There is a non-degenerate C^*-morphism $\mu\colon \mathbb{K} \to \delta_\infty(B)' \cap \mathcal{M}(B)$ with $T^*(\mu(e_{i,j}) \otimes e_{11})T = 1 \otimes e_{i,j}$, e.g. $\mu(c) \otimes e_{11} := T(1 \otimes c)T^*$.

We can μ define $\mu\colon \mathbb{K} \to \mathcal{M}(B)$ explicit by $\mu(e_{k,\ell}) := s_k s_\ell^*$.

The equations $T(1 \otimes e_{m,1}) = s_m \otimes e_{1,1}$ imply $(1 \otimes e_{1,n})T^* = s_n^* \otimes e_{1,1}$ and

$$T(1 \otimes e_{m,n})T^* = T(1 \otimes e_{m,1})(1 \otimes e_{1,n})T^* = s_m s_n