_0(\cdot)s_0^*u_1 = rH_0(\cdot)$$

It follows that

$$[k \oplus_{s,t} h_0] + [h_0] + [0] = [h_0] + [0]\ .$$

`From` $u \in \mathcal{U}(\mathrm{Der}(H_0(D), J))$ `to` (k, uw):

Recall that $F \subseteq C \cap \mathcal{N}(H_0(D), J)$ in the following calculations.

SURJECTIVITY:

Let $u \in \mathcal{U}(\mathrm{Der}(H_0(D), J))$, then there exists an element $g \in F$ and a C^*-morphism $k\colon D \to J$ with $[k] \in S(h_0\,;\, D, E)$, such that $w := 1 + g \in \mathcal{U}_0(F + \mathbb{C}\cdot 1)$ and

$$(uw)^*H_0(\cdot)uw = (k + \beta h_0) \oplus_{s_0,t_0} H_0\,.$$

Indeed: Let $\partial_u(x) := ux - xu$ for $x \in E$. Then $u^*\partial_u(H_0(D)) \subseteq J$. and generates a separable C^*-subalgebra B of J. Let $b_0 \in B_+$ a strictly positive contraction of B and $f := b_0 + \beta(b_0)$. By assumptions 4.4.6(iii,iv,v) there are projections $p, q \in F$ with $p_0 \leq q \leq p$ with $qf = f$, $p_0 \neq q$, $q \neq p$. By Lemma 4.4.7(ix) there exists $w \in \mathcal{U}_0(F + \mathbb{C}1)$ such that $q = wp_0w^*$. Since $w \in \mathcal{U}_0(C) \subseteq \mathrm{Der}(H_0(D), J)$, we get $uw \in \mathrm{Der}(H_0(D), J)$ and $[uw] = [u] \in \mathrm{K}_1(\mathrm{Der}(H_0(D), J))$.

Then $(1-q)u^*H_0(a)u = (1-q)H_0(a)$ and $w \in \mathcal{U}_0(C)$. Thus $(1-p_0)(uw)^*H_0(a)(uw) = (1-p_0)H_0(a)$ and

$$h(a) := s_0^*p_0(uw)^*H_0(a)(uw)s_0$$

is a C^*-morphism. Since uws_0 is an isometry we get $[h] \in S(H_0\,;\, D, E)$. The C^*-morphism h satisfies

$$h \oplus_{s_0,t_0} H_0 = (uw)^*H_0(\cdot)(uw)\,,$$

and $h(a)-s_0^*H_0(a)s_0 \in J$ for $a \in D$. Since $s_0^*H_0(a)s_0 = h_0(a)+\beta h_0(a)$ by Theorem 4.4.6(iv), $h = k + \beta h_0$ with $[k] \in S(H_0\,;\, D, E)$ and $k(D) \subseteq J$, and by Lemma 4.4.7(vii) that $[k] \in S(h_0\,;\, D, E)$, $uw \in \mathcal{U}(k)$, and $[uw] = [u] \in \mathrm{K}_1(\mathrm{Der}(H_0(D), J))$. In particular,

$$(k + \beta h_0) \oplus_{s_0,t_0} H_0 = (uw)^* H_0(\cdot)(uw)\,.$$

`Where is next needed??`

The C^*-morphism $h'\colon a \in D \mapsto h'(a) := upu^*H_0(a) = us_0h(\cdot)s_0^*u^*$ maps D into J, therefore it satisfies $[h'] = [h] + [0] = [h]$, $[h'] = [k + \beta h_0]$ and $h' \oplus_{s_0,t_0} H_0 = u_1^* H_0(\cdot)u_1$ for some unitary $u_1 \in \mathrm{Der}(H_0(D), J + \beta(J))$ such that $u_1 := v_1uw_1$ for some $v_1 \in C$ and $w_1 \in \mathcal{N}(H_0(D), J + \beta(J))$.

`Next: From (DC) to (wDC)?`

We consider now the special case, where $u \in \mathcal{U}_0(E)$ and $k \in S(h_0; D, E)$ satisfy

$$(k + \beta h_0) \oplus_{s_0,t_0} H_0 = u^* H_0(\cdot)u\,,$$

and suppose in addition that $u \in \mathcal{U}(C) \cdot \mathcal{U}(\mathcal{N}(H_0(D), J + \beta J))$.

Let B_0 the separable C^*-algebra of J that is generated by $k(D) \cup h_0(D)$, $g \in B_0$ a strictly positive contraction of B_0. By assumption (iii) of Theorem 4.4.6 there exists $q_1 \in F$, $q_1 \geq p_0$ with $q_1(g + \beta g) = g + \beta g$ and $q_1 \neq p_0$.

Above we have seen that $(k + \beta h_0) \oplus_{s_0,t_0} H_0 = u^* H_0(\cdot)u\,.$ implies $u \in \mathrm{Der}(H_0(D), J)$.

We suppose now that a given $u \in \mathcal{U}(\mathrm{Der}(H_0(D), J))$ satisfies the assumption of the decomposition condition (DC), i.e., that there is $v \in C$ such that $w := v(u \oplus_{s,t} 1) \in 1 + \mathcal{N}(H_0(D), J + \beta(J))$.

This implies $(u \oplus_{s,t} 1) \in \mathcal{U}(C) \cdot \mathcal{U}(\mathcal{N}(H_0(D), J + \beta J))$.

We show that the latter implies that $[k] + [h_0] = [h_0]$:

`Recall:`

(DC) If $u \in \mathcal{U}_0(E)$ satisfies $uH_0(a) - H_0(a)u \in J$ for all $a \in D$, then there exists a unitary $v \in C := H_0(D)' \cap E$ such that

$$v(u \oplus_{s,t} 1) \in \mathcal{N}(H_0(D), J + \beta(J)) + \mathbb{C} \cdot 1\,.$$

THIS IMPLIES:

If $u \in \mathcal{U}_0(E)$ and $u \in \mathrm{Der}(H_0(D), J)$ then

$[u] = [u \oplus 1] = [w] - [v]$ with $v \in \mathcal{U}(C)$ and $w \in \mathcal{U}(\mathcal{N}(H_0(D), J))$.

Thus, the kernel of $\mathrm{K}_1(\mathrm{Der}(H_0(D), J)) \to \mathrm{K}_1(E)$ is contained in $\gamma(\mathrm{K}_1(C))$.

We know that $\mathrm{K}_1(C) \to \mathrm{K}_1(E)$ is surjective, cf. . ?????????, because H_0 dominates (absorbs) zero.

Let $q_1 \geq p_0$ as above. Then $w = 1 + y$ for some $y \in \mathcal{N}(H_0(D), J + \beta(J))$. There is a separable C^*-algebra $B \subseteq J$ such that $B + \beta(B)$ contains $H_0(D)y \cup yH_0(D)$. If

$b_0 \in B_+$ is a strictly positive contraction for B, then there exists a projection $q_2 \in F \subseteq C$ with $q_2 \geq q_1$, $q_2 \neq q_1$ and $q_2(b_0 + \beta(b_0)) = b_0 + \beta(b_0)$ by Theorem 4.4.6(iii). It follows $q_2 H_0(a) y = H_0(a) y = H_0(a) y q_2$, $q_2 H_0(a) w = H_0(a) q_2 + q_2 H_0(a) y = H_0(a) w q_2$ and $q_2 w H_0(a) = w H_0(a) q_2$ in the same way. Moreover $q_2 - q_1 \in F$ is a non-zero projection and there is a unitary $z_3 \in (1 + F) \cap \mathcal{U}_0(F + \mathbb{C} \cdot 1)$ with $z_3^*(q_2 - q_1) z_3 = p_0$.

Let $z_1, z_2 \in 1 + F$ unitaries with $z_1^* q_1 z_1 = p_0$ and $z_2^* q_2 z_2 = p_0$, cf. assumption (v) of Theorem 4.4.6.

We get:

??? Then $p_0 H_0(\cdot) z^* w z = H_0(\cdot) z^* w z p_0$.

`New approach:`

The crucial points are:

$$q_2 u^* H_0 u = q_2 w^* H_0 w = w^* q_2 H_0(\cdot) w$$

and

$$q_2((k + \beta h_0) \oplus_{s_0, t_0} H_0) = s_0(k + \beta h_0) s_0^* + (q_2 - p_0) H_0$$

and that $q_2 H_0$ and $(q_2 - p_0) H_0$ are unitarily equivalent to $p_0 H_0 = s_0(h_0 + \beta h_0) s_0^*$ by unitaries $v_1, v_2 \in C$: Say $q_2 H_0 = v_1^* p_0 H v_1$ and $(q_2 - p_0) H_0 = v_2^* p_0 H v_2$.

Since h_0 dominates zero, we get that $[q_2 u^* H_0 u] = [h_0 + \beta h_0]$. Let

$$h_1(a) := t_0^*(q_2 - p_0) H_0(a) t_0 = t_0^* v_1 p_0 H_0(a) v_1^* t_0 \,.$$

Then $t_0 h_1(a) t_0^* = (q_2 - p_0) H_0(a)$. Thus $[k + \beta h_0] + [h_1] = [h_0 + \beta h_0]$.

We show that h_1 dominates zero:

By Theorem 4.4.6(iii) – with $f := 0$ – there is a projection $q_3 \in F$ with $q_2 \leq q_3$ and $0 \neq q_4 = q_3 - q_2 \leq 1 - p_0 = t_0 t_0^*$. It follows that the projection $q_5 := t_0^* q_4 t_0$ is Murray–von-Neumann equivalent to $q_4 = t_0 q_5 t_0^*$ and satisfies $h_1(\cdot) q_5 = 0$. The assumption (v) of Theorem 4.4.6 allows to find a unitary $u_4 \in 1 + F \subseteq C$ with $u^* q_4 u = q_0 = s_0 s_0^*$. The element $T := s_0^* u^* t_0 q_5 \in E$ satisfies $T^* T = 1$ and $T T^* = q_5$. Thus, $T^* h_1(\cdot) T = 0$, and h_1 dominates zero.

It follows $[0] + [h_1] = [h_1]$, i.e.,

$$t_0 h_1(\cdot) t_0^* = (q_2 - p_0) H_0(\cdot) = v_2^* p_0 H_0(\cdot) v_2$$

is unitarily equivalent to h_1 by Proposition 4.3.5(i). We obtain

$$[h_1] = [p_0 H_0(\cdot)] = [0] + [h_0 + \beta h_0] = [h_0 + \beta h_0]$$

by Lemma 4.4.7(ii). It yields $[k + \beta h_0] + [h_0 + \beta h_0] = [h_0 + \beta h_0]$. Summing up, we get the existence of a unitary $U \in E$ with

$$s_0(k + \beta h_0) s_0^* + t_0(h_0 + \beta h_0) t_0^* = U^*(h_0 + \beta h_0) U \,.$$

Since $k(D) \cup h_0(D) \subseteq J$ and $J \cap \beta(J) = \{0\}$, it follows that $s_0 k(a) s_0^* + t_0 h_0(a) t_0^* = U^* h_0(a) U$ for all $a \in D$, i.e., $[k] + [h_0] = [h_0]$.

`Next Part of proof not complete !!! ??`

The plan (!!!) is to apply assumption 4.4.6(iii) to suitable separable C^*-subalgebras $M \subseteq J + \beta J$ to get projection $p, q \in F$ with $p_0 \leq p$, $p_0 \leq q$ and $p_0 \neq p$, such that there exists a unitary $V \in E$ with the (needed) property

$$V^* H_0(\cdot) q V = s_0(k(\cdot) + \beta h_0(\cdot)) s_0^* + (p - p_0) H_0(\cdot)\,.$$

By Part (v), there are unitaries U_1, U_2 and U_3 in $1 + F \subseteq C$ with $U_1^* p_0 U_1 = q$, $U_2^* p_0 U_2 = p - p_0$ and $U_3^* p_0 U_3 = p$. We get that

$$U_4^*(H_0(\cdot)p_0)U_4 = (k + \beta h_0) \oplus_{s_0,R} ((U_2^*(H_0(\cdot)p_0)U_2 \oplus_{R,s_0} 0)$$

where $U_4 := U_1 V$, $R \in C$ is an isometry with with $RR^* = 1 - p_0$ and $R(p - p_0) = (p - p_0)R = (p - p_0)$, e.g. $R := U_3^*(1 - p_0)U_2 + (p - p_0)$. It implies

$$[h_0 + \beta h_0] + [0] = [k + \beta h_0] + [h_0 + \beta h_0] + [0]\,.$$

Since $h_0 + \beta h_0$ absorbs zero, we get $[h_0 + \beta h_0] = [k + \beta h_0] + [h_0 + \beta h_0]$ on unitaries equivalence classes (with Cuntz addition outside the brackets $[.]$ and ordinary addition of linear maps inside $[.]$). The unitary equivalence of $h_0 + \beta h_0$ and $(k + \beta h_0) \oplus (h_0 + \beta h_0) = (k \oplus h_0) + (\beta h_0 \oplus \beta h_0)$ induces a unitary equivalence of h_0 and $k \oplus h_0$ because $J \cap \beta(J) = 0$. This means $[k] + [h_0] = [h_0]$.

□

Lemma 4.4.16. *The assumptions* (i)–(vi) *in Theorem 4.4.6 imply the following properties* (i)-(iv)*.*

(i) *There exist isometries $s_2, t_2 \in E$ with $s_2 s_2^* + t_2 t_2^* = 1$, $t_2 \in C$, $s_2^* H_0(\cdot) s_2 = h_0$, $p_2 := s_2 s_2^* \leq p_0$.*

Moreover, p_2 is a properly infinite projection in the ideal $C \cap \mathcal{N}(H_0(D), J)$ of C with $0 = [p_2]$ in $\mathrm{K}_0(C \cap \mathcal{N}(H_0(D), J))$, i.e., there exists a unital C^*-morphism from $\mathcal{O}_2$ into $p_2 C p_2$.

The isometry s_2 satisfies also $\beta(s_2)^* H_0(\cdot) \beta(s_2) = \beta h_0$.

(ii) *The projection p_0 is the sum $p_0 = q + r$ of properly infinite projections $q, r \in C$ with $q \in \mathcal{N}(H_0(D), J)$ and $r \in \mathcal{N}(H_0(D), \beta J)$. For each decomposition $p_0 = q + r$ of this kind holds $[qH_0(\cdot)] = [h_0]$ and $[rH_0(\cdot)] = [\beta h_0]$.*

(iii) *If $e \in E$ satisfies $e^* H_0(D) e \subseteq J + \beta J$ then there exist elements $x, y, z \in E$ with $\max\{\|x\|, \|y\|, \|z\|\} \leq \|e\|$ and a unitary $w \in 1 + F$ such that $e = wqx + wry + z$, $H_0(D)z = \{0\}$, $z^*(wqx) = 0$ and $z^*(wqy) = 0$, where $q, r \in C$ are projections with $p_0 = q + r$ and $q, \beta(r) \in \mathcal{N}(H_0(D), J)$.*

(iv) *Let $T_1, \ldots, T_n \in E$ such that $k(a) := \sum_{j=1}^n T_j^* H_0(a) T_j \in J + \beta J$ for all $a \in D$. Then there exist $S_1, S_2 \in E$, such that $k = k_1 + \beta k_2$ with $k_\ell(a) = S_\ell^* h_0(a) S_\ell$ for $a \in D$, $\ell \in \{1, 2\}$.*

In particular, if $[k] \in S(H_0\,;\, D, E)$ and $k(D) \subseteq J + \beta J$, then $k = k_1 + \beta k_2$ with unique $k_1, k_2 \in S(h_0\,;\, D, E)$.

New numbers X-6

PROOF. (i): By Lemma 4.4.7(ii), there exists a unitary $w \in E$ with

$$w^*(h_0 + \beta h_0)w = sh_0s^* + t\beta h_0t^* .$$

The isometry $T := ws \in E$ satisfies $T^*(h_0 + \beta h_0)T = h_0$. Let $s_2 := s_0T$. Then $p_2 := s_2s_2^* \leq p_0 = s_0s_0^*$ and $s_2^*H_0(\cdot)s_2 = h_0$. Thus $p_2H_0(D) = s_2h_0(D)s_2^* \subseteq J$, $p_2 \in C$, $p_2Cp_2 = s_2(h_0(D)' \cap E)s_2^*$ and $p_2 \in \mathcal{N}(H_0(D), J)$.

We get $p_2Cp_2 \subseteq C \cap \mathcal{N}(H_0(D), J)$, because $p_2cp_2 \leq \|c\|p_2$ for $c \in C_+$, $p_2 \in C \cap \mathcal{N}(H_0(D), J)$ and because $\mathcal{N}(H_0(D), J) = (\pi_J)^{-1}(\mathrm{Ann}(\pi_J(H_0(D)), J))$ is a hereditary C^*-subalgebra of E.

In particular, $s_2ss_2^*$ and $s_2ts_2^*$ generate a unital copy $s_2C^*(s,t)s_2^*$ of $\mathcal{O}_2$ that is unitally contained in the corner p_2Cp_2 of the closed ideal $C \cap \mathcal{N}(H_0(D), J)$ of C.

Since there is a unital C^*-morphism from $\mathcal{O}_2$ into p_2Cp_2 – with unit p_2 –, p_2 is properly infinite in $C \cap \mathcal{N}(H_0(D), J)$ and $[p_2] = 0$ in $\mathrm{K}_0(C \cap \mathcal{N}(H_0(D), J))$.

It follows that $[1 - p_2] = [1] = 0$ in $\mathrm{K}_0(C)$.

Since $t_0t_0^* \leq 1 - p_2$ and $t_0 \in C$, we get that $1 - p_2$ is full and properly infinite in C. By Lemma 4.2.6(ii), 1 and $1 - p_2$ are MvN-equivalent in C, i.e., there exists an isometry $t_2 \in C$ with $t_2t_2^* = 1 - s_2s_2^*$.

The equation $\beta(s_2)^*H_0(\cdot)\beta(s_2) = \beta h_0$ holds, because $\beta H_0 = H_0$. The corner $\beta(p_2)C\beta(p_2)$ of C is a corner of the ideal $C \cap \mathcal{N}(H_0(D), \beta(J))$ of C.

(ii): Let s_2 as in Part (i). Since

$$[h_0] + [\beta h_0] = [h_0 \oplus_{s,t} \beta h_0] = [h_0 + \beta h_0]$$

by Lemma 4.4.7(ii), and since $s_0^*H_0(\cdot)s_0 = h_0 + \beta h_0$ by assumption (iv) of Theorem 4.4.6, there exists a unitary $w \in E$ such that $z = (s_2 \oplus_{s,t} \beta(s_2))ws_0^*$ is a partial isometry in C with $z^*z = p_0$ and $zz^* = sp_2s^* + t\beta(p_2)t^*$ – compare Lemma 4.3.4(ii) and proof of Proposition 4.4.3(i).

The inequality $ss^* + t\beta(p_2)t^* \leq 1$, implies $s(1 - p_2)s^* \leq 1 - zz^*$. Using that $p_2 \leq p_0$, and that $1 - p_0 = t_0t_0^*$ and $s(1 - p_0)s^* = st_0t_0^*s^*$ are properly infinite projections in C, we obtain that $1 - zz^*$ is properly infinite in C. Since $1 - zz^*$ is properly infinite and $[1 - zz^*] = [1 - p_0] = [t_0t_0^*] = [1]$ in $\mathrm{K}_0(C)$, Lemma 4.2.6(ii) applies to $1 - zz^*, 1 \in C$, and there exists an isometry $T \in C$ with $TT^* = 1 - zz^*$.

The element $W := z + Tt_0^*$ is a unitary in C with

$$p_0 = (z^*z)^2 = W^*zz^*W = W^*(sp_2s^* + t\beta(p_2)t^*)W .$$

Hence $q := W^*sp_2s^*W = (W^*ss_2)(W^*ss_2)^*$ and $r := W^*t\beta(p_2)t^*W$ are properly infinite projections in C that are MvN-equivalent in C to p_2 and $\beta(p_2)$, and satisfy $p_0 = q + r$.

Since $\beta H_0 = H_0$ and $s^*W, t^*W \in C$, we get $q \in \mathcal{N}(H_0(D), J)$ and $r \in \mathcal{N}(H_0(D), \beta J)$, because $p_2 \in \mathcal{N}(H_0(D), J)$.

If $p_0 = q + r$ with $q \in \mathcal{N}(H_0(D), J)$ and $r \in C \cap \mathcal{N}(H_0(D), \beta J)$ are given, then $k_1(a) := qH_0(a)$ and $k_2(a) := rH_0(a)$ satisfy, by assumption (iv) of Theorem 4.4.6, that

$$k_1(a) + k_2(a) = p_0 H_0(a) = s_0(h_0(a) + \beta h_0(a)) s_0^* \,.$$

Since $J \cap \beta J = \{0\}$ and $\beta(s_0) = s_0$ it follows that $k_1 = s_0 h_0(\cdot) s_0^* = \beta k_2$, i.e., $[k_1] = [\beta k_2] = [h_0] + [0] = [h_0]$.

(iii): Let $e \in E$ and $e^* H_0(a^* a) e \in J + \beta J$ for all $a \in D$. Then $H_0(D) e \subseteq J + \beta J$. Let $f \in J + \beta J$ a strictly positive element of the separable C^*-subalgebra A of $J + \beta J$ that is generated by $H_0(D) e$.

There exists a projection $p \in F$ with $p_0 \leq p$ and $pf = f$ by assumption (iii) of Theorem 4.4.6. In particular $H_0(D)(1 - p)e = \{0\}$.

By assumption (v) of Theorem 4.4.6, there is a unitary $w \in 1 + F$ with $w p_0 w^* = p$. Let $z := (1-p)e$, $x := q w^* e$, and $y := r w^* e$ for projections $q, r \in C$ with $p_0 = q + r$, $q, \beta(r) \in \mathcal{N}(H_0(D), J)$. Then $\max\{ \|x\|, \|y\|, \|z\| \} \leq \|e\|$ and $wqx + wry + z = e$, and $z^* w q = 0 = z^* w r$ follows from $(1-p) w p_0 = 0$.

(iv): Let $k \colon D \to E$ with $[k] \in S(H_0\,; D, E)$ and $k(D) \subseteq J + \beta J$. By definition of $S(H_0\,; D, E)$, there exists an isometry $T \in E$ with $T^* H_0(\cdot) T = k$.

More generally, if $T_1, \ldots, T_n \in E$ such that $k(a) := \sum_{j=1}^n T_j^* H_0(a) T_j \in J + \beta J$ for all $a \in D$, then $k(a) = T^* H_0(a) T$ for $T := \sum_{j=1}^n S_j T_j$ with isometries $S_1, \ldots, S_n \in C^*(s,t) \subseteq H_0(D)' \cap E$. In particular, $T^* H_0(D) T \subseteq J + \beta J$. By Part (ix), there exists a unitary $w \in 1 + F \subseteq C$, and $x, y, z \in E$ with norms $\leq \|T\|$ such that $T = wqx + wry + z$ and $H_0(D) z = \{0\}$, where $q, r \in C$ are projections with $q, \beta(r) \in \mathcal{N}(H(D), J)$. It follows $T^* H_0(\cdot) T = x^* q H_0(\cdot) x + y^* r H_0(\cdot) y$.

The c.p. maps $k_1 := x^* q H_0(\cdot) x$ and $k_0 := y^* r H_0(\cdot) y$ satisfy $k = k_0 + k_1$. Let $k_2 := \beta k_0$, then $k = k_1 + \beta k_2$. Since $J \cap \beta(J) = \{0\}$ and $\beta^2 = \mathrm{id}$, the maps k_1 and k_2 are uniquely determined by the map $k = k_1 + \beta k_2$.

Now use that $[q H_0(\cdot)] = [h_0]$, $[r H_0(\cdot)] = [\beta h_0]$ by Lemma 4.4.16(ii). It means that there are unitaries $u_1, u_2 \in E$ with $q H_0(\cdot) = u_1^* h_0(\cdot) u_1$ and $r H_0(\cdot) = u_2^* \beta h_0(\cdot) u_2$.

It follows that $k_1 = S_1^* h_0(\cdot) S_1$ with $S_1 := u_1 x$ and $k_2 = S_2^* h_0(\cdot) S_2$ with $S_2 = \beta(u_2 y)$.

If $\|T\| \leq 1$ then $\|S_j\| \leq 1$ for $j = 1, 2$, and k is a c.p. contraction. If k is moreover multiplicative then k_1 and k_2 must be multiplicative, because $J \cdot \beta J = J \cap \beta J = \{0\}$. If k is multiplicative, then we can use that h_0 dominates zero by Lemma 4.4.7(v), and find, by Proposition 4.3.6(ii), isometries $T_1, T_2 \in E$ with $T_1^* h_0(\cdot) T_1 = k_1$ and $T_2^* h_0(\cdot) T_2 = k_2$. This means that $k_1, k_2 \in S(h_0\,; D, E)$, if, moreover, $\|T\| \leq 1$ and k is multiplicative. □

LEMMA 4.4.17. *The following properties of* $\mathrm{Der}(H_0(D), J)$*,* $C = H_0(D)' \cap E$ *and* $\mathcal{N}(H_0(D), J)$ *follow from assumptions* (i)-(vi) *of Theorem 4.4.6.*

(o) *If* $Q \in C$ *is a projection and* $k(a) := Q \cdot H_0(a)$ *for* $a \in D$*, then* $[k] \in S(H_0\,; D, E)$.

(xv) *If $k\colon D \to J$ and $u \in \mathcal{U}(E)$ are given with $u^* H_0(\cdot) u = k(\cdot) \oplus_{s_2,t_2} H_0(\cdot)$, then $u \in \mathrm{Der}(H_0(D), J)$.*

What about the unitary $W_0 := s_2^* s_0 + t_2^* t_0$ that transforms

$$k(\cdot) \oplus_{s_2,t_2} H_0(\cdot)$$

into $k(\cdot) \oplus_{s_0,t_0} H_0(\cdot)$??

Is NOT useful as transformation

If $u \in \mathrm{Der}(H_0(D), J)$ then there exists a unitary $w \in C := H_0(D)' \cap E$ with $0 = [wu] \in \mathrm{K}_1(E)$ ([8]).

Then $[k] + [h_0] = [h_0]$ if and only if there exist $v \in C$ with $vu \in \mathcal{N}(H_0(D), J) + 1$.

Part (xv) is shown in the below ????? given proof of Theorem 4.4.6.

What about the general relations between $u, u' \in \mathcal{U}(E)$ for k and k' with $[k'] + [h_0] = [k] + [h_0]$?

What about the unitary for $[k_1 + \beta h_0] + [k_2 + \beta h_0]$?

(xvi) *The set $P := \mathcal{U}(C) \cdot \mathcal{U}(\mathcal{N}(H_0(D), J) + \mathbb{C} \cdot 1)$ is an open subgroup of $\mathcal{U}(\mathrm{Der}(H_0(D), J))$. $\mathcal{U}(\mathcal{N}(H_0(D), J) + \mathbb{C} \cdot 1)$ is a closed normal subgroup of $\mathcal{U}(\mathrm{Der}(H_0(D), J))$.*

The set of $u \in \mathcal{U}(\mathrm{Der}(H_0(D), J))$ with the property that $u \oplus_{s,t} 1 \in P$ is an open subgroup of $\mathcal{U}(\mathrm{Der}(H_0(D), J))$.

Each element of $\mathrm{Der}(H_0(D), J)$, $\mathcal{N}(H_0(D), J) + \mathbb{C} \cdot 1$ and C are K_1-surjective and satisfy that $[u_1] = [u_2]$ if and only if $(u_1^* u_2) \oplus_{s,t} 1$ is in $\mathcal{U}_0(\mathrm{Der}(H_0(D), J))$ (respectively in $\mathcal{U}_0(\mathcal{N}(H_0(D), J))$, or $\mathcal{U}_0(C)$).

In particular:

If $x = [u] \in \mathrm{K}_1(\mathrm{Der}(H_0(D), J))$ for some $u \in \mathcal{U}(\mathrm{Der}(H_0(D), J))$ and if $x = \mu_1(y) + \mu_2(z)$ for some $y = [v_1] \in \mathrm{K}_1(C)$ and $z = [v_2] \in \mathrm{K}_1(\mathcal{N}(H_0(D), J))$, where $\mu_1\colon \mathrm{K}_1(C) \to \mathrm{K}_1(\mathrm{Der}(H_0(D), J))$ and $\mu_2\colon \mathrm{K}_1(\mathcal{N}(H_0(D), J)) \to \mathrm{K}_1(\mathrm{Der}(H_0(D), J))$ are induced by the canonical inclusion. Then $(u^* v_1 v_2) \oplus_{s,t} 1 \in \mathcal{U}_0(\mathrm{Der}(H_0(D), J))$.

more details? others? ??

Since $\mathcal{N}(H_0(D), J)$ is an ideal of $\mathrm{Der}(H_0(D), J)$ and is a full hereditary C^*-subalgebra of E and since $C := H_0(D)' \cap E \subseteq \mathrm{Der}(H_0(D), J)$ contains the copy of $C^*(s,t) \subseteq C$ of $\mathcal{O}_2$, the natural maps from $\mathcal{U}(\mathrm{Der}(H_0(D), J))$ and $\mathcal{U}(E)$ into $\mathrm{K}_1(\mathrm{Der}(H_0(D), J))$ and $\mathrm{K}_1(E)$ are surjective. We can use Lemma 4.2.20(ii) to obtain that $[u_1] = [u_2] \in \mathrm{K}_1(\mathrm{Der}(H_0(D), J))$ if $[u_1] = [u_2] \in \mathrm{K}_1(E)$ and $u_2^* u_1 \in 1 + \mathcal{N}(H_0(D), J)$.

Proof. (o): Let $T := s_1(1 - Q) + t_1 Q$ for the isometries s_1, t_1 as in Lemma 4.4.7(vi). Then $T^* T = 1$ and $T^* H_0(\cdot) T = Q H_0(\cdot) = k$. Thus, $[k] \in S(H_0\,;\, D, E)$.

If moreover $k(D) \subseteq J + \beta J$, then Lemma 4.4.16(iv) applies and $k = k_1 + \beta k_2$ with unique $k_1, k_2 \in S(h_0\,;\, D, E)$.

[8] Notice here that $(wu)^* H_0(\cdot) wu = u^* H_0(\cdot) u$.

(i): Let $A := H_0(D) \subseteq E$. Clearly $\mathrm{Der}(A, J) = \pi_J^{-1}\big(\pi_J(A)' \cap (E/J)\big)$. Thus, it is a C^*-subalgebra of E and $C := A' \cap E \supset \mathrm{Der}(A, J)$. In the same way $\mathcal{N}(A, J) = \pi_J^{-1}(\mathrm{Ann}(\pi_J(A), E/J))$, where $\mathrm{Ann}(\pi_J(A), E/J)$ means the two-sided annihilators of the elements of $\pi_J(A)$. Since $\mathrm{Ann}(\pi_J(A), E/J)$ is a closed ideal of $\pi_J(A)' \cap (E/J)$, the C^*-algebra $\mathcal{N}(A, J)$ is a closed ideal of $\mathrm{Der}(A, J)$.

Similar arguments work with $J + \beta(J)$ in place of J. Thus, $\mathcal{N}(A, J + \beta(J))$ is a closed ideal of $\mathrm{Der}(A, J + \beta(J))$.

Let $e \in E$ with $ea - ae \in J$ for all $a \in A$, i.e., $e \in \mathrm{Der}(A, J)$. Since $A := H_0(D)$ is separable, the C^*-algebra $M \subseteq J$ generated by the image of $a \in A \mapsto ea - ae$ is separable, and M contains a strictly positive element f. Assumption (iii) of Theorem 4.4.6, gives a projection $p \in F \subseteq C$ with $p_0 \leq p$ and $pf = f = fp$. Thus $px = x = xp$ for all $x \in M$, and it follows that $e(1-p), (1-p)e \in C$. Since $p \in C$ we get that $e - pep \in C$, and $pepa - apep \in J$ for all $a \in A$.

Let $u \in 1 + F \subseteq C$ with $u^*pu = p_0$. Then $pep = ugu^*$ for $g := p_0u^*eup_0$ and g satisfies $\partial_g(a) = p_0u^*(ea - ae)up_0 \in J$ for $\partial_g(a) := ga - ag$ and $a \in A$, i.e., $g \in \mathrm{Der}(A, J)$.

By Lemma 4.4.16(ii), p_0 is the sum $p_0 = q + r$ of properly infinite projections $q, r \in C$ with $q \in \mathcal{N}(A, J)$ and $r \in \mathcal{N}(A, \beta J)$.

Since $\mathcal{N}(A, J)$ is an ideal of $\mathrm{Der}(A, J) \supset C$ and $q \in \mathcal{N}(A, J)$, we get that

$$gq = g(1-r),\ qg = (1-r)g,\ (1-r)gr = qgr \ \in \mathcal{N}(A, J)\,.$$

It follows $g - rgr \in \mathcal{N}(A, J)$ and $rgr = g - (g - rgr) \in \mathrm{Der}(A, J)$.

The C^*-algebra $\mathcal{N}(A, \beta(J))$ is a hereditary C^*-subalgebra of E, and $r \in \mathcal{N}(A, \beta(J))$. Thus, $rgr \in \mathcal{N}(A, \beta(J))$. Since $rgra - argr \in J \cap \beta J = \{0\}$ for all $a \in A$, we get $rgr \in C$. Since $u \in 1 + F \subseteq C$, it follows $urgru^* \in C$.

Let $e_1 := (e - pep) + urgru^*$ and $e_2 := u(g - rgr)u^*$. Since $pep = ugu^*$, we get $e = e_1 + e_2$. Above we have seen that $e_1 \in C$ and $e_2 \in \mathcal{N}(A, J)$.

We consider $\mathrm{Der}(A, J + \beta J)$ and – more generally – the case where X is a countable subset of $\mathrm{Der}(A, J+\beta J)$: Every $e \in X$ satisfies $\partial_e(a) := ea - ae \in J + \beta J$ for all $a \in A$, and the linear map ∂_e is the sum $\partial_e = T_e + \beta S_e$, where $T_e, S_e \colon A \to J$ are bounded linear maps, because $J \cap \beta J = \{0\}$. Let G denote a separable C^*-subalgebra of $J \subseteq \beta J$ that contains the separable subsets $T_e(A) \cup S_e(A)$ for all $e \in X$ and satisfies $\beta(G) = G$. Let $f \in G_+$ a strictly positive contraction of G. There is a projection $p \in F \subseteq C$ with $p \geq p_0$ and $pf = f$ by 4.4.6(iii). It follows that $ea - ae = pepa - apep$ and $e - pep \in C$ for all $e \in X$. By 4.4.6(v), there is a unitary $w \in 1 + F \subseteq C = A' \cap E$ with $w^*pw = p_0$.

It follows that $p\partial_e(a) = \partial_e(a) = \partial_e(a)p = p\partial_e(a)p = \partial_{pep}$ for $a \in A$ and $e \in X$.

In particular, $(1-p)\partial_e(A) = \{0\} = \partial_e(A)(1-p)$ for all $e \in X$.

Recall that $F \subseteq \mathcal{N}(A, J + \beta J) \cap C$ and that $\mathcal{N}(A, J + \beta J)$ is a hereditary C^*-subalgebra of E. Thus $pep \in \mathcal{N}(A, J + \beta J)$ for each orthogonal projection

$p \in \mathcal{N}(A, J + \beta J)$ and $e \in E$. Since $p \in F \subseteq \mathcal{N}(A, J + \beta J)$ and $w \in 1 + F \subseteq C$, we get that $e - pep \in C$ and $pep \in \mathcal{N}(A, J + \beta J)$ for all $e \in X$. In particular, $\mathrm{Der}(A, J + \beta J) = C + \mathcal{N}(A, J + \beta J)$.

(ii): If $[k] + [H_0] = [H_0]$ then $[k \oplus_{s_2,t_2} H_0] = [H_0]$. There exists $u \in \mathcal{U}(E)$ with

$$u^* H_0(\cdot) u \;=\; k \oplus_{s_2,t_2} H_0 \;=\; s_2 k(\cdot) s_2^* + (1 - p_2) H_0(\cdot)\,,$$

where p_2, s_2 and t_2 are as in Lemma 4.4.16(i). It follows $ut_2 \in C$, because $t_2 \in C$, $(1 - p_2) = t_2 t_2^*$ and $H_0(\cdot) u (1 - p_2) = u(1 - p_2) H(\cdot)$. Furthermore, up_2u^* commutes with $H_0(D)$ and, for $a \in D$, $up_2u^* H_0(a) = us_2 k(a) s_2^* u^* \subseteq J$. In particular, $k(a) = s_2^* u^* H_0(a) u s_2$. Recall that $p_2 H_0(\cdot) = s_2 h_0(\cdot) s_2^*$.

We get $u^* H_0(a) u - H_0(a) = s_2(k(a) - h_0(a)) s_2^* \in J$ for all $a \in D$, because $k(D) \subseteq J$. Thus, $u \in \mathrm{Der}(H_0(D), J)$.

Clearly $v^* H_0(\cdot) v = s_0 k(\cdot) s_0^* + (1 - p_0) H_0(\cdot)$ with $v := u(s_2 s_0^* + t_2 t_0^*)$. Then $vt_0 \in C$ and $v \in \mathrm{Der}(H_0(D), J + \beta(J))$.

Since $p_2, p_0 \in \mathcal{N}(H_0(D), J + \beta J)$ and $s_2 s_0^* = p_2 (s_2 s_0^*) p_0$, the partial isometry $s_2 s_0^*$ is in $\mathrm{Der}(H_0(D), J + \beta(J))$ but is not in $\mathrm{Der}(H_0(D), J)$, because $p_0 = s_0 s_0^* = (s_2 s_0^*)^* s_2 s_0^*$ is not in $\mathrm{Der}(H_0(D), J)$.

`Next also (xv):`

If $[k] + [h_0] = [h_0]$ in $S(h_0\,;\, D, E)$, then $u = w_1 u_1$ with $u_1 \in 1 + \mathcal{N}(H_0(D), J)$ and $w_1 \in C$.

(iii): Let $Y \subseteq \mathcal{U}(E)$ an at most countable subset of the unitaries in E, and suppose that $u \in \mathrm{Der}(H_0(D), J + \beta J)$ for all $u \in Y$. If G is the (norm-)closure of the subgroup of $\mathcal{U}(E)$ generated by Y, then $G \subseteq \mathrm{Der}(H_0(D), J + \beta J)$, because $\mathrm{Der}(H_0(D), J + \beta J)$ is a C^*-algebra by Part (i).

If we take for X in the proof of Part (i) the sub-group of G that is algebraical generated by Y, then we get a projection $p \in F \subseteq C$ and a unitary $w \in 1 + F$, such that $p \geq p_0$, $u - pup \in C$ for all $u \in G$, and $w^* p w = p_0$. Moreover $pup \in \mathcal{N}(H_0(D), J + \beta J)$ for all $u \in G$, because $w \in C$, $p_0 \in \mathcal{N}(H_0(D), J + \beta J)$ and $\mathcal{N}(H_0(D), J + \beta J)$ is an ideal of $\mathrm{Der}(H_0(D), J + \beta J)$.

It follows that $(1 - p) u^* H_0(\cdot) u = (1 - p) H_0(\cdot)$ for all $u \in G$. This implies that $(1 - p_0)(uw)^* H_0(\cdot) uw = (1 - p_0) H_0(\cdot)$, and $Q := uwp_0(uw)^*$ is a projection in C, i.e., p_0 commutes with $(uw)^* H_0(\cdot) uw$. Let $k(a) := s_0^* (uw)^* H_0(a) uws_0$, i.e., $s_0 k(a) s_0^* = p_0 (uw)^* H_0(a) uw$, then $k \in S(H_0\,;\, D, E)$ by Part (o) and

$$(uw)^* H_0(\cdot) uw = k \oplus_{s_0,t_0} H_0\,.$$

Since

$$(1 - p_0) \cdot \big((uw)^* H_0(\cdot) uw - H_0(\cdot)\big) = (1 - p_0)(wu)^* \partial_{wu} H_0(\cdot) = 0\,,$$

$p_0 H_0(\cdot) = s_0\big(h_0(\cdot) + \beta h_0(\cdot)\big) s_0^*$ and $uw \in \mathrm{Der}(H_0(D), J + \beta J)$ it follows that, for $a \in D$,

$$s_0\big(k(a) - h_0(a) - \beta h_0(a)\big) s_0^* \;=\; (uw)^* \partial_{uw}(H_0(a)) \in J + \beta J\,.$$

Thus, $k(a) \in J + \beta J$ for $a \in D$. Since $k \in S(H_0\,;\, D, E)$ it implies $k = k_1 + \beta k_2$ for unique $k_1, k_2 \in S(h_0\,;\, D, E)$ by Lemma 4.4.7(x).

If moreover $u \in \mathrm{Der}(H_0(D), J)$, then the above arguments show that $k(a) - h_0(a) - \beta h_0(a) \in J$ for each $a \in D$. This implies $k_2 = h_0$ because $J \cap \beta J = \{0\}$.

(iv): Let G a separable (norm-) closed subgroup of $\mathcal{U}(\mathrm{Der}(H_0(D), J + \beta J))$. By the proof of Part (iii) there exist a projection $p \in F \subseteq C$, and a unitary $w \in 1 + F$ such that $p \geq p_0$, $u - pup \in C$ for all $u \in G$, and $w^* p w = p_0$. Moreover $pup \in \mathcal{N}(A, J + \beta J)$ for all $u \in G$. It follows that $(1-p)u^* H_0(\cdot)u = (1-p)H_0(\cdot)$ for all $u \in G$. It follows that there exists an isometry R with $R^*(1-p)R = 1$, i.e., $RR^* \leq 1 - p$, and with $H_0(D)RR^* = \{0\}$:

Indeed, by Lemma 4.4.7(vi), there exist isometries $s_1, t_1 \in E$ with $t_1 \in C$, $s_1 s_1^* + t_1 t_1^* = 1$, $p_0 t_1 = p_0 = t_1 p_0$, $s_1 s_1^* H_0(\cdot) = 0$ and $t_1 H_0(\cdot) = H_0 = H_0(\cdot) t_1$. It implies $s_1 s_1^* = 1 - t_1 t_1^* \leq 1 - p_0$. Since $w \in C$ and $w p_0 w^* = p$, the isometry $R := w s_1$ satisfies $RR^* \leq 1 - p = w(1-p_0)w^*$, and $R^* H_0(\cdot) R = s_1^* H_0(\cdot) s_1 = 0$. Then $RER^* \perp H_0(D)$, and for all $u \in G$,

$$R^* u^* H_0(\cdot) u R = R^*(1-p) u^* H_0(\cdot) u R = R^*(1-p) H_0(\cdot) R = 0\,.$$

Let $S := Rs$ and $T := (1 - RR^*) + RtR^*$. Then S and T are isometries in E, $TT^* = (1 - RR^*) + Rtt^*R^*$, and $SS^* \leq RR^* \perp u^* H_0(D) u$, $Tu^* H_0(\cdot) = (1 - RR^*) u^* H_0(\cdot) = u^* H_0(\cdot)$, $H_0(\cdot) u T = H_0(\cdot) u$ for all $u \in G$, and $SS^* + TT^* = (1 - RR^*) + Rss^*R^* + Rtt^*R^* = 1$.

(v): Let $S, T \in E$ the isometries from Part (iv). It is well-known that $W_u := Su^*S^* + TuT^*$ is in $\mathcal{U}_0(E)$, and straight calculation shows $W_u^* H_0(\cdot) W_u = u^* H_0(\cdot) u$ for all $u \in G$. It follows $uW_u^* \in C$ and $[W_u]_E = 0$ in $\mathrm{K}_1(E)$.

(vi): For any $u \in E$ holds $v^* H_0(a) v = u^* H_0(a) u$ for $v := (SuS^* + TT^*)$. Then $w := vu^* = SuS^*u^* + TT^*u^*$ is in C.

TYPO ????????

Unitaries u_1 and u_2 in $\mathrm{Der}(H_0(D), J)$ have same class in $\mathrm{K}_1(\mathrm{Der}(H_0(D), J))$, if and only if, the corresponding – in this way defined – v_1 and v_2 are homotopic in $\mathcal{U}(\mathrm{Der}(H_0(D), J))$.

(I.e., the new sort of $v \in \mathcal{U}_0(E)$ has the property that, any two of them are homotopic in $\mathcal{U}(\mathrm{Der}(H_0(D), J))$ if they have the same K_1-class in $\mathrm{K}_1(\mathrm{Der}(H_0(D), J))$.)

This implies ????

(vii): To be shown: If $u \in \mathcal{U}(\mathrm{Der}(H_0(D), J))$, then there exists a unitary $v \in 1 + F \subseteq C$ and $k \in S(h_0\,;\, D, E)$, such that with $w = uv$ holds

$$w^* H_0(\cdot) w = (k + \beta h_0) \oplus_{s_0, t_0} H_0\,.$$

`Compare with` $k \oplus_{s_2, t_2} H_0$ `??`

(viii): To be shown: ??????

For every $u \in \mathcal{U}(\mathrm{Der}(H_0(D), J))$ there exist $w \in \mathcal{U}(C)$ and $k \in S(h_0; D, E)$ with $w^*(u^* H_0(\cdot) u) w = k \oplus_{s_0,t_0} H_0$, such that $1 - uw \in \mathcal{N}(H_0(D), J)u$?????.

`It would imply:` $u^* - w \in u^* \mathcal{N}(H_0(D), J)u = \mathcal{N}(H_0(D), J)$. It is desirable, but still not prove-able. ????

(xiv): $[k + \beta h_0] + [h_0] = [h_0 + \beta h_0]$, is the same as $[k] + [h_0 + \beta h_0] = [h_0 + \beta h_0]$ by Lemma 4.4.7(i). Since $[k] + [h_0 + \beta h_0] = [k \oplus_{s,t} (h_0 + \beta h_0)]$, there exists a unitary $u \in E$ with

$$(u^* sk(a) s^* u + u^* th_0(a) t^* u - h_0(a)) + (u^* t\beta h_0(a) tu - \beta h_0(a)) = 0$$

for all $a \in D$. Since $J \cap \beta(J) = J\beta(J) = \{0\}$ it follows $u^*\big(sk(\cdot)s^* + th_0(\cdot)t^*\big)u = h_0$, i.e., $[k] + [h_0] = [h_0]$.

(xv): Let $k\colon D \to J$ and $u \in \mathcal{U}(E)$ with $u^* H_0(\cdot) u = k(\cdot) \oplus_{s_2,t_2} H_0(\cdot)$.

Then $k = s_2^* u^* H_0(\cdot) u s_2 \in S(H_0\,; D, E)$ and $k \in S(h_0\,; D, E)$ by Lemma 4.4.7(x).

Suppose $[k] + [h_0] = [h_0]$, ...?????

Since $s, t \in h_0(D)' \cap E$ for the isometries s, t in Theorem 4.4.6(i), we get $W_0(h_0 \oplus_{s_2,t_2} h_0) W_0^* = h_0$ for the unitary $W_0 := s s_2^* + t t_2^*$.

If $[k] + [h_0] = [h_0]$, then there is a unitary $V_0 \in E$ with $V_0^*(k \oplus_{s_2,t_2} h_0) V_0 = h_0 = p_2 H_0(\cdot)$. The unitary $V_1 := V_0 W_0$ satisfies

$$V_1^*(k \oplus_{s_2,t_2} h_0) V_1 = h_0 \oplus_{s_2,t_2} h_0\,.$$

The unitary $T := (s_2)^2 s_2^* + s_2 t_2 s_2^* t_2^* + t_2 (t_2^*)^2$ satisfies for all $X, Y, Z \in E$ that

$$T\big(X \oplus_{s_2,t_2} (Y \oplus_{s_2,t_2} Z)\big) = \big((X \oplus_{s_2,t_2} Y) \oplus_{s_2,t_2} Z\big)T\,.$$

Notice that $H_0 = h_0 \oplus_{s_2,t_2} H_0$. It implies

$$H_0 = h_0 \oplus (h_0 \oplus H_0) = T^*((h_0 \oplus h_0) \oplus H_0)T$$

Let $W_1 := V_1 \oplus 1$ and $v := T^* W_1^* T = T^*(V_1^* \oplus 1)T$. Then $rv = r = vr$ for $r := T^* t_2 t_2^* T = t_2^2 (t_2^2)^* = t_2(1 - p_2) t_2^*$, $1 - r = p_2 + t_2 p_2 t_2^*$ is in $C \cap \mathcal{N}(H_0(D), J)$, because the latter is an ideal of C and $t_2 \in C$. It implies $t_2 H_0(D) p_2 t_2^* \subseteq J$. Thus $v \in 1 + (1 - r)E(1 - r) \subseteq 1 + \mathcal{N}(H_0(D), J)$, and satisfies:

$$v^* H_0 v = v^* T^*((h_0 \oplus h_0) \oplus H_0) T v = T^* W_1((h_0 \oplus h_0) \oplus H_0) W_1^* T =$$
$$T^*\big((k \oplus h_0) \oplus H_0\big)T = \big(k \oplus (h_0 \oplus H_0)\big) = k \oplus_{s_2,t_2} H_0\,.$$

It follows that $uv^* = w \in C$, i.e., that u is the product wv of a unitary $v \in 1 + \mathcal{N}(H_0(D), J)$ and a unitary $w \in C$.

`Check again:`

Now we consider the opposite direction: Suppose that $u = wv$ with v a unitary in $1 + \mathcal{N}(H_0(D), J)$ and $w \in \mathcal{U}(C)$. Then

$$v^* H_0(\cdot) v = k(\cdot) \oplus_{s_2,t_2} H_0(\cdot)\,.$$

and there is normal $g \in \mathcal{N}(H_0(D), J)$ with $v = g + 1$. The sets $H_0(D)g$ and $\partial_v(H_0(D)) = \partial_g(H_0(D))$ together generate a separable C^*-subalgebra of J. By

Theorem 4.4.6(ii) there exists $p \in F$ with $p \geq p_0$, $p \neq p_0$ such that $p(H_0(a)g - gH_0(a))p = H_0(a)g - gH_0(a)$ and $H_0(\cdot)gp = H_0(\cdot)g = H_0(\cdot)pg$. If we add to the last equation $H_0(\cdot)p$, then we get $H_0(\cdot)vp = H_0(\cdot)pv$. It follows $v^*H_0(\cdot)vp = v^*H_0(\cdot)pv$, $H_0(\cdot)pvp - pvpH_0(\cdot) = H_0(\cdot)v - vH_0(\cdot)$ and $v^*H_0(\cdot)v(1-p) = H_0(\cdot)(1-p)$. Since $p = p_0 + r$ for some $r \neq 0$, it follows $r = rt_0t_0^*$, $v^*H_0(\cdot)pv = v^*H_0(\cdot)vp = s_2k(\cdot)s_2^* + rH_0(\cdot)$. By Theorem 4.4.6(v), there exist unitaries $W_1, W_2 \in 1 + F$ with $W_1^*pW_1 = p_0$ and $W_2^*rW_2 = p_0$. Then $H_0(\cdot)p = W_1H_0(\cdot)p_0W_1^*$ and $H_0(\cdot)r = W_2(H_0(\cdot)p_0)W_2^*$. Recall that $H_0(\cdot)p_0 = s_0(h_0 + \beta h_0)s_0^*$. It gives

$$[h_0 + \beta h_0] + [0] = [k] + [h_0 + \beta h_0] + [0]\,.W_2H_0(\cdot)p_0W_2^*t_2)t_2^*$$

By Lemma 4.4.7(ii,i), this is equivalent to $[h_0 + \beta h_0] = [k + \beta h_0] + [h_0]$ It follows $[h_0] = [k] + [h_0]$ by Part (xiv).

`??` `to be filled in` □

We study at first the case, where the **OLD !!!! assumptions (I) and (II)** are satisfied (in addition to (i)-(vii)):

If $u \in \mathrm{Der}(H_0(D), J)$ is unitary, then, by Lemma 4.4.17(v), there exists $w \in C$ such that $u^*H_0(a)u = (wu)^*H_0(a)(wu)$ for all $a \in A$ and $wu \in \mathcal{U}_0(E)$.

Then by assumption (I) there exists a unitary $v \in C \cap \mathcal{U}_0(E)$ such that for $u' = wuv \in \mathcal{U}_0(E)$

$$(u' - 1)\beta(J) = \{0\}\,.$$

`to be filled in ??` ??????????????????????

`Start:`
`towards isomorphism of kernel and` Γ

Now we take a more K-theoretic approach for the study of the **general situation**:

Let $C_2 := h_0(D)' \cap E$. Then $G(h_0\,;\,D, E) \cong \ker(\mathrm{K}_0(C_2) \to \mathrm{K}_0(E))$ by ??????????? **??** from Lemma 4.2.20 ???

It holds $C_2 \cong p_2Cp_2$ via the *-isomorphism $b \in C_2 \mapsto s_2bs_2^*$.

The subalgebras $\mathrm{Ann}(H_0(D), E)$ and $C \cap \mathcal{N}(H_0(D), J)$ are ideals of C, and $\mathrm{Ann}(H_0(D), E) \subseteq C \cap \mathcal{N}(H_0(D), J)$.

The projection $p_2 + \mathrm{Ann}(H_0(D), E)$ is properly infinite in $C/\mathrm{Ann}(H_0(D), E)$, which is a full C^*-subalgebra of

$$J_2 := (C \cap \mathcal{N}(H_0(D), J))/\mathrm{Ann}(H_0(D), E)\,.$$

Since H_0 dominates zero, we get that $\mathrm{Ann}(H_0(D), E)$ is a full hereditary C^*-subalgebra of E. Now Lemma 4.2.20 shows that

$$G(H_0\,;\,D, E) \cong \mathrm{K}_0(C/\mathrm{Ann}(H_0(D))) \cong \ker(\mathrm{K}_0(C) \to \mathrm{K}_0(E))\,.$$

The same happens with $\mathrm{Ann}(h_0(D),E) \subseteq C_2$ in E. Moreover, $s_2 b s_2^* \in \mathrm{Ann}(H_0(D),E)$, if and only if, $b \in \mathrm{Ann}(h_0(D),E)$. Let

$$A := C/\,\mathrm{Ann}(H_0(D),E)\,.$$

The algebra J_2 is a closed ideal of A with $A/J_2 \cong C/(C \cap \mathcal{N}(H_0(D),J))$ and the natural map $G(h_0\,;\,D,E) \to G(H_0\,;\,D,E)$ transforms to

$$\mathrm{K}_0(C_2/\,\mathrm{Ann}(h_0(D),E)) \cong \mathrm{K}_0(J_2) \to \mathrm{K}_0(A)\,.$$

The surjectivity of $G(h_0\,;\,D,E) \to G(H_0\,;\,D,E)$ is equivalent to the exactness of the sequence

$$\mathrm{K}_1(A) \to \mathrm{K}_1(A/J_2) \to_\partial \mathrm{K}_0(J_2) \to \mathrm{K}_0(A) \to 0\,.$$

One can use the identity $\mathrm{Der}(H_0(D),J) = C + \mathcal{N}(H_0(D),J)$, i.e., that

$$A/J_2 \cong \mathrm{Der}(H_0(D),J)/\,\mathcal{N}(H_0(D),J)\,,$$

the natural map $\mathrm{K}_1(C) \to \mathrm{K}_1(\mathrm{Der}(H_0(D),J))$ and the splitting (by Lemma 4.2.20) of the exact sequence

$$0 \to \mathrm{K}_1(\mathcal{N}(H_0(D),J)) \to \mathrm{K}_1(\mathrm{Der}(H_0(D),J)) \to \mathrm{K}_1(A/J_2) \to 0\,,$$

to verify that the quotient $\mathrm{K}_1(A/J_2)/\partial(\mathrm{K}_1(A))$ of $\mathrm{K}_1(A/J_2)$ by the image of $\partial\colon \mathrm{K}_1(A) \to \mathrm{K}_1(A/J_2)$ is isomorphic to $\Gamma(H_0(D),J,E)$ as defined before Theorem 4.4.6.

It seems likely that the following argument gives that the natural map $\mathrm{K}_1(A) \to \mathrm{K}_1(A/J_2)$ is zero, i.e., that $\mathrm{K}_1(J_2) \to \mathrm{K}_1(A)$ is surjective too. The only difficult point in such an attempt is the verification of assumption (ii) of Theorem 4.4.6 for the “new” system.

Let $\mathcal{P}_\infty$ denote the unique pi-sun algebra in the UCT-class with $\mathrm{K}_0(\mathcal{P}_\infty) \cong \{0\}$ and $\mathrm{K}_1(\mathcal{P}_\infty) \cong Z$ If we repeat all arguments above with E, J, β, F, H_0, h_0, s, t, s_0, t_0, and u_1, but *replaced* by $E \otimes \mathcal{P}_\infty$, $J \otimes \mathcal{P}_\infty$, $F \otimes 1$, $\beta \otimes \mathrm{id}$, $H_0(\cdot) \otimes 1$, $h_0(\cdot) \otimes 1$, $s \otimes 1$, ..., then one gets also that $\mathrm{K}_1(J_2) \to \mathrm{K}_1(A)$ is surjective, provided assumption (ii) of Theorem 4.4.6 can be verified by the new system, at least in a suitable approximate or asymptotic sense.

Remark 4.4.18. One can show that the following conditions (I) and (II) together imply that $[k \oplus h_0] \mapsto [k \oplus H_0]$ is injective.

(I) If $u \in \mathcal{U}_0(E)$ is in $C + \mathcal{N}(H_0(D),J)$ then there exists a unitary $w \in C \cap \mathcal{U}_0(E)$ such that $(wu-1)\beta(J) = \{0\}$.

`Alternatively(?): ... such that` $vu \in 1 + \mathcal{N}(H_0(D), J + \beta(J))$.

(II) If $v \in \mathcal{U}_0(E)$ is in $C + \mathcal{N}(H_0(D),J)$, $vp_0v^* \in C \cap \mathcal{N}(H_0(D),J)$ and $(v-1)\beta(J) = \{0\}$, then $k(\cdot) := (vp_0v^*)H_0(\cdot)$ satisfies

$$[k] + [h_0 + \beta h_0] = [h_0 + \beta h_0]\,.$$

5. Generalizations and limitations

The following remarks and corollaries discuss some limitations of the arguments in above given proofs and generalize them partly for "soft" asymptotic considerations.

We need in later chapters local estimates for an approximate version of Proposition 4.3.5(i). The following remark and corollary give estimates in very special situations, well applicable e.g. to singly generated C^*-algebras D.

REMARK 4.5.1. Let $h_1\colon D \to E$ a C^*-morphism and $s_1, s_2, t \in E$ isometries with $s_1 s_1^* + s_2 s_2^* = 1$.

Define a c.p. contraction $h_2\colon D \to E$ by $h_2(a) := t^* h_1(a) t$ for $a \in D$ and isometries $t_1 := (1 - tt^*) + ts_1 t^*$, $t_2 := ts_2$ in E.

Let $C(s_1, s_2; y) := \| [s_1, y] \| + \| [s_2, y] \|$ denote the sum of norms of the commutators of $y \in E$ with s_1 and s_2, and define by

$$\operatorname{curv}(h_2, a) := \max\big(\| h_2(a^*a) - h_2(a^*)h_2(a) \| ,\ \| h_2(aa^*) - h_2(a)h_2(a^*) \| \big)^{1/2}$$

the **local curvature** of the completely positive contraction h_2 at $a \in D$, i.e., the failure of h_2 to be multiplicative at the elements a and a^*.

Then the isometries t_1, t_2 satisfy $t_1 t_1^* + t_2 t_2^* = 1$ and for the Cuntz sum holds

$$\|h_1(a) - (h_1 \oplus_{t_1,t_2} h_2)(a)\| \le C\big(s_1, s_2; h_2(a)\big) + \operatorname{curv}(h_2, a)\,.$$

If $h_3\colon D \to E$ is another C^*-morphism, then we denote by

$$\operatorname{var}(h_2, h_3; a) := \max\{ \|h_2(x) - h_3(x)\| \,;\ x = a,\ a^*a,\ aa^* \}\,,$$

the **local variation** of h_2 and h_3 at $a \in D$, i.e., the distance of h_2 and h_3 on $\{a, a^*, a^*a, aa^*\}$.

The C^*-morphism $h_1 \oplus_{t_1,t_2} h_3\colon D \to E$ satisfies, for a *contraction* $a \in E$, that

$$\begin{aligned} &\|h_1(a) - (h_1 \oplus_{t_1,t_2} h_3)(a)\| \\ \le\ & C\big(s_1, s_2; h_3(a)\big) + C\big(s_1, s_2; h_3(a) - h_2(a)\big) + 4 \cdot \operatorname{var}(h_2, h_3; a)^{1/2} \\ \le\ & C\big(s_1, s_2; h_3(a)\big) + 10 \cdot \operatorname{var}(h_2, h_3; a)^{1/2}\,. \end{aligned}$$

PROOF. Obviously, the elements $t_1 := (1 - tt^*) + ts_1 t^*$ and $t_2 := ts_2$ of E are isometries with $t_1 t_1^* + t_2 t_2^* = 1$. Let $p := tt^*$,

$$X(a) := h_1(a) - \big(h_1(a) \oplus_{t_1,t_2} h_2(a)\big)$$

and recall that $h_2 := t^* h_1(\cdot) t$.

Thus, $ph_1(a)p = th_2(a)t^*$, $pt_1 h_1(a) t_1^* p = ts_1 h_2(a) s_1^* t^*$ and

$$pX(a)p = th_2(a)t^* - ts_1 h_2(a) s_1^* t^* - ts_2 h_2(a) s_2^* t = t\Delta(a)t^*$$

for $\Delta(a) := h_2(a) - (h_2 \oplus_{s_1,s_2} h_2)(a)$. Clearly, for $y \in E$ and $q_k := s_k s_k^*$,

$$\|y - (y \oplus_{s_1,s_2} y)\| \le \|yq_1 - s_1 y s_1^*\| + \|yq_2 - s_1 y s_1^*\| = \|ys_1 - s_1 y\| + \|ys_2 - s_2 y\| \le 4\|y\|\,,$$

because $q_1 + q_2 = 1$, $s_j^* q_k = \delta_{j,k} s_j$ and $\|y s_j^*\| = \|y\|$. It follows that

$$\|pX(a)p\| \le \|\Delta(a)\| \le C\big(s_1, s_2; h_2(a)\big)\,.$$

The equations $(1-p)t_1 = (1-p) = t_1^*(1-p)$ and $pt_1 = ts_1$, $pt_2 = t_2 = ts_2$ show that

$$p \cdot (h_1(a) - X(a)) = t(h_2(a) - \Delta(a))t^* = (h_1(a) - X(a)) \cdot p\,,$$

$(1-p)X(a)(1-p) = (1-p)(h_1(a) - t_1 h_1(a) t_1^*)(1-p) = 0$, and that

$$pX(a)(1-p) + (1-p)X(a)p = ph_1(a)(1-p) + (1-p)h_1(a)p\,.$$

If we use that $\|x \pm y\| = \max(\|x\|, \|y\|)$ if $x^* y = 0 = x y^*$, then we get for $z \in E$ that

$$\begin{aligned} \|[z,p]\| &= \|pz(1-p) - (1-p)zp\| = \\ \|pz(1-p) + (1-p)zp\| &= \max(\,\|pz(1-p)\|\,,\ \|(1-p)zp\|\,)\,. \end{aligned}$$

It follows that above estimates sum up to

$$\|X(a)\| \,\le\, C\big(s_1, s_2; h_2(a)\big) \,+\, \max\big(\,\|ph_1(a)(1-p)\|,\, \|(1-p)h_1(a)p\|\,\big)\,.$$

Use now that for $p := tt^*$ and $h_2 := t^* h_1(\cdot) t$ holds

$$\|h_2(a^*a) - h_2(a)^* h_2(a)\| \,=\, \|(1-p)h_1(a)p\|^2\,.$$

We obtain

$$\operatorname{curv}(h_2, a) = \max\big(\,\|\, ph_1(a)(1-p)\,\|\,,\, \|\,(1-p)h_1(a)p\,\|\,\big) \,=\, \|[h_1(a), tt^*]\|\,.$$

This implies the proposed estimate $C\big(s_1, s_2; h_2(a)\big) + \operatorname{curv}(h_2, a)$ of $\|h_1(a) - (h_1 \oplus_{t_1,t_2} h_2)(a)\|$.

To verify the estimate of the norm of $h_1(a) - (h_1 \oplus_{t_1,t_2} h_3)(a)$ consider following inequalities:

$$\begin{aligned} \|h_1(a) - (h_1 \oplus_{t_1,t_2} h_3)(a)\| &\le \|h_3(a) - h_2(a)\| + \|h_1(a) - (h_1 \oplus_{t_1,t_2} h_2)(a)\|\,, \\ C\big(s_1, s_2; h_2(a)\big) &\le C\big(s_1, s_2; h_3(a)\big) + C\big(s_1, s_2; h_2(a) - h_3(a)\big) \\ \text{and}\quad C\big(s_1, s_2; h_2(a) - h_3(a)\big) &\le 4\|h_2(a) - h_3(a)\|\,. \end{aligned}$$

A rough estimate of $\operatorname{curv}(h_2, a)^2$ can be seen from

$$\begin{aligned} \|h_2(a^*a) - h_2(a)^* h_2(a)\| &\le \|h_3(a^*a) - h_2(a^*a)\| + \|h_3(a)^* h_3(a) - h_2(a)^* h_2(a)\| \\ &\le (2\|a\| + 1) \cdot \operatorname{var}(h_2, h_3; a)\,. \end{aligned}$$

Since $\operatorname{var}(h_2, h_3; a^*) = \operatorname{var}(h_2, h_3; a)$, we get $\operatorname{curv}(h_2, a)^2 \le 3 \cdot \operatorname{var}(h_2, h_3; a)$ for $\|a\| \le 1$.

Notice that

$$\|h_3(a) - h_2(a)\| \le \sqrt{2} \cdot \|h_3(a) - h_2(a)\|^{1/2} \le \sqrt{2} \cdot \operatorname{var}(h_2, h_3; a)^{1/2}\,,$$

for all *contractions* $a \in E$, in particular, $4\|h_3(a) - h_2(a)\| \le 6 \cdot \operatorname{var}(h_2, h_3; a)^{1/2}$.

It leads in case $\|a\| \le 1$ to the proposed estimates

$$C\big(s_1, s_2; h_3(a)\big) + C\big(s_1, s_2; h_3(a) - h_2(a)\big) + 4 \cdot \operatorname{var}(h_2, h_3; a)^{1/2}$$

and the bigger upper estimate

$$C\big(s_1, s_2; h_3(a)\big) + 10 \cdot \mathrm{var}(h_2, h_3; a)^{1/2}$$

for the norm of $h_1(a) - (h_1 \oplus_{t_1,t_2} h_3)(a)$. □

The proof of the following corollary is based on the estimates in Remark 4.5.1.

COROLLARY 4.5.2. *If $T, S \in E$ are isometries and $h, k \colon D \to E$ are C^*-morphisms, then there exists a unitary $U \in E \otimes \mathcal{O}_2$ such that*

$$\|U^*(h(a) \otimes 1)U - k(a) \otimes 1\| \ \leq\ 8 \cdot \mu(S, T;\, h, k;\, a)^{1/2}\,, \quad \forall\, a \in D\,, \tag{5.1}$$

where $\mu(S, T;\, h, k;\, a)$ denotes – for fixed $a \in D$ – the maximum of

$$\{\|S^* h(x) S - k(x)\|\,,\ \|T^* k(x) T - h(x)\|\,;\ x = a, a^*a, aa^*\}\,.$$

The Inequality (5.1) holds even if the unit element of E is not necessarily properly infinite, i.e., no orthogonality of SS^* and TT^* is required, i.e., it is not necessary that $C^*(S, T)$ is an image of $\mathcal{E}_2$.

PROOF. Given h, k, S, T, consider the C^*-morphisms

$$h_1 := h(\cdot) \otimes 1 \quad \text{and} \quad k_1 := k(\cdot) \otimes 1\,,$$

and define the “linking” completely positive contractions

$$h_2 := (S^* h(\cdot) S) \otimes 1 \quad \text{and} \quad k_2 := (T^* k(\cdot) T) \otimes 1\,.$$

We can take $s_1 := 1 \otimes r_1 \in E \otimes \mathcal{O}_2$ and $s_2 := 1 \otimes r_2$ in Remark 4.5.1 for the canonical generators r_1, r_2 of $\mathcal{O}_2 = C^*(r_1, r_2)$. Then s_1 and s_2 commute with the elements of $h_i(D) \cup k_j(D)$, $i, j \in \{1, 2\}$, and the estimates in Remark 4.5.1 apply to the C^*-morphisms h_1, $h_3 := k_1$ and the c.p. contraction $h_2 = t^* h_1(\cdot) t$ for $t := S \otimes 1$, respectively to k_1, $k_2 = t^* k_1(\cdot) t$ for $t := T \otimes 1$ and $k_3 := h_1$ (in place of h_1, t, h_2, h_3 in Remark 4.5.1).

Notice that $C\big(s_1, s_2; h_i(a)\big)$, $C\big(s_1, s_2; k_j(a)\big)$ and $C\big(s_1, s_2; h_i(a) - k_j(a)\big)$ are zero for $i, j = 1, 2$, and that the estimates in Remark 4.5.1 changes therefore to simpler ones, as e.g. to

$$\|h_1(a) - (h_1 \oplus_{t_1,t_2} k_1)(a)\| \ \leq\ 4 \cdot \mathrm{var}(h_2, k_1; a)^{1/2}\,,$$

and – with interchanged roles –

$$\|k_1(a) - (k_1 \oplus_{t_3,t_4} h_1)(a)\| \ \leq\ 4 \cdot \mathrm{var}(k_2, h_1; a)^{1/2}\,,$$

where we let $t_1 := (1 - SS^*) \otimes 1 + SS^* \otimes r_1$, and $t_2 := S \otimes r_2$ (build by $t := S \otimes 1$ from $s_k := 1 \otimes r_k$), and $t_3 := (1 - TT^*) \otimes 1 + TT^* \otimes r_1$ and $t_4 := T \otimes r_2$ (build by $t := T \otimes 1$ from $s_k := 1 \otimes r_k$).

If $U := t_1t_4^* + t_2t_3^*$ then $U(k_1 \oplus_{t_3,t_4} h_1) = (h_1 \oplus_{t_1,t_2} k_1)U$, and we obtain the estimate

$$\|U^*h_1(a)U - k_1(a)\| \le$$
$$\|h_1(a) - (h_1 \oplus_{t_1,t_2} k_1)(a)\| + \|k_1(a) - (k_1 \oplus_{t_3,t_4} h_1)(a)\| \le$$
$$4 \cdot \mathrm{var}(h_2, k_1; a)^{1/2} + 4 \cdot \mathrm{var}(k_2, h_1; a)^{1/2} \le$$
$$8 \cdot \mu(S,T;\, h,k;\, a)^{1/2} .$$

Here we have used that

$$\mu(S,T;\, h,k;\, a) = \max(\|k_2(x) - h_1(x)\|, \|h_2(x) - k_1(x)\| ;\; x = a, a^*a, aa^*) ,$$

i.e., that

$$\mu(S,T;\, h,k;\, a) = \max\bigl(\mathrm{var}(h_2, k_1; a), \mathrm{var}(k_2, h_1; a)\bigr) .$$

Notice finally that $\|U^*(h(a) \otimes 1)U - k(a) \otimes 1\| = \|U^*h_1(a)U - k_1(a)\|$. □

REMARK 4.5.3. The methods of estimates in the proofs of Remark 4.5.1 and Corollary 4.5.2 can be generalized to prove the following more flexible and general result (with different $U \in E$):

If $s_1, s_2, s_1', s_2' \in E$ are isometries, $s_1s_1^* + s_2s_2^* = 1 = s_1'(s_1')^* + s_2'(s_2')^*$, $h, k \colon D \to E$ are C^*-morphisms, and $S, T \in E$ are isometries, then there exists a unitary $U \in E$ that satisfies for all contractions $a \in D$ the inequality

$$\|U^*h(a)U - k(a)\| \le C\bigl(s_1, s_2; h(a)\bigr) + C\bigl(s_1', s_2'; k(a)\bigr) + 20 \cdot \mu(S,T;\, h,k;\, a)^{1/2} ,$$

where $\mu(S,T;\, h,k;\, a)$ is the maximum of

$$\{\|S^*h(x)S - k(x)\| ,\; \|T^*k(x)T - h(x)\| ;\; x = a, a^*a, aa^*\} ,$$

as defined in Corollary 4.5.2.

PROOF. Let $h_1 := h$, $h_2 := S^*h(\cdot)S$, and $h_3 := k$ and use the Cuntz addition $\oplus' := \oplus_{t_1,t_2}$ with isometries t_1, t_2 build by (s_1', s_2', S) in place of (s_1, s_2, t) in Remark 4.5.1, then we get that

$$\|h(a) - (h(a) \oplus' k(a))\| \le C\bigl(s_1', s_2'; k(a)\bigr) + 10 \cdot \mathrm{var}(S^*hS, k; a)^{1/2} .$$

If we take for Remark 4.5.1 $h_1 := k$, $h_2 := T^*k(\cdot)T$, $h_3 := h$ and use $\oplus := \oplus_{t_1,t_2}$ with t_1, t_2 build by (s_1, s_2, T) in place of (s_1, s_2, t) in Remark 4.5.1, then we obtain the estimate:

$$\|k(a) - (k(a) \oplus h(a))\| \le C\bigl(s_1, s_2; h(a)\bigr) + 10 \cdot \mathrm{var}(T^*kT, h; a)^{1/2} .$$

Now we use that

$$\mu(S,T;\, h,k;\, a) = \max\bigl(\mathrm{var}(S^*hS, k; a), \mathrm{var}(T^*kT, h; a)\bigr)$$

and take a unitary $U \in E$ with $U^*(x \oplus' y)U = y \oplus x$ for $x, y \in E$, then we get the upper estimate

$$C\bigl(s_1', s_2'; k(a)\bigr) + C\bigl(s_1, s_2; h(a)\bigr) + 20 \cdot \mu(S,T;\, h,k;\, a)^{1/2}$$

of $\|U^*h(a)U - k(a)\|$. □

REMARK 4.5.4. Let $A := H_0(D)$ and $C := A' \cap E$. The algebras $\mathcal{N}(A, J)$, $\beta(\mathcal{N}(A, J)) = \mathcal{N}(A, \beta J)$ and $\mathcal{N}(A, J + \beta J)$ are hereditary C^*-subalgebras of E, $\mathcal{N}(A, J) \cap \mathcal{N}(A, \beta J) = \mathrm{Ann}(A, E)$ (because $J \cap \beta J = 0$), and $\mathcal{N}(A, J) \cup \mathcal{N}(A, \beta J) \subseteq \mathcal{N}(A, J + \beta J)$.

The elements $s_2, s_3 \in E$ defined `check ref!!` Part (x) of Lemma 4.4.7 have the property that the partial isometry $Z := s_2 s_3^*$ satisfies $Z^*Z \in \mathcal{N}(A, \beta J)$, $ZZ^* \in \mathcal{N}(A, J)$, and $Z^*Z, ZZ^* \notin \mathrm{Ann}(A, J)$. Thus, $Z \in \mathcal{N}(A, J + \beta J) \setminus \mathrm{Ann}(A, J)$.

Conjecture: The partial isometry Z is not contained in the smallest β-invariant C^*-subalgebra of $\mathcal{N}(A, J + \beta J)$ generated by $\mathcal{N}(A, J)$, i.e.,

$$Z \notin C^*(\mathcal{N}(A, J) \cup \mathcal{N}(A, \beta J)) .$$

A positive answer seems likely, because otherwise there exist $n \in \mathbb{N}$, $a_1, \ldots, a_n, b_1, \ldots, b_n \in \mathcal{N}(A, J)$ such that $Z = b_1^*\beta(a_1) + \ldots + b_n^*\beta(a_n)$.

REMARK 4.5.5. The observations in Part (i) of Lemma 4.4.7 and the assumptions of Theorem 4.4.6 together *are not enough* to to give a general proof that $[k_1] = [k_2]$ and $k_1(B) \subseteq J$ imply $[k_1 + \beta k_3] = [k_2 + \beta k_3]$ for *all* C^*-morphisms $k_j \colon B \to J$, $j \in \{1, 2, 3\}$, of an arbitrary separable C^*-algebra B.

But, since $[k_1] = [k_2]$ and $k_1(B) \subseteq J$ together imply that there exists $u \in \mathcal{U}_0(E)$ with $u^*k_1(\cdot)u = k_2$ by Lemma 4.4.7(i), one can construct, with help of suitable paths of positive contraction in J_+, a norm-continuous path of unitaries $U(\xi) \in \mathcal{U}_0(J + \mathbb{C}1) \subset \mathcal{U}_0(E)$ for $\xi \in [0, \infty)$ such that $U(0) = 1$ and

$$\lim_{\xi \to \infty} U(\xi)^* k_1(b) U(\xi) = k_2(b) \quad \text{for all } b \in B .$$

Then $U(\xi)c = c = cU(\xi)$ for all $c \in \beta J \subset \mathrm{Ann}(J, E)$ and

$$\lim_{\xi \to \infty} U(\xi)^*(k_1(b) + \beta k_3(b))U(\xi) = k_2(b) + \beta k_3(b) \quad \text{for all } b \in B ,$$

i.e., $k_1 + \beta k_3$ and $k_2 + \beta k_3$ are unitarily homotopic in E in the sense of Definition 5.0.1, which is sometimes weaker than k_1 and k_2 being homotopic or unitary equivalent.

By symmetry – given by β – this shows also that for C^*-morphisms $k_j \colon B \to J$, $j \in \{1, 2, 3, 4\}$, the equations $[k_1] = [k_2]$ and $[k_3] = [k_4]$ imply that $k_1 + \beta k_3$ and $k_2 + \beta k_4$ are unitarily homotopic in E.

We apply Theorem 4.4.6 mainly to special cases where the ideal J is moreover sub-Stonean, i.e., has the property that, for each $a, b \in J_+$ with $ab = 0$, there exist contractions $c, d \in J_+$ with $ac = a$, $bd = b$ and $cd = 0$.

One can show that $[k_1] = [k_2]$ and $k_j(B) \subset J$ for $j \in \{1, 2\}$ imply $[k_1 + \beta k_3] = [k_2 + \beta k_3]$ for *all* C^*-morphisms $k_3 \colon B \to J$ if J is sub-Stonean in addition to the other assumptions of Theorem 4.4.6.

It is not clear if the assumptions of Theorem 4.4.6 allow to deduce from $[k_j] + [h_0] = [h_0]$ ($j \in \{1, 2\}$) that $[k_1 + \beta k_2] + [h_0 + \beta h_0] = [h_0 + \beta h_0]$ in the case where J is *not* sub-Stonean.

PROOF. If $[k_1] = [k_2]$ and $k_1(B) \subseteq J$ then there exists $u \in \mathcal{U}_0(E)$ with $u^* k_1(\cdot) u = k_2$ by Lemma 4.4.7(i).

There are $T_1, \ldots, T_n \in E$ with $T_m^* = -T_m$ for $m = 1, \ldots, n$, i.e., with $(iT_m)^* = iT_m$ in case of complex E, such that $u = \exp(T_1) \cdot \ldots \cdot \exp(T_n)$.

We can define C^*-morphisms $h_m \colon B \to J$ $(m = 1, \ldots, n-1)$ by $h_1 := k_1$, $h_{m+1}(\cdot) := \exp(-T_m) h_m(\cdot) \exp(T_m)$. Notice that $k_2 = h_{n+1}$.

Something unclear here!

Unitary homotopy, as defined in Definition 5.0.1 is an equivalence relation (in particular is *transitive*) and it suffices to show that of

????? of Theorem 4.4.6 ????

i.e., $k_1 + \beta k_3$ and $k_2 + \beta k_3$ are unitarily homotopic in E in the sense of Definition 5.0.1, which is sometimes weaker than being homotopic or unitary equivalent.

$h_m + \beta k_3$ and $h_{m+1} + \beta k_3$ are unitarily homotopic for $m = 1, \ldots, n$ (respectively are unitary equivalent by a unitary in $\mathcal{U}_0(J + \mathbb{C} \cdot 1)$ if J is sub-Stonean).

Thus, we may suppose that $n = 1$ and that $k_2 = \exp(-T) k_1(\cdot) \exp(T)$ with $T^* = -T$.

Let $T \in E$ with $T^* = -T$, and suppose first that J is a sub-Stonean C^*-algebra. In fact, we need only the weaker property of J that for every $g \in J_+$ there exists $f \in J_+$ with $\|f\| \leq 1$ and $gf = g$. Then we find a positive contraction $f \in J_+$ with $xf = x$ for all $x \in k_1(B)$ and a positive contraction $e \in J_+$ with $fe = e$ and $fT^\ell = f(eTe)^\ell$ for all $\ell \in \mathbb{N}$.

Indeed:
$k_1(B)$ contains a strictly positive contraction g_1, and there exists a contraction $f \in J_+$ with $fg_1 = g_1$. The C^*-subalgebra of J, generated by the countable subset $Y := \{ f, fT^n \,;\ n \in \mathbb{N} \}$ of J, contains a strictly positive contraction g_2. We find a positive contraction $e \in J_+$ with $g_2 e = g_2$. It satisfies $ye = y$ for all $y \in Y$, which implies $fT = fTe = (fe)(Te) = f(eTe)$, and that

$$fT^{n+1} = fT^{n+1}e = (fT^n)Te = (fT^n e)Te = fT^n(eTe)\,.$$

It follows by induction that $fT^n = f(eTe)^n$. Thus, $f\exp(T) = f\exp(eTe)$ and

$$k_1(b)\exp(T) = k_1(b) f \exp(T) = k_1(b) f \exp(eTe) = k_1(b)\exp(eTe) \quad \text{for all } b \in B\,.$$

If we use that $(eTe)^* = eT^*e = -eTe$ and $B^* \cdot B = B$, then we obtain that $\exp(eTe) \in \mathcal{U}_0(J + \mathbb{C} \cdot 1) \subset \mathcal{U}_0(E)$ and, for all $b \in B$,

$$\exp(-eTe)(k_1(b) + \beta k_3(b))\exp(eTe) = (\exp(-T) k_1(b) \exp(T)) + \beta k_3(b)\,.$$

We can reduce the proof of the general *unitary homotopy* to the sub-Stonean case if we consider k_1 and $\exp(-T)k_1(\cdot)\exp(T)$ as maps into suitable sub-Stonean ideals, e.g. if we use that

(1) $I := \mathrm{C_b}([0,\infty),J)/\,\mathrm{C_0}([0,\infty),J)$ is naturally isomorphic to a closed ideal of

$$\mathrm{C_b}([0,\infty),E)/\,\mathrm{C_0}([0,\infty),E) \supset E\,,$$

(2) $J = E \cap I$ is a C^*-subalgebra of I, and
(3) I is a sub-Stonean C^*-algebra.

Property (3) is easy to see. The above considerations show that, for given $T \in E$ with $T^* = -T$, there is a positive contraction $e \in I_+$ such that

$$\exp(-T)k_1(\cdot)\exp(T) \;=\; \exp(-eTe)k_1(\cdot)\exp(eTe)\,.$$

It means equivalently that $\exp(-T)k_1(b)\exp(T) = \lim_{\xi\to\infty} U(\xi)^*k_1(b)U(\xi)$ for all $b \in B$, where we define

$$U(\xi) :=\; \exp(g(\xi)Tg(\xi)) \in \mathcal{U}_0(J + \mathbb{C}\cdot 1) \subset \mathcal{U}_0(E)$$

with $g \in \mathrm{C_b}([0,\infty),J)$ a positive contraction that satisfies $g + \mathrm{C_0}([0,\infty),J) = e$. In particular, $\xi \mapsto U(\xi)$ is norm-continuous and $U(\xi) \in \mathcal{U}_0(\beta J' \cap E)$. It follows that $k_1 + \beta k_3$ and $\exp(-T)k_1(\cdot)\exp(T) + \beta k_3$ are unitarily homotopic via $\xi \mapsto U(\xi)$ for $T \in E$ with $T^* = -T$.

This proves finally that $[k_1] = [k_2]$ and $k_j(B) \subseteq J$ for $j = 1, 2, 3$ imply the unitary homotopy of $k_1 + \beta k_3$ and $k_2 + \beta k_3$. □

REMARK 4.5.6. There are also isometries s_1 and t_1 with $s_1s_1^* + t_1t_1^* = 1$ and $t_1H_0(\cdot) = H_0 = H_0(\cdot)t_1$ as proposed in Part (vi) of Lemma 4.4.7, but with interchanged role of p_0 and $1 - p_0$, i.e., we find those isometries $s_1, t_1 \in E$ with the additional properties $s_1^*p_0s_1 = 1$, $(1 - p_0)t_1 = (1 - p_0) = t_1(1 - p_0)$ instead of $s_1^*(1 - p_0)s_1 = 1$, $p_0t_1 = p_0 = t_1p_0$.

We do not know if in some applications (!) for given $g \in (J + \beta J)_+$ there exists isometries s_1, t_1 with above properties and the additional property that $t_1g = g = gt_1$, i.e., that in addition to $p_0s_1 = s_1$ holds $gs_1 = 0$. It means that there exists a full properly infinite projection $q \in p_0Ep_0$ with $qg = 0$.

PROOF. By Proposition 4.3.6(v), it suffices to find an isometry $R \in E$ with $(1 - p_0)R = 0$ and $R^*H_0(\cdot)R = 0$, i.e., with $R^*p_0H_0(\cdot)R = 0$.

There exists $u \in \mathcal{U}(E)$ with $s_0(h_0 + \beta h_0)s_0^* = u^*(h_0 + \beta h_0)u$ by Lemma 4.4.7(i). Let $R := s_0ut_0$. Then $p_0 = s_0s_0^*$, $s_0^*H_0s_0 = h_0 + \beta h_0$ and $s_0^*t_0 = 0$ imply $p_0R = R$, and $R^*H_0(\cdot)R = 0$. □

Here are some additional remarks concerning the C^*-subalgebras $C^*(p,q)$ and $C^*(p,q,1)$ generated by projections $p, q \in A$.

REMARK 4.5.7. Let A a unital C^*-algebra that is $\mathbb{Z}_2$-graded by $\beta_A \in \mathrm{Aut}(A)$ and let $F_1, F_2 \in A$ symmetries (i.e., $F_k^* = F_k$ and $F_k^2 = 1$) of degree one (i.e., $\beta_A(F_k) = -F_k$).

Then the unital C^*-subalgebra $B := C^*(F_1, F_2)$ of A satisfies $\beta_A(B) = B$.

It follows from Parts (iii) and (v) of Lemma 4.1.3 that there exists a grading preserving unital C^*-epimorphism φ from the universal (real or complex) C^*-algebra $C^*(P,Q,1) \subset \mathrm{C}([0,\pi/2],M_2)$ onto B with $\varphi(1-2P) = F_1$ and $\varphi(1-2Q) = F_2$.

Here we take the *odd* $\mathbb{Z}_2$-grading on $C^*(P,Q,1)$ given as the restriction to $C^*(P,Q,1)$ of the $\mathbb{Z}_2$-grading β on $\mathrm{C}([0,\pi/2],M_2)$ defined by $\beta(f)(\varphi) := Z^* f(\varphi) Z$ for $f \in \mathrm{C}([0,\pi/2],M_2)$ with $Z := [\zeta_{jk}] \in M_2 \subset \mathrm{C}([0,1],M_2)$ with $\zeta_{jk} := j-k$, $j,k \in \{1,2\}$.

In particular, if $\|F_1 - F_2\| < 2$ then there exists $h \in C^*(F_1,F_2)$ of degree zero (i.e., $\beta_A(h) = h$), with $h^* = -h$, and $\|h\| < \pi/2$ such that $F_2 = \exp(-h)F_1\exp(h)$.

The $\mathbb{Z}_2$-grading β of $\mathrm{C}([0,\pi/2],M_2)$ is odd in case $M_2 := M_2(\mathbb{R})$ and is even if $M_2 := M_2(\mathbb{C})$, because there is no symmetry S in $M_2(\mathbb{R})$ and $\mu \in \mathbb{R}$ with $Z = \mu S$, but $(iZ)^* = iZ =: S$ is a symmetry in $M_2(\mathbb{C})$.

Remark 4.5.8. A continuous path $\xi \in [0,1] \mapsto p_\xi \in A$ of projections p_ξ with $p_0 = p$ and $p_1 = q$ for projections $p,q \in A$ with $\|p-q\| < 1$, can be defined by $p_\xi := (U(\xi)+1)/2$ with symmetries $U(\xi) := |T(\xi)|^{-1}T(\xi)$ obtained from the path

$$T(\xi) := \sin(\xi\pi/2)(2q-1) + \cos(\xi\pi/2)(2p-1)$$

of self-adjoint invertible operators $T(\xi)$ with $T(\xi)^2 \geq 2(1-\|p-q\|^2)$ in $A + \mathbb{C}\cdot 1$, cf. [**73**, prop. 4.6.6] and proof of [**816**, prop. 5.2.6].

Parts (v) and (vi) of Lemma 4.1.3 show that the minimal length of a continuous path $\xi \mapsto u(\xi) \in \mathcal{U}(A)$ of unitary operators with $u(0) = 1$ and $u(1)^*pu(1) = q$ is exactly $\arcsin\|p-q\|$, because the *lower* bound for this length can be seen in M_2 itself.

Remark 4.5.9. There is an alternative way in the *complex case* to get the parameters for the C^*-morphisms of the universal unital C^*-algebra $C^*(P,Q,1)$ generated by projections P,Q into M_2 by considering the isomorphism of $C^*(P,Q,1)$ with universal C^*-algebras

$$C^*(P,Q,1) = C^*(s,t) \cong C^*(\mathbb{Z}_2 * \mathbb{Z}_2) \cong C^*(\mathbb{Z} \rtimes \mathbb{Z}_2) \cong \mathrm{C}(S^1) \rtimes \mathbb{Z}_2$$

with self-adjoint isometries $s := 1-2P$, $t := 1-2Q$, $\mathbb{Z} \subset \mathbb{Z}_2 * \mathbb{Z}_2$ given by $n \in \mathbb{Z} \mapsto (st)^n \in \mathbb{Z}_2 * \mathbb{Z}_2$ and the $\mathbb{Z}_2$-action $n \mapsto -n$ on $\mathbb{Z}$ realized by $(st)^n \mapsto s(st)^n s = (st)^{-n}$. Finally, $C^*(\mathbb{Z})$ will be naturally identified with $\mathrm{C}(\widehat{\mathbb{Z}}) = \mathrm{C}(S^1)$. We get a parametrization by $\varphi \in (0,\pi/2)$ of the simple quotients of $\mathrm{C}(S^1) \rtimes \mathbb{Z}_2$ with the 4 characters attached at 0 and $\pi/2$ in the same way as the parametrization given by the embedding of $C^*(P,Q,1)$ into $\mathrm{C}([0,\pi/2],M_2)$ with the 4 characters attached at 0 and $\pi/2$.

Let $F := [f_{jk}] = \mathrm{diag}(-1,1)Z \in M_2$ the flip-symmetry with $f_{jk} := |1-\delta_{jk}|$. Then the inner automorphism $U^*(\cdot)U$ of $M_2(\mathbb{C})$ given e.g. by the unitary $U := [u_{jk}] \in M_2(\mathbb{C})$ with entries $u_{11} := -i/\sqrt{2} =: -u_{21}$ and $u_{12} := u_{22} := 1/\sqrt{2}$ transforms all pairs of unitary elements $\mathrm{diag}(e^{2i\varphi},e^{-2i\varphi}), F \in M_2(\mathbb{C})$ into the pairs $t(\varphi), s$ defined in our case as

$$(1-2P)(1-2Q(\varphi)),\ 1-2p \in \mathrm{O}(2) \subset M_2(\mathbb{R}).$$

Notice here that

$$st(\varphi) = (1-2P)(1-2Q(\varphi)) = (1-2P)\exp(-\varphi Z)(1-2P)\exp(\varphi Z) = \exp(2\varphi Z)$$

with P, Z, Q as in Lemma 4.1.3(iii). Then it suffices to check that $U^*U = 1_2$, $FU = U\,\mathrm{diag}(-1,1)$ and $\mathrm{diag}(i,-i)U = UZ$, to obtain that the parameter $\varphi \in [0, \pi/2]$ defines the same C^*-morphism from $C^*(P, Q, 1)$ into M_2.

6. On K-theory of corona C^*-algebras

The homotopy of id and δ_2 and that $\mathcal{O}_2$ is a pi-sun algebra can be used to derive that they are unitary equivalent in

$$\ell_\infty(\mathcal{O}_2)/c_0(\mathcal{O}_2)\,.$$

It turns out that this property implies that $\mathcal{O}_2$ has a central sequence of unital copies of $\mathcal{O}_2$...

Some almost $\mathcal{E}$-theory results:

Suppose that B is a σ-unital C^*-algebra and that $\mathcal{M}(B)$ is properly infinite, i.e., that $\mathcal{O}_\infty$ is unitally contained in $\mathcal{M}(B)$, let A a separable C^*-subalgebra of B, and suppose that there is a sequence of point-norm continuous paths of c.p. contractions $V_{n,\xi} \colon A \to B$ ($n \in \mathbb{N}$, $\xi \in [0,1]$) given, where $\mathcal{M}(B)$ is properly infinite, i.e., there are isometries $S, T \in \mathcal{M}(B)$ with $S^*T = 0$.

Is this the Def. of "properly infinite" C*-algebras?

We can manage that $SS^* + TT^* = 1$ if $[1_{\mathcal{M}(B)}] = 0$ in $\mathrm{K}_0(\mathcal{M}(B))$ (e.g. this is the case if B is stable) and other-wise we find the isometries $S, T \in \mathcal{M}(B)$ such that $1 - SS^* + TT^*$ is a properly infinite full projection, e.g. we can replace S, T by TS, ST and have $T^2(T^2)^* \leq 1 - (TSS^*T^* + STT^*S^*)$.

Notice that $[1 - SS^* + TT^*] = -[1]$ in $\mathrm{K}_0(\mathcal{M}(B))$.

We define

(i) a unital C^*-morphism $\lambda \colon \mathcal{O}_\infty \to \mathcal{M}(B)$ by $\lambda(T_n) := S_n := T^{n-1}S$ (with $T^0 := 1$) and

(ii) $V_{\infty,\alpha} \colon A \to B_\infty := \ell_\infty(B)/c_0(B)$ for $\alpha \in \{0,1\}$ by

$$V_{\infty,\alpha}(a) := (V_{1,\alpha}(a), V_{2,\alpha}(a), \ldots) + c_0(B)\,.$$

Now fix a linear filtration $X_1 \subseteq X_2 \subseteq$ of A by finite-dimensional subsets with $\bigcup_n X_n$ dense in A.

Then there exists "Cuntz-averages"

$$W_n := \sum_{k=1}^{k_n} S_k V_{n,\xi_k} S_k^*$$

of the $V_{n,\xi}$ ($\xi \in [0,1]$) with suitable $0 = \xi_1 < \xi_2 < \ldots < \xi_{k_n} = 1$ and unitaries $U_n \in \mathcal{M}(B)$ with

(iii) $\|V_{n,\tau_k}(a) - V_{n,\tau_{k+1}}(a)\| < 2^{-n}$ for $a \in X_n$, and

(iv) $S^*U_n = S_1^*S^*$, $S_k^*T^*U_n = S_{k+1}^*S^*$ for $k = 1, \ldots, k_n - 1$ and $S_{k_n}^*T^*U_n = T^*$, i.e., with suitable partial isometry $Z_n \in \mathcal{M}(B)$ the unitary U_n is given by

$$U_n := SS_1^*S^* + TS_1S_2^*S^* + \ldots + TS_kS_{k+1}^*S^* + TS_{k_n-1}S_{k_n}^*S^* + TS_{k_n}T^* + Z_n .$$

The partial isometry $Z_n \in \mathcal{M}(B)$ used in the definition of the unitary U_n exists by our assumptions on the isometries S, T, because $S_k = T^{k-1}S$.

$$Y := SS_1^*S^* + TXS^* + TS_{k_n}T^* ,$$

with

$$X := \sum_{k=1}^{k_n-1} S_kS_{k+1}^* .$$

Then $X^*S_{k_n} = 0 = S_{k_n}^*X$, $X^*X = \sum_{k=1}^{k_n-1} S_{k+1}S_{k+1}^*$ and

$$XX^* =???? = \sum k = 1^{k_n-1} S_kS_k^* .$$

$S_kS_{k+1}^*S_{\ell+1}S_\ell^* = \delta_{k,\ell}S_kS_k^*$

$$\sum_{k,\ell=1}^{k_n-1} S_kS_{k+1}^*\, S_{\ell+1}S_\ell^* = \sum_{k=1}^{k_n-1} S_kS_k^*$$

It follows

$$Y^*Y = (\sum_{j=1}^{k_n} S_jS_j^*) \oplus_{S,T} 1$$

and

$$YY^* = 1 \oplus_{S,T} (\sum_{j=1}^{k_n} S_jS_j^*)$$

The projection $P_{k_n} := 1 - \sum_{j=1}^{k_n} S_jS_j^*$ is full and properly infinite by construction of the S_k, because $P_{k_n}S_\ell = S_\ell$ for $\ell > k_n$.

Then $W_\infty(a) := (W_1(a), W_2(a), \ldots) + c_0(B)$ is a c.p.c. map from A into B_∞ and $U_\infty = (U_1, U_2, \ldots) + c_0(B)$ is a unitary in $\mathcal{M}(B_\infty)$ that satisfies

$$U_\infty^*(V_{\infty,0} \oplus_{S,T} W_\infty)U_\infty = W_\infty \oplus_{S,T} V_{\infty,1}$$

in $B_\infty := \ell_\infty(B)/c_0(B)$.

The same happens for B_ω in place of B_∞, simply by passing to the quotient B_ω of B_∞ and by observing that this epimorphism maps $\mathcal{M}(B_\infty)$ unitally into $\mathcal{M}(B_\omega)$.

A bit more technical work is needed for the construction of ?????

The key trick of N.Ch. Phillips in [**627**] is the construction of suitable interpolations between the above defined “Cuntz averages” for point norm continuous maps $V_{t,\xi} \in \mathrm{CP}(A, B)$ ($t \in [0, \infty)$, $\xi \in [0, 1]$), i.e., construct fitting strictly continuous paths $A \ni a \mapsto W_t(a) \in B$ in the approximately inner c.p.c. maps $W_t \in \mathrm{CP}(A, B)$

that satisfy that $V_{t,0} \oplus W_t$ and $W_t \oplus V_{t,0}$ are asymptotic unitarily equivalent by a norm-continuous path $t \to U(t)$ of unitaries in $\mathcal{M}(B)$.

We do this in case of special classes of $V_{t,\xi} \in \mathcal{C} \subseteq \mathrm{CP}(A, B)$ that cover the cases considered by N.Ch. Phillips.

Further plan for topics:
Applications to unital endomorphisms of $\mathcal{O}_\infty$
(all are unitarily homotopic),
permutation $C*$-morphisms of $\mathcal{O}_\infty \otimes \mathcal{O}_\infty$, $\mathcal{O}_\infty \otimes \mathcal{O}_\infty \otimes \cdots$
(are all unitarily homotopic)
and to the n-repeat $\delta_n \colon \mathcal{O}_{\mathrm{n}} \to \mathcal{O}_{\mathrm{n}}$
(δ_n unitarily homotopic to $\mathrm{id}_{\mathcal{O}_{\mathrm{n}}}$,
unital endomorphisms are all unitarily homotopic to id
existence of asymptotic central path of copy of $\mathcal{O}_2$ in $\mathcal{O}_2$).

Following should be a remark in Chp.4?
But with target $\mathcal{O}_2$ replaced by $Q(\mathbb{R}_+, \mathcal{O}_2)$? Partly some appears even in ?? Chp.1.!. But at beginning of Chp.5 there are some calculations in this direction

All unital C^*-morphisms $h \colon \mathcal{O}_2 \to A$ are unitarily homotopic to each other, if and only if, they are homotopic, – and in “good cases” of A (e.g. if A is K_1-injective)– if and only if, the related unitaries are in $\mathcal{U}_0(A)$?

$h_1, h_2 \colon \mathcal{O}_2 \to \mathrm{Q}(\mathbb{R}_+, A)$ both are in “general position” and represent the zero element of $[\mathrm{Hom}_u(\mathcal{O}_2, \mathrm{Q}(\mathbb{R}_+, A))]$, because they dominate each other. In general the unitary equivalence can not be given by a unitary in $\mathcal{U}_0(\mathrm{Q}(\mathbb{R}_+, A))$. Example: The unital free product $\mathcal{O}_2 * \mathrm{C}(S^1) \cong \mathcal{O}_2 * \mathcal{O}_2$.

The latter could be deduced from a very special case of Theorem A: There is a unital $g \colon \mathcal{O}_2 \otimes \mathcal{O}_2 \to \mathcal{O}_2$, and $a \mapsto h(a) := g(a \otimes 1)$ is unitarily homotopic inside $\mathcal{O}_2$ to $\mathrm{id}_{\mathcal{O}_2}$. Then $h_1(g((\cdot) \otimes 1))$ and $h_2(g((\cdot) \otimes 1))$ dominate each other asymptotically by

Corollary ?? (on the asymptotic domination of residually nuclear C^*-morphisms $h_k \colon A \to B$ of stable separable C^*-algebras A and B, where A is exact and separable and B is s.p.i.).

Suppose that E is strongly purely infinite, and that A is separable and exact, (or if E is not s.p.i., that A is separable, s.p.i. and exact). Then every nuclear C^*-morphism $\varphi \colon A \to E$ extends to a C^*-morphism $\psi \colon A \otimes \mathcal{O}_\infty \to \mathrm{Q}(\mathbb{R}_+, E)$, by Proposition 3.0.4.

Let $g_k \colon A \otimes \mathcal{O}_\infty \to E$ $(k = 1, 2)$ C^*-morphisms such that the C^*-morphisms $h_k(a) := g_k(a \otimes 1)$ generate the same m.o.c. cone in $\mathrm{CP}(A, E)$, then h_1 and h_2 1-step-dominate each other in $\mathrm{Hom}(A, E^\infty)$ or $\mathrm{Hom}(A, \mathrm{Q}(\mathbb{R}_+, E))$.

If the h_k are injective and nuclear, then they generate the same m.o.c. cone, if and only if, for each $a \in A_+$, the elements $h_1(a)$ and $h_2(a)$ generate the same ideal of E.

In particular, for any two injective unital nuclear C^*-morphisms $g_1, g_2 \colon A \otimes \mathcal{O}_2 \to E$ that induce the same action of $\mathrm{Prim}(E)$ on A the C^*-morphisms h_1 and h_2 are unitarily homotopic.

Because one finds isometries $S, T \in \mathrm{Q}(\mathbb{R}_+, E)$ with $S^* h_1(\cdot) S = h_2$ and $T^* h_2(\cdot) T = h_1$ by simplicity and nuclearity of the h_k and the pure algebraic fact that there commutant algebras contain (possibly different) copies of $\mathcal{O}_2$ unitally.

Then we get from Chapter 4 that h_1 and h_2 both are unitarily equivalent in $\mathrm{Q}(\mathbb{R}_+, E)$ to $h_1 \oplus h_2$.

The situation of unital C^*-morphisms form $\mathcal{O}_2$ into the stable corona $\mathrm{Q}^{\mathrm{s}}(B)$ is different:

The (usual) *homotopy classes* of the unital $h \colon \mathcal{O}_2 \to \mathrm{Q}^{\mathrm{s}}(B)$ are in bijective correspondence to $\mathrm{K}_0(B) \cong \mathrm{K}_1(\mathrm{Q}^{\mathrm{s}}(B))$ by the K_1-bijectivity of stable coronas by Proposition **??**, but there is *only one* (sic !) class of *unitary homotopy*.

More generally, for every unital C^*-algebra E with properly infinite unit that satisfies $0 = [1_E] \in \mathrm{K}_0(E)$ there is up to unitary homotopy only one unital C^*-morphism $h \colon \mathcal{O}_2 \to E$, cf. Section **??**, but the homotopy classes of unital $h \in \mathrm{Hom}(\mathcal{O}_2, E)$ is identical with $\mathcal{U}(E)/\mathcal{U}_0(E)$, which is isomorphic to $\mathrm{K}_1(E)$ if and only if E is K_1-injective in addition (As is e.g. the case where E stable corona $E = \mathrm{Q}^{\mathrm{s}}(A)$ of a σ-unital C^*-algebra A or where E is strongly purely infinite.)

An example is the Calkin algebra $\mathcal{C} := \mathcal{C}(\ell_2) := \mathcal{L}(\ell_2)/\mathbb{K}(\ell_2)$. Then each unital C^*-morphism $\psi \colon \mathcal{O}_2 \to \mathcal{C}$ is up to unitary equivalence given by multiplying the $\pi_{\mathbb{K}} \circ \rho(s_j)$ with a unitary in $\mathcal{C}$ from the left. The multiplication with images of Toeplitz operators T^n or $(T^*)^m$ exhausts all cases (up to unitary equivalence in $\mathcal{C}$?).

Corollary 4.6.1. *There is a copy of $\mathcal{O}_{\mathrm{n}}$ unitally contained in ${\mathcal{O}_{\mathrm{n}}}' \cap \mathrm{Q}(\mathbb{R}_+, \mathcal{O}_{\mathrm{n}})$, i.e., there exists a point-norm continuous path of u.c.p. maps $V_t \colon \mathcal{O}_{\mathrm{n}} \otimes \mathcal{O}_{\mathrm{n}} \to \mathcal{O}_{\mathrm{n}}$ such that $\lim_{t\to\infty} \|V_t(a \otimes 1) - a\| = 0$ for all $a \in \mathcal{O}_{\mathrm{n}}$, $\lim_{t\to\infty} \|[a, V_t(1 \otimes b)]\| = 0$ for all $a, b \in \mathcal{O}_{\mathrm{n}}$ and*

$$\lim_{t\to\infty} \|V_t(1 \otimes b^* b) - V_t(1 \otimes b)^* V_t(1 \otimes b)\| = 0 \quad \textit{for all } b \in \mathcal{O}_{\mathrm{n}}\,.$$

The proof should follow from a "unsuspended" E-theory argument concerning asymptotic homotopy of id and δ_n considered in $\mathrm{Q}(\mathbb{R}_+ \times [0,1], \mathcal{O}_{\mathrm{n}})$, respectively the then unitary equivalence $\delta_n(a) = U^* a U$ in $\mathrm{Q}(\mathbb{R}_+, \mathcal{O}_{\mathrm{n}})$ for $a \in \mathcal{O}_{\mathrm{n}} \subseteq \mathrm{Q}(\mathbb{R}_+, \mathcal{O}_{\mathrm{n}})$. The unital embedding $\mathcal{O}_{\mathrm{n}} \to {\mathcal{O}_{\mathrm{n}}}' \cap \mathrm{Q}(\mathbb{R}_+, \mathcal{O}_{\mathrm{n}})$ is defined by the elements $U s_j$ $(j = 1, \ldots, n)$.

Corollary 4.6.2. *For every strongly purely infinite, unital, separable and nuclear C^*-algebra A there is a copy of $\mathcal{O}_\infty \otimes \mathcal{O}_\infty \otimes \cdots$ unitally contained in $A' \cap \mathrm{Q}(\mathbb{R}_+, A)$.*

It uses that $\mathcal{O}_\infty \subseteq \mathcal{M}(A)$ (unitally) and the nuclear map $a \to s_1 a s_1^* + s_2 a s_2^*$ is asymptotical 1-step dominated by id_A, because every nuclear ideal system preserving c.p. map is approximately 1-step inner. (See study of nuclear c.p. maps in s.p.i. algebras).

Find contraction $T \in \mathrm{Q}(\mathbb{R}_+, \mathcal{M}(A))$ with $s_1 a s_1^* + s_2 a s_2^* = T^* a T$ it implies that $\delta_{jk} \cdot a = s_j^* T^* a T s_k = t_j^* a t_k$ for the contractions $t_k := T s_k$.

More ???? Tensor by $\mathbb{K}$ first or not? ...

We shall see in Chapter 10 that this implies that $A \otimes \mathcal{O}_\infty \cong A$ for every purely infinite separable nuclear A, using that there exists a unital C^*-morphism $\eta \colon \mathcal{O}_\infty \to \mathrm{C}([0,1], \mathcal{O}_\infty \otimes \mathcal{O}_\infty)$ with $\pi_0(\eta(b)) = b \otimes 1$ and $\pi_1(\eta(b)) = 1 \otimes b$ by $\eta(s_n)(t) :=$????? ?????????????? `exact formulations needed!!!` And where is the proof? of .

COROLLARY 4.6.3. *If B is separable, nuclear and strongly purely infinite then there exists a norm-continuous path of *-monomorphisms $h_t \colon B \otimes \mathcal{O}_\infty \to B$ such that* $\lim_{t\to\infty} \|h_t(b \otimes 1) - b\| = 0$.

Next corollary will be used in Chapter 5.

COROLLARY 4.6.4. *Suppose that A is a unital C^*-algebra and $h_1, h_2 \in \mathrm{Hom}(\mathcal{O}_2, A)$ are unital C^*-morphisms, then there exists a norm-continuous path $t \in [0, \infty) \mapsto u(t) \in \mathcal{U}(A)$ such that $h_2(x) = \lim_{t\to\infty} u(t)^* h_1(x) u(t)$ for all $x \in \mathcal{O}_2$.*

PROOF. There exist a unital C^*-morphism $k_0 \colon \mathcal{O}_2 \to {\mathcal{O}_2}' \cap \mathrm{Q}(\mathbb{R}_+, \mathcal{O}_2)$, by Corollary 4.6.1.

`Give exact and precise reference!`

We write $\mathcal{O}_2 := C^*(s_1, s_2)$, $s_1^* s_1 = 1 = s_2^* s_2$, $s_1 s_1^* + s_2 s_2^* = 1$.

The unital C^*-morphisms $h_1, h_2 \colon \mathcal{O}_2 \to A$ extend to unital C^*-morphisms H_1 and H_2 from $\mathrm{Q}(\mathbb{R}_+, \mathcal{O}_2)$ to $\mathrm{Q}(\mathbb{R}_+, A)$ with $H_\ell | \mathcal{O}_2 = h_\ell$ ($\ell \in \{1, 2\}$).

Then $k_\ell := H_\ell \circ k_0$ are unital C^*-morphisms from $\mathcal{O}_2$ into $h_\ell(\mathcal{O}_2)' \cap \mathrm{Q}(\mathbb{R}_+, A)$ ($\ell \in \{1, 2\}$).

It suffices to show that there exists a unitary $U \in \mathrm{Q}(\mathbb{R}_+, A)$ with $U^* h_1(s_j) U = h_2(s_j)$, $j \in \{1, 2\}$.

`To be filled in` ?? □

`?? Is next Lemma 4.6.5 in a good position? Move it to Chapter 5?`

LEMMA 4.6.5. *Suppose that B is a stable C^*-algebra and that $\psi \colon D \to \mathcal{M}(B)$ is a C^*-morphism from separable D to $\mathcal{M}(B)$.*

The relative commutant $\delta_\infty(\psi(D))' \cap \mathcal{M}(B)$ of the image of the infinite repeat $\delta_\infty \circ \psi$ has trivial K_*-groups and is closed in the strict topology.

The infinite repeat $\delta_\infty\colon \mathcal{M}(B) \to \mathcal{M}(B)$ is given by $\delta_\infty(b) := \sum_n s_n b s_n^*$ for $b \in \mathcal{M}(B)$ where $s_1, s_2, \ldots$ is a sequence of isometries in $\mathcal{M}(B)$ with $\sum_n s_n s_n^* = 1$ strictly convergent, cf. Remark 5.1.1(8) and Lemma 5.1.2(i,ii).

Proof. Let $F := \delta_\infty(\psi(D))' \cap \mathcal{M}(B)$. It is closed under strict convergence. Certainly, $\delta_\infty(\mathcal{M}(B))' \cap \mathcal{M}(B) \subseteq F$. By Lemma 5.1.2(i),

early citations ? ??

there are isometries $t_1, t_2, \ldots$ in $\delta_\infty(\mathcal{M}(B))' \cap \mathcal{M}(B)$ such that $\sum t_n t_n^*$ strictly converges to 1. By Lemma 5.1.2(ii), there are isometries r_1 and r_2 in $\delta_\infty(\mathcal{M}(B))' \cap \mathcal{M}(B)$ with $r_1 r_1^* + r_2 r_2^* = 1$.

Let $h\colon \mathcal{M}(B) \to \mathcal{M}(B)$ denote the infinite repeat of id which is defined by $t_1, t_2, \ldots$, cf. Remark 5.1.1(8).The element $h(b) = \sum$ is in F if $b \in F$, because F is strictly closed. Thus, $h|F$ is a unital *-endomorphism of F. Let $u := r_1 t_1^* + \sum r_2 t_n t_{n+1}^*$. The right side converges strictly to a unitary u in $\mathcal{M}(B)$ by proof of Lemma 5.1.2(i) (see e.g. Remark 5.1.1(2) for the strict convergence). Since its summands are in F, we get $u \in F$. It holds $u^*(b \oplus_{r_1,r_2} h(b))u = h(b)$ for $b \in F$ by the convergence argument in Remark 5.1.1(2) and in the proof of Lemma 5.1.2(ii). Thus $\mathrm{K}_*(F) = 0$ ([9]). □

The following Lemma 4.6.6 is a K_1-counterpart to Proposition 4.4.3(iii). 4.4.3(iii) correct? ??

Lemma 4.6.6. *Suppose that B is stable and σ-unital, D is stable and separable, and that $H\colon D \to \mathcal{M}(B)$ is a non-degenerate C^*-morphism such that $\delta_\infty \circ H$ is unitarily equivalent to H (by an unitary in $\mathcal{M}(B)$).*

Let $E := \mathrm{Q}^{\mathrm{s}}(B) = \mathcal{M}(B)/B$, $H_0 := \pi_B \circ H$, $C := H_0(D)' \cap E$, and let $\mathcal{U}(H(D), B)$ denote the set of unitaries in $\mathcal{M}(B)$ that commute modulo B element-wise with $H(D)$.

(i) *$\mathcal{U}(H(D), B)$ is closed under Cuntz addition and $U \mapsto [U + B]$ is an additive epimorphism from $\mathcal{U}(H(D), B)$ onto the kernel of $i_1\colon \mathrm{K}_1(C) \to \mathrm{K}_1(E)$, where $i_1 = \mathrm{K}_1(i)$ for the inclusion map $i\colon C \hookrightarrow E$.*

(ii) *Let $U_1, U_2 \in (H(D), B)$ and let $U := U_1 \oplus 1$, $U' := U_2 \oplus 1$. Then $[U_1 + B] = [U_2 + B]$ in $\mathrm{K}_1(H_0(D)' \cap E)$,*
if and only if,
there exist $U'' \in \mathcal{U}(H(D), B)$ such that $U'' - U \in B$ and U' is homotopic to U'' in $\mathcal{U}(H(D), B)$,
if and only if,
there exist $U'', V \in \mathcal{U}(H(D), B)$ such that $V^* U' V$ is homotopic to U'' in $\mathcal{U}(H(D), B)$ and $(U'' - U)H(D) \subseteq B$.

[9] More generally, the existence of a unital endomorphism $h\colon F \to F$ with $[h \oplus \mathrm{id}_F] = [h]$ and $h \circ \mathcal{C} \subseteq \mathcal{C}$ implies $\mathrm{KK}(\mathcal{C}; A, F) = 0$ for all our generalized KK-theories in Chapter 8.

PROOF. There exists a unital C^*-morphism $\mathcal{O}_2 \to \delta_\infty(\mathcal{M}(B))' \cap \mathcal{M}(B)$. The latter is contained in $H(D)' \cap \mathcal{M}(B)$. It defines the needed isometries $s_1, s_2 \in H(D)' \cap \mathcal{M}(B)$, cf. e.g. Lemma 5.1.2(ii).

?? Is it good to ref Chp 5 here?

(i): It is easy to see that $\mathcal{U}(H(D), B)$ is closed under Cuntz addition, because $\mathcal{O}_2$ commutes with $H(D)$. The image of $\mathcal{U}(H(D), B)$ under $U \to U + B \in E$ goes into the unitary group of C. $\mathrm{K}_1(\mathcal{M}(B)) = 0$ because B is stable. Thus $[U+B]_E = 0$ in $\mathrm{K}_1(E)$ because $[U]_{\mathcal{M}(B)} = 0$ in $\mathrm{K}_1(\mathcal{M}(B))$. The Cuntz addition in $\mathcal{M}(B)$ induces the Cuntz addition in E: $(U_1 \oplus U_2) + B = (U_1 + B) \oplus (U_2 + B)$. By Lemma 4.2.6(v),the natural map from the unitaries of C into $\mathrm{K}_1(C)$ is an additive epimorphism with respect to Cuntz addition on C.

It remains to show that $U \to [U + B]$ is an epimorphism onto the kernel of $\mathrm{K}_1(C) \to \mathrm{K}_1(E)$. Let $x \in \mathrm{K}_1(C)$ be in the kernel of $i_1 \colon \mathrm{K}_1(C) \to \mathrm{K}_1(E)$. Then there is a unitary in $u \in C$ with $[u]_C = x$, $[u]_E = 0$. Since $1_E \subseteq \mathcal{O}_2 \subseteq C \subseteq E$, we can use Lemma 4.2.6(v,2) and get $[u \oplus 1]_C = [u]_C = x$ and that $u \oplus 1$ is homotopic to 1 in the unitaries of E. Thus, there is a unitary $U \in \mathcal{M}(B)$ with $U + B = u \oplus 1$. U commutes element-wise with $H(D)$ modulo B, because $U + B = u \oplus 1 \in C = ((H(D) + B)/B)' \cap E$.

(ii): Let $U' := U_1 \oplus 1$, $U'' := U_2 \oplus 1$ and $v_1 := U_1 + B$ and $v_2 := U_2 + B$ the corresponding unitaries in C. By Lemma 4.2.6(v,2), $[v_1]_C = [v_2]_C$ if and only if $v_1 \oplus 1 = U' + B$ is homotopic to $v_2 \oplus 1 = U'' + B$ in the unitaries of C. This homotopy can be lifted to a continuous arc $t \in [0, 1] \mapsto U(t)$ in the unitaries of $\mathcal{M}(B)$ starting from $U(0) = U'$ and ending at $U'' := U(1)$. Then $U'' - U \in B$. But if V is a unitary in $\mathcal{M}(B)$ such that $V + B \in C$ then V commutes element-wise with $H(D)$ modulo B. Thus $U(t) \in \mathcal{U}(H(D), B)$ for $t \in [0, 1]$.

Conversely, let $U := U_1 \oplus 1$, $U' := U_2 \oplus 1$ and suppose that there exist unitaries $V, U'' \in \mathcal{U}(H(D), B)$ and a continuous arc $t \in [0, 1] \mapsto U(t)$ into $\mathcal{U}(H(D), B)$ with $U(0) = V^* U' V$, $U(1) = U''$ and $(U'' - U)H(D) \subseteq B$.

Let $v_1 := U_1 + B$, $v_2 := U_2 + B$, $v_3 := V + B$ and $v_4 := U'' + B$. Then $[v_2]_C = [v^3(v_2 \oplus 1)v_3]_C = [v_4]_C$ in $\mathrm{K}_1(C)$, because $[1]_C = 0$ and $t \mapsto U(t) + B$ connects $v^3(v_2 \oplus 1)v_3$ and v_4 in the unitaries of C.

On the other hand, $v_1 \oplus 1, v_4 \in C$, $(v_1 \oplus 1) - v_4$ is in the annihilator $\mathrm{Ann}(H_0(D))$ of $H_0(D)$ in E, and $[v_1 \oplus 1]_E = [v_4]_E = 0$ in $\mathrm{K}_1(E)$. By Proposition 5.5.12(ii), $H_0 \colon D \to E$ dominates zero, because $(\pi_B)^{-1}(H_0(D)) = B + H(D)$ contains the stable and non-degenerate C^*-subalgebra $H(D)$. Therefore, the two-sided annihilator $\mathrm{Ann}(H_0(D))$ of $H_0(D) \subseteq E$ is a *full* hereditary C^*-subalgebra of E. The annihilator $\mathrm{Ann}(H_0(D))$ is an ideal of $C = H_0(D)' \cap E$. Thus, Lemma 4.2.20(ii) applies to $N := \mathrm{Ann}(H_0(D)) \subseteq C \subseteq E$ and $v_1 \oplus 1$, $v_4 \in C$. We get $[v_1] = [v_1 \oplus 1] = [v_4] = [v_1]$ in $\mathrm{K}_1(C)$. □

COROLLARY 4.6.7. *Suppose that $J \subseteq E \subseteq F$ are C^*-subalgebras of F and satisfy the following conditions* (i)–(v)*:*

(i) $1_F \in E$.
(ii) J *and is an ideal of* F.
(iii) *For every* $b \in J_+$ *there is* $c \in J_+$ *with* $\|c\| = 1$ *and* $cb = b$.
(iv) *For every* $c \in J_+$ *there is an isometry* $t \in E$ *with* $ct = 0$.
(v) E *contains a copy of* $\mathcal{O}_2$ *unitally.*

If A *is a* σ*-unital* C^**–algebra, and* $h_1, h_2 \colon A \to J$ *are* C^**-morphisms, then the following* (a)–(c) *are equivalent:*

(a) $h_2 = U^* h_1(\cdot) U$ *for a unitary* U *in the* connected component $\mathcal{U}_0(E)$ of 1 *in the group* $\mathcal{U}(E)$ *of unitaries of* E.
(b) h_1 *and* h_2 *are unitarily equivalent in* F.
(c) h_1 *and* h_2 *are unitarily equivalent in* $\mathcal{M}(J)$.

Proof. (a)⇒(b)⇒(c): There are natural unital C^*-morphisms

$$E \to F \to \mathcal{M}(J)$$

that fix the elements of J by assumptions (i) and (ii).

(c)⇒(a): Suppose that $U \in \mathcal{M}(J)$ is a unitary with $h_2 = U^* h_1(\cdot) U$. Let $e \in A_+$ a strictly positive element of A, and let $b := h_1(e) + h_2(e)$. By (iii) and (iv), there are $c \in J_+$ and $t \in E$ with $\|c\| \leq 1$, $cb = b$, $ct = 0$ and $t^* t = 1$. It follows $ch_k(\cdot) = h_k = h_k(\cdot)c$ $(k = 1, 2)$, and $t^*(h_1(a) + h_2(a))t = 0$ for $a \in A$. Let $x := cUc$. Then x is a contraction in $J \subseteq E$ that satisfies $x^* h_1(\cdot) x = h_2$ and $x h_2(\cdot) x^* = h_1$. Since $t \in E$ and E contains a copy of $\mathcal{O}_2$ unitally by (v), the Parts (iii) and (iv,c) of Proposition 4.3.6 apply: There is $V \in \mathcal{U}_0(E)$ with $V^* h_1(\cdot) V = h_2$. □

Remark 4.6.8. We consider in Chapters 7 and 9, the case, where $F := \mathrm{Q}(\mathrm{C}_0(X, B)) := \mathcal{M}(\mathrm{C}_0(X, B)) / \mathrm{C}_0(X, B)$, $E := \mathrm{C}_\mathrm{b}(X, \mathcal{M}(B)) / \mathrm{C}_0(X, B)$ and $J := \mathrm{Q}(X, B) := \mathrm{C}_\mathrm{b}(X, B) / \mathrm{C}_0(X, B)$ for stable σ-unital B and a σ-compact locally compact Hausdorff space X.
Note that in this particular case, J is the (two-sided) annihilator $\mathrm{Ann}(C, F)$ of the C^*-subalgebra $C := \pi_{\mathrm{C}_0(X,B)}(\mathrm{C}_0(X) \cdot 1)$ of the center of F.

Finally, we say some words about the groups $G_\approx(h_0\,;\, D, E)$ in case where D and h_0 are unital and E is K_1-injective, because this is important for the comparison of stable extensions with unital extension in case where $E = \mathrm{Q}^\mathrm{s}(B) = \mathcal{M}(B)/B$ for some σ-unital stable B.

Remark 4.6.9. Suppose that D is *unital*, that $h_0 \colon D \to E$ is *unital* and that isometries $t_1, t_2 \in E$ are canonical generators of a copy of $\mathcal{O}_2$ in E. Let $h \in \mathrm{Hom}(D, E)$.

Recall that $[h]_\approx \in [\mathrm{Hom}(D, E)]_\approx$ denotes the class of $k \in \mathrm{Hom}(D, E)$ with $k = u^* h(\cdot) u$ for a unitary in the *connected component* $\mathcal{U}_0(E)$ of 1 in in the unitary group $\mathcal{U}(E)$, and that $[\mathrm{Hom}(D, E)]_\approx$ becomes a semigroup with Cuntz addition $[h_1]_\approx + [h_2]_\approx := [h_1 \oplus_{s_1, s_2} h_2]_\approx$ (see Proposition 4.3.2).

Suppose now – in addition – that $[h_0]_\approx + [h_0]_\approx = [h_0]_\approx$ in $([\mathrm{Hom}(D,E)]_\approx, +)$. The proof of Proposition 4.3.5(iii) shows that this equivalently means that there is $u \in \mathcal{U}_0(E)$ such that $s_1 := ut_1$, $s_2 := ut_2 \in h_0(D)' \cap E$.

Notice that $s_1^* s_1 = s_2^* s_2 = 1$ and $s_1 s_1^* + s_2 s_2^* = 1$, and that $[h_1 \oplus_{t_1,t_2} h_2]_\approx = [h_1 \oplus_{s_1,s_2} h_2]_\approx$ for all $h_1, h_2 \in \mathrm{Hom}(D,E)$. Therefore we can write $\oplus$ for $\oplus_{s_1,s_2}$.

We can define a subset $S_\approx(h_0\,;\, D,E) \subseteq [\mathrm{Hom}(D,E)]_\approx$:

$$S_\approx(h_0\,;\, D,E) := \{[h]_\approx \,;\, \exists (h' \in \mathrm{Hom}(D,E)) : [h]_\approx + [h']_\approx = [h_0]_\approx\}.$$

Since $[h_0]_\approx + [h_0]_\approx = [h_0]_\approx$, the set $S_\approx(h_0\,;\, D,E)$ is a sub-semigroup of $[\mathrm{Hom}(D,E)]_\approx$. The set $G_\approx(h_0\,;\, D,E) := [h_0]_\approx + S_\approx(h_0\,;\, D,E)$ is a subgroup of $S_\approx(h_0\,;\, D,E)$ that is naturally isomorphic to the Grothendieck group $\mathrm{Gr}(S_\approx(h_0\,;\, D,E))$ of $S_\approx(h_0\,;\, D,E)$ by Lemma 4.2.3.

The definition of $S_\approx(h_0\,;\, D,E)$ shows that $[h]_\approx \in S_\approx(h_0\,;\, D,E)$ implies that there is $u \in \mathcal{U}_0(E)$ with $h = s_1^* u^* h_0(\cdot) u s_1$. In particular, $h\colon D \to E$ is unital.

Conversely, if $u \in \mathcal{U}_0(E)$ and if $h := s_1^* u^* h_0(\cdot) u s_1$ is multiplicative, then $us_2(s_2u)^* = 1 - us_1(s_1u)^*$ commutes with $h_0(D)$ and $s_1 s_1^* = 1 - s_2 s_2^*$ commutes with $u^* h_0(D) u$ (by Lemma 4.3.4(i)), and $h' := s_2^* u^* h_0(\cdot) u s_2$ is a unital C^*-morphism with $[h]_\approx + [h']_\approx = [h_0]_\approx$. $[h]_\approx$ is in $G_\approx(h_0\,;\, D,E)$, if and only if, there are $u, v \in \mathcal{U}_0(E)$ with $h = s_1^* u^* h_0(\cdot) u s_1$ and $h_0 = s_1^* v^* h(\cdot) v s_1$. Thus, *there is a natural semigroup morphism* $[h]_\approx \in S_\approx(h_0\,;\, D,E) \to [h] \in S(h_0\,;\, D,E)$. *It defines a natural group morphism of Grothendieck groups:* $G_\approx(h_0\,;\, D,E) \to G(h_0\,;\, D,E)$.

PROPOSITION 4.6.10. *Suppose that D and E are unital, that $h_0\colon D \to E$ is unital, and that isometries $t_1, t_2 \in E$ are canonical generators of a copy of $\mathcal{O}_2$ in E with $[h_0]_\approx = [h_0 \oplus_{t_1,t_2} h_0]_\approx$.*

If E is K_1-injective, then the group-morphisms of Remark 4.6.9 define natural exact sequences:

(i) $\mathrm{K}_1(h_0(D)' \cap E) \to \mathrm{K}_1(E) \to G_\approx(h_0\,;\, D,E) \to G(h_0\,;\, D,E) \to 0$. *Here* $\mathrm{K}_1(h_0(D)' \cap E) \to \mathrm{K}_1(E)$ *is induced by* $h_0(D)' \cap E \hookrightarrow E$.

(ii) $0 \to G(h_0\,;\, D,E) \to G(h_0 \oplus 0; D,E) \to \mathrm{K}_0(E)$, *where* $[h] \mapsto [h] + [0]$ *for* $[h] \in G(h_0\,;\, D,E)$ *and* $[k] \mapsto [k(1)] \in \mathrm{K}_0(E)$ *for* $[k] \in G(h_0 \oplus 0; D,E)$.

PROOF. We use the $s_1, s_2 \in h_0(D)' \cap E$ defined in Remark 4.6.9.

(i): An element $h \in \mathrm{Hom}(D,E)$ defines an element $[h]$ of $S(h_0\,;\, D,E)$, if and only if, there is $h' \in \mathrm{Hom}(D,E)$ with $[h] + [h'] = [h_0]$. It follows that the last observation of Remark 4.6.9 applies almost verbatim to $S(h_0\,;\, D,E)$ and $G(h_0\,;\, D,E)$, in particular:
$[h] \in G(h_0\,;\, D,E)$, if and only if, there are $u, v \in \mathcal{U}(E)$ with $h = s_1^* u^* h_0(\cdot) u s_1$ and $h_0 = s_1^* v^* h(\cdot) v s_1$.
Since $u(1 \oplus u^*) s_1 = u s_1$ and since $[u(1 \oplus u^*)] = 0$ in $\mathrm{K}_1(E)$ we may suppose that, in addition, $[u] = 0 = [v]$ in $\mathrm{K}_1(E)$.

Now we use the assumption that E is K_1-injective. Then for $h \in \mathrm{Hom}(D, E)$ holds: $[h] \in G(h_0\,;\, D, E)$ if and only if $[h]_\approx \in G_\approx(h_0\,;\, D, E)$. Thus:
If E is K_1-injective, then the natural morphism $G_\approx(h_0\,;\, D, E) \to G(h_0\,;\, D, E)$ is *surjective*.

If $[h]_\approx$ is in $G_\approx(h_0\,;\, D, E)$ then $[h] \in G(h_0\,;\, D, E)$. Then $[h] = [h_0]$ if and only if $h = u^* h_0(\cdot) u$ for some $u \in \mathcal{U}(E)$. Thus, the kernel of $G_\approx(h_0\,;\, D, E) \to G(h_0\,;\, D, E)$ is the set of equivalence classes $[u^* h_0(\cdot) u]_\approx$ with $u \in \mathcal{U}(E)$. If $u_1^* h_0(\cdot) u_1 = v^* u_2^* h_0(\cdot) u_2 v$ for $v \in \mathcal{U}_0(E)$, then $(u_2 v u_2^*) u_2 u_1^* \in h_0(D) \cap E$, i.e., $u_2 u_1^* \in \mathcal{U}_0(E) \cdot \mathcal{U}(h_0(D)' \cap E)$.
Conversely, $[u_1^* h_0(\cdot) u_2]_\approx = [u_2^* h_0(\cdot) u_2]_\approx$ if $u_2 u_1^* \in \mathcal{U}_0(E) \cdot \mathcal{U}(h_0(D)' \cap E)$. In particular, $\varsigma[u] \in \mathrm{K}_1(E) \mapsto [u^* h_0(\cdot) u]_\approx$ is well-defined, because $\mathrm{K}_1(E) \cong \mathcal{U}(E)/\mathcal{U}_0(E)$ by Lemma 4.2.6(iv) and Lemma 4.2.10.
Since $(u^* h_0(\cdot) u) \oplus v^* h_0(\cdot) v = (u \oplus v)^* h_0(\cdot)(u \oplus v)$ the map $\varsigma \colon \mathrm{K}_1(E) \to G_\approx(h_0\,;\, D, E)$ is additive by Lemma 4.2.6(iv). It follows: $\ker(\varsigma) = \{[u]\,;\, u \in \mathcal{U}_0(E) \cdot \mathcal{U}(h_0(D)' \cap E)\}$. In particular, $\ker(\varsigma)$ is contained in the image of the natural map $\eta_1 \colon \mathrm{K}_1(h_0(D)' \cap E) \to \mathrm{K}_1(E)$, for the inclusion $\eta \colon h_0(D)' \cap E \hookrightarrow E$.

The natural map $\mathcal{U}(h_0(D)' \cap E)/\mathcal{U}_0(h_0(D)' \cap E) \to \mathrm{K}_1(h_0(D)' \cap E)$ is surjective by Lemma 4.2.6(v). Therefore, if $[u] \in \mathrm{K}_1(E)$ is in $\eta_1(\mathrm{K}_1(h_0(D)' \cap E))$, there is $v \in \mathcal{U}(h_0(D)' \cap E)$ with $[v] = [u]$. We get $u \in \mathcal{U}_0(E) \cdot \mathcal{U}(h_0(D)' \cap E)$ by K_1-injectivity of E.

(ii): The map $[h] \to [h] + [h_0] + [0]$ defines (obviously) a semigroup morphism from $S(h_0\,;\, D, E)$ into $G(h_0 \oplus 0\,;\, D, E)$.

The map is injective on $G(h_0\,;\, D, E)$:
Let $[h] \in G(h_0\,;\, D, E)$ with $[h_0 \oplus 0] = [h \oplus h_0 \oplus 0]$, then $[h_0] = [h \oplus h_0]$: By assumption, there is a unitary $u \in E$ with $u^* s_1 h_0(\cdot) s_1^* u = s_1^2 h(\cdot)(s_1^*)^2 + s_1 s_2 h_0(\cdot) s_2^* s_1^*$. In particular, $u^* s_1 s_1^* u = s_1 s_1^*$. Thus $v := s_1^* u s_1$ is unitary, and $v^* h_0(\cdot) v = h \oplus h_0$.

The map $\tau \colon [h] \in [\mathrm{Hom}(D, E)] \mapsto [h(1)] \in \mathrm{K}_0(E)$ is a semigroup morphism by Lemma 4.2.6(i). Since $[1] = 0$ we get $[h(1) \oplus h_0(1) \oplus 0] = 0$ in $\mathrm{K}_0(E)$ if $h(1) = 1$. Hence, the image of $G(h_0\,;\, D, E) \to G(h_0 \oplus 0\,;\, D, E)$ is in the kernel of $G(h_0 \oplus 0\,;\, D, E) \to \mathrm{K}_0(E)$.

Now let $[k] \in S(h_0 \oplus 0\,;\, D, E)$ and $[k(1)] = 0$ in $\mathrm{K}_0(E)$. We are going to show that there is $[h] \in G(h_0\,;\, D, E)$ with $[k] + [h_0] + [0] = [h] + [h_0] + [0]$ in $G(h_0 \oplus 0\,;\, D, E)$:

There is an isometry $t \in E$ with $p = k(1) \oplus 1 \oplus 0 \geq tt^*$ and $[p] = 0$ in $\mathrm{K}_1(E)$, thus, there is an isometry $s \in E$ with $ss^* = p$, cf. Lemma 4.2.6(ii).

By assumption, there is an isometry $r \in E$ with $r^* s_1 h_0(\cdot) s_1^* r = k$. Let $h_1 := s^*(k \oplus h_0 \oplus 0)s$, then $h_1(1) = 1$ and $h_1 := z_1^* h_0(\cdot) z_1 + z_2^* h_0(\cdot) z_2 = w^* h_0(\cdot) w$ for $z_1 := s_1^* r (s_1^2)^*$, $z_2 := s_2^* s_1^*$ and $w := s_1 z_1 + s_2 z_2$. Then $w^* w = h(1) = 1$ and $h_1 \in \mathrm{Hom}(D, E)$, hence $h_1 \in S(h_0\,;\, D, E)$.

There is a unitary $u \in E$ with $u^*(h_1 \oplus h_0 \oplus 0) u = k \oplus h_0 \oplus 0$:

We have $s h_1(\cdot) s^* = k \oplus h_0 \oplus 0$.

Since $(ss_2)^* ss_1 = 0$, there is an isometry $q \in E$ with $qq^* = 1 - (ss_1)(ss_1)^*$. Let $v := s_1 s_1^* s^* + s_2 q^* \in \mathcal{U}(E)$ with $v^* s_1 = s_1 s$ and $v^* s_2 = q$. We get:

$$v^*(h_1 \oplus 0)v = s_1(k \oplus h_0 \oplus 0)s_1^* = (k \oplus h_0 \oplus 0) \oplus 0\,.$$

Since $[0]+[0] = [0]$ and $[h_0]+[h_0] = [h_0]$ in $([\mathrm{Hom}(D,E)],+)$, we get $[h]+[h_0]+[0] = [k] + [h_0] + [0]$ for $h := h_1 \oplus h_0$. Note that $[h] \in G(h_0\,;\,D,E)$. □

The proof of the isomorphism $\mathrm{KK}(\mathcal{C};\,A, B_{(1)}) \cong \mathrm{Ext}(\mathcal{C};\,A,B)$ for trivially graded A and B in Chapter 8 uses a characterization of the defining relations of elements given in Chapter 5, and this characterization

Precise reference? To Chp.5 ?? ??

uses the following observation:

Lemma 4.6.11. *Let $h\colon D \to E$ a C^*-morphism such that $C := h(D)' \cap E$ contains a copy of $\mathcal{O}_2 = C^*(s_1, s_2)$ unitally, and that h dominates zero.*

If $p, q \in C$ are projections and $V \in \mathcal{U}(E)$ a unitary that satisfy $V^* h(\cdot)pV = h(\cdot)q$, $[p] = [q]$ in $\mathrm{K}_0(E)$ and $[V] = 0$ in $\mathrm{K}_1(E)$, then there exist projections $r_1, r_2 \in \mathrm{Ann}(h(D),E) \subseteq C$ such that $[p \oplus r_1] = [q \oplus r_2]$ in $\mathrm{K}_0(C)$.

Moreover, there exists a unitary $U \in \mathcal{U}_0(h(D)' \cap E)$ with $U^*(p \oplus r_1 \oplus 1 \oplus 0)U = q \oplus r_2 \oplus 1 \oplus 0$, where $\oplus = \oplus_{s_1,s_2}$.

Proof. The proof can be reduced to the splitting of the 6-term exact into the split-exact sequence

$$0 \to \mathrm{K}_*(\mathrm{Ann}(h(D),E)) \to \mathrm{K}_*(C) \to \mathrm{K}_*(C/\,\mathrm{Ann}(h(D),E)) \to 0$$

with splitting maps $\mathrm{K}_*(C) \to \mathrm{K}_*(\mathrm{Ann}(h(D),E)) \cong \mathrm{K}_*(E)$ given by the inclusion map $C \hookrightarrow E$, see Lemma 4.2.20.

Here we give an alternative elementary approach, that gives explicit elements that are useful for the study of generalized extension groups $\mathrm{Ext}(\mathcal{C}\,;\,A,B)$ considered in Chapter 5. We write $\oplus$ for the specified Cuntz sum $\oplus_{s_1,s_2}$.

Since $\mathrm{K}_0(C)$ and $\mathrm{K}_0(E)$ are groups, it suffices to consider the case where p is the range of an isometry in C and q is properly infinite in C. We can do this simply by passing from (p,q,V) to the projections $p_1 := p \oplus (1-p)$ and $q_1 := q \oplus (1-p)$, and the unitary $V_1 \in \mathcal{U}(C)$ given by $V_1 := V \oplus_{s_1,s_2} 1$. Then $p_1 = TT^*$ for the isometry $T := s_1 p + s_2(1-p) \in C$. Thus, p_1 is range of an isometry. and $[p_1]_C = [p]_C + [1-p]_C = 0$ in $\mathrm{K}_0(C)$, $[q_1]_C = [q]_C - [p]_C$ in $\mathrm{K}_0(C)$ and $[q_1]_E = [q]_E - [p]_E = 0$ in $\mathrm{K}_0(E)$. Since $h(\cdot) \oplus h(\cdot) = h$, the unitary V_1 satisfies $V_1^* h(\cdot) p_1 V_1 = h(\cdot) q_1$.

To keep notation simple we suppose in the following that p itself is a range of an isometry. Let $t_1 \in C$, $t_2 \in E$ the isometries defined in Proposition 4.3.6(i) with $t_1 t_1^* + t_2 t_2^* = 1$ and $h(D)t_2 = \{0\}$.

The projections $p' := t_1 p t_1^* + t_2 t_2^*$ and $q' := t_1 q t_1^* + t_2 t_2^*$ are in C, satisfy $ph(\cdot) = p'h(\cdot)$ and $qh(\cdot) = q'h(\cdot)$ and have same classes $0 = [p]_C = [p']$ and $[q]_C = [q']_C$ in $\mathrm{K}_0(C)$ and $[p']_E = [p]_E = [q]_E = [q']_E$ in $\mathrm{K}_0(E)$. This is because

$t_2t_2^* = 1 - t_1t_1^* \in C$ and $t_1^*t_1 = 1$ imply $[t_2t_2^*] = 0$ in $\mathrm{K}_0(C)$ and $\mathrm{K}_0(E)$. Moreover, $t_2\mathcal{O}_2t_2^*$ is unitally contained in $F := t_2Et_2^* = (1-t_1t_1^*)E(1-t_1t_1^*)$ and $fh(D) = \{0\}$ for all $f \in F$. Notice that F is contained in the closed ideal $\mathrm{Ann}(h(D), E)$ of C.

The projections 1, $t_2t_2^*$, $1-t_1^*pt_1$ and $1-t_1^*qt_1$ are in C and majorize the properly infinite projection $t_2t_2^*$ of C. The have all the same class $[1] = 0$ in $\mathrm{K}_0(E)$ and $t_2t_2^*$ is full in E. Thus, by Lemma 4.2.6(ii), there are partial isometries $v, w \in E$ with $v^*v = 1 - t_1pt_1^*$, $vv^* = t_2t_2^*$, $w^*w = 1 - t_1qt_1^*$ and $ww^* = t_2t_2^*$. Let $S := t_1pt_1^* + v$ and $T := t_1qt_1^* + w$, then S and T are isometries in E with $SS^* = p'$, $TT^* = q'$, $St_1pt_1^* = t_1pt_1^*$ and $Tt_1qt_1^* = t_1qt_1^*$. Thus, $S^*h(\cdot)S = t_1pt_1^*h(\cdot)t_1pt_1^* = t_1h(\cdot)pt_1^*$ and $T^*h(\cdot)T = t_1h(\cdot)qt_1^*$.

It follows, that $W^*S^*h(\cdot)SW = T^*h(\cdot)T$ for the unitary $W = t_1Vt_1^* + t_2t_2^*$. Hence, $SWT^* \in C$ by Lemma 4.3.4(ii), and defines a Murray–von-Neumann equivalence between p' and q'. Thus $[p] = [p'] = [q'] = [q]$ in $\mathrm{K}_0(C)$. By Lemma 4.2.6(iv,b), there is $U \in \mathcal{U}_0(C)$ with $U^*(p \oplus 1 \oplus 0)U = q \oplus 1 \oplus 0$. □

7. Additional remarks and further plans for Chp.4

`plan: ??`

`Some of following is contained in Lem.4.2.6 and around.`

(0.1) $V(A)$ `common name?`

Recall that $V(A)$ denotes the set of all Murray–von-Neumann equivalence classes $[p]$ of projections $p \in A$. It has *partially* defined commutative "addition" $[p] + [q] := [r + s]$, if there exist projections $r, s \in A$ with $sr = 0$ and $[r] = [p]$ and $[s] = [q]$.

If the addition of MvN-classes – $[p]$ with $[q]$, $[q]$ with $[r]$, $[p] + [q]$ with $[r]$ and $[p]$ with $[q] + [r]$ – are all defined, then the associative law holds: $[p] + ([q] + [r]) = ([p] + [q]) + [r]$.

The addition is always defined if the unit element $1_{\mathcal{M}(A)}$ of the multiplier algebra $\mathcal{M}(A)$ of A is properly infinite, and then $V(A)$ is a commutative semigroup. If, in addition, A contains a full projection p, then $[q] \in V(A) \to [e_{11} \otimes q] \in V(\mathbb{K} \otimes A)$ is an isomorphism of semigroups, and $\mathrm{K}_1(A)$ is naturally isomorphic to the Grothendieck group of the semigroup $V(A)$.

Lemma 4.7.1. *Suppose that p is a full and properly infinite projection in a C^*-algebra A.*

For any projection $q \in A$ there exists a projection $r \in pAp$ such that $p - r$ is full and properly infinite in A and $q \sim r$.

For any two projections $r, s \in A$ the sum $[r] + [s]$ exists in $V(A)$. Its representative is full and properly infinite if one of the projections is full and properly infinite.

$[q] \in [p] + V(A)$ if and only if q is full and properly infinite in A.

If $p \in A$ is a full and properly infinite projection, then for any projection $p \in A$ there exists a full and properly infinite projection $r \in A$ with $[q] + [r] = [p]$.

In particular, the Murray–von-Neumann equivalence classes of full and properly infinite projections in A build a subgroup $[p] + V(A)$ of $V(A)$ with (unique) neutral element $[r]$ that satisfies $[p] + [r] = [p]$.

If $p \in A$ is full and properly infinite, then $[p] + [q] = [p] + [r]$ in $V(A)$, if and only if, $[q] = [r]$ in $\mathrm{K}_0(A)$.

$\mathrm{K}_0(A)$ is naturally isomorphic to the sub-semigroup $[p] + V(A)$ of $V(A)$.

If $p \in A$ is a properly infinite projection, i.e., if there exist partial isometries $u, v \in A$ with $u^*u = v^*v = p$, $uu^* \leq p$, $vv^* \leq p$ and $u^*v = 0$, then $p_0 := p - vv^*$ is a properly infinite projection in A that generates the same ideal as p, and p_0Ap_0 contains a copy of $\mathcal{O}_2$ unitally, in particular $[p_0] = 2[p_0]$ in $V(A)$.

LEMMA 4.7.2. *If $p \in A$ is full and properly infinite, then $u \in \mathcal{U}(pAp) \mapsto [(1-p) + u] \in \mathrm{K}_1(A)$ is a surjective map.*

If A is unital, $u \in \mathcal{U}(A)$, $p \in A$ projection with $0 = [u] \in \mathrm{K}_1(A)$, $\|pu - up\| < 1$ and p and $1 - p$ both full and properly infinite in A. Then u is in the connected component $\mathcal{U}_0(A)$ of 1_A in $\mathcal{U}(A)$.

`Above lem contained in` K_1`-injectivity/surjectivity stuff?`

(1.0) Suppose that A contains a full and properly infinite projection $p \in A$. Then:

The map $u \in \mathcal{U}(pAp) \mapsto [u + (1-p)] \in \mathrm{K}_1(A)$ defines a group epimorphism from $\mathcal{U}(pAp)$ *onto* $\mathrm{K}_1(A)$.

The algebra A contains also a full projection p_0 with $[p_0] = 2[p_0]$ in $V(A)$, i.e., with the property that p_0Ap_0 contains a copy of $\mathcal{O}_2$ unitally.

The natural semigroup morphism $[q] \in V(A) \mapsto [q] \in \mathrm{K}_0(A)$ is surjective.

The set $V(A) + [p_0]$ is a subgroup of $V(A)$ that is identical with the set of the MvN–equivalence classes of all full properly infinite projections in A.

The restriction of the semigroup epimorphism $V(A) \to \mathrm{K}_0(A)$ to $V(A) + [p_0]$ is a group *isomorphism* from $V(A) + [p_0]$ onto $\mathrm{K}_0(A)$.

Suppose that A is unital and 1_A is properly infinite.

It allows to define "additions" in $\mathcal{U}(A)$ and in $\mathrm{Proj}(A)$ by $U \oplus V := s_1Us_1^* + s_2Vs_2^* + (1 - s_1s_1^* - s_2s_2^*)$ and $p \oplus q := s_1ps_1^* + s_2qs_2^*$.

It defines an addition in $\mathcal{U}(A)/\mathcal{U}_0(A)$ and in $V(A)$ that is compatible with the multiplication in $\mathcal{U}(A)/\mathcal{U}_0(A)$, – respectively with the addition in $V(A \otimes \mathbb{K})$.

It turns out that $q \to [q \otimes e_{1,1}] \in V(A \otimes \mathbb{K})$ induces an isomorphism from $(V(A), +)$ onto $V(A \otimes \mathbb{K})$ with the usual bloc-wise addition. (In fact: $(p+q) \otimes e_{1,1}$ is MvN-equivalent to $p \otimes e_{1,1} + q \otimes e_{2,2}$ if $pq = 0$ and for each projection $p \in A \otimes \mathbb{K}$ there exists $q \in A$ with $[q \otimes e_{1,1}] = [p]$ in $V(A \otimes \mathbb{K})$.)

Furthermore, $U \oplus V$ is homotopic to $(UV) \oplus 1$ in $\mathcal{U}(A)$. $[U \oplus 1] = [U]$ in $\mathrm{K}_1(A)$ for all $U \in \mathcal{U}(A)$. It holds $U \oplus 1 \in \mathcal{U}_0(A)$ iff $[U] = 0$ in $\mathrm{K}_1(A)$. Moreover, if $T \in A$ is an isometry, such that $1 - TT^*$ is a full properly infinite projection then $[TUT^* + (1 - TT^*)] = [U]$ in $\mathrm{K}_1(A)$ for all $U \in \mathcal{U}(A)$, and $[U] = 0$ implies that $TUT^* + (1 - TT^*) \in \mathcal{U}_0$.

(1.1) In particular, every C^*-algebra A with a properly infinite unit 1_A is K_*-surjective, i.e., the natural semigroup morphism $V(A) \to \mathrm{K}_0(A)$ and the natural group morphism $\mathcal{U}(A) \to \mathrm{K}_1(A)$ are surjective.

(1.2) Every unital s.p.i. algebras is K_*-injective in the sense that: This is now shown in Chp. 4 in case of unital p.i. C^*-algebras, with help of the squeezing property. Refere to it!

(0) $V(A) + [1_A]$ is the subgroup of $V(A)$ of all full properly infinite projections. The natural morphism from $V(A)$ to $\mathrm{K}_0(A)$ defines an isomorphism from $V(A) + [1_A]$ onto $\mathrm{K}_0(A)$.
The element $[1_A]$ is the *neutral* element of $V(A) + [1_A]$, if and only if, A contains a copy of $\mathcal{O}_2$ unitally.

(1) The natural group morphism from $\mathcal{U}(A)$ to $\mathrm{K}_1(A)$ is surjective and has kernel $\mathcal{U}_0(A)$.

(1.3) If A is a unital s.p.i. algebra, then 1_A is properly infinite and the group $V(A) + [1_A]$ consists of all MvN-equivalence classes of *full* projections in A (because every element of A is properly infinite).

There is a copy of $\mathcal{O}_\infty = C^*(s_1, s_2, \ldots)$ unitally contained in A, because A is, in particular,

purely infinite, i.e., each non-zero element of A is properly infinite.

Exact reference! ??

We have seen in Chapter 3 that every s.p.i. algebra B satisfies the following property:
For every finitely generated Abelian C^*-subalgebra $A \subseteq B_\omega$ with at most 1-dimensional maximal ideal space $\mathrm{Prim}(A)$ *there exists a C^*-morphism*

$$h \colon A \otimes \mathcal{O}_\infty \to B_\omega \quad \text{with} \quad h(a \otimes 1) = a \ \forall\, a \in B\,.$$

(Notice that $U = h(U \otimes (tt^*)) + h(U \otimes (1 - tt^*))$ is homotopic to the unitary $h(U \otimes (tt^*)) + h(1 \otimes (1 - tt^*)) = TUT^* + (1 - TT^*)$ with $T := h(1 \otimes t)$ if $1_B, U \in A$ and U is unitary, because the unitary group of $\mathrm{C}(S^1, \mathcal{O}_2)$ is connected.)

Now use that $\mathrm{K}_*(B_\omega) = (\mathrm{K}_*(B))_\omega$ (as $\mathbb{Z}_2$-graded groups), and get: A unitary $U \in B$ (respectively a projection $p \in B$) is homotopic to 1 in $\mathcal{U}(B)$ (respectively to $q \in B$ in $\mathrm{Proj}(B)$), if and only if, it is homotopic to 1 (respectively to q) in the unitaries (respectively projections) of B_ω.

Thus, it suffices to proof the K_1-injectivity of B_ω. This follows from the homotopy of $U \sim_h TUT^* + (1 - TT^*)$ in $\mathcal{U}(h(C^*(U) \otimes \mathcal{O}_\infty))$, where $T := h(1 \otimes t)$, for a non-unitary isometry $t \in \mathcal{O}_\infty$.

More generally, if for every commuting pair (b_1, b_2) of self-adjoint elements in a given unital C^*-algebra B and $\varepsilon > 0$ there exists isometries $s, t \in B$ with $s^*t = 0$ and $\|sb_j - b_js\| < \varepsilon$ $(j = 1, 2)$ then B is K_1-injective.

This is, because then 1_B is properly infinite, and – with $\varepsilon := 1/4$ – the following criteria holds for $u = b_1 + ib_2$ with $[u] = 0$ in $\mathrm{K}_1(B)$ and $p := ss^*$.

which criterium ? from Kt_1-injectivity proposition?????, squeezing property?? $\|s^*ut\| < 2\varepsilon$.

(2) **Transfer** to here, and generalize, the unitary homotopy for $(\mathrm{id} \oplus h_0)^k$ considered in Chapter 11. **??**.

(3) Let $J \subseteq E$ a closed ideal, and let $H_0 \colon D \to E$ a *-monomorphism such that $H_0(D)' \cap E$ contains a copy of $\mathcal{O}_2$ unitally, and that there is an isometry $T \in E$ with $TT^*H_0(D) = \{0\}$.

Recall that $S(H_0\,; D, E)$ is the set of unitary equivalence classes $[h]$ where $h \in \mathrm{Hom}(D, E)$ is dominated by H_0. Then, obviously, $[h] \in S(H_0\,; D, E)$ with $h(D) \subseteq J$ is a sub-semigroup $S(H_0\,; D, E; J)$ of $S(H_0\,; D, E)$.

Let B a C^*-subalgebra of E. We denote by $V(B)$ the Murray–von-Neumann equivalence classes of projections in B with (partial) addition given by sums of orthogonal representatives. If $\mathcal{M}(B)$ has a properly infinite unit, then $V(B)$ is a commutative semigroup such that $[p] \in V(B) \to [e_{11} \otimes p] \in V(\mathbb{K} \otimes B)$ is an isomorphism from $V(B)$ onto $V(\mathbb{K} \otimes B)$.

We define a map $\theta_0 \colon S(H_0\,; D, E) \to V(H_0(D)' \cap E)$ by $\theta_0(h) := [tt^*]$ for some isometry $t \in E$ with $h := t^*H_0(\cdot)t$.

Let $B := H_0(D)' \cap \mathcal{N}(H_0(D), J)$, where $\mathcal{N}(H_0(D), J) \subseteq E$ denotes the hereditary C^*-subalgebra of E of the elements $x \in E$ with $xH_0(D) \cup H_0(D)x \subseteq J$, i.e.,

$$\mathcal{N}(H_0(D), J) = (\pi_J)^{-1}(\mathrm{Ann}(\pi_J(H_0(D)), E/J)) .$$

There is a natural semigroup morphism $[p]_B \in V(B) \mapsto [p]_C \in V(C)$ where $C := H_0(D)' \cap E$.

The following lemma is used to compare the semigroups $\mathrm{SR}(\mathcal{C}\,; A, B)$ of Chapter 7 with WvN-equivalence classes of projections in $H_0(D)' \cap \mathcal{N}(H_0(D), J)$.

Lemma 4.7.3. *Let $(H_0\,; D, E; J)$, B and θ_0 as above (with $[H_0] + [0] = [H_0]$ and $[H_0] + [H_0] = [H_0]$). Let $C := H_0(D)' \cap E$. Then:*

(o) *B is a closed ideal of C and $V(B)$ is a hereditary sub-semigroup of $V(C)$.*

(i) *The map θ_0 is well-defined and is a semigroup isomorphism from $S(H_0\,; D, E)$ onto the sub-semigroup of classes $[p] \in V(C)$ with the property that there is an isometry $t \in E$ with $[tt^*] = [p]$ in $V(C)$.*

(ii,a) *Let $V_0(C)$ the kernel of the natural morphism $V(C) \to \mathrm{K}_0(C)$.*
If $T \in E$ is an isometry with $TT^*H_0(D) = \{0\}$, then $TT^* \in C$,

$$\theta_0(S(H_0\,; D, E)) = [TT^*] + V_0(C) .$$

(ii,b) *The Grothendieck group of* $[TT^*] + V_0(C)$ *is naturally isomorphic to the kernel of* $\mathrm{K}_0(C) \to \mathrm{K}_0(E)$.

If $F := \mathrm{Ann}(H_0(D), E)$ *denotes the two-sided annihilator of* $H_0(D)$ *in* E*, then* F *is an ideal of* C*, the Grothendieck group* $G(H_0\,;\, D, E) := H_0 + S(H_0\,;\, D, E)$ *of* $S(H_0\,;\, D, E)$*, and it holds:*

$$G(H_0\,;\, D, E) \cong \mathrm{K}_0(C/F) \cong \ker(\mathrm{K}_0(C) \to \mathrm{K}_0(E))\,.$$

(iii) *Let* $V_0(B)$ *denote the kernel of* $V(B) \to \mathrm{K}_0(E)$. $[TT^*] \in V_0(B)$ *and* $\theta_0(S(H_0\,;\, D, E;\, J)) = \theta_0(S(H_0\,;\, D, E)) \cap V(B)$.

If $T \in E$ *is an isometry with* $TT^* H_0(D) = \{0\}$ *then* $TT^* \in V_0(B)$, $V_0(B) = V(B) \cap V_0(C)$ *and*

$$\theta_0(S(H_0\,;\, D, E; J)) = [TT^*] + V_0(B)\,.$$

PROOF. Let $C := H_0(D)' \cap E$.

(o): If $b, c, e \in C$ and $bH_0(D) \subseteq J$, then $H_0(D)cbe = cbeH_0(D) = cbH_0(D)e \subseteq J$. Thus, B is an ideal of C. The same argument shows that $[p]_C = [q]_C$ in $V(C)$ and $p \in B$ implies $q \in B$ and $[p]_B = [q]_B$ in $V(B)$. It follows that $V(B)$ is a hereditary sub-semigroup of $V(C)$, in the sense that $[p] + [q] \in V(B) \subseteq V(C)$ implies $[p], [q] \in V(C)$.

(i): See the arguments in the proof of Part (i) of Proposition 4.4.3.

(ii,a): Since $TT^* H_0(a) = 0 = H_0(a)TT^*$ for all $a \in D$, the projection TT^* is in $B \subseteq C$. Let $r, s \in C$ canonical generators of a unital copy of $\mathcal{O}_2$, and let p a projection in C with $[p] = 0$ in $\mathrm{K}_0(E)$. Then $q := rTT^*r^* + sps^*$ is a projection in C with $[q] = [TT^*] + [p] = [1_C] + [p]$ in $V(C)$, and there exists an isometry $t \in E$ with $tt^* \in C$ and $[q] = [tt^*]$ in $V(C)$.

To see this, we can use the isomorphism $V(E) + [1] \cong \mathrm{K}_0(E)$ and the fact that $V(E) + [1]$ is identical with the MvN-classes of all properly infinite elements: Since $[q] = [p] + [TT^*] = [p] + [1]$ in $V(E)$, the projection q is properly infinite and full in E. Since $[1] = 0$ in $\mathrm{K}_0(E)$ it follows that $[q] = [p] = 0$ in $\mathrm{K}_0(E)$. Thus $[q] = [1]$ in $V(E)$.

(ii,b): $F \to C \to E$ defines an isomorphism $\mathrm{K}_0(G) \cong \mathrm{K}_0(E)$ that makes that the sequence $0 \to \mathrm{K}_*(F) \to \mathrm{K}_*(C) \to \mathrm{K}_*(C/F) \to 0$ is split exact with $\mathrm{K}_*(C) \to \mathrm{K}_*(E) \cong \mathrm{K}_*(F)$ as splitting map.

(iii): Let $[h] \in S(H_0\,;\, D, E; J)$ and $h = t^* H_0(\cdot)t$. Then $tt^* \in C$ by (i) and $tt^* H_0(a^*a)tt^* \in J$ for all $a \in D$. Thus, $H_0(D)tt^* \subseteq J$ and $tt^* \in B$. It follows that $\theta_0(S(H_0\,;\, D, E; J)) \subseteq V(B) \subseteq V(C)$.

If $\theta_0(h) \in V(B)$ and $h = t^* H_0(\cdot)t$ for some isometry $t \in E$, then $tt^* \in C$ and $[tt^*]_C = [q]_C$ in $V(C)$ for some $q \in B$. It follows $tt^* \in B$ and $h = t^*(tt^*)H_0(\cdot)t$ maps D into J, i.e., $h \in S(H_0\,;\, D, E; J)$.

Hence, $\theta_0(S(H_0\,;\, D, E; J)) = \theta_0(S(H_0\,;\, D, E)) \cap V(B)$.

Now notice that $([TT^*]+V(C))\cap V(B) = [TT^*]+V(B)$, because $[TT^*] \in V(B)$ and $V(B)$ is hereditary in $V(C)$. □

Can the Grothendieck group of $S(H_0\,;\, D, E; J)$ be calculated with help of K_*-groups of B, C and J ?

REMARK 4.7.4. The following observation yields alternative proofs of some parts of Lemma 4.2.6, e.g. of Part (v,5).

A unitary $u \in \mathcal{U}(E)$ satisfies $u\,tt^* = tt^*$ for some isometry $t \in E$, if and only if, u is conjugate to $(u \oplus 1) + p_{[-1]}$, i.e., if there is a unitary $V \in \mathcal{U}(E)$ with $V^*uV = (u \oplus 1) + p_{[-1]}$. The unitary V can be chosen such that $[V] = 0$ in $\mathrm{K}_1(E)$.

PROOF. If $V \in \mathcal{U}(E)$ satisfies $V^*uV = (u \oplus 1) + p_{[-1]} = s_1us_1^* + (1 - s_1s_1^*)$, then $uVs_2 = Vs_2$, thus $utt^* = tt^*$ for the isometry $t := Vs_2$.

If $t \in E$ is an isometry with $utt^* = tt^*$, then let $P := t(1 - s_1s_1^*)t^*$. The projection P is splitting, because $P \geq (ts_2)(ts_2)^*$ and $P(ts_1)(ts_1)^* = 0$. Since P is MvN-equivalent to $1 - s_1s_1^*$, there exists a unitary V_1 with $V_1^*PV_1 = 1 - s_1s_1^*$. It follows $V_1^*uV_1(1 - s_1s_1^*) = (1 - s_1s_1^*)$ and $u_1 := s_1^*V_1^*uV_1s_1$ is a unitary in E such that $u = s_1u_1s_1^* + (1 - s_1s_1^*)$, i.e., $V_1^*uV_1 = (u_1 \oplus 1) + p_{[-1]}$.

We use now the "corrected" direct sum formula $U \oplus' V := (U \oplus V) + p_{[-1]}$ on the unitary elements $U, V \in \mathcal{U}(E)$, and get $V_1^*uV_1 = u_1 \oplus' 1$. It follows that $V_2^*(u \oplus' 1)V_2 = (u_1 \oplus' 1) \oplus' 1$ for $V_2 := V_1 \oplus' 1$. The corrected direct sum is still commutative and associative up to unitary equivalence by the unitaries U_c and U_d defined in Equations (2.3) and (2.4), i.e., $(U \oplus' V) \oplus' W$ and $U \oplus' (V \oplus' W)$ are unitarily equivalent by unitaries in $\mathcal{U}_0(E)$. We get that there is a unitary V in the classes $\mathcal{U}_0(E)V_1$ such that $V^*uV = u \oplus' 1$.

We can replace V by $V' := V(1 \oplus' V^*)$ that satisfies $0 = [V'] \in \mathrm{K}_1(E)$. □

CHAPTER 5

Generalized Weyl–von Neumann Theorems

?? Revise section structure !!

Remove two-fold text !! very urgent!!!

We generalize in this chapter the Weyl–von-Neumann theorem along lines indicated by Voiculescu and Kasparov ([**798**], [**404**], see [**42**] for an elementary account and use Lemma 2.1.22 to see that they are special cases of Theorem A). The definition, viewpoints and results are different from the generalization of some aspects of the classical Weyl–von Neumann theorem by S. Zhang in [**845**].

The generalized Weyl–von Neumann Theorem 5.6.2 will be an ingredient of the proofs of Theorem A and of the important special case of Theorem M, – the Theorem 6.3.1 –, considered in Chapter 6 under the additional assumption that the C^*-algebra B in Theorem M has *residual nuclear separation* (cf. Definition 1.2.3), i.e., that the m.o.c. cone $\mathcal{C}_{rn} \subseteq \mathrm{CP}_{\mathrm{nuc}}(B, B)$ is separating for B. This additional assumption will be removed finally in Chapter 12, by showing that in ultrapowers and asymptotic algebras those additional conditions are in the considered cases for sufficiently big separable C^*-subalgebras are satisfied, all this only by using combinations of results obtained in all Chapters 7-11 together.

We *assume* in Chapter 6, in addition to the assumptions of Theorem M, that the related universal weakly residually nuclear C^*-morphism $H_{rn} \colon B \to \mathcal{M}(B)$ from B into its multiplier algebra $\mathcal{M}(B)$ is non-degenerate, faithful and that the induced ideal-system action of $\prime(B)$ on B is simply the identity map ????

([1])

???? HERE and a bit below ???????

Explain H_{rn} by use of action and by use of suitable $\mathcal{C}$.

In case of trivially graded stable separable A, B and non-degenerate m.o.c. cone $\mathcal{C}$ we should have exact sequences

$$0 \to \mathrm{Ext}(\mathcal{C}; A, B) \to \mathrm{K}_0(\pi_B(H_{\mathcal{C}}(A))' \cap \mathrm{Q}(B)) \to \mathrm{K}_0(\mathrm{Q}(B)) \cong \mathrm{K}_1(B) \to 0\,,$$

and

$$0 \to \mathrm{KK}(\mathcal{C}; A, B) \to \mathrm{K}_1(\pi_B(H_{\mathcal{C}}(A))' \cap \mathrm{Q}(B)) \to \mathrm{K}_1(\mathrm{Q}(B)) \cong \mathrm{K}_0(B) \to 0\,.$$

[1] The author got in between, by a self-contained study of relations between coherent and non-coherent Dini-spaces, refining and applying basic results from lattice theory, that each separable stable C^*-algebra has this property anyway. But here we use an other way of proof that considers properties of ultra-powers of strongly purely infinite C^*-algebras.

Since $H_{\mathcal{C}}(A)' \cap \mathcal{M}(B)$ contains a copy of $\mathcal{O}_2$ unitally we get K_*-surjectivity.

What about K_*-injectivity here??

For $\mathrm{K}_0(H_{\mathcal{C}}(A)' \cap \mathcal{M}(B))$ only the full properly infinite projections in $H_{\mathcal{C}}(A)' \cap \mathcal{M}(B)$ are uniquely defined by its value in $\mathrm{K}_1(H_{\mathcal{C}}(A)' \cap \mathcal{M}(B))$.

We must check if $H_{\mathcal{C}}(A)' \cap \mathcal{M}(B)$ is K_1-bijective! ?

... for the considered stable separable B and that there exists a C^*-morphism $h\colon A \to \mathcal{M}(B)$ that defines the action of $\mathrm{Prim}(B)$ on A.

Relation to more general $\mathcal{C}$ and induced actions have to be explained / refer to Chapter 3.

This ??? additional assumptions will be removed in Chapter 12 completely using results of Chapters 3, and 7 -11 .

Here in Chapter 5 we allow weaker/stronger ??? assumptions.

Perhaps Chapter 3 should present the relations between actions and cones ...

In particular, $C' \cap \mathrm{Q^s}(B)$ should be σ-sub-Stonean ...???

Should here also obtain finally that $\mathcal{O}_2 \otimes \mathcal{O}_2 \otimes \cdots$ is (unitally) contained in $\mathcal{O}_2$, and that this allows to prove that $\mathcal{O}_2$ can be written as its own infinite tensor product

??? if each unital ind-lim of $\mathcal{O}_2$ is $\mathcal{O}_2$.

Need the approximate unitary equivalence of all unital endomorphisms of $\mathcal{O}_2$ and more generally of $\mathcal{O}_{\mathrm{n}}$, $\mathcal{O}_\infty$.

¡ ¡ ¡ Given at end of Chapter 4 ??

Its generalization to weakly residually nuclear maps – and, more generally and systematic, to maps in a given m.o.c. cone $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ – will be used in Chapters 6 and 12 for the final proof of Theorem K.

`Compare above and below text`

First we prove an almost "tautological" universal version of a generalized Weyl–von-Neumann theorem (Theorem 5.6.2) and show some of its consequences:

We apply it to give an alternative proof for the stability criteria of M. Rørdam and J. Hjelmborg for σ-unital C^*-algebras and its extensions (cf. [**373**], [**688**]). We specialize it to the cases of extensions with splitting c.p. maps that are weakly nuclear, weakly residually nuclear, or are in suitable general m.o.c. cones $\mathcal{C} \subseteq \mathrm{CP}(A, B)$. It gives the base to define general cone-related Ext-groups $\mathrm{Ext}(\mathcal{C};\, A, B)$ and we display explicit defining relations that will be used in Chapters 8 and 9 to establish the functorial isomorphism of $\mathrm{Ext}(\mathcal{C};\, A, B)$ with $\mathrm{KK}(\mathcal{C};\, A, B_{(1)})$ – alone the lines of early work of G. Kasparov – and its isomorphism with the a generalized version of "Rørdam groups" $\mathrm{R}(\mathcal{C};\, A, B)$ defined in Chapter 7, that generalize groups of asymptotic morphisms appearing (implicitly) in early work of G. Elliott and M. Rørdam.

Later applications of our general WvN-theorems (in the spirit of Voiculescu and Kasparov) for the proofs of isomorphisms between the in Chapters 1, 4 and 7 – 9 considered types of operator class groups use the key results from Chapters 3 and 4.

We need some basic definitions, e.g. our version of unitarily homotopic morphisms in the following Definition 5.0.1 will be used frequently.

Recall that the C^*-algebra $\mathcal{M}(A) \subseteq \mathcal{L}(A, A)$ denotes the multiplier algebra of a C^*-algebra A.

DEFINITION 5.0.1. Let $h_j \colon A \to \mathcal{M}(B)$, $j = 1, 2$, C^*-morphisms, and let V a completely positive contraction from A into the multiplier algebra $\mathcal{M}(B)$ of B.

We call h_1 and h_2 **unitarily homotopic** if there is a *norm-continuous* map $t \mapsto U(t)$ from the non-negative real numbers $\mathbb{R}_+$ into the *unitaries* in $\mathcal{M}(B)$, such that,

(i) $h_2(a) - U(t)^* h_1(a) U(t) \in B$ for all $t \in \mathbb{R}_+$ and $a \in A$, and
(ii) $\lim_{t\to\infty} \| h_2(a) - U(t)^* h_1(a) U(t) \| = 0$ for all $a \in A$.

Let B σ-unital and stable. Question:
What happens if we require only that
$t \mapsto U(t)$ satisfies (i, ii) and is only *strictly* continuous?

Comments on this question to be checked:

It says then only that $h_1 \colon A \to \mathcal{M}(B)$ and $h_2 \colon A \to \mathcal{M}(B)$ are unitarily equivalent in $C := \mathrm{C}_{\mathrm{b,st}}\big([0, \infty), \mathcal{M}(B)\big) / \mathrm{C}_{\mathrm{b}}([0, \infty), B)$, where we take the natural injective "constant" C^*-morphism $\mathcal{M}(B) \subset \mathrm{C}_{\mathrm{b,st}}\big([0, \infty), \mathcal{M}(B)\big)$.

In case of our Definition 5.0.1 we get that $U \in \mathrm{C}_{\mathrm{b}}([0, \infty), \mathcal{M}(B))$.

Is the strict topology – restricted to $\mathrm{C}_{\mathrm{b}}([0, \infty), B)$ – is the same as the norm topology on $\mathrm{C}_{\mathrm{b}}([0, \infty), B)$?

We have often to do with the case where B is stable and σ-unital. Then $\mathcal{U}(\mathcal{M}(B)) = \mathcal{U}_0(\mathcal{M}(B))$, and there exist $y_1, \ldots, y_n \in \mathcal{M}(B)$ with $y_k^* = -y_k$ such that $U(1) = \exp(y_1) \cdot \ldots \cdot \exp(y_1)$. Then $h_2(a) - U(1)^* h_1(a) U(1) \in B$ for all $a \in A$. Let $V := \pi_B(U(1))$ Thus, $\pi_B \circ h_2 = V^* \pi_B \circ h_1(\cdot) V \in \mathrm{Q}(B)$. and $V \in \mathcal{U}_0(\mathrm{Q}(B))$. If, in addition, h_2 is unitarily equivalent to $\delta_\infty \circ h_2$ in $\mathcal{M}(B)$, then we can replace here $\pi_B \circ h_2$ by $\pi_B \circ \delta_\infty \circ h_2$.

The path $t \mapsto U(t) \in \mathcal{U}(\mathcal{M}(B))$ defines an element U in $\mathcal{U}(\mathcal{M}(\mathrm{C}_0(\mathbb{R}_+, B))) = \mathcal{U}_0(\mathcal{M}(\mathrm{C}_0(\mathbb{R}_+, B)))$ with the property $h_2(a)U - Uh_1(a) \in \mathrm{C}_0(\mathbb{R}_+, B)$, where we use the natural unital inclusions $\mathcal{M}(B) \subset \mathcal{M}(\mathrm{C}(\mathbb{R}_+, B)) \subseteq \mathcal{M}(\mathrm{C}_0(\mathbb{R}_+, B))$

Notice here that $\mathrm{C}_0(\mathbb{R}_+, B)$ is again stable and σ-unital if B has this properties.

If $\mathcal{M}(B)$ contains a copy of $\mathcal{O}_2$ unitally, then we can define Cuntz addition $h_1 \oplus h_2$ on $\mathrm{Hom}(A, \mathcal{M}(B))$ (cf. Chapter 4). We say that "h_1 **asymptotically absorbs** h_2" if h_1 and $h_1 \oplus h_2$ are unitarily homotopic.

The C^*-morphism h_1 **asymptotically dominates** a completely positive contraction $V\colon A \to \mathcal{M}(B)$ if there is a *norm-continuous* map $t \mapsto S(t)$ from the non-negative real numbers $\mathbb{R}_+$ into the *isometries* in $\mathcal{M}(B)$, such that,

(i) $V(a) - S(t)^* h_1(a) S(t) \in B$ for $t \in \mathbb{R}_+$ and $a \in A$, and
(ii) $\lim_{t\to\infty} \| V(a) - S(t)^* h_1(a) S(t) \| = 0$ for all $a \in A$.

Notice that h_1 and h_2 are unitarily homotopic, (respectively h_1 asymptotically dominates V), if and only if, h_1 and h_2 are unitarily equivalent in (respectively h_1 dominates V in) $\mathrm{C_b}(\mathbb{R}_+, \mathcal{M}(B))/\,\mathrm{C_0}(\mathbb{R}_+, B) \supset \mathcal{M}(B)$. If B is unital, then this algebra is the same as $\mathrm{Q}(\mathbb{R}_+, B) := \mathrm{C_b}(\mathbb{R}_+, B)/\,\mathrm{C_0}(\mathbb{R}_+, B)$.

This "algebraic" reformulation allows to apply the observations on Cuntz additions from Sections 3 and 4 of Chapter 4, e.g. it implies immediately that h_1 asymptotically absorbs h_2, i.e., h_1 is unitarily homotopic to $h_1 \oplus h_2$, if and only if, h_1 asymptotically dominates $h_1 \oplus h_2$ and $h_2 \oplus h_2$ is unitarily homotopic to h_2, cf. Proposition 4.3.5(i,iii).

`The asymptotic domination of all unital` $h_1, h_2\colon \mathcal{O}_2 \to E$
`(of each other) should be clear ??`
`Compare all arguments with observations in Chapter 4!!!`

From nuclearity of $\mathcal{O}_2$ (and $\mathcal{D}_2 := {\mathcal{O}_2}^{\otimes\infty} \cong \mathcal{O}_2$?) one gets:

$\mathcal{O}_\infty \in {\mathcal{O}_2}' \cap \mathrm{Q}(\mathbb{R}_+, \mathcal{O}_2)$ unitally, and that there exist paths of approximate inner u.c.p. maps $V_t\colon \mathcal{O}_2 \to \mathcal{O}_2$ with $V_\infty\colon \mathcal{O}_2 \to \mathrm{Q}(\mathbb{R}_+, \mathcal{O}_2)$ is a unital C^*-morphism with $V_\infty(\mathcal{O}_2) \subseteq {\mathcal{O}_2}' \cap \mathrm{Q}(\mathbb{R}_+, \mathcal{O}_2)$ implemented by some isometry in $T \in \mathrm{Q}(\mathbb{R}_+, \mathcal{O}_2)$ with $T^* a T = V_\infty(a)$ for $a \in \mathcal{O}_2$. Thus, the images of h_1 and h_2 commute with unital copies of $\mathcal{O}_2$ and 1-step dominate each other in $\mathrm{Q}(\mathbb{R}_+, E)$ by nuclearity of $\mathcal{O}_2$. It implies that h_1 and h_2 are unitary equivalent by a unitary in $\mathrm{Q}(\mathbb{R}_+, E)$. It means that unital C^*-morphisms $h_1, h_2\colon \mathcal{O}_2 \to E$ are unitary homotopic (with $B := E$ and $A := \mathcal{O}_2$).

The unitary homotopy of id with δ_2 on $\mathcal{O}_2$, implies that id is unitary homotopic to an endomorphism $k\colon \mathcal{O}_2 \to \mathcal{O}_2$ with $k(\mathcal{O}_2)' \cap \mathcal{O}_2 \cong \mathcal{O}_2$, and moreover there exists unital C^*-morphisms $k, k'\colon \mathcal{O}_2 \to \mathcal{O}_2$ with $k'(\mathcal{O}_2) \subseteq k(\mathcal{O}_2)' \cap \mathcal{O}_2$ and linear span of $k(\mathcal{O}_2) \cdot k'(\mathcal{O}_2)$ dense in $\mathcal{O}_2$.

Thus, all unital $h_1, h_2\colon \mathcal{O}_2 \to E$ are unitarily homotopic inside $h_k(\mathcal{O}_2) \subseteq E$ to unital homomorphisms $g_k\colon \mathcal{O}_2 \to h_k(\mathcal{O}_2) \subseteq E$ such that $g_k(\mathcal{O}_2)' \cap E$ contains a copy of $\mathcal{O}_2$ unitally. This implies that both $h_k(\mathcal{O}_2)' \cap \mathrm{Q}(\mathbb{R}_+, E)$ contain (possibly different) unital copies of $\mathcal{O}_2$.

Since they 1-step dominate each other and commute with (possibly different) copies of $\mathcal{O}_2$ in $\mathrm{Q}(\mathbb{R}_+, E)$, they are unitarily equivalent in $\mathrm{Q}(R_+, E)$.

It means that unital $h_1, h_2\colon \mathcal{O}_2 \to E$ are unitarily homotopic with respect to $A := \mathcal{O}_2$ and $B := E$. In particular h_1 is homotopic to some unitary equivalent of h_2, because near generators of copies of $\mathcal{O}_2$ in E are homotopic.

This applies to all unital C^*-morphisms $h_1, h_2 \colon \mathcal{O}_2 \to E$ of $\mathcal{O}_2$ into a unital C^*-algebra E and shows that they are unitarily homotopic (with respect to $A := \mathcal{O}_2$ and $B := E$):

For every unital C^*-algebra E with properly infinite unit element that satisfies $0 = [1_E] \in \mathrm{K}_0(E)$ there is up to unitary homotopy exactly one unital C^*-morphism $h \colon \mathcal{O}_2 \to E$.

`Does the latter not require that` E `is` K_1`-injective?`
`Answer: No, as above/below considerations show!`

It shows that *unitary equivalence* implies unitary homotopy, but in general even not point-norm homotopy of h_1 and h_2 in $\mathrm{Hom}(A, B)$.

A unitary homotopy with norm-continuous path of unitaries $t \mapsto U(t) \in \mathcal{U}(\mathcal{M}(B))$ implies homotopy – in $\mathrm{Hom}(A, \mathcal{M}(B))$ with point-norm topology – if A is σ-unital and $\mathcal{U}(\mathcal{M}(B)) = \mathcal{U}_0(\mathcal{M}(B))$. In particular, $h_1 \otimes \mathrm{id}_{\mathbb{K}}$ and $h_2 \otimes \mathrm{id}_{\mathbb{K}}$ are homotopic in $\mathrm{Hom}(A \otimes \mathbb{K}, J \otimes \mathbb{K})$, if h_1 and h_2 are unitarily homotopic in $\mathcal{M}(B \otimes \mathbb{K})$ and if J is an *ideal* of $\mathcal{M}(B)$ that contains $h_1(A)$.

Unitary equivalent C^*-morphisms $h_1, h_2 \colon A \to \mathcal{M}(B)$ are both non-degenerate if one of its is non-degenerate (i.e., $h_k(A)B = B$).

But this is not necessarily the case for unitarily homotopic C^*-morphisms:

For example let $B := A := \mathbb{K}$, $h_1(a) := a$, $h_2(a) := TaT^*$ with $T \in \mathcal{L}(\ell_2)$ an isometry with $(1-TT^*)\ell_2$ of infinite dimension (i.e., related to a unital copy of $\mathcal{O}_2$). One can find here a norm-continuous path $t \in [0, \infty) \colon U(t) \in \mathcal{U}(\mathcal{M}(\mathbb{K}))$ of unitaries in $\mathcal{L}(\ell_2)$ with $U(0) = 1$ and $\|U(t)^* a U(t) - TaT^*\| \to 0$ for $t \to \infty$. This particular sort of *unitary* homotopy can be given explicit by using that $\mathcal{U}(\mathcal{M}(\mathbb{K})) = \mathcal{U}_0(\mathcal{M}(\mathbb{K}))$ and the fact that any trace-preserving *-endomorphism h_2 of the algebra $\mathbb{K}$ of compact operators of a separable (complex) Hilbert space is unitary homotopic to $h_1 := \mathrm{id}_{\mathbb{K}}$.

(One can use here that the set of all isometries $T \in \mathcal{L}(\ell_2(\mathbb{N})) \cong \mathcal{M}(\mathbb{K})$ with $(1-TT^*)\ell_2$ of infinite dimension is path-connected in operator norm to the isometry $T(\delta_n) := \delta_{2n}$, $n = 1, 2, \ldots$.)

Notice that it is in general not possible to start with the additional condition $U(0) = 1$ in the definition of unitary homotopy as the following counterexample shows:

Let $\mathcal{H} := \ell_2(\mathbb{N})$, $B := \mathbb{K}(\mathcal{H})$, $a_0 \in \ell_\infty(\mathbb{N}) \subseteq \mathcal{L}(\mathcal{H})$ the projection given by $(0, 1, 0, 1, \ldots)$, and $A := C^*(1, a_0) \subseteq \ell_\infty(\mathbb{N})$.

There exists $T \in \mathcal{M}(B) = \mathcal{L}(\ell_2)$ with $Ta_0 - a_0T \notin \mathbb{K}$, $T^* = -T$, $\|T\| < 1$, e.g. $T := 3^{-1}(S^* - S)$ for the 1-step forward shift S of $\ell_2(\mathbb{N})$ (Toeplitz operator with index $= -1$), $S(\alpha_1, \alpha_2, \ldots) = (0, \alpha_1, \alpha_2, \ldots)$. Then $\exp(-T)a_0\exp(T) - a_0 \notin \mathbb{K} =: B$.

Let $h_1 := \mathrm{id}_A$ and $h_2(a) := \exp(-T)h_1(a)\exp(T)$, i.e., $\exp(T)h_2(a) - h_1(a)\exp(T) = 0$, $U(t) := \exp(T)$ for all $t \in [0, \infty)$ (constant). In particular $h_2(a) - U(t)^* h_1(a) U(t) = 0 \in \mathbb{K} =: B$ for all $t \in [0, \infty)$.

It does not exists $t \mapsto V(t) \in \mathcal{U}(\mathcal{M}(\mathbb{K}))$ norm-continuous, unitary, with $V(0) = 1$, $V(t)^* h_1(a) V(t) - h_2(a) \in \mathbb{K}$ for all $t \in [0, \infty)$ and $a \in A$, because it would imply $[\exp(T), h_1(a_0)] \in \mathbb{K}$.

A similar example is on some other place. **??**

????????

because there are natural isomorphisms $\mathrm{KK}(A, B) \cong \mathrm{Ext}(A, SB)$ for separable stable σ-unital A and B, and because

$$\mathrm{KK}(A, B) \cong \ker(\mathrm{K}_1(H_0(A)' \cap \mathrm{Q}(B)) \to \mathrm{K}_1(\mathrm{Q}(B)) \cong \mathrm{K}_0(B)),$$

cf. Chapter 8.

We shall see below and in Chapter 7, that it does *not* matter if we replace in the above definitions of asymptotic domination and of asymptotic absorption the norm-continuity of $t \mapsto S(t)$, respectively of $t \mapsto U(t)$ by the – much weaker – strict continuity if A is *stable*, h_1 is *non-degenerate* and $V(A) \subseteq B$ (respectively $h_2(A) \subseteq B$, respectively h_2 is also non-degenerate and $h_1(A) \cup h_2(A) \subseteq B$). It means, that we can *replace* a weakly continuous path $t \mapsto S(t)$ (respectively $t \mapsto U(t)$) in this cases by *norm-continuous* paths that do the same job, but are rather different from the given weakly continuous paths and have a different isometry $S(t_0)$ (respectively unitary $U(t_0)$) at the starting point $t_0 \geq 0$.

`Give Ref's to places of proofs`
`of ‘‘strictly ..." to ‘‘norm- ...’’ !!!`
`Give example of different start points of paths !!!`

The situation of unital C^*-morphisms form $\mathcal{O}_2$ into the stable corona $\mathrm{Q}^{\mathrm{s}}(B)$ of B (see Definition 5.4.7) is different:

The homotopy classes of the unital C^*-morphisms $h\colon \mathcal{O}_2 \to \mathrm{Q}^{\mathrm{s}}(B)$ are equivalent to $\mathcal{U}(\mathrm{Q}^{\mathrm{s}}(B))/\mathcal{U}_0(\mathrm{Q}^{\mathrm{s}}(B))$, thus are in bijective correspondence to $\mathrm{K}_1(\mathrm{Q}^{\mathrm{s}}(B))$ by the K_1-bijectivity of stable coronas, cf. Proposition 4.2.15. Thus, they are classified by $\mathrm{K}_0(B) \cong \mathrm{K}_1(\mathrm{Q}^{\mathrm{s}}(B))$.

But there is *only one* full non-unital C^*-morphism $h\colon \mathcal{O}_2 \to \mathrm{Q}^{\mathrm{s}}(B)$ up to *unitary homotopy*. `<-- Example? Why?`

`Sort above/below text (red and blue)!!!`

?????? Give Ref's!!!

The unital C^*-morphisms $h\colon \mathcal{O}_2 \to \mathcal{M}(B)$ for σ-unital stable B are *all* homotopic, because of $\mathcal{U}(\mathcal{M}(B)) = \mathcal{U}_0(\mathcal{M}(B))$ by the Cuntz-Higson Theorem, cf. Proposition 4.2.15, *and* unital C^*-morphisms $h_0, h_1\colon \mathcal{O}_2 \to A$ are unitarily homotopic to each other, if and only if, the unitary $u := h_0(s_1)h_1(s_1^*) + h_0(s_2)h_1(s_2^*)$ is in $\mathcal{U}_0(A)$, by Corollary ?? cf. Section ?? of Chapter 4. Clearly they are all *homotopic* if and only if $\mathcal{U}(A) = \mathcal{U}_0(A)$.

But the homotopy classes of unital $h \in \mathrm{Hom}(\mathcal{O}_2, E)$ is identical with $\mathcal{U}(E)/\mathcal{U}_0(E)$, which is isomorphic to $\mathrm{K}_1(E)$ if and only if E is K_1-injective (in addition).

All *non-unital* C^*-morphisms $h \in \mathrm{Hom}(\mathcal{O}_2, E)$ with the property that the projections $h(1)$ and $1 - h(1)$ are full in E and that $1 - h(1)$ is properly infinite are homotopic in $\mathrm{Hom}(\mathcal{O}_2, E)$ and are unitary homotopic. Clearly, the latter happens for all non-unital $h \in \mathrm{Hom}(\mathcal{O}_2, E)$ if E is simple and purely infinite.

Compare for the non-purely infinite case the elements of $\mathrm{Hom}(\mathcal{O}_2, E)$ for the stable corona $E := \mathrm{Q}^{\mathrm{s}}(M_{2^\infty})$ of M_{2^∞} in Section 8.

1. Strict convergence in Multiplier algebras

Here we give some later used unconditional strict convergence results for completely bounded maps defined with help of certain strictly "unconditional square-summable" sequences. We introduce some natural C^*-subalgebras in $\mathcal{M}(B)$ of stable (not necessarily σ-unital) B, and describe a certain "expanding" path of projections in $\mathcal{O}_2 \otimes \mathbb{K} \subset \mathcal{M}(B)$ for σ-unital stable C^*-algebras B.

A very important point for application of extension theory is the "stability" of the σ-unital C^*-algebras under consideration. We select for reference some elementary equivalent descriptions in Part (8). There are others and other proofs for the here given equivalences and descriptions. We use (or misuse) our proof of the following Remarks 5.1.1 – in particular of Parts (1) and (8) – to give also a survey on multiplier algebras and their strict topology from our viewpoints and with our terminology ([2]).

Remarks 5.1.1. The **strict topology** on $\mathcal{M}(B) \subseteq \mathcal{L}(B)$ is given by the semi-norms $d \in \mathcal{M}(B) \mapsto \|L_d(a)\| + \|R_d(b)\|$, where $a, b \in B$ ([3]), this topology is different to the **strong topology** on $\mathcal{M}(B) \subseteq \mathcal{L}(B)$, induced by the *strong operator topology* on $\mathcal{L}(B)$. The latter is defined by the semi-norms $T \mapsto \|T(a)\|$ with $a \in B$ and $T \in \mathcal{L}(B)$ only.

(Since $\mathcal{M}(B)$ has a natural C^*-algebra imbedding as a C^*-subalgebra of B^{**}, we can write $R_d(a)$ as ad and $L_d(a)$ as da for $a \in B$ and $d \in \mathcal{M}(B) \subseteq \mathcal{L}(B)$.)

The strong and the strict topology coincide on the set of normal elements $d \in \mathcal{M}(B)$, because $\|ad\| = \|da^*\|$ for $d \in \mathcal{M}(B)$ with $d^*d = dd^*$ and $a \in B$. In particular this topologies coincide on the unitary group of $\mathcal{M}(B)$ and on bounded sets of self-adjoint elements in $\mathcal{M}(B)$.

A *bounded* net in $\{b_\tau\} \subset \mathcal{M}(B)$ converges strongly (resp. strictly = *strongly) to an element of $b \in \mathcal{M}(B)$ if $\lim \|b_\tau c - bc\| = 0$ (resp. if $\lim \|b_\tau c - bc\| = 0$ and

[2] Keep always in mind the simple observation in Part (2) of the the following Remarks.

[3] In some cases, e.g. $B = \mathbb{K}$, it is on bounded parts the same as the *-*strong topology.*

$\lim \|db_\tau - db\| = 0$) for all c in a subset $X \subseteq \mathcal{M}(B)$ (resp. for all d in a subset $Y \subseteq \mathcal{M}(B)$ such that $\operatorname{span}(XB)$ and $\operatorname{span}(BY)$ are dense in B.

If B is σ-unital and $e \in B_+$ is a strictly positive element, the strict topology is metrizable with metric $\rho(b,c) := \|(b-c)e\| + \|e(b-c)\|$ on *bounded parts* of $\mathcal{M}(B)$.

A *series* $\sum_n d_n$ means the sequence of its partial sums $e_k := \sum_{n=1}^k d_n$ with $d_n \in \mathcal{M}(B)$. It converges **unconditional** strictly to $T \in \mathcal{M}(B)$ if $\sum_n d_{\gamma(n)}$ converges also strictly in $\mathcal{M}(B)$ for each permutation γ of $\mathbb{N}$. The series $\sum_n d_n$ denotes also the sum (if it exists).

If $\sum_n d_n$ converges unconditional in strict topology, then for its sum holds $\sum_n d_{\gamma(n)} = \sum_n d_n$ for each permutation γ of $\mathbb{N}$, because this is true for the series $\sum_n f(d_n)$ and each linear functional $f \in B^*$, where B^* is considered as a (complemented) subspace of $\mathcal{M}(B)^*$ by $B \triangleleft \mathcal{M}(B)$.

(1) A C^*-morphism $h\colon A \to \mathcal{M}(B)$ extends *uniquely* to a unital and *strictly continuous* C^*-morphism $\mathcal{M}(h)$ from $\mathcal{M}(A)$ into $\mathcal{M}(B)$, if and only if, the linear span of the set $h(A) \cdot B$ is dense in B. (In fact the closed linear span of $h(A) \cdot B$ is identical with the *set* of elements $h(a) \cdot b$, $a \in A$ and $b \in B$, because the proof of G.K. Pedersen shows that the $y \in X$ in the factorization $e \cdot y = x$ can be taken in the closed convex cone $\overline{B_+ \cdot x}$ of X, cf. G.K. Pedersen's proof a C^*-version of the Cohen Factorization Theorem outlined in Section 11 of Appendix A.

Def. of ‘‘non-degenerate’’ is used first in Part (7), but also
in Chapters 1, 2 and 3
(and perhaps Chapter 4 ?)

We call the C^*-morphism h **non-degenerate** if $h(A)B$ is dense in B. A C^*-subalgebra $C \subseteq \mathcal{M}(B)$ is a **non-degenerate subalgebra** if CB is dense in B.

(2) Suppose that $x = (x_1, x_2, \ldots)$ and $y = (y_1, y_2, \ldots)$ are sequences in $\mathcal{M}(B)$ such that the sums $\sum x_n x_n^*$ and $\sum y_n y_n^*$ converge strongly to elements X and Y of $\mathcal{M}(B)_+$. We identify $\ell_\infty(\mathcal{M}(B))$ naturally with the multiplier algebra of $c_0(B) \cong B \otimes c_0$.

Original d_n have been changed to b_n
for later notational reasons.
Check changes in proofs (!), other references, applications!!

Then, for every bounded sequence $b = (b_1, b_2, \ldots) \in \ell_\infty(\mathcal{M}(B))$, the series $\sum y_n b_n x_n^*$ converges strictly and unconditionally to an element $\Gamma(b_1, b_2, \ldots)$ in $\mathcal{M}(B)$. It defines a strictly continuous and completely bounded linear map

$$\Gamma : \quad (b_1, b_2, \ldots) \in \ell_\infty(\mathcal{M}(B)) = \mathcal{M}(c_0(B)) \;\mapsto\; \sum y_n b_n x_n^* \in \mathcal{M}(B)\,.$$

The mapping Γ maps $c_0(B)$ into B and has cb-norm

$$\|\,\Gamma\,\|_{\mathrm{cb}} \;\leq\; \big(\|X\| \cdot \|Y\|\big)^{1/2}\,.$$

This convergence observation turns the proofs of Lemma 5.1.2, Proposition 5.4.1 and some others into straight-forward calculations – sometimes left to the reader, as e.g. in the proof of Corollary 2.2.11(i) where this observation is used implicitly.

(3) The applications of the unconditional strict convergence of the expressions Γ – observed in Remark (2) – use sometimes quasi-central commutative approximate units of σ-unital C^*-algebras B to construct suitable sequences (x_n) and (y_n) that satisfy the assumptions in Part (2):

Let $e \in B_+$ any strictly positive element in B of norm $\|e\| = 1$, $A \subseteq \mathcal{M}(B)$ a separable C^*-subalgebra, and take a linear filtration of A by vector sub-spaces $X_n \subseteq A$ of finite dimension with the properties that $X_n = X_n^* := \{x^* ;\ x \in X_n\} \subseteq X_{n+1}$, $\dim(X_n) < \infty$ and $\bigcup_n X_n$ is dense in A.

Separation arguments for convex combinations of $f(e)$ with suitable non-decreasing functions f show that there exists a strictly decreasing zero-sequence $\alpha_1 > \alpha_2 > \cdots$ in $(0,1)$ and non-decreasing functions $f_n \in \mathrm{C}_0((0,1])_+$, $n := 0, 1, 2, \ldots$, with properties $f_0(t) := t$, $f_n(t) = 0$ for $t \in [0, \alpha_n]$,

$$f_n f_{n+1} = f_n,\ \ \|f_n\| = 1,\ \text{ and }\ \|f_0 - f_n f_0\| < 4^{-n}\,,$$

and the property that, for each $b \in X_n$ and $m > n$, the commutators have estimates

$$\|\,[f_n(e), b]\,\| \ +\ \|[(f_m(e) - f_n(e))^{1/2}, b]\,\| \ <\ 4^{-n}\|b\|\,.$$

The properties imply $f_n|[\varepsilon, 1] = 1$ and $\|\, e - f_n(e)e\,\| < \varepsilon$ for $n \geq 1 - \log(\varepsilon)$.

(4) Especially let $x_n := y_n := g_n := (f_n(e) - f_{n-1}(e))^{1/2}$ for $n > 1$ and $x_1 := y_1 := g_1 := f_1^{1/2}(e)$ in Remark (2) with f_n selected for $X_n \subseteq A \subseteq \mathcal{M}(B)$ as in Remark (3).

The sum $\sum_n g_n^* g_n$ converges strictly to 1 and the in Remark (2) defined map $\Gamma \colon \ell_\infty(\mathcal{M}(B)) \to \mathcal{M}(B)$ with $x_n := y_n := g_n^*$ is a *unital* completely positive map with $a - \Gamma(a, a, \ldots) \in B$ for all $a \in A$.

(5) If $g_1, g_2, \ldots$ are as in Remarks (3) and (4), constructed for a given filtration X_n of $A \subseteq \mathcal{M}(B)$ and a given strictly positive contraction $e \in B_+$, and if $d_1, d_2, \ldots$ is a bounded sequence in $\mathcal{M}(B)$ with $\sum_n \|d_n g_n - g_n d_n\| < \infty$, then the series $\sum_n d_n g_n$ converges strictly to an element $d \in \mathcal{M}(B)$.

In particular, let $P \subseteq \mathbb{N}$ and (d_n) defined by $d_n := 1$ if $n \in P$ and $d_n := 0$ if $n \in \mathbb{N}\backslash P$. The corresponding positive contraction $S := S_P := \sum_{n\in P} g_n \in \mathcal{M}(B)_+$ is not necessarily in B.

But we get from Remark (4) that

$$Sa - aS\,,\ SaS \,+\, (1 - S^2)^{1/2} a (1 - S^2)^{1/2} \,-\, a \ \in B \quad \forall\, a \in A\,.$$

The operator S satisfies $S^2 = \sum_{n\in P} g_n^2$ if $|p - q| > 1$ for all $p, q \in P$ with $p \neq q$.

(6) Suppose that a sequence of contractions $d_1, d_2, \ldots \in \mathcal{M}(B)$, a self-adjoint contraction $a^* = a \in \mathcal{M}(B)$ and the sequence $g_1, g_2, \ldots$ defined in Remark (4) satisfy

(i) $\sum_\ell \nu_\ell < \infty$ for $\nu_\ell := \sup_{n\geq \ell}\bigl(\max_{1\leq k\leq n} \|d_k g_n - g_n d_k\|\,\bigr)$,

(ii) $\sum_\ell \mu_\ell < \infty$ for $\mu_\ell := \sup_{n\geq \ell} \|g_n a - a g_n\|$, and
(iii) $\lim_{n\to\infty} \|g_n d_n^* a d_{n+1} g_{n+1}\| = 0$.

Then $d_1, d_2, \ldots, a$ and $d := \sum_n d_n g_n$ satisfy

$$d^* a d \,-\, \Gamma(d_1^* a d_1\,,\; d_2^* a d_2\,,\; \ldots) \,\in\, B\,.$$

(7) D is a **corner** of B, if D is a hereditary C^*-subalgebra of B and $D+\mathrm{Ann}(D)$ is a *non-degenerate* C^*-subalgebra of B.

It says equivalently that there is a projection $p \in \mathcal{M}(B)$ with $D = pBp$.

A subset $X \subseteq B$ **generates a corner** of B, if the closure of the linear span of $C^*(X) \cdot B \cdot C^*(X)$ is a corner of B.

(In fact the set of products $c \cdot b \cdot c$ with $b \in B$ and contractions $c \in C^*(X)_+$ in an approximate unit of $C^*(X)$ is identical with the hereditary C^*-subalgebra of B generated by $C^*(X)$ as the Cohen factorization theorem [**621**, Thm. 4.1] shows, cf. also Theorem A.11.1.)

(8) Recall that B is a **stable C^*-algebra** if there exists an isomorphism ψ from $B \otimes \mathbb{K}$ onto B, where $\mathbb{K} := \mathbb{K}(\ell_2)$ denotes the compact operators $\mathbb{K} := \mathbb{K}(\ell_2)$ on $\ell_2(\mathbb{N})$.

This is equivalent to the existence of a C^*-algebra C and a C^*-algebra isomorphism from $C \otimes \mathbb{K}$ onto B.

The following criterium is necessary and sufficient for the stability of a (not necessarily σ-unital) C^*-algebra B:
There exists a sequence $s_1, s_2, \ldots$ of isometries in $\mathcal{M}(B)$ such that $\sum_n s_n s_n^*$ converges strictly to 1 *in $\mathcal{M}(B)$.*

Given a sequence $s_1, s_2, \ldots \in \mathcal{M}(B)$ of isometries with $\sum_n s_n s_n^*$ strictly convergent to 1, then $\delta_\infty(b) := \sum_n s_n b s_n^*$ for $b \in \mathcal{M}(B)$ defines a faithful strictly continuous unital *-endomorphism of $\mathcal{M}(B)$.

It holds $u^* \delta_\infty(b) u = \sum_n t_n b t_n^*$ by a unitary $u \in \mathcal{M}(B)$ with $t_n = u s_n$ for $n = 1, 2, \ldots$ if $t_1, t_2, \ldots$ is any other sequence of isometries in $\mathcal{M}(B)$ with $\sum_n t_n t_n^* = 1$ (strictly convergent).

The unitary equivalence class $[\delta_\infty]$ has representatives $\delta_\infty \colon \mathcal{M}(B) \to \mathcal{M}(B)$ determined by $s_1, s_2, \ldots$. We call this class (and sometimes the endomorphisms $\sum_n s_n(\cdot)s_n$ in this class) the **infinite repeat** (on $\mathcal{M}(B)$) of the identity mapping $\mathrm{id}_{\mathcal{M}(B)}$ of $\mathcal{M}(B)$. Then $\delta_\infty(b)$ (or its unitary equivalence class $[\delta_\infty(b)]$) is the *infinite repeat of the element $b \in \mathcal{M}(B)$.*

There exists a C^*-morphism $\mu \colon \mathbb{K} \to \mathcal{M}(B)$ with following properties (a,b,c):

(a) $\mu(\mathbb{K}) \subset \delta_\infty(B)' \cap \mathcal{M}(B)$,
(b) $\delta_\infty(b)\mu(k) \in B$ for $b \in B$ and $k \in \mathbb{K}$, and

(c) the (unique) C^*-morphism $\varphi\colon B \otimes \mathbb{K} \to B$ with $\varphi(b \otimes k) = \delta_\infty(b)\mu(k)$ is an isomorphism from $B \otimes \mathbb{K}$ *onto* B that maps $J \otimes \mathbb{K}$ onto J for each ideal J of B.

If a C^*-morphism $\mu\colon \mathbb{K} \to \mathcal{M}(B)$ satisfies conditions (a,b,c) then $\mu(\mathbb{K}) \cdot B = B$.

The C^*-morphisms $\mu\colon \mathbb{K} \to \mathcal{M}(B)$ with properties (a,b,c) are uniquely defined by the given sequence $s_1, s_2, \ldots \in \mathcal{M}(B)$ of isometries with $\sum s_n s_n^* = 1$ – *up to unitary equivalence by unitaries in* $\delta_\infty(B)' \cap \mathcal{M}(B)$.

One of the C^*-morphisms $\mu\colon \mathbb{K} \to \delta_\infty(B)' \cap \mathcal{M}(B)$ with properties (a,b,c) can be defined by $\mu(p_{j,k}) := s_j s_k^*$ for $j, k \in \mathbb{N}$, if the unitary equivalence class $[\delta_\infty]$ is realized by given isometries $s_1, s_2, \ldots$, i.e., if $\delta_\infty(\cdot) := \sum_n s_n(\cdot)s_n^*$.

The isomorphism φ from $B \otimes \mathbb{K}$ onto B defined by $\mu\colon \mathbb{K} \to \mathcal{M}(B)$ with properties (a,b,c) has the property that the corresponding C^*-morphism $b \mapsto \varphi(b \otimes p_{1,1})$ is a *-endomorphism of B, that is approximately 1-step inner as a c.p. contraction.

The C^*-morphism $\varphi((\cdot) \otimes p_{1,1})$ is unitarily homotopic to id_B if B is σ-unital.

If $b \in B_+$, then $\varphi(b \otimes e_{1,1})$ is Murray–von-Neumann equivalent to b. In particular, $\varphi(J \otimes \mathbb{K}) = J$ for each $J \in \mathcal{I}(B)$.

This property of the "natural" φ is different from the properties of very random and possibly not well-behaved *-isomorphism ψ from $B \otimes \mathbb{K}$ onto B – as allowed in the *definition* of stability –, because in general the isomorphism $\varphi \circ \psi^{-1}$ of B does not fix the ideal-system $\mathcal{I}(B)$ of B and is not approximately unitarily equivalent to id_B by unitaries in $\mathcal{M}(B)$.

The non-degenerate *-monomorphism $\mu\colon \mathbb{K} \to \mathcal{M}(B)$ with properties (a,b,c) has the "dual" property that

$$\mu(\mathbb{K})' \cap \mathcal{M}(B) = \delta_\infty(\mathcal{M}(B))\,.$$

It implies that $\delta_\infty(\mathcal{M}(B))$ is closed in $\mathcal{M}(B)$ with respect to the strict topology on $\mathcal{M}(B)$.

The strictly continuous extension $\mathcal{M}(\mu)\colon \mathcal{M}(\mathbb{K}) \cong \mathcal{L}(\ell_2) \to \mathcal{M}(B)$ of μ is a unital *-monomorphism, has image in $\delta_\infty(\mathcal{M}(B))' \cap \mathcal{M}(B)$ and the norm-closed unit-ball of $\mathcal{M}(\mu)(\mathcal{L}(\ell_2))$ is also *closed in the strict topology* of $\mathcal{M}(B)$.

The strictly closed C^*-subalgebra $\delta_\infty(\mathcal{M}(B))' \cap \mathcal{M}(B)$ of $\mathcal{M}(B)$ can be larger than $\mathcal{M}(\mu)(\mathcal{L}(\ell_2))$, e.g. if the center of $\mathcal{M}(B)$ is not trivial.

For each non-degenerate C^*-morphism $\psi\colon \mathbb{K}(\ell_2) \to \mathcal{M}(B)$, the topology induced via $\mathcal{M}(\psi)^{-1}$ on $\mathcal{M}(\mathbb{K}) = \mathcal{L}(\ell_2)$ by the strict topology on $\mathcal{M}(B)$ coincides on bounded parts with the *-strong operator topology on $\mathcal{L}(\ell_2)$.

(9) The $(s_1, s_2, \ldots)$-existence criteria for stability in Remark (8) shows that

B and $B + h(A)$ are stable if A is stable and $h\colon A \to \mathcal{M}(B)$ is a non-degenerate C^*-morphism.

In particular, B is stable if B contains a non-degenerate stable C^*-subalgebra.

`To be worked out in detail:`

(10) Let $C_1, C_2, \ldots$ a contable sequence of separable unital C^*-algebras, $\mathbb{K}\otimes D$ a σ-unital stable C^*-algebra, and let $B := \mathbb{K} \otimes D \otimes C_1 \otimes C_2 \otimes \cdots$ the infinite tensor product. We define unital C^*-subalgebras $G_1 \subset G_2 \subset \cdots$ of $\mathcal{M}(B)$ by the following conditions:

`To be defined. Sort of infinite` $\mathcal{E}(C_n, C_{n+1}) \subseteq \mathcal{M}(B)$ `build with help an approximately central approximate unit of` B `that is approximately central for` $h(A)$ `of a given` `C*-morphism`

$$h \colon A \to \mathcal{M}(B).$$

?????

Then for every C^*-morphism $h \colon A \to \mathcal{M}(B)$ of a separable C^*-algebra A there exists $n_0 := n_0(h(A)) \in \mathbb{N}$ such that $[h(A), G_n] \subseteq B$ for all $n \geq n_0$ and, for each $a \in A$, $\|[h(a), g_n]\| \to 0$ for any sequence of contractions $g_n \in G_n$.

(With n_0 depending from an approximate unit in $\mathbb{K} \otimes D$ that is quasi-central for $h(A)$.)

TO BE FILLED IN – for almost central sequences...

Lemma, ???? Idea ???, corona property ...

Case $B := \mathbb{K} \otimes D \otimes C_1 \otimes C_2 \otimes \cdots$ $A \subseteq \mathcal{M}(B)$ separable C^*-subalgebra. Then one can find *tensorial residuum* if $1 \otimes 1_1 \otimes \cdots \otimes 1_{n_k} \otimes C_{n_{k+1}} \otimes \cdots$ commuting modulo B with A... provided that the C_n are unital simple and separable ... MORE conditions ???

Proofs of Remarks (1)–(10):

We say here something about the different definitions of multipliers, multiplier algebras, its relation to factorization properties of C^*-algebra modules and the interrelation between the (by them defined) strict, strong and weak* topologies on bounded subsets of C^*-subalgebrasof multiplier algebras. And we explain the often required "non-degeneracy" of modular morphisms for the often needed verification of unconditional strict convergence of series.

(0.1) **General multiplier algebras**:

If B is a Banach algebra and $\rho \colon B \to \mathcal{L}(X)$ is an algebra homomorphism, then the "action" ρ of B on X, respectively the (left) B-module X defined by $b \cdot x := \rho(b)(x)$ is called **non-degenerate** if $\text{span}(\rho(B)X)$ is dense in X.

To simplify some arguments we use later the special case for C^*-algebras B of the Cohen factorization theorem ([4]) given by G.K. Pedersen [**621**, Thm. 4.1] (with 13 lines of proof):

[4] P. Cohen [**?**] proved 1959 that Banach algebras B with bounded approximate left-unit have the factorization property. In 1964, E. Hewitt [**363**] and P. Koosis [**491**] showed that this factorization property also holds for non-degenerate Banach B-modules.

If a C^*-algebra B acts on a Banach space X from left with $\|b\cdot x\| \leq \|b\|\|x\|$ and if $\mathrm{span}(B \cdot X)$ *is dense in X, then for each $\varepsilon > 0$ and $x \in X$ there exists $e \in B_+$ and $y \in X$ with $e \cdot y = x$, $\|e\| \leq 1$, $\|y - x\| < \varepsilon$.*

In fact, the proof of G.K. Pedersen, shows that the $y \in X$ in the factorization $e \cdot y = x$ can be chosen in the closed convex cone $\overline{B_+ \cdot x}$ of X, cf. Section 11 of Appendix A.

Since one can here replace X likewise by $\overline{B \cdot x}$ or by $c_0(X)$ with left action $b \cdot (x_1, x_2, \ldots) = (b \cdot x_1, b \cdot x_2, \ldots)$, we can find a positive contraction $a \in B$ and $y \in \overline{B \cdot x}$ (respectively $(y_1, y_2, \ldots) \in c_0(X)$) with $b \cdot y = x$ and $\|x - y\| < \varepsilon$ (respectively with $b \cdot y_n = x_n$ and $\|x_n - y_n\| < \varepsilon$ for $n = 1, 2, \ldots$). The latter implies in particular for $X := B$ that for $a, b \in B$ there are $e \in B_+$, $c \in \overline{B_+ a}$ and $d \in \overline{B_+ b}$ with $ec = a$, $ed = b$ and $\|e\| \leq 1$.

If B is a σ-unital C^*-algebra and X a non-degenerate B-module with $\|b\cdot x\| \leq \|b\|\,\|x\|$, then one can find, for each given strictly positive contraction $b_0 \in B_+$ and $\varepsilon > 0$ and $x \in X$, a factorization $e \cdot y = x$ with $\|y - x\| < \varepsilon$ where $y \in X$ and $e := \varphi(b_0)$, φ an increasing continuous function with $f(0) = 0$ and $f(1) \leq 1$.

Except the latter, all this is also true for Banach algebras B with an approximate unit consisting of contractions. (But one has to use for such algebras B the estimates from the generalization of the Cohen factorization given by E. Hewitt or P. Koosis.)

In particular, the following definition and arguments work more generally for Banach algebras B that contains an approximate unit $\{e_\tau\}$ with $\| e_\tau \| \leq 1$.

Notice that the non-degeneracy of the action of B on X implies that $x \in \overline{B \cdot x}$ and and thus, that $B \cdot x = \{0\}$ is equivalent to $x = 0$.

This allows to extend the action of B on X in a unique way to a left module action of the **left-multiplier algebra** of B , i.e., of the operator-norm closed subalgebra $\mathcal{M}_\ell(B)$ of $\mathcal{L}(B)$ of bounded **left multipliers** $L \in \mathcal{L}(B)$ of B, that are defined by its property

$$L(ab) = L(a)b \quad \text{for all } a, b \in B\,.$$

(The elements $L \in \mathcal{M}_\ell$ are also called "left centralizers" of B, where we have to consider B as subalgebra of $\mathcal{L}(B)$.)

The extension of the B-modul X to an $\mathcal{M}_\ell(B)$-modul X with $(L_b) \cdot' x = b \cdot x := \rho(b)(x)$ is uniquely defined for $L \in \mathcal{M}_\ell(B)$ and $y \in X$ via Cohen factorization $y := b \cdot x$ by

$$L \cdot' (b \cdot x) := L(b) \cdot x \quad \text{for } b\,.$$

The definition of $L \cdot' y$ is justified, because the right side is equal to $\lim_\tau L(e_\tau b) \cdot x$, because L is bounded and $e_\tau b \to b$. Since $L(ea) \cdot x = L(e) \cdot (a \cdot x) = L(eb) \cdot y$ for $a \cdot x = b \cdot y$, it follows that the action of $\mathcal{M}_\ell(B)$ is well-defined. It is then not difficult to check that $(L, x) \mapsto L \cdot' x$ is bi-linear in L and $x \in X$ and $\|L \cdot' x\| \leq \|L\|\|x\|$. See [**621**, thm. 5.9] and proof of [**621**, thm. 5.10] for the case where B is a C^*-algebra.

Obviously an operator $T \in \mathcal{L}(B)$ is in $\mathcal{M}_\ell(B)$ if and only $TR_b = R_bT$ for all $b \in B$, where $R_b(a) := ab$ for $a \in B$. This shows that $\mathcal{M}_\ell(B)$ is closed in $\mathcal{L}(B)$ with respect to the strong operator topology.

If a Banach algebra B contains (two-sided) bounded approximate unit, then the Cohen factorization theorem, applied to B as a left module over B, shows that the subalgebra $\mathcal{M}_\ell(B) \subset \mathcal{L}(B)$ is the closure of the (then to B isomorphic) subalgebra $\{L_b\,;\ b \in B\} \subset \mathcal{L}(B)$ with respect to the strong operator topology on $\mathcal{L}(B)$.

We use now that for every *Banach space* X, the space $\mathcal{L}(X)$ is *complete* as locally convex vector space with respect to the *strong* operator topology (an immediate consequence of the Banach-Steinhaus uniform boundedness theorem).

It implies that $\mathcal{M}_\ell(B)$ equipped with the strong operator topology is the *completion* of B with respect to the uniform structure defined on $B \times B$ by the system of semi-metrics $\rho_c(a, b) := \|(b - a)c\|$ $(c \in B)$, if B has a *bounded two-sided approximate unit*.

Let $\eta_B \colon B \hookrightarrow B^{**}$ the natural isometry from B into its second conjugate Banach *space* B^{**}. We identify the elements $b \in B$ later with its image $\eta_B(b) \in B^{**}$.

If B has a (left) approximate unit consisting of *contractions* in B then there exists an element $e \in B^{**}$ with the properties $\|e\| \leq 1$ and $(R_b)^{**}(e) = \eta_B(b)$ for all $b \in B$.

It follows that the map $T \in \mathcal{L}(B) \mapsto T^{**}(e) \in B^{**}$ defined on $\mathcal{L}(B)$ has an *isometric* restriction λ to $\mathcal{M}_\ell(B)$ that satisfies

$$(R_b)^{**}\lambda(T) = \eta_B(Tb) \quad \text{and} \quad \|\lambda(T)\| = \|T\| \quad \text{for } b \in B,\ T \in \mathcal{M}_\ell(B)\,. \tag{1.1}$$

If $X \in B^{**}$ satisfies $(R_b)^{**}T \in \eta_B(B)$ for all $b \in B$ then $T(b) := \eta_B^{-1}((R_b)^{**}X)$ defines an element $T \in \mathcal{M}_\ell(B)$ with $\lambda(T) = X$.

If, moreover, the linear span of the elements $(R_b)^*\rho$ for $b \in B$ and $\rho \in B^*$ is norm-dense in B^* then the element $e \in B^{**}$ with the property $(R_b)^{**}(e) = b$ for all $b \in B$ and the map $\lambda\colon \mathcal{M}_\ell(B) \to B^{**}$ with the quoted property is unique.

The latter is the case for C^*-algebras B, by the Kaplansky density theorem for $B \subseteq B^{**}$.

Notice that that $(R_b)^{**}(X) = X \cdot \eta_B(b)$ in the W*-algebra B^{**} for $b \in B$ and $X \in B^{**}$ if B is a C^*-algebra B, i.e., the equation (1.1) becomes

$$\gamma(T)\eta_B(a) = \eta_B(Ta)\,.$$

It implies that γ is an isometric algebra isomorphism from $\mathcal{M}_\ell$ into B^{**} with $\gamma(L_b) = \eta_B(b)$.

If $X \in B^{**}$ satisfies $X\cdot \in B \subset B^{**}$ then there exists $T \in \mathcal{M}_\ell(B)$ with $X = \gamma(T)$ for $T(b) := \eta_B^{-1}(X\eta_B(b))$.

It defines a multiplicative isometric algebra representation of $\mathcal{M}_\ell(B)$ into the W*-algebra B^{**}. The image of λ is the algebra of left-multipliers of $\eta_B(B) \subseteq B^{**}$ inside B^{**}.

Recall that each C^*-algebras B has an approximate unit consisting of contractions and the linear span of the elements $(R_b)^*(\rho)$ with $b \in B$ and $\rho \in B^*$ (where $R_b(a) := ba$) is norm-dense in B^*, cf. [**616**, thm. 4.1.2] and use that each ρ is in the norm closure of $(R_b)^* \cdot \rho$ ($b \in B$, $\|b\| \leq 1$), because B is *-ultra-strong dense in second conjugate W*-algebra B^{**} by Kaplansky density theorem cf. [**616**, thm. 2.3.3]. In particular, in this case $e = 1 := 1_{B^{**}}$ and $\gamma(T) := T^{**}(1)$ for $T \in \mathcal{M}_\ell(B)$.

Thus a natural isometric linear map $\lambda\colon \mathcal{M}_\ell(\eta_B)\colon \mathcal{M}_\ell(B) \hookrightarrow B^{**}$ is given by the restriction of the natural linear map

$$T \in \mathcal{L}(B) \mapsto T^{**}(e) \in B^{**}$$

to $\mathcal{M}_\ell(B)$, where T^{**} here is the bi-adjoint of the operator $T \in \mathcal{L}(B)$ and e is the unique cluster point of an approximate unit consisting of contractions in B.

The restriction of the map $T \mapsto T^{**}(e)$ to the elements in the algebra of left multipliers $\mathcal{M}_\ell(B) \subseteq \mathcal{L}(B)$ of the map $T \to T^{**}(1)$ from $\mathcal{L}(B)$ to B^{**} is isometric and multiplicative if the *Banach* algebra B contains a two-sided approximate unit consisting of contractions and the elements $(R_b)^*(\rho)(\cdot) := \rho((\cdot)b)$ for $\rho \in B^*$ and $b \in B$ are norm-dense in the dual Banach space B^* of B. Here e denotes the (then) unique element in B^{**} with $(R_b)^{**}(e) = b$ for all $b \in B$. In particular the map $\gamma\colon \mathcal{M}_\ell(B) \to B^{**}$ is uniquely defined for all C^*-algebras B.

The general (two-sided) **multiplier algebra** of a Banach algebras B (not necessarily with involution operation on B) is defined as the set of pairs (L, R) of operators $L, R \in \mathcal{L}(B)$ that satisfy $(R(b)) \cdot c = b \cdot (L(c))$, $L(ab) = L(a)b$ and $R(ab) = aR(b)$ for $a, b, c \in B$. Notice that left and right multiplication (L_a, R_a) by $a \in B$ defines a two-sided multiplier for each $a \in B$.

The property $(R(b)) \cdot c = b \cdot (L(c))$ for all $b, c \in B$ of the pair $(L, R) \in \mathcal{L}(B) \times \mathcal{L}(B)$ alone implies that $a(L(bc) - L(b)c) = 0 = (R(ab) - aR(b))c$ for all $a, b, c \in B$. Thus implies automatically that L and R are left and right multipliers if e.g. B contains a (two-sided) approximate unit. Moreover, then the pair (L, R) is determined uniquely by L alone and the property that to this (special sort of) left multipliers L there exists a right multiplier such that (L, R) is a two-sided multiplier.

In a Banach *-algebra B one can transform each right multiplier R into a left multiplier $\widehat{R} \in \mathcal{M}_\ell(B)$ by the anti-linear map on $\mathcal{L}(B)$ (of order 2) given by $\widehat{R}(a) := R(a^*)^*$. If a Banach *-algebra B contains an approximate unit then the two-sided multipliers are the pairs of left multipliers $(L, \widehat{R})$ that satisfy $(\widehat{R}(a))^* b = a^* L(b)$, where $\widehat{R}$ is uniquely determined by L (if R exists for L). We rename them and describe them as pairs $(S, T) \in \mathcal{M}_\ell(B) \times \mathcal{M}_\ell(B)$ and the defining property is the relation

$$a^* S(b) = T(a)^* b \quad \text{for all } \; a, b \in B\,, \tag{1.2}$$

that is equivalent to $\widehat{S}(b)a = bT(a)$ for $a, b \in B$.

If B contains an approximate unit (e_τ) with $\|e_\tau\| \leq 1$ then Equation (1.2) implies that $\|S\| = \|T\|$. In this way we can define on the two-sided multiplies (S,T) a norm $\|(S,T)\| := \max\{\|S\|, \|T\|\} = \|S\|$.

(0.2) **Two-sided multipliers of C^*-algebras**: We use the *equivalent* definition for the two-sided multiplier algebra $\mathcal{M}(B)$ in case of C^*-algebras B that better suites for our applications:

We define $\mathcal{M}(B)$ as the norm-closed sub-algebra of $\mathcal{M}_\ell(B) \subseteq \mathcal{L}(B)$ consisting of all operators $T \in \mathcal{M}_\ell(B)$ with the property that there exists $S \in \mathcal{L}(B)$ that satisfies Equation (1.2).

This equations yield automatically that the operator-norm inherited from $\mathcal{L}(B)$ is the same as the C^*-norm of the C^*-algebra $\mathcal{M}(B)$.

The reader should notice the we have in fact a stronger observation (going back to an old remark of J. von Neumann):
Alone the property that S and T are abstract maps from B into B (without supposing linearity as precondition) that satisfy $a^*S(b) = T(a)^*b$ for all $b, c \in B$ allows to see, using the property $\|d^*d\| = \|d\|^2 = \|dd^*\|$ of C^*-norms and the closed graph theorem, that S and T must be *linear* operators that are bounded and have the properties $\|T\| = \|S\|$, $T(bc) = (Tb)c$, $S(bc) = (Sb)c$ and that S is uniquely determined by T. Then $S := T^* \in \mathcal{M}_\ell(B)$ is *well-defined* for T in this closed subalgebra $\mathcal{M}(B)$ of $\mathcal{M}_\ell(B)$ by $T^* := S$.

The natural *-monomorphism of B onto an essential ideal of $\mathcal{M}(B) \subseteq \mathcal{L}(B)$ is given by $b \in B \mapsto L_b \in \mathcal{L}(B)$, where $L_b(c) := bc$ for $b, c \in B$. We *identify* B with its image in $\mathcal{M}(B)$ via $b \leftrightarrow L_b$.

The so-called *strong topology* and *strict topology* on $\mathcal{M}(B) \subseteq \mathcal{L}(B)$ is given by the restriction to $\mathcal{M}(B)$ of the usual strong operator topology on $\mathcal{L}(B)$, that is given by the family of semi-norms $T \mapsto \|Tb\|$ with $b \in B$, and the strict topology is given by the family of semi-norms $T \mapsto \|Tb\|$ and $T \mapsto \|T^*b\|$, where $T^* \in \mathcal{L}(B)$ is defined as above by $(T^*a)^*b = a^*(Tb)$ for $a, b \in B$.

Obviously this implies that in case of σ-unital B we can take a strictly positive contraction $b_0 \in B_+$ and get with $T \mapsto \|Tb_0\| + \|T^*b_0\|$ a *defining norm* on $\mathcal{M}(B)$ that defines the strict topology on *bounded parts* of $\mathcal{M}(B)$.

Let $\eta_B \colon B \hookrightarrow B^{**}$ the natural *-monomorphism from B into its second conjugate W*-algebra B^{**}. Sometimes we identify the elements $b \in B$ with its image $\eta_B(b) \in B^{**}$.

A natural and unital C^*-monomorphism $\mathcal{M}(\eta_B) \colon \mathcal{M}(B) \hookrightarrow B^{**}$ is given by the restriction of the natural linear map

$$\gamma \colon T \in \mathcal{L}(B) \mapsto T^{**}(1) \in B^{**}$$

to $\mathcal{M}(B)$, where T^{**} here is defined as the bi-adjoint of the operator $T \in \mathcal{L}(B)$ and $1 := 1_{B^{**}}$ is the unit element of the W*-algebra B^{**}.

Look at next. Is it mentioned above?

The restriction of the map $T \mapsto T^{**}(1)$ (with $1 = 1_{B^{**}}$) to the elements in the algebra of left multipliers $\mathcal{M}_\ell(B) \subseteq \mathcal{L}(B)$ of the map $T \to T^{**}(1)$ from $\mathcal{L}(B)$ to B^{**} is isometric and multiplicative if the Banach algebra B contains a two-sided approximate unit consisting of contractions and the elements $(R_b)^*(\rho)(\cdot) := \rho((\cdot)b)$ for $\rho \in B^*$ and $b \in B$ are norm-dense in the dual Banach space B^* of B. Here $1 := 1_{B^{**}}$ denotes the (then) unique element in B^{**} with $(R_b)^{**}(1) = b$ for all $b \in B$.

Thus, if B is a C^*-algebra, then it is a C^*-algebra monomorphism if restricted to $\mathcal{M}(B) \subseteq \mathcal{L}(B)$ because, $B_+ \ni e_\tau \to 1$ in B^{**} with $\sigma(B^{**}, B^*)$ topology, e.g.

$$T(b) = T^{**}(1 \cdot b) = \lim_\tau T(e_\tau \cdot b) = T^{**}(e_\tau)b = T^{**}(1)b$$

for all $b \in B^{**}$. To see this, use that T^{**} is $\sigma(B^{**}, B^*)$-continuous and that the unit ball of B is $\sigma(B^{**}, B^*)$-dense in the unit ball of B^{**}.

The image of $T \in \mathcal{M}(B) \mapsto T^{**}(1_{B^{**}})$ is a C^*-algebra isomorphism from $\mathcal{M}(B)$ onto the C^*-subalgebra of the W*-algebra B^{**} of elements $d \in B^{**}$ with the property $dB \subseteq B$ and $Bd \subseteq B$, where we have the elements $b \in B$ naturally identified with its images $\eta_B(b) \in B^{**}$ in the second conjugate W*-algebra B^{**}.

We say that a C^*-morphism $h\colon B \to M$ from a C^*-algebra B into a W*-algebra M that is **weakly non-degenerate** if 1_M is contained in the $\sigma(M, M_*)$-closure of $h(B)$.

If h is weakly non-degenerate then there exists a unique C^*-morphism $\mathcal{M}(h)\colon \mathcal{M}(B) \to M$ with the property $\mathcal{M}(h)|B = h$. The C^*-morphism $\mathcal{M}(h)$ is unital and maps $\mathcal{M}(B)$ into the C^*-subalgebra of M given by the two-sided multipliers $m \in M$ of $h(B)$ in M, i.e., $mh(B) \cup h(B)m \in h(B)$ for $m \in \mathcal{M}(h)(\mathcal{M}(B))$.

If $h\colon B \to M$ is *faithful* and *weakly non-degenerate* then $\mathcal{M}(h)$ is faithful and each two-sided multiplier m of $h(B)$ is in the image $\mathcal{M}(h)(\mathcal{M}(B))$, because then $L\colon b \mapsto h^{-1}(mh(b))$ and $R\colon b \mapsto h^{-1}(h(b)m)$ define a pair $(L, R) \in \mathcal{L}(B) \times \mathcal{L}(B)$ that defines an element $T \in \mathcal{M}(B)$ with $\mathcal{M}(h)(T)h(b) = mh(b)$. Now use that 1_M is in the $\sigma(M, M_*)$-closure of $h(B)$.

The latter applies to $B := \mathbb{K}(\mathcal{H})$, $M := \mathcal{L}(\mathcal{H})$ and to $h\colon b \in \mathbb{K}(\mathcal{H}) \to b \in \mathbb{K}(\mathcal{H})$ and yields that $\mathcal{M}(\mathbb{K}(\mathcal{H}))$ is naturally isomorphic to $\mathcal{L}(\mathcal{H})$ by an isomorphism that fixes the compact operators.

The strict closure of any convex subset $Z \subseteq \mathcal{M}(B)$ coincides with the intersection of $\mathcal{M}(B) \subseteq B^{**}$ with its closure $\overline{Z}$ in the $\sigma(B^{**}, B^*)$-topology, because all strictly continuous linear functionals $f\colon \mathcal{M}(B) \to \mathbb{C}$ are of the form $f = g \circ \mathcal{M}(\eta_B)$ with $g \in B^* \subseteq B^{**}$.

This can be seen from the existence of $b_1, \ldots, b_n \in B$ for a given *strictly* continuous linear functionals $f \in \mathcal{M}(B)^*$ that satisfy $|\, f(T) \,| \leq \sum_{k=1}^n \|Tb_k\| + \|T^*b_k\|$ for all $T \in \mathcal{M}(B)$, and from the fact that the unit-ball of B is strictly dense in the unit ball of $\mathcal{M}(B)$ because each C^*-algebra has an approximate unit $\{e_\tau\}$ consisting of positive contractions:

The net $e_{\tau'}(Te_\tau) \in B$ – with possibly different τ', τ - converges strictly to T.

The strict density of the unit ball of B in the unit ball of $\mathcal{M}(B)$ implies also directly that a strictly continuos linear functional f on $\mathcal{M}(B)$ satisfies $\|f\| = \|f|B\|$. Hence, f is *determined* by its restriction to B, i.e., is the same as $g|\,\mathcal{M}(B)$ of the natural extension of $g := f|B \in B^*$ to an $\sigma(B^*, B^{**})$-continuous extension to an element of $\mathcal{M}(B) \subseteq B^{**}$.

If $\rho\colon B \to \mathcal{L}(\mathcal{H})$ is a non-degenerate *-representation of B on a Hilbert space $\mathcal{H}$, i.e., if $\mathrm{span}(\rho(B)\mathcal{H})$ is dense in $\mathcal{H}$, then ρ is also a non-degenerate C^*-morphism from B into $\mathcal{M}(\mathbb{K}(\mathcal{H}))$.

This is because the closure of the linear span $\mathrm{span}(\rho(B)\mathbb{K}(\mathcal{H}))$ is equal to $\rho(B) \cdot \mathbb{K}(\mathcal{H})$ by Cohen factorization and is a closed right ideal R of $\mathbb{K}(\mathcal{H})$.

Indeed: It is easy to see that $\mathbb{K}(\mathcal{H})\mathcal{H} = \mathcal{H}$ and that $R\mathcal{H} = P\mathcal{H}$ and $P\mathbb{K}(\mathcal{H}) = R$ with a unique projection $P \in \mathcal{L}(\mathcal{H})$ for all closed right ideals R of $\mathbb{K}(\mathcal{H})$.

Since $\mathcal{M}(\mathbb{K}(\mathcal{H}))$ is naturally isomorphic to $\mathcal{L}(\mathcal{H})$, a *-representation $\rho\colon B \to \mathcal{L}(\mathcal{H})$ is non-degenerate if and only if ρ is non-degenerate as a C^*-morphism from B into $\mathcal{M}(\mathbb{K}(\mathcal{H}))$.

(This says equivalently that $\rho(B)\mathcal{H} = \mathcal{H}$ if and only if $\rho(B)\mathbb{K}(\mathcal{H}) = \mathbb{K}(\mathcal{H})$.)

If the latter is the case we get the unique unital strictly continuous extension $\mathcal{M}(\rho)\colon \mathcal{M}(B) \to \mathcal{M}(\mathbb{K}(\mathcal{H})) = \mathcal{L}(\mathcal{H})$ with the property $\mathcal{M}(\rho)(b) = \rho(b)$ for $b \in B$.

`Next has also overlaps with (0.3):`

`MOVE TO to` $\mathcal{M}(\mathbb{K})$ `study !?!` CROSS REF to????

(uniqueness extensions $\mathcal{M}(h)$ of non-degenerate h are explained in ???????? where??? "uniqueness of $\mathcal{M}(h)$ for non-degenerate h"

Should be in Chp. 3 – or in Chp.2, or even in Chp.1)

The *-representation $\rho\colon B \to \mathcal{L}(\mathcal{H}) \cong \mathcal{M}(\mathbb{K}(\mathcal{H}))$ is non-degenerate as C^*-morphism from B to $\mathcal{M}(\mathbb{K}(\mathcal{H}))$ if and only if ρ is non-degenerate as a representation of B over $\mathcal{H}$, i.e., the linear span of $\rho(B)\mathbb{K}(\mathcal{H})$ dense in $\mathbb{K}(\mathcal{H})$ if and only if the linear span of $\rho(B)\mathcal{H}$ is dense in $\mathcal{H}$.

`See also further above/below for next:`

The latter holds because $\mathbb{K}(\mathcal{H})\mathcal{H} = \mathcal{H}$. (Alternative argument: A closed right ideal R of $\mathbb{K}$ is equal to $\mathbb{K}$ if and only if the linear span of $R\mathcal{H}$ is dense in $\mathcal{H}$.)

The proof of the uniqueness is similar to the below given proof in proof-part (1a) of the uniqueness of $\mathcal{M}(h)\colon A \to \mathcal{M}(B)$ for non-degenerate $h\colon A \to \mathcal{M}(B)$.

The existence of $\mathcal{M}(\rho)$ comes by restriction to $\mathcal{M}(B) = \mathcal{M}(\eta_B)(\mathcal{M}(B)) \subseteq B^{**}$ of the unital and normal extension $\overline{\rho}\colon B^{**} \to \mathcal{L}(\mathcal{H})$ of ρ to B^{**}, of ρ – using that $\mathcal{L}(\mathcal{H}) \cong (\overline{\mathcal{H}}\widehat{\otimes}\mathcal{H})^*$, with $\widehat{\otimes}$ the maximal uniform Grothendieck tensor product, i.e., $\overline{\mathcal{H}}\widehat{\otimes}\mathcal{H}$ is the ideal of nuclear operators X with the norm $\|X\|_{nuc}$, and that $\overline{\mathcal{H}}\widehat{\otimes}\mathcal{H}$ is a complemented subspace of $\mathcal{L}(\mathcal{H})^*$ – as adjoint $\overline{\rho}$ of $\rho^*|\overline{\mathcal{H}}\widehat{\otimes}\mathcal{H}$. The proofs are straight-forward by calculations (cf. functional analysis textbooks).

Moreover, $\mathcal{M}(\rho)(\mathcal{M}(B))$ is contained in the bi-commutant $\rho(B)''$, which is the smallest von-Neumann subalgebra of $\mathcal{L}(\mathcal{H})$ that contains $\rho(B)$.

It is the *-strong closure of $\rho(B)$ if ρ is non-degenerate, by using the bi-commutation theorem of J. von Neumann.

Indeed, if $U \in \mathcal{L}(\mathcal{H})$ is unitary and $U\rho(b) = \rho(b)U$ for all $b \in B$, then $(U\mathcal{M}(\rho)(T) - \mathcal{M}(\rho)(T)U)\rho(b) = 0$ for all $b \in B$. Since $\rho(B)\mathcal{H}$ is dense in $\mathcal{H}$ it follows $U\mathcal{M}(\rho)(T) = \mathcal{M}(\rho)(T)U$, i.e., $\mathcal{M}(\rho)(T) \in \rho(B)''$.

If, in addition, ρ is faithful on B then $\mathcal{M}(\rho)$ is faithful on $\mathcal{M}(B)$, because $\mathcal{M}(\rho)(T) = 0$ implies $\rho(TB) = \{0\}$, i.e., $TB = \{0\}$ and $T = 0$.

If the non-degenerate ρ is moreover faithful, then the image $\mathcal{M}(\rho)(\mathcal{M}(B))$ of $\mathcal{M}(\rho)$ is identical with the set of operators $Y \in \mathcal{L}(\mathcal{H})$ with $Y\rho(b), Y^*\rho(b) \in \rho(B)$ for all $b \in B$. Indeed: Such Y defines bounded linear maps $T, S \in \mathcal{L}(B)$ by $Tb := \rho^{-1}(Y\rho(b))$ and $Sb := \rho^{-1}(Y^*\rho(b))$ that satisfy $T(bc) = (Tb)c$ and $(Sb)^*c = b^*(Tc)$ for $b, c \in B$. Thus, $T \in \mathcal{M}(B)$ and $\mathcal{M}(\rho)(T)\rho(b) = \rho(Tb) = Y\rho(b)$ for $b \in B$. Since $\rho(B)\mathcal{H}$ has dense span in $\mathcal{H}$ it follows $\mathcal{M}(\rho)(T) = Y$.

In particular, $\mathcal{M}(B)$ can be identified with the C^*-subalgebra of the bi-dual W*-algebra $B^{**} \supseteq B$ given by the elements $T \in B^{**}$ with $Tb, bT \in B$ for all $b \in B$. This is because B^{**} is isomorphic to a von-Neumann algebra on a suitable Hilbert space $\mathcal{H}$ and the corresponding representation of B is *-strongly dense in B^{**}.

We notice that any non-degenerate *-representation $\rho\colon B \to \mathcal{L}(\mathcal{H}) \cong \mathcal{M}(\mathbb{K}(\mathcal{H}))$ is also a non-degenerate C^*-morphism into $\mathcal{M}(\mathbb{K}(\mathcal{H})) = \mathcal{L}(\mathcal{H})$, despite of different definitions.

The norm-closed linear span $R \subseteq \mathbb{K}(\mathcal{H})$ of $\rho(B) \cdot \mathbb{K}(\mathcal{H})$ is a non-degenerate left B-module via ρ. Application of Cohen factorization shows that $\rho(B) \cdot \mathbb{K}(\mathcal{H}) = R$ is a closed right-ideal of $\mathbb{K}(\mathcal{H})$. The closed right ideals R of $\mathbb{K}(\mathcal{H})$ are all of the form $R = P \cdot \mathbb{K}(\mathcal{H})$ for some orthogonal projection $P \in \mathcal{L}(\mathcal{H})$ given by the closed subspace $R \cdot \mathcal{H}$ of $\mathcal{H}$.

Since $\rho(B)\mathcal{H} = \mathcal{H}$ by non-degeneracy of ρ and – obviously – $\mathbb{K}(\mathcal{H}) \cdot \mathcal{H} = \mathcal{H}$ we get $P = 1$. This shows that $\rho\colon B \to \mathcal{M}(\mathbb{K}(\mathcal{H}))$ is non-degenerate, i.e., $\rho(B) \cdot \mathbb{K}(\mathcal{H}) = \mathbb{K}(\mathcal{H})$, if we apply Cohen factorization for the non-degenerate left B-module $\mathbb{K}(\mathcal{H})$.

We obtain that $\mathcal{M}(\rho)\colon \mathcal{M}(B) \to \mathcal{M}(\mathbb{K}(\mathcal{H})) \cong \mathcal{L}(\mathcal{H})$ is strictly continuous.

`NEW:`

(0.3) **The strict topology on** $\mathcal{M}(B)$:

Recall that the strict topology on the two-sided multiplier algebra $\mathcal{M}(B) \subseteq \mathcal{L}(B) \oplus \mathcal{L}(B)$ is given on the pairs $(L, R) \in \mathcal{M}(B)$ by semi-norms $(L, R) \mapsto \|L(b)\| + \|R(b)\|$ with $b \in B$. Clearly the family defines the same locally convex topology as the family of semi-norms given by $(L, R) \mapsto \| L(b) \| + \| R(c) \|$ with $b, c \in B$.

In case of C^*-algebras B (or Banach *-algebras with bounded approximate unit) this strict topology is given by the semi-norms $T \in \mathcal{M}(B) \mapsto \|Tb\| + \|T^*b\|$ for $b \in B_+$.

The norm topology on B is the same as the strict topology on $B \subseteq \mathcal{M}(B)$, if and only if, B is unital, because B is strictly dense in $\mathcal{M}(B)$, an approximate unit $\{ e_\tau \}$ in the positive contractions converges strictly to 1 in $\mathcal{M}(B)$.

If B is non-unital and σ-unital, then B contains a sequence $b_1, b_2, \ldots B_+$ with $\|b_n\| = 1$ such that $b_n \to 0$ strictly in $\mathcal{M}(B)$.

`Older stuff below in blue:`

The finite rank operators $a \in \mathbb{K}(\mathcal{H})$ are norm-dense in $\mathbb{K}(\mathcal{H})$. Thus, is suffices to find, for each finite rank projection $p \in \mathbb{K}(\mathcal{H})$ and $\varepsilon > 0$, a positive contraction $e = e(p, \varepsilon) \in B$ with $\| \rho(e)x_k - x_k \| < \varepsilon/\sqrt{n}$ for $k = 1, \ldots n$ where $n :=$ rank of p and $x_1, \ldots, x_n \in \mathcal{H}$ is an orthonormal basis of $p\mathcal{H}$, because then $\|p - \rho(e)p\| < \varepsilon$. Since the positive elements $e \in B_+$ with $\|e\| < 1$ build an approximate unit for B and $\mathrm{span}(\rho(B)\mathcal{H})$ is dense in $\mathcal{H}$ we can find such $e \in B_+$. In fact, the Cohen factorization theorem for non-degenerate left B-modules gives an $e \in B_+$ with $\rho(e)x_k = x_k$ and $\|e\| = 1$.

`TO DO still here`

(0.4) **The strict topology on** $\mathcal{M}(\mathbb{K}) \cong \mathcal{L}(\ell_2)$:

`HERE WE NEED FIRST that` $\mathcal{M}(\mathbb{K}) = \mathcal{L}(\ell_2)$.

Has been shown with several methods above(?).

Recall that we have seen above that $\mathcal{M}(\mathbb{K}(\mathcal{H}))$ is naturally isomorphic to $\mathcal{L}(\mathcal{H})$ by the isomorphism from $\mathcal{L}(\mathcal{H})$ to $\mathcal{M}(\mathbb{K}(\mathcal{H}))$ that fixes $\mathbb{K}(\mathcal{H})$.

Let $\mathcal{H}$ a Hilbert space (of arbitrary dimension) and $\mathbb{K} := \mathbb{K}(\mathcal{H})$ the essential closed ideal of $\mathcal{L}(\mathcal{H})$ of compact operators on $\mathcal{H}$.

There is natural isomorphism from $\mathcal{M}_\ell(\mathbb{K})$ onto $\mathcal{L}(\mathcal{H})$ that fixes the elements of $\mathbb{K}$, because $\mathbb{K}$ is an ideal of $\mathcal{L}(\mathcal{H})$ and $\mathcal{L}(\mathcal{H})$ is in a natural way the second conjugate of $\mathbb{K}$.

In particular, $\mathcal{M}_\ell(\mathbb{K}) = \mathcal{M}(\mathbb{K}) \cong \mathcal{L}(\mathcal{H})$ and the natural isomorphism from $\mathcal{M}(\mathbb{K})$ onto $\mathcal{L}(\mathcal{H})$ is continuous with respect to the strict topology on $\mathcal{M}(\mathbb{K})$ and *-ultra-strong topology on $\mathcal{L}(\mathcal{H})$.

In the same way $\mathcal{M}_\ell(\mathbb{K}) \to \mathcal{L}(\mathcal{H})$ is continuous with respect to the strong operator topology on $\mathcal{M}_\ell(\mathbb{K}) \subset \mathcal{L}(\mathbb{K})$ induced from $\mathbb{K}$ and the strong operator topology on $\mathcal{L}(\mathcal{H})$ induced from $\mathcal{H}$.

It turns out that the strict topology on $\mathcal{M}(\mathbb{K})$ and the strong* topology on $\mathcal{L}(\mathcal{H})$ coincide on bounded parts. (Similar: Both strong topologies on bounded parts of $\mathcal{M}_\ell(\mathbb{K}) = \mathcal{L}(\mathcal{H})$ coincide.)

It follows that for any (non-zero) non-degenerate representation $\psi \colon \mathbb{K} \to \mathcal{M}(B)$ (or any *weakly* non-degenerate $\psi \colon \mathbb{K} \to M$ into a W*-algebra M) induce via $\mathcal{M}(\psi)^{-1}$ on bounded parts of $\mathcal{M}(\mathbb{K})$ exactly the strict topology.

In particular, on bounded parts of $\mathcal{M}(\mathbb{K})$ the strict, *-strong and *-ultrastrong topology coincide.

Alternatively:

Since $\mathbb{K}$ is essential in $\mathcal{L}(\mathcal{H})$ there is a natural unital *-monomorphism (say η) from $\mathcal{L}(\mathcal{H})$ into $\mathcal{M}(\mathbb{K})$.

Conversely the natural *-representation $T \in \mathbb{K} \mapsto T \in \mathcal{L}(\mathcal{H})$ of $\mathbb{K}$ on $\mathcal{H}$ extends to a faithful unital C^*-morphism (say λ) from $\mathcal{M}(\mathbb{K})$ into the W*-algebra $\mathbb{K}^{**} \cong \mathcal{L}(\mathcal{H})$.

The unital C^*-morphisms $\lambda \circ \eta$ form $\mathcal{M}(\mathbb{K})$ to $\mathcal{M}(\mathbb{K})$ fixes the elements of $\mathbb{K} \subseteq \mathcal{M}(\mathbb{K})$. The uniqueness of an extension of the non-degenerate C^*-morphism $\mathrm{id}_{\mathbb{K}}$ to a C^*-morphism from $\mathcal{M}(\mathbb{K})$ into $\mathcal{M}(\mathbb{K})$ follows from above discussed Cohen factorization factorization theorem and implies that $\lambda \circ \eta = \mathrm{id}_{\mathcal{M}(\mathbb{K})}$. Since η and λ are faithful it follows that η must be surjective, i.e., η is an isomorphism from the *abstract* C^*-algebra $\mathcal{M}(\mathbb{K}) \subseteq \mathcal{L}(\mathbb{K})$ onto $\mathcal{L}(\mathcal{H})$ that fixes $\mathbb{K}(\mathcal{H})$.

We compare the strict topology on $\mathcal{M}(\mathbb{K}(\mathcal{H})) \cong \mathcal{L}(\mathcal{H})$ with the *-ultra-strong topology on $\mathcal{L}(\mathcal{H})$ and consider the topologies induced on $\mathcal{L}(\ell_2(\mathbb{N}))$ by $\mathcal{M}(\rho)^{-1}$ from *any* non-degenerate *-representation $\rho\colon \mathbb{K}(\ell_2(\mathbb{N})) \to \mathcal{L}(\mathcal{H})$:

We get

(α)

Bounded norm-closed convex parts of $\mathcal{M}(\rho)(\mathbb{K}(\ell_2(\mathbb{N})))$ are strictly closed ??? in $\mathcal{M}(\mathbb{K}(\mathcal{H}))$???,

and that the by $\mathcal{M}(\rho)^{-1}$ induced topology on $\mathcal{M}(\mathbb{K}(\ell_2(\mathbb{N})))$ is the same as the strict topology with respect to $\mathbb{K}(\ell_2(\mathbb{N}))$.

(β) Strict topology in the multiplier algebra $\mathcal{M}(\mathbb{K})$

(respectively $\mathcal{M}(B) \subseteq B^{**}$ is finer or equal to *-ultra-strong topology, and they coincide on bounded parts.

(But it is not unlikely that they are globally different, because its restrictions to $\ell_\infty(\mathbb{N}) \subseteq \mathcal{L}(\ell_2(\mathbb{N})) \cong \mathcal{M}(\mathbb{K}(\ell_2(\mathbb{N})))$ coincides with the strong operator topologies given by the multiplier actions of $\ell_\infty(\mathbb{N})$ on $c_0(\mathbb{N})$ respectively on $\ell_2(\mathbb{N})$.)

Strict topology in the multiplier algebra $\mathcal{M}(\mathbb{K})$

(respectively $\mathcal{M}(B) \subseteq B^{**}$ is finer or equal to *-ultra-strong topology, and they coincide on bounded parts.

`Older stuff below in blue:`

The finite rank operators $a \in \mathbb{K}(\mathcal{H})$ are norm dense in $\mathbb{K}(\mathcal{H})$. Thus, is suffices to find, for each finite rank projection $p \in \mathbb{K}(\mathcal{H})$ and $\varepsilon > 0$, a positive contraction $e = e(p, \varepsilon) \in B$ with $\| \rho(e)x_k - x_k \| < \varepsilon/\sqrt{n}$ for $k = 1, \ldots n$ where $n :=$ rank of p and $x_1, \ldots, x_n \in \mathcal{H}$ is an orthonormal basis of $p\mathcal{H}$, because then $\|p - \rho(e)p\| < \varepsilon$.

Since the positive elements $e \in B_+$ with $\|e\| < 1$ build an approximate unit for B and $\mathrm{span}(\rho(B)\mathcal{H})$ is dense in $\mathcal{H}$ we can find such $e \in B_+$. In fact, the Cohen factorization theorem for non-degenerate left B-modules gives an $e \in B_+$ with $\rho(e)x_k = x_k$ and $\|e\| = 1$.

The same argument shows that the *-ultra-strong topology on $\mathcal{M}(\mathbb{K}(\mathcal{H})) = \mathcal{L}(\mathcal{H})$ is coarser than the strict topology on $\mathcal{M}(\mathbb{K}(\mathcal{H}))$, because the *-ultra-strong topology is the *-strong topology for the left multiplication $\mathcal{L}(\mathcal{H})$ on the Hilbert-Schmidt class operators ($HS(\mathcal{H}) \cong \overline{\mathcal{H}} \otimes_2 \mathcal{H}$):

There the same argument as for given above for $B := \mathbb{K}(\mathcal{H})$ works for the left multiplication on (new) $B := HS(\mathcal{H})$, i.e., holds for the action of $\mathcal{L}(\mathcal{H}) = \mathcal{M}(\mathbb{K})$ on the Hilbert space tensor product $\overline{\mathcal{H}} \otimes_2 \mathcal{H} \cong HS(\mathcal{H})$.

`Alternatively (done above):`

The Cohen factorization theorem applies to left action of $\mathbb{K}(\mathcal{H})$ on the Hilbert-Schmidt class operators and gives that the strict topology on $\mathcal{M}(\mathbb{K}(\mathcal{H}))$ is finer than the *-ultra-strong topology on all subsets of $\mathcal{M}(\mathbb{K}(\mathcal{H})) \cong \mathcal{L}(\mathcal{H})$.

It follows that they coincide on bounded parts of $\mathcal{M}(\mathbb{K})$.

But it says nothing about the behavior on unbounded parts.

(1.) **Existence and uniqueness of $\mathcal{M}(h)$:**

(1.0) **Uniqueness and strict continuity of $\mathcal{M}(h)$:**

Let A and B C^*-algebras, $h\colon A \to \mathcal{M}(B)$ a C^*-morphism and $\psi\colon \mathcal{M}(A) \to \mathcal{L}(B)$ any algebra homomorphism with the property $\psi|A = h$. Then ψ and h have the property $\psi(X)(h(a)b) = \psi(X)(\psi(a)b) = \psi(Xa)b = h(Xa)b$ for $X \in \mathcal{M}(A)$, $a \in A$ and $b \in B$.

Thus, ψ is uniquely determined by its restriction $h := \psi|A$ on the closed linear span $L \subseteq B$ of $h(A)B$ and $\psi(1)b = b$ for $b \in L$. In particular ψ is unital and is *uniquely determined* if the linear span of $h(A)B$ is dense in B.

If $\mathrm{span}(h(A)B)$ is dense in B, then ψ is also a C^*-morphism from $\mathcal{M}(A)$ into $\mathcal{M}(B) \subseteq \mathcal{L}(B) := \mathcal{L}(B, B)$, because $\psi(X)(h(a)b) = h(Xa)b$ implies

$$(\psi(X)(h(a_1)b_1))^*(h(a_2)b_2) = b_1^* h(a_1^* X^* a_2)b_2 = (h(a_1)b_1)^*(\psi(X^*)(h(a_2)b_2)),$$

i.e., $(\psi(X)b_1)^* b_2 = b_1^*(\psi(X^*)b_2)$ if we pass to the closure of $\mathrm{span}(h(A)B)$. We get that $\psi(X)$ is in $\mathcal{M}(B) \subseteq \mathcal{L}(B)$ and $\psi(X^*) = \psi(X)^*$ if the linear span of $h(A)B$ is dense in B.

Such extensions ψ of h are automatically strictly continuous if $h(A)B$ is dense in $B\,zz$:

Then the B is also a non-degenerate left Banach module over A with left-action $a \cdot b := h(a)b$ for $a \in A$ and $b \in B$, and the Cohen factorization theorem applies to it:

For each $b_1, b_2 \in B$ there exist contractions $a_1, a_2 \in A$ and $c_1, c_2 \in B$ with $\|c_j - b_j\| < 1/2$ such that $b_j = h(a_j)c_j$. It follows that the semi-norm

$$X \mapsto \|\psi(X)b_1\| + \|\psi(X^*)b_2\|$$

on $\mathcal{M}(A)$ is less or equal to the semi-norm by

$$X \mapsto (1 + \|b_1\| + \|b_2\|)(\|Xa_1\| + \|X^*a_2\|).$$

This latter semi-norms are continuous with respect to the strict topology on $\mathcal{M}(A)$. It implies that ψ is strictly continuous.

If conversely a *unital and strictly continuous* $\psi\colon \mathcal{M}(A) \to \mathcal{M}(B)$ with $\psi(a) = h(a)$ exist, then an approximate unit $(e_\tau) \subset A_+$ of A converges strictly to $1 \in \mathcal{M}(A)$, and $h(e_\tau)b = \psi(e_\tau)b$ converges to $b = \psi(1)b$ for each $b \in B$. Thus $h(A)B$ is dense in B i.e., h is non-degenerate.

(1.1) **Existence of** $\mathcal{M}(h)$:

Suppose that $h\colon A \to \mathcal{M}(B)$ is a non-degenerate C^*-morphism, i.e., the linear span of $h(A)B$ is dense in B.

The Cohen factorization theorem applies to the Banach left A-module B with product $a \cdot b := h(a)b$.

Then B is also in a unique way a Banach module over $\mathcal{M}_\ell(A)$ with a product $L \cdot' b \in B$ defined by $L \cdot' b := L(a) \cdot c = h(L(a))c$ for $b = h(a)c$ and $L \in \mathcal{M}_\ell(A)$. It satisfies $L(a) \cdot b = L \cdot' (h(a)b)$, $\|L \cdot' b\| \leq \|L\| \cdot \|b\|$. This defines a contractive Banach algebra homomorphism from $\mathcal{M}_\ell(A)$ into $\mathcal{L}(B)$.

But in this special case holds the additional property $L \cdot' (bc) = (L \cdot' b)c$ for $a \in A$, $b, c \in B$ and $L \in \mathcal{M}_\ell(A)$. Indeed, let $b = h(a)d$, then $bc = h(a)dc$ and $L \cdot' bc = L(a) \cdot dc = h(L(a))dc = (h(L(a))d)c == (L \cdot' b)c$.

Hence $\mathcal{M}_\ell(L)(b) := L \cdot' b$ defines a contractive Banach algebra homomorphism $\mathcal{M}_\ell(h)$ from $\mathcal{M}_\ell(A)$ into $\mathcal{M}_\ell(B) \subseteq \mathcal{L}(B)$ with $\mathcal{M}_\ell(L_a)(b) = h(a)b$ for $a \in A$ and $b \in B$.

Since – in our picture – $\mathcal{M}(A) \subseteq \mathcal{M}_\ell(A) \subseteq \mathcal{L}(A)$ and $\mathcal{M}(B) \subseteq \mathcal{M}_\ell(B)$, we can define $\mathcal{M}(h)\colon \mathcal{M}(A) \to \mathcal{M}_\ell(B)$ as the restriction of $\mathcal{M}_\ell(h)$ to $\mathcal{M}(A)$, i.e., by $\mathcal{M}(h)(X)b := X \cdot' b$ for $X \in \mathcal{M}(A)$ and $b \in B$. This becomes automatically a C^*-morphism from $\mathcal{M}(A)$ into $\mathcal{M}(B)$ as we have seen in proof-part (1.0).

`Older version for the existence proof:`

The following is a special case of the above considered *weakly non-degenerate* C^*-morphism from B into a W*-algebra.

Let $\rho\colon B \to \mathcal{L}(\mathcal{H})$ a faithful and non-degenerate *-representation on a Hilbert space $\mathcal{H}$. The representation ρ extends to a faithful unital *-representation $\mathcal{M}(\rho)\colon \mathcal{M}(B) \to \mathcal{L}(\mathcal{H})$ with $\mathcal{M}(\rho)(b) = \rho(b)$ for $b \in B$.

Let $d\colon A \to \mathcal{L}(\mathcal{H})$ the *-representation defined by $d(a) = \mathcal{M}(\rho)(h(a))$. In particular, $d(a)\rho(b) = \rho(h(a)b)$.

Since ρ and h are non-degenerate, the linear spans of $h(A)B$ and $\rho(B)\mathcal{H}$ are dense in B respectively in $\mathcal{H}$. Thus, the linear span of $d(A)\rho(B)\mathcal{H} = \rho(h(A)B)\mathcal{H}$ is dense in $\mathcal{H}$, and $d\colon A \to \mathcal{L}(H)$ is non-degenerate. We know from Proof-part (1.1) that a non-degenerate *-representation $d\colon A \to \mathcal{L}(\mathcal{H})$ extend uniquely to a non-degenerate *-representation $\mathcal{M}(d)\colon \mathcal{M}(A) \to \mathcal{L}(\mathcal{H})$ with $\mathcal{M}(d)(X)d(a) = d(Xa)$.

We get

$$\mathcal{M}(d)(X)\rho(h(a)b) = \mathcal{M}(d)(X)d(a)\rho(b) = d(Xa)\rho(b) = \rho(h(Xa)b)$$

for all $X \in \mathcal{M}(A)$, $a \in A$ and $b \in B$. Since the linear span of $h(A)B$ is dense in B, it follows that $\mathcal{M}(d)(X)\rho(b) \in \rho(B)$ and $\mathcal{M}(d)(X)^*\rho(b) = \mathcal{M}(d)(X^*)\rho(b) \in \rho(B)$ for all $b \in B$. Thus, $\mathcal{M}(d)(\mathcal{M}(A)) \subseteq \mathcal{M}(\rho)(\mathcal{M}(B))$ by the characterization of the image $\mathcal{M}(\rho)(\mathcal{M}(B))$ of $\mathcal{M}(B)$ in $\mathcal{L}(\mathcal{H})$.

We let $\mathcal{M}(h) := \mathcal{M}(\rho)^{-1}(\mathcal{M}(d)(X))$. This is a unital C^*-morphism from $\mathcal{M}(A)$ into $\mathcal{M}(B)$ that satisfies $\mathcal{M}(h)(X)h(a)b = h(Xa)b$ and is the desired extension to $\mathcal{M}(A)$, because

$$\mathcal{M}(\rho)(\mathcal{M}(h)(X)h(a)b) = \mathcal{M}(d)(X)\rho(h(a)b) = d(Xa)\rho(b) = \mathcal{M}(\rho)(h(Xa)b)\,.$$

(2) **Proofs for Part(2)**: Let $p_{j,k}$ denote the matrix units of $\mathbb{K}$. Then the series $c := \sum_n x_n \otimes p_{1,n}$ and $d := \sum_n y_n \otimes p_{1,n}$ are unconditional strictly convergent series in $\mathcal{M}(B \otimes \mathbb{K})$ ([5]).

Indeed, partial sums, i.e., $c(S) := \sum_{n\in S} x_n \otimes p_{1,n}$ over a finite set $S \subset \mathbb{N}$ of indices, are norm-bounded by $\|X\|^{1/2}$ respectively by $\|Y\|^{1/2}$.

More precisely: Let $p_m := p_{1,1} + \cdots + p_{m,m}$, where $p_{j,k} \in \mathbb{K}$ are partial isometries that define canonical matrix units $\mathbb{K}$ for the standard basis of ℓ_2. Then

$$gXh^* \otimes p_{1,1} - (g \otimes 1)c(S)((h \otimes 1)c(S))^* = g(X - \sum_{n\in S} x_n x_n^*)h^* \otimes p_{1,1}\,,$$

for all $g, h \in \mathcal{M}(B)$, $\sum_{n\in S} x_n x_n^* \leq X$, $c(S)(e \otimes p_m) = \sum_{n\in S, n\leq m}(x_n e) \otimes p_{1,n}$ and $(e \otimes p_m)c(S) = \sum_{n\in S, n\leq m}(ex_n) \otimes p_{1,n}$ for each $e \in \mathcal{M}(B)$.

Since the partial sums $c(S)$ are bounded in $\mathcal{M}(B \otimes \mathbb{K})$ by $\|X\|^{1/2}$, and since the semi-norms

$$\rho_m(s,t) := \max(\|(s-t)(e \otimes p_m)\|, \|(e \otimes p_m)(s-t)\|)$$

for $m \in \mathbb{N}$ and positive contractions $e \in B_+$ define the strict topology on bounded parts of $\mathcal{M}(B \otimes \mathbb{K})$, it follows that $\sum_n x_n \otimes p_{1,n}$ converges strictly in $\mathcal{M}(B \otimes \mathbb{K})$.

That the convergence is also unconditional can be seen as follows:

For each contraction $e \in B_+$, $m \in \mathbb{N}$ and $\varepsilon > 0$ there exists $n := n(e, m, \varepsilon) \in \mathbb{N}$ such that $n \geq m$, $c(S)(e \otimes p_m) = c(S')(e \otimes p_m)$ and $\|(e \otimes p_m)(c(S) - c(S'))\| < \varepsilon$ for all finite subsets $S, S' \subset \mathbb{N}$ with $\{1, \ldots, n\} \subseteq S' \cap S$. The latter property implies the unconditional strict convergence of $c := \sum_n x_n \otimes p_{1,n}$ in $\mathcal{M}(B \otimes \mathbb{K})$, i.e., that for each permutation γ of the positive integers $\mathbb{N}$ the series $\sum_n x_{\gamma(n)} \otimes p_{1,\gamma(n)}$ converges strictly to the same element of $\mathcal{M}(B \otimes \mathbb{K})$ as $c := \sum_n x_n \otimes p_{1,n}$ does.

Thus, the series c and d are unconditional strictly convergent and its sums are *elements* of $\mathcal{M}(B \otimes \mathbb{K})$. We use again c and d as notation for the sums of the series,

[5] The convergence is usually not absolute!

because in this particular case the entries of the series can be restored from the sum, e.g.

$$x_n \otimes p_{1,n} = c(1 \otimes p_{n,n}) .$$

The c and d are row matrices if one considers $\mathcal{M}(B \otimes \mathbb{K})$ naturally as a subset of the set of all infinite matrices $[T_{i,j}] \in M_\infty(\mathcal{M}(B))$ with entries $T_{i,j}$ from $\mathcal{M}(B)$:

If we use a fixed non-degenerate inclusion of $c_0(B) = B \otimes c_0$ into $B \otimes \mathbb{K}$ then we get "natural" unital C^*-monomorphisms

$$\mathcal{M}(B) \otimes 1 \subset \ell_\infty(\mathcal{M}(B)) \cong \mathcal{M}(c_0(B)) \subset \mathcal{M}(B \otimes \mathbb{K}) \subset M_\infty(\mathcal{M}(B)) ,$$

where the first two strict inclusion are strictly continuous. This inclusions are naturally defined: If we choose a system of matrix units $p_{j,k}$ for $\mathbb{K}$, we get natural inclusions $c_0 \subset \mathbb{K}$, $c_0(B) = B \otimes c_0 \subset B \otimes \mathbb{K}$ and can use the isomorphism $\ell_\infty(\mathcal{M}(B)) \cong \mathcal{M}(c_0(B))$. The map $b \in \mathcal{M}(B \otimes \mathbb{K}) \mapsto dbc^*$ is obviously a strictly continuous completely bounded map with cb-norm equal to $\|c\| \cdot \|d\| \leq (\|S\|\|T\|)^{1/2}$. The in Remark (2) defined map Γ satisfies $\Gamma(b) \otimes p_{1,1} = dbc^*$ for $b \in \ell_\infty(\mathcal{M}(B)) \subset \mathcal{M}(B \otimes \mathbb{K})$.

The proposed unconditional strict convergence of the series $\Gamma(b_1, b_2, \ldots)$ follows now from the unconditional strict convergence of the sum $\sum_n (\delta_{n,k} b_k)$ to $(b_1, b_2, \ldots)$ in $\mathcal{M}(c_0(B)) \cong \ell_\infty(\mathcal{M}(B))$.

Since $d^* bc^* \in B \otimes p_{1,1}$ for $d \in B \otimes \mathbb{K}$, we get that $\Gamma(b_1, b_2, \ldots) \in B$ for $(b_1, b_2, \ldots) \in c_0(B)$.

(3): Let $\varphi_0(t) := t$ for $t \in [0, 1]$ and

$$\varphi_k(t) := \min(1, \max(2^k t - 1, 0)) = (2^k t - 1)_+ - (2^k t - 2)_+$$

for $k = 1, 2, \ldots$. Then there exists $1 =: k_0 < k_1 < k_2 < \cdots$ and $f_n(t)$ in the convex span of $\varphi_{k_n}, \ldots, \varphi_{k_{n+1}-1}$ such that the functions f_n have the properties quoted in Part (3). Here we use the method of Akemann and Pedersen as described in proof of [**43**, thm. 2] or in [**616**, thm. 3.12.14, cor. 3.12.15]. See more details and discussion in Section 3. The proposed estimates for norms of $[(f_{n+1}(e) - f_n(e))^{1/2}, x]$ follow also from the estimates in Lemma 5.3.2.

(4): Let $T(a) := a - \Gamma(a, a, \ldots)$ the linear map from A into $\mathcal{M}(B)$ with norm ≤ 2, where Γ is defined as in Part (2) with $x_n := y_n := g_n := (f_n(e) - f_{n-1}(e))^{1/2}$ for $n > 1$ and $x_1 := y_1 := g_1 := f_1^{1/2}(e)$ in Remark (2) with f_n selected for $X_n \subset A \subseteq \mathcal{M}(B)$ as in Remark (3).

$x_n := y_n := g_n := (f_n(e) - f_{n-1}(e))^{1/2}$.

Check Notations and estimates !?? **??**

If $a^* = a \in X_n$ with $\|a\| \leq 1$ then $T(a) = \sum_n (ag_n - g_n a) g_n$ and $\|ag_n - g_n a\| < 4^{-n}$ by part (3). Since $ag_n \in B$, it follows $T(a) \in B$ for a in a dense linear subspace of A, and that $T(A) \subseteq B$ by continuity of T.

(5): Let $g_1, g_2, \ldots$ as in (4) and $d_1, d_2, \ldots \in \mathcal{M}(B)$ as in (5), then $g_n h_n = g_n = h_n g_n$ for $h_1 := f_2(e)^{1/2}$ and $h_n := (f_{n+1}(e) - f_{n-2}(e))^{1/2}$ for $n > 1$ where $f_0 := 0$,

$$\sum d_n g_n = \sum h_n (d_n g_n) h_n + \sum (1 - h_n) d_n g_n \,,$$

$\|(1 - h_n) d_n g_n\| < \|d_n g_n - g_n d_n\|$, and $\sum h_n^2$ converges strictly to 2 in $\mathcal{M}(B)$.

Since $g_p g_q = 0$ if $|p - q| > 1$, it follows $S_P^2 = \sum_{n \in P} g_n^2$ if $|p - q| > 1$ for all $p \neq q \in P$.

It holds $Sa - aS \in B$ for the contractions $a^* = a \in X_n$, because $\|g_n a - a g_n\| < 4^{-n}$ by part (3). Thus, the continuous derivation $a \mapsto Sa - aS$ from A into $\mathcal{M}(B)$ maps A into B, i.e., $\pi_B(S) \in \pi_B(A)' \cap (\mathcal{M}(B)/B)$.

It follow that $\pi_B(SaS + (1 - S^2)^{1/2} a (1 - S^2)^{1/2}) = \pi_B(a)$ for all $a \in A$.

(6): Since $\sum \|d_n g_n - g_n d_n\| \leq \sum_n \nu_n < \infty$, the series $\sum_n d_n g_n$ converges (unconditional) strictly in $\mathcal{M}(B)$ by part (5). Let $d := \sum_n d_n g_n$ denote its sum.

Denote by $Z_{k,j}$ the sum of the series $\sum_n g_{2n-j}(d_{2n-j}^* a d_{2n-j+k}) g_{2n-j+k}$ for $j = 0, 1$ and $k \in \mathbb{N}$, that is strictly convergent in $\mathcal{M}(B)$ by part (2), because $\|d_{2n-j}^* a d_{2n-j+k}\| \leq \|a\|$ and the sums $\sum_n g_{2n-j+k}^2$ and $\sum_n g_{2n-j}^2$ are strictly convergent in $\mathcal{M}(B)$ by part (5).

Let $h_n := (g_{n-1}^2 + g_n^2 + g_{n+1}^2 + g_{n+2}^2)^{1/2}$ ($g_0 := 0$). The series $\sum_n h_n^2$ converges strictly to some positive element in $\mathbb{R}_+ - B_+$. By condition (iii) and part (3),

$$Z_{1,0} + Z_{1,1} = \sum_n h_n (g_n d_n^* a d_{n+1} g_{n+1}) h_n \in B \,,$$

because $g_n \in B$ and the sequence $(\, g_n d_n^* a d_{n+1} g_{n+1} \,)_n$ is in $c_0(\mathcal{M}(B))$ by condition (iii). It follows that $S_1 := (Z_{1,0} + Z_{1,1})^* + (Z_{1,0} + Z_{1,1}) \in B$.

If $k > 1$ then the elements $z_n := g_{2n-j}(d_{2n-j}^* a d_{2n-j+k}) g_{2n-j+k}$ satisfy

$$\|z_n\| \leq \|a g_{2n+k-j} - g_{2n+k-j} a\| + 2 \max_{1 \leq k \leq 2n-j+k} \|d_k g_{2n+k-j} - g_{2n+k-j} d_k\|$$

for $k > 1$ and $j \in \{0, 1\}$, by conditions (i) and (ii). Moreover, $z_n^* z_m = 0 = z_m z_n^*$ for $n \neq m$. Thus $\sum_n z_n$ converges *absolute* to $Z_{k,j}$ for $k > 1$, $j = 0, 1$, and its norm can be estimated by

$$\|Z_{k,j}\| \leq \mu_{2+k-j} + 2\nu_{2+k-j} \,.$$

Since $(\sum_\ell \mu_\ell) + 2(\sum_\ell \nu_\ell) < \infty$, it follows that

$$\sum_k \|Z_{k,j}\| \leq \sum_k \mu_{2+k-j} + 2 \sum_k \nu_{2+k-j} < \infty$$

for $j = 0, 1$. It implies that the series $S_2 := \sum_{k>1} (Z_{k,0} + Z_{k,1})^* + (Z_{k,0} + Z_{k,1})$ with entries in B converges to an element of B.

It is not difficult to see from the partial sums that the series corresponding to $d^* a d - \Gamma(d_1^* a d_1, d_2^* a d_2, \ldots)$ converges *strictly* to the sum $S_1 + S_2 \in B$.)

(7): The isomorphism $D + \mathrm{Ann}(D) \cong D \oplus \mathrm{Ann}(D)$ implies

$$\mathcal{M}(D + \mathrm{Ann}(D)) \;\cong\; \mathcal{M}(D) \oplus \mathcal{M}(\mathrm{Ann}(D))$$

and that the natural *-monomorphism $\iota\colon D + \mathrm{Ann}(D) \to B$ has a unital strictly continuous extension $\mathcal{M}(\iota)\colon \mathcal{M}(D + \mathrm{Ann}(D)) \to \mathcal{M}(B)$ if ι is non-degenerate.

Define $p := \mathcal{M}(\iota)(1_{\mathcal{M}(D)})$. Then $pBp = D$. Conversely, if $D = pBp$ then $(1-p)B(1-p) = \mathrm{Ann}(D)$ and $pep + (1-p)e(1-p)$ becomes an approximate unit of B if e runs through an approximately central (for p) approximate unit of B.

(8): `final part of TEXT in (8):`

Recall that B is a **stable C^*-algebra** if there exists an isomorphism ψ from $B \otimes \mathbb{K}$ onto B for the compact operators $\mathbb{K} = \mathbb{K}(\ell_2)$ on $\ell_2(\mathbb{N})$.

This is equivalent to the existence of a C^*-algebra C and a C^*-algebra isomorphism from $C \otimes \mathbb{K}$ onto B.

The following criterium is necessary and sufficient for the stability of a (not necessarily σ-unital) C^*-algebra B:
There exists a sequence $s_1, s_2, \ldots$ of isometries in $\mathcal{M}(B)$ such that $\sum_n s_n s_n^*$ converges strictly to 1 in $\mathcal{M}(B)$.

It holds $u^* \delta_\infty(b) u = \sum_n t_n b t_n^*$ by a unitary $u \in \mathcal{M}(B)$ with $t_n = u s_n$ for $n = 1, 2, \ldots$ if $t_1, t_2, \ldots$ is any other (countable) sequence of isometries in $\mathcal{M}(B)$ with $\sum_n t_n t_n^* = 1$.

In this sense the unitary equivalence class $[\delta_\infty]$ has "representatives" $\delta_\infty\colon \mathcal{M}(B) \to \mathcal{M}(B)$ determined by $s_1, s_2, \ldots$. We call this class (and sometimes its members $\sum_n s_n(\cdot)s_n$) the **infinite repeat** (on $\mathcal{M}(B)$) of the identity mapping $\mathrm{id}_{\mathcal{M}(B)}$ of $\mathcal{M}(B)$.

Then $\delta_\infty(b)$ (or its unitary equivalence class $[\delta_\infty(b)]$) is the *infinite repeat of the element* $b \in \mathcal{M}(B)$.

Moreover, there exists C^*-morphism $\mu\colon \mathbb{K} \to \mathcal{M}(B)$ with the properties

(a) $\mu(\mathbb{K}) \subset \delta_\infty(B)' \cap \mathcal{M}(B)$,
(b) $\delta_\infty(b)\mu(k) \in B$ for $b \in B$ and $k \in \mathbb{K}$, and
(c) the (unique) C^*-morphism $\varphi\colon B \otimes \mathbb{K} \to B$ with $\varphi(b \otimes k) = \delta_\infty(b)\mu(k)$ is an *isomorphism* from $B \otimes \mathbb{K}$ *onto* B.

The C^*-morphism $\mu\colon \mathbb{K} \to \mathcal{M}(B)$ with properties (a,b,c) is uniquely defined by the given sequence $s_1, s_2, \ldots \in \mathcal{M}(B)$ of isometries with $\sum s_n s_n^* = 1$ – up to unitary equivalence by unitaries in $\delta_\infty(B)' \cap \mathcal{M}(B)$.

One of the corresponding C^*-morphisms $\mu\colon \mathbb{K} \to \delta_\infty(B)' \cap \mathcal{M}(B)$ can be defined by $\mu(p_{j,k}) := s_j s_k^*$ for $j, k \in \mathbb{N}$, if the unitary equivalence class $[\delta_\infty]$ is realized by given isometries $s_1, s_2, \ldots$, i.e., $\delta_\infty(\cdot) := \sum_n s_n(\cdot)s_n^*$.

The isomorphism φ from $B \otimes \mathbb{K}$ onto B defined by $\mu\colon \mathbb{K} \to \mathcal{M}(B)$ – with properties (a,b,c) – has the property that the corresponding C^*-morphism $b \mapsto \varphi(b \otimes e_{11})$ is a *-endomorphism of B, that is approximately 1-step inner if considered as a c.p. contraction.

The C^*-morphism $\varphi((\cdot)\otimes p_{1,1}) = s_1(\cdot)s_1^*$ is unitarily homotopic to id_B if B is σ-unital:

??????????????

Moreover, if $b \in B_+$, then $\varphi(b\otimes p_{1,1})$ is Murray–von-Neumann equivalent to b. In particular,

$$\varphi(J\otimes \mathbb{K}) = J \quad \forall\ J \lhd B\,.$$

This property of the "natural" φ is different from the properties of very random and possibly not well-behaved *-isomorphism ψ from $B\otimes\mathbb{K}$ onto B – as allowed in the *definition* of stability –, because in general the isomorphism $\varphi\circ\psi^{-1}$ of B does not fix the ideal-system $\mathcal{I}(B)$ of B and is not approximately unitarily equivalent to id_B by unitaries in $\mathcal{M}(B)$.

The non-degenerate *-monomorphism $\mu\colon \mathbb{K}\to\mathcal{M}(B)$ has the important "dual" property that

$$\mu(\mathbb{K})'\cap\mathcal{M}(B) \;=\; \delta_\infty(\mathcal{M}(B))\,.$$

It shows that $\delta_\infty(\mathcal{M}(B))$ is closed in $\mathcal{M}(B)$ with respect to the strict topology of $\mathcal{M}(B)$.

The strictly continuous extension $\mathcal{M}(\mu)\colon \mathcal{M}(\mathbb{K})\cong\mathcal{L}(\ell_2)\to\mathcal{M}(B)$ of μ is a unital *-monomorphism, has image in $\delta_\infty(\mathcal{M}(B))'\cap\mathcal{M}(B)$ and the norm-closed unit-ball of $\mathcal{M}(\mu)(\mathcal{L}(\ell_2))$ is also *closed in the strict topology* of $\mathcal{M}(B)$.

The strictly closed C^*-subalgebra $\delta_\infty(\mathcal{M}(B))'\cap\mathcal{M}(B)$ of $\mathcal{M}(B)$ can be larger than $\mathcal{M}(\mu)(\mathcal{L}(\ell_2))$, e.g. if the the center of $\mathcal{M}(B)$ is not trivial, because the center of $\mathcal{M}(B)$ is identical with the commutant of $\delta_\infty(B)\cdot\mu(\mathbb{K})$ in $\mathcal{M}(B)$, and $\delta_\infty(B)\cdot\mu(\mathbb{K})$ generates B if the center of $\mathcal{M}(B)$ is not trivial.

For each non-zero C^*-morphism $\rho\colon \mathbb{K}(\ell_2)\to\mathcal{M}(B)$, the topology induced by $\mathcal{M}(\rho)^{-1}$ on $\mathcal{M}(\mathbb{K})=\mathcal{L}(\ell_2)$ from the strict topology on $\mathcal{M}(B)$ coincides on bounded parts with the *-strong operator topology on $\mathcal{L}(\ell_2)$. Moreover, $\mathcal{M}(\rho)(\mathbb{K})$ is strictly closed if ρ is non-degenerate.

HERE: BEGIN NEW PROOF of (8) 27.10.2015 19:30

If B is stable then there exists a sequence of isometries $s_1, s_2, \ldots$ in $\mathcal{M}(B)$ such that $\sum s_n s_n^*$ converges strictly to 1 in $\mathcal{M}(B)$:

Is φ good notation?

If B is stable then there exist (by definition of stability) a C^*-algebra C and a C^*-algebra isomorphism $\varphi\colon C\otimes\mathbb{K}\to B$ from $C\otimes\mathbb{K}$ onto B, where $\mathbb{K}:=\mathbb{K}(\ell_2(\mathbb{N}))$.

If C is unital, then $\rho(k) := \varphi(1\otimes k)$ defines a non-degenerate C^*-morphism from $\mathbb{K}$ into B.

If C is not unital, then the strictly continuous extension $\mathcal{M}(\varphi)\colon \mathcal{M}(C\otimes\mathbb{K})\to\mathcal{M}(B)$ is a strictly continuous isomorphism from $\mathcal{M}(C\otimes\mathbb{K})$ onto $\mathcal{M}(B)$.

The algebra $C\otimes\mathbb{K}$ is an essential ideal of $\mathcal{M}(C)\otimes\mathbb{K}$. Thus, there is a unique *-monomorphism γ from $\mathcal{M}(C)\otimes\mathbb{K}$ into $\mathcal{M}(C\otimes\mathbb{K})$ with $\gamma(T\otimes k_1)(c\otimes k_2) =$

$(Tc) \otimes (k_1 k_2)$ for $T \in \mathcal{M}(C)$, $c \in C$ and $k_1, k_2 \in \mathbb{K}$. Then $\gamma|(1 \otimes \mathbb{K})$ is non-degenerate. It implies that

$$\rho(k) := \mathcal{M}(\varphi)(\gamma((1 \otimes k)))$$

is a non-degenerate C^*-morphism from $\mathbb{K}$ into $\mathcal{M}(B)$. Recall that here "non-degenerate" means that $\rho(\mathbb{K})B = B$ (by using e.g. Cohen factorization).

The *-monomorphism ρ extends uniquely to a faithful strictly continuous unital C^*-morphism $\mathcal{M}(\rho)$ from $\mathcal{M}(\mathbb{K})$ into $\mathcal{M}(B)$.

Any bijective map η from $\mathbb{N} \times \mathbb{N}$ onto $\mathbb{N}$ defines isometries $t_n \in \mathcal{L}(\ell_2) \cong \mathcal{M}(\mathbb{K})$ with $\sum_n t_n t_n^*$ converging *-strongly to 1 if we let $t_n(e_k) := e_{\eta(n,k)}$.

Since, as discussed above, on bounded parts of $\mathcal{M}(\mathbb{K}) \cong \mathcal{L}(\ell_2)$ the *-strong, *-ultra-strong and strict topology coincide, and since μ is strictly continuous, we get that the isometries $s_n := \mathcal{M}(\gamma)(t_n)$ define a sequence of isometries in $\mathcal{M}(B)$ with the property that $\sum_n s_n s_n^*$ converges strictly to 1 in $\mathcal{M}(B)$.

Suppose now that B is a C^*-algebra such that its multiplier algebra $\mathcal{M}(B)$ contains a sequence $s_1, s_2, \ldots \in \mathcal{M}(B)$. We define a rather canonical C^*-isomorphism φ from $B \otimes \mathbb{K}$ onto B:

The isometries $s_1, s_2, \ldots$ define (the unitary equivalence class of) the *infinite repeat*

$$\delta_\infty(b) := \sum_n s_n b s_n^*$$

for $b \in \mathcal{M}(B)$, because it follows from Remark (2) – with $x_n := y_n := s_n^*$ and $b_n := b$ – that $\delta_\infty(b) := \sum_n s_n b s_n^*$ is strictly unconditional convergent. The unconditional convergence allows to check that δ_∞ is a unital *-endomorphism of $\mathcal{M}(B)$.

It holds $u^* \delta_\infty(b) u = \sum_n t_n b t_n^*$ by a unitary $u \in \mathcal{M}(B)$ with $t_n = u s_n$ for $n = 1, 2, \ldots$ if $t_1, t_2, \ldots$ is any other sequence of isometries in $\mathcal{M}(B)$ with $\sum_n t_n t_n^* = 1$ (strictly convergent), because Part (2) shows that the sums $\sum_n t_n s_n^*$ and $\sum_n s_n t_n^*$ are unconditionally strictly convergent to contractions $u, v \in \mathcal{M}(B)$. Then the unconditionality of the strict convergence of all four series allows to verify that $vu = uv = 1$ by calculation.

The Remark (2) also implies that δ_∞ is strictly continuous and is determined up to unitary equivalence if it is build from different choices of sequence of isometries $s_1, s_2, \ldots \in \mathcal{M}(B)$ with $\sum_n s_n s_n^* = 1$ (strictly), compare Lemma 5.1.2(i,ii) and its proof.

There is a natural C^*-morphism $\mu \colon \mathbb{K} \to \mathcal{M}(B)$ that is uniquely defined on the elementary matrices $p_{j,k}$ by $\mu(p_{j,k}) := s_j s_k^*$, as calculation shows.

Notice that μ can be different from the formerly defined $\rho \colon \mathbb{K} \to \mathcal{M}(B)$, e.g. if $B = C \otimes \mathbb{K}$ with unital C.

We show that above defined $\mu \colon \mathbb{K} \to \mathcal{M}(B)$ has the in Part (8) listed properties (a), (b) and (c):

Ad(a): $\mu(\mathbb{K}) \subset \delta_\infty(B)' \cap \mathcal{M}(B)$ because for $b \in B$ and $j, k \in \mathbb{N}$

$$s_j s_k^* (\sum_n s_n b s_n^*) = s_j b s_k^* = (\sum_n s_n b s_n^*) s_j s_k^* .$$

Ad(b): $\delta_\infty(b)\mu(k) \in B$ for $b \in B$ and $k \in \mathbb{K}$, because the calculation in Part(a) implies that $(b \otimes k) \mapsto \delta_\infty(b)\mu(k)$ extends to a C^*-morphism $\varphi \colon B \otimes \mathbb{K} \to \mathcal{M}(B)$ with $\varphi(b \otimes p_{j,k}) \in B$. Since the linear span of matrix units $p_{j,k}$ is dense in $\mathbb{K}$ it follows that $\varphi(B \otimes \mathbb{K}) \subseteq B$.

Ad(c): The C^*-morphism $\varphi \colon B \otimes \mathbb{K} \to B$ is with $\varphi(b \otimes k) = \delta_\infty(b)\mu(k)$ is an *isomorphism* from $B \otimes \mathbb{K}$ *onto* B.

Indeed: By Lemma 2.2.3 the kernel of φ is $= \{0\}$, because from $\varphi(b \otimes k) = 0$ it would follow that $s_j b s_k^* = \delta_\infty(b) s_j s_k^* = 0$ for a matrix unit $p_{j,k} \in \mathbb{K}$ with $p_{j,j} k p_{k,k} = \xi p_{j,k} \neq 0$.

The sequence $s_1, s_2, \ldots$ defines a partial isometry $T \in \mathcal{M}(B \otimes \mathbb{K})$ by $T := \sum_n s_n \otimes p_{1,n}$ with $T^*T = 1$ and $TT^* = 1 \otimes p_{1,1}$ by $s_n s_m^* \otimes p_{1,n} p_{m,1} = \delta_{m,n} 1 \otimes p_{1,1}$.

$T(b \otimes p_{j,k})T^* = T \sum_n b s_n^* \otimes p_{j,k} p_{n,1} = T((b s_k^*) \otimes p_{j,1})$ =?????

$\sum_n s_n b s_k^* \otimes p_{1,n} p_{j,1} = s_j b s_k^* \otimes p_{11} = (\delta_\infty(b) \cdot s_j s_k^*) \otimes p_{1,1}$. This means $T(b \otimes p_{j,k})T^* = \varphi(b \otimes p_{j,k}) \otimes p_{1,1}$. Thus, $TcT^* = \varphi(c) \otimes p_{1,1}$ for all $c \in B \otimes \mathbb{K}$. Moreover, $T^*T = 1$ and $T(B \otimes \mathbb{K})T^* = B \otimes p_{1,1}$.

`Until HERE new 2015 Oct 30`

??? by ??? the is a ???? natural C^*-morphism $\mu \colon \mathbb{K} \to \mathcal{M}(B)$ with the in Part (8) quoted properties (a,b,c) uniquely defined by the given sequence $s_1, s_2, \ldots \in \mathcal{M}(B)$ of isometries with $\sum s_n s_n^* = 1$ – up to unitary equivalence by unitaries in $\delta_\infty(B)' \cap \mathcal{M}(B)$.

`The below given arguments do not systematically prove the statements in (8). Write new proofs!`

??

(only for parts of 8?);

Suppose $s_1, s_2, \ldots \in \mathcal{M}(B)$ are isometries with $\sum s_n s_n^* = 1$ (strictly convergent) are given.

FROM “STABLE” TO $s_1, s_2, \ldots$

If, conversely, isometries $s_1, s_2, \ldots \in \mathcal{M}(B)$ are given with $\sum_n s_n s_n^*$ is (unconditional) strictly convergent to $1_{\mathcal{M}(B)}$ then we can define a strictly continuous unital positive map $\delta_\infty \colon \mathcal{M}(B) \to \mathcal{M}(B)$. The strict continuity of δ_∞ and the (easy to check) multiplicative property of $\delta_\infty | B$ imply that δ_∞ is a strictly continuous $*$-endomorphism of $\mathcal{M}(B)$.

??????

It turns out that there exists C^*-morphism $\mu \colon \mathbb{K} \to \mathcal{M}(B)$ with the properties $\mu(\mathbb{K}) \subset \delta_\infty(B)' \cap \mathcal{M}(B)$ such that $\delta_\infty(b)\mu(k) \in B$ for $b \in B$ and $k \in \mathbb{K}$ *and* such that the (unique) C^*-morphism $\varphi\colon B \otimes \mathbb{K} \to B$ with $\varphi(b \otimes k) = \delta_\infty(b)\mu(k)$ is a *-isomorphism from $B \otimes \mathbb{K}$ onto B.

`Indicate proof of non/uniqueness:`

The C^*-morphism μ with the described properties is determined up to unitary equivalence by unitaries in $\delta_\infty(B)' \cap \mathcal{M}(B)$.

The isomorphism φ from $B \otimes \mathbb{K}$ onto B defined by $\mu\colon \mathbb{K} \to \mathcal{M}(B)$ with properties (a,b,c) has the property that the corresponding C^*-morphism $b \mapsto \varphi(b \otimes e_{11})$ is a *-endomorphism of B, that is approximately 1-step inner if considered as a c.p. contraction. Moreover, if $b \in B_+$, then $\varphi(b \otimes e_{11})$ is Murray–von-Neumann equivalent to b. In particular,

$$\varphi(J \otimes \mathbb{K}) = J \quad \forall\, J \triangleleft B\,.$$

This property of the "natural" φ is different from the properties of very random and possibly not well-behaved *-isomorphisms ψ from $B \otimes \mathbb{K}$ onto B – as allowed in the *definition* of stability –, because in general the isomorphism $\varphi \circ \psi^{-1}$ of B does not fix the ideal-system $\mathcal{I}(B)$ of $B$and is not approximately unitarily equivalent to id_B by unitaries in $\mathcal{M}(B)$.

The non-degenerate *-monomorphism $\mu\colon \mathbb{K} \to \mathcal{M}(B)$ has the important property that

$$\mu(\mathbb{K})' \cap \mathcal{M}(B) = \delta_\infty(\mathcal{M}(B))\,.$$

In particular:
$\delta_\infty(\mathcal{M}(B))$ is closed in $\mathcal{M}(B)$ with respect to the strict topology of $\mathcal{M}(B)$.

The strictly continuous extension $\mathcal{M}(\mu)\colon \mathcal{M}(\mathbb{K}) \cong \mathcal{L}(\ell_2) \to \mathcal{M}(B)$ of μ is a unital *-monomorphism, has image in $\delta_\infty(\mathcal{M}(B))' \cap \mathcal{M}(B)$ and the norm-closed unit-ball of $\mathcal{M}(\mu)(\mathcal{L}(\ell_2))$ is also closed in the strict topology of $\mathcal{M}(B)$.

The strictly closed C^*-subalgebra $\delta_\infty(\mathcal{M}(B))' \cap \mathcal{M}(B)$ of $\mathcal{M}(B)$ can be larger than $\mathcal{M}(\mu)(\mathcal{L}(\ell_2))$, e.g. if the center of $\mathcal{M}(B)$ is not trivial, because the center of $\mathcal{M}(B)$ is identical with the commutant of $\delta_\infty(B)\cdot\mu(\mathbb{K})$ in $\mathcal{M}(B)$, and $\delta_\infty(B)\cdot\mu(\mathbb{K})$ generates B.

`Next should be partly in the proof`

Since μ is non-degenerate and $B \neq \{0\}$, μ is faithful and extends to a faithful and strictly continuous C^*-morphism $\mathcal{M}(\mu)\colon \mathcal{M}(\mathbb{K}) \to \mathcal{M}(B)$ by the considerations (0) given in the proof.

Let $d\colon B \to \mathcal{L}(\mathcal{H})$ any non-degenerate *-representation on a Hilbert space $\mathcal{H}$ (i.e., $d(B)\mathcal{H} = \mathcal{H}$, using factorization).

compare ?????????

Then $d\colon B \to \mathcal{M}(\mathbb{K}(\mathcal{H})) \cong \mathcal{L}(\mathcal{H})$ is non-degenerate in the sense of Part (1), and $\mathcal{M}(d)\colon \mathcal{M}(B) \to \mathcal{M}(\mathbb{K}(\mathcal{H}))$ is strictly continuous.

Thus $\mathcal{M}(d) \circ \mathcal{M}(\mu)$ is strictly continuous on $\mathcal{M}(\mathbb{K}(\ell_2))$ and the topology induced on $\mathcal{M}(\mathbb{K})$ by $\mathcal{M}(\mu)^{-1}$ from the strict topology of $\mathcal{M}(B)$ is between the strict topology of $\mathcal{M}(\mathbb{K})$ and the topology on $\mathcal{M}(\mathbb{K})$ that is induced by $(\mathcal{M}(d) \circ \mathcal{M}(\mu))^{-1}$ on $\mathcal{M}(\mathbb{K})$ from the strict topology of $\mathcal{M}(\mathbb{K}(\mathcal{H}))$.

The strict topology on $\mathcal{M}(\mathbb{K}(\mathcal{H}))$ is on bounded parts the same as the *-strong topology.

Every non-degenerate representation of $\mathbb{K}(\mathcal{H})$ on some other Hilbert space $\mathcal{H}_2$ induces on $\mathcal{M}(\mathbb{K}(\mathcal{H})) = \mathcal{L}(\mathcal{H})$ the same strict topology as its "native" coming from the identical representation over $\mathcal{H}$.

The topology induced by $\mathcal{M}(\mu)^{-1}$ on $\mathcal{M}(\mathbb{K}(\ell_2)) = \mathcal{L}(\ell_2(\mathbb{N}))$ from the strict topology on $\mathcal{M}(B)$ is the same for each non-degenerate C^*-morphism $\mu\colon \mathbb{K}(\ell_2) \to \mathcal{M}(B)$.

This "universal" strict topology on $\mathcal{M}(\mathbb{K}) = \mathcal{L}(\ell_2)$ coincides on bounded parts of $\mathcal{L}(\ell_2)$ with the *-strong operator topology on $\mathcal{L}(\ell_2)$. In particular, $\mathcal{M}(\mu)(\mathcal{M}(\mathbb{K}))$ *is strictly closed in* $\mathcal{M}(B)$ *if* $\mu(\mathbb{K})$ *is non-degenerate.*

The strict closure $\overline{h(A)}^{\text{str}} \subseteq \mathcal{M}(B)$ of the image $h(A) \subseteq \mathcal{M}(B)$ of any non-degenerate C^*-morphism $h\colon A \to \mathcal{M}(B)$ of a stable C^*-algebra A contains the image $\mathcal{M}(h)(\mathcal{M}(A))$ of the strictly continuous unital extension $\mathcal{M}(h)\colon \mathcal{M}(A) \to \mathcal{M}(B)$, just by strict continuity of $\mathcal{M}(h)$, but *in general* $\mathcal{M}(h)(\mathcal{M}(A))$ is *not* strictly closed for non-degenerate h.

The closure of $\mathcal{M}(h)(\mathcal{M}(A))$ in $\mathcal{M}(B)$ with respect to the strict topology of $\mathcal{M}(B)$ coincides with the intersection of $\mathcal{M}(B) \subseteq B^{**}$ with the $\sigma(B^{**}, B^*)$ closure of $\mathcal{M}(h)(\mathcal{M}(A))$ in B^{**}.

(a) *There exists a sequence* $s_1, s_2, \ldots$ *of isometries in* $\mathcal{M}(B)$ *such that* $\sum_n s_n s_n^*$ *converges strictly to* 1 *in* $\mathcal{M}(B)$*, if and only if,* B *is stable:*

There exists a sequence of isometries $t_1, t_2, \ldots \in \mathcal{M}(\mathbb{K}) = \mathcal{L}(\ell_2)$ with $\sum t_n t_n^*$ strictly convergent to 1. The isometries t_n can be given explicitly in $\mathcal{L}(\ell_2)$ as $t_n := I \circ J_n$ by a fixed isometry I from $\ell_2 \otimes \ell_2$ onto ℓ_2 composed with the isometries $J_n(x) := e_n \otimes x$ for $x \in \ell_2(\mathbb{N})$ and for the canonical basis $\{e_1, e_2, \ldots\}$ of $\ell_2(\mathbb{N})$.

The strict convergence $\sum t_n t_n^* = 1$ in $\mathcal{M}(\mathbb{K})$ follows from the fact that the *-strong topology on $\mathcal{L}(\ell_2) \cong \mathcal{M}(\mathbb{K})$ coincides with the strict topology *on bounded parts* of $\mathcal{M}(\mathbb{K}) \cong \mathcal{L}(\ell_2)$.

The here used coincidence of the *-strong topology and the strict topology *on bounded parts* of $\mathcal{M}(\mathbb{K}) \cong \mathcal{L}(\ell_2)$ follows from the norm-density of the finite rank operators in $\mathbb{K}$.

Since the *-ultra-strong topology coincides with the *-strong topology on bounded parts of $\mathcal{L}(\ell_2)$, we get that strict (given by $\mathcal{L}(\ell_2) \cong \mathcal{M}(\mathbb{K}(\ell_2))$ and *-ultra-strong topology coincide on bounded parts.

`Do the strict topology and *-ultra-strong topology coincide also on unbounded parts of` $\mathcal{L}(\mathcal{H})$`?`

It is – perhaps – the case if and only if, strict and *-ultra-strong topology coincide on $\mathcal{M}(\mathbb{K}(\ell_2(\mathbb{N})))$. The latter seems not to be the case (?!).

Are the two the strong operator topologies on $\ell_\infty(\mathbb{C}) = \mathcal{M}(c_0\mathbb{C})$ for its natural actions on c_0 or ℓ_2 different on *unbounded* parts?

Does there exist an unbounded *net* in ℓ_∞ that that converges in the strong operator topology on $\mathcal{L}(\ell_2)$ to zero but does not converge in the strong operator topology in $\mathcal{M}(c_0) = \ell_\infty \subset \mathcal{L}(c_0)$?

It is the same problem with the "global" difference of the strong operator topology for the left multiplication of $\mathcal{L}(\ell_2)$ on $\mathbb{K}$, Hilbert-Schmidt class, ore trace class.

Semi-norms for *-ultra-strong topology on $\mathcal{L}(\mathcal{H})$:

$T \mapsto (\sum_n \|T^*x_n\|^2 + \|Tx_n\|^2)^{1/2}$ where $x_n \in \ell_2$, $\sum_n \|x_n\|^2 < \infty$. It is the same as $\mathrm{tr}((T^*T + TT^*)S)^{1/2} = (\|TS^{1/2}\|_2^2 + \|T^*S^{1/2}\|_2^2)^{1/2}$ for some positive trace class operator S. Then $R := S^{1/2}$ is Hilbert-Schmidt, and

$$\max(\|TR\|_2, \|T^*R\|_2) \leq (\|TR\|_2^2 + \|T^*R\|_2^2)^{1/2} \leq \|TR\|_2 + \|T^*R\|_2$$

Notice here that $\|X\| = \|X\|_\infty \leq \|X\|_p$ for all $p \geq 1$ and $X \in \mathcal{L}(\ell_2)$ with $(\|X\|_p)^p = \mathrm{tr}((X^*X)^{p/2}) < \infty$.

Alternatively:

The Hilbert-Schmidt class operator R can be Cohen factorized into $aR_1 = R$ with $a \in \mathbb{K}$ and R_1 in Hilbert-Schmidt class.

Since $\|TR\|_2 = \|TaR_1\|_2 \leq \|Ta\| \cdot \|R_1\|_2$ for $T \in \mathcal{L}(\ell_2) = \mathcal{M}(\mathbb{K})$ it follows that *-ultra-strong topology is coarser than strict topology or is equal to it:

Result:
If an (possibly unbounded) net converges to an operator T in strict topology, then it converges also in *-ultra-strong topology.

Recall that strict topology on $\mathcal{M}(\mathbb{K}) = \mathcal{L}(\ell_2)$ is defined by the semi-norms $T \mapsto \|Ta\| + \|T^*b\|$ where $a, b \in \mathbb{K}$.

If we use Cohen factorization, then the strict topology on $\mathcal{L}(\ell_2)$ is also defined by the semi-norms $T \mapsto \|Tc\| + \|T^*c\|$ with $c \in c_0(\mathbb{N})_+ \subset \mathbb{K}(\ell_2(\mathbb{N}))$.

Restricted to $T \in \ell_\infty(\mathbb{N})$ it is the strong operator norm on $\ell_\infty(\mathbb{N})$ defined by the multiplication $c \mapsto Tc$ of elements $c \in c_0(\mathbb{N})$ with T.

If one wants to compare this with the right multiplication action of ℓ_∞ on the Hilbert-Schmidt class HS $\cong \ell_2(\mathbb{N} \times \mathbb{N})$, then one has to use the restriction of the *-ultra-strong topology on $\mathcal{L}(\ell_2)$ to $\ell_\infty \subset \mathcal{L}(\ell_2)$.

The (left-)actions of $\mathcal{M}(\mathbb{K})$ on $\mathbb{K}$ and HS are isometric with respect to the operator norm on $\mathcal{M}(\mathbb{K}) = \mathcal{L}(\ell_2)$.

The induced strong topologies have same (countable) zero *sequences*:

If X is a Banach space and $T_1, T_2, \ldots \in \mathcal{L}(X)$ converges to zero in the strong (or the "ultra-strong") topology to zero, then $\|T_1\|, \|T_2\|, \ldots$ is a bounded sequence by the uniform boundedness theorem.

Now one can use that the norms $\|T\|$ of $T \in \mathcal{M}(\mathbb{K}) \subset \mathcal{L}(\mathbb{K})$ and $T \in \mathcal{L}(\ell_2) = \mathcal{M}(\mathbb{K})$ coincide and that strict and *-ultra-strong topologies on bounded parts of $\mathcal{M}(\mathbb{K})$ coincide.

It follows that differences in the convergence structures for *-ultra-strong or strict topology on $\mathcal{M}(\mathbb{K})$ can be only found if one considers unbounded nets of high cardinality that converge in *-ultra-strong topology but not in strict topology.

Suppose that there exists an isomorphism ψ from a C^*-algebra $C \otimes \mathbb{K}$ onto B. Let $\mathcal{M}(\psi)$ denote its strictly continuous extension to an isomorphism from $\mathcal{M}(C \otimes \mathbb{K})$ onto $\mathcal{M}(B)$. Its inverse is given by $\mathcal{M}(\psi)^{-1} = \mathcal{M}(\psi^{-1})$ and, therefore, is strictly continuous. Notice that there are natural strictly continuous unital *-monomorphisms $\mathcal{M}(\varphi_1)\colon \mathcal{M}(C) \to \mathcal{M}(C \otimes \mathbb{K})$ and $\mathcal{M}(\varphi_2)\colon \mathcal{M}(\mathbb{K}) \to \mathcal{M}(C \otimes \mathbb{K})$ that are the strictly continuous extensions of the non-degenerate C^*-morphisms $\varphi_1\colon C \to \mathcal{M}(C \otimes \mathbb{K})$ and $\varphi_2\colon \mathbb{K} \to \mathcal{M}(C \otimes \mathbb{K})$ that are determined by the properties $\varphi_1(c)(c_1 \otimes k) = (c \cdot c_1) \otimes k$ and $\varphi_2(k)(c \otimes k_1) = c \otimes (k \cdot k_1)$. We write $1 \otimes t$ for $\mathcal{M}(\varphi_2)(t)$ if $t \in \mathcal{M}(\mathbb{K}) \cong \mathcal{L}(\ell_2)$.

There is a non-degenerate C^*-morphism $\lambda\colon \mathbb{K} \to \mathcal{M}(B)$ that is given by $\lambda(k) := \mathcal{M}(\psi)(1 \otimes k)$ for $k \in \mathbb{K}$, i.e., $\lambda = \mathcal{M}(\psi) \circ \varphi_2$. It extends to a unital *-monomorphism $\mathcal{M}(\lambda) = \mathcal{M}(\psi) \circ \mathcal{M}(\varphi_2)\colon \mathcal{M}(\mathbb{K}) \to \mathcal{M}(B)$, that is strictly continuous on bounded parts. The isometries $s_n := \mathcal{M}(\lambda)(t_n) = \mathcal{M}(\psi)(1 \otimes t_n)$ have the property that $\sum s_n s_n^*$ converges strictly to 1 in $\mathcal{M}(B)$, because $\sum t_n t_n^*$ converges strictly to 1 and $\mathcal{M}(\lambda)$ is strictly continuous on bounded parts.

Conversely suppose that $\mathcal{M}(B)$ contains a sequence $s_1, s_2, \ldots$ of isometries in $\mathcal{M}(B)$ such that $\sum_n s_n s_n^*$ converges strictly to 1.

Then $\delta_\infty(b) := \sum_n s_n b s_n^*$ converges strictly to an element $\delta_\infty(b)$ of $\mathcal{M}(B)$ and the map $\delta_\infty\colon \mathcal{M}(B) \to \mathcal{M}(B)$ is strictly continuous and unital on $\mathcal{M}(B)$.

Indeed: If $b \in B$ and $\varepsilon > 0$, then there is $m \in \mathbb{N}$ with $\|b - (s_1 s_1^* + \ldots + s_m s_m^*)b\| < \varepsilon/2$ and there exists a contraction $e \in B_+$ with $\| s_k^* b - e s_k^* b \| < \varepsilon/2m$. It gives $\|b - \delta_\infty(e)b\| < \varepsilon$.

Thus $\delta_\infty(B)B$ is dense in B, i.e., $\delta_\infty|B$ is non-degenerate. It follows that $\delta_\infty = \mathcal{M}(\delta_\infty|B)$ is the unique strictly continuous unital extension of $\delta_\infty|B$ to $\mathcal{M}(B)$.

Then there is a unique C^*-morphism $\mu\colon \mathbb{K} \to \delta_\infty(B)' \cap \mathcal{M}(B)$ that satisfies $\mu(e_{k,\ell}) := s_k s_\ell^*$.

The range projections $p_n := s_n s_n^*$ satisfy $p_m \leq 1 - p_n$ because $p_n + p_m \leq 1$ for $m \neq n$. It implies $p_m p_n = 0$. Thus $\sum_n s_n s_n^* \leq 1$ implies $s_i^* s_j = s_i^* p_i p_j s_j = 0$ for $i \neq j$. In particular, B is the closure of its *-subalgebra $B_0 := \bigcup_n P_n B P_n$ for $P_n := p_1 + \cdots + p_n \in \mathcal{M}(B)$.

Let $e_{i,j}$ denote the canonical matrix units of $\mathbb{K} \subset M_\infty(\mathbb{C})$. We define an isometry $T \in \mathcal{M}(B \otimes \mathbb{K})$ with $TT^* = 1_{\mathcal{M}(B)} \otimes e_{1,1}$ by the "row matrix"

$$T := s_1 \otimes e_{1,1} + s_2 \otimes e_{1,2} + \ldots . \tag{1.3}$$

We use the natural embedding

$$\mathcal{M}(B \otimes \mathbb{K}) \subset M_\infty(\mathcal{M}(B)) \subseteq B^{**}\overline{\otimes}\mathcal{L}(\ell_2(\mathbb{N}))$$

that describes the elements of $\mathcal{M}(B \otimes \mathbb{K})$ as matrices over $\mathcal{M}(B)$ then above T becomes the row matrix

$$T \cong [s_1, s_2, \ldots] \in M_{1,\infty}(\mathcal{M}(B)) \subset M_\infty(\mathcal{M}(B))\,.$$

The sum $\sum_n s_n \otimes e_{1,n}$ is unconditional strictly convergent in $\mathcal{M}(B\otimes\mathbb{K})$ by Remark (2) if we take there $y_n := s_n \otimes 1$, $d_n := 1 \otimes 1$ and $x_n := 1 \otimes e_{n,1}$. Since

$$(s_n^* \otimes e_{m,1})T = (s_n^* \otimes e_{m,1})(s_n \otimes e_{1,n}) = 1 \otimes e_{m,n}\,,$$

we get $T^*(s_n \otimes e_{1,n}) = 1 \otimes e_{n,n}$ and $T^*T = 1\otimes 1$. The identities $(s_k \otimes e_{1,k})(s_n^* \otimes e_{n,1}) = \delta_{k,n} s_k s_n^* \otimes e_{11}$, imply that $TT^* = 1 \otimes e_{11}$. It follows that the map

$$H\colon b \in \mathcal{M}(B) \mapsto H(b) := T^*(b \otimes e_{11})T$$

defines a unital *-monomorphism H from $\mathcal{M}(B)$ into $\mathcal{M}(B \otimes \mathbb{K})$ that is strictly continuous (on bounded parts) and maps B into $B \otimes \mathbb{K}$, because $T \in \mathcal{M}(B \otimes \mathbb{K})$.

The *-monomorphism H maps $\mathcal{M}(B)$ *onto* $\mathcal{M}(B\otimes\mathbb{K})$, i.e., is an isomorphism, H maps B *onto* $B \otimes \mathbb{K}$, and the inverse map $H^{-1}\colon \mathcal{M}(B \otimes \mathbb{K}) \to \mathcal{M}(B)$ is given on $\mathcal{M}(B) \odot \mathbb{K}$ by $H^{-1}(b \otimes e_{jk}) = \delta_\infty(b) s_j s_k^*$:

Indeed, if $a \in \mathcal{M}(B\otimes\mathbb{K})$, then $a = T^*(TaT^*)T = H(TaT^*)$ and $TaT^* = b\otimes e_{11}$ for some $b \in \mathcal{M}(B)$.

Since H is verified to be an isomorphism from $\mathcal{M}(B)$ onto $\mathcal{M}(B \otimes \mathbb{K})$, $H(B)$ must be a closed ideal of $\mathcal{M}(B\otimes\mathbb{K})$. The definition $H := T^*((\cdot)\otimes e_{11})T$ of H with $T \in \mathcal{M}(B \otimes \mathbb{K})$ implies that $H(B) \subseteq B \otimes \mathbb{K}$.

Since B is an essential ideal of $\mathcal{M}(B)$ that is dense in $\mathcal{M}(B)$ with respect to the strict topology, $H(B)$ is a closed ideal of $B\otimes\mathbb{K}$ that is strictly dense in $B\otimes\mathbb{K}$. Thus $H(B) = B \otimes \mathbb{K}$.

(Alternatively one can prove that $b \otimes e_{n,m} \in T^*(B \otimes e_{1,1})T$ by showing that $B \otimes 1 = T^*(\delta_\infty(B) \otimes e_{1,1})T$, $T^*(s_n s_m^* \otimes e_{1,1})T = 1 \otimes e_{n,m}$ and $\delta_\infty(B) s_n s_m^* \in B$. See more below.)

Let $\psi := H|B$ and $\varphi\colon B \otimes \mathbb{K} \to B$ the inverse of $\psi = H|B$. Then $\mathcal{M}(\varphi)$ and $\mathcal{M}(\psi)$ are strictly continuous and $H = \mathcal{M}(\varphi)^{-1}$.

We can use the above defined isomorphism $\varphi\colon B \otimes \mathbb{K} \to B$ to define the other in part (8) proposed C^*-morphisms:

We have that $(s_\ell^* \otimes e_{11})T = 1 \otimes e_{1,\ell}$. It implies $T^*(s_k b s_\ell^*) \otimes e_{11}T = b \otimes e_{k,\ell}$ and $T^*(\delta_\infty(b) \otimes e_{11})T = b \otimes 1$ for all $b \in \mathcal{M}(B)$.

`Next blue NEW / BETTER APPROACH?:`

Let $\delta_\infty(b) := \sum_n s_n b s_n^*$ where $b \in \mathcal{M}(B)$, $s_1, s_2, \ldots \in \mathcal{M}(B)$ with $\sum_n s_n s_n^* = 1_{\mathcal{M}(B)}$ and $s_m^* s_n = \delta_{m,n} 1_{\mathcal{M}(B)}$.

Let $T \in \mathcal{M}(B \otimes \mathbb{K})$ the isometry defined by Equation (1.3).
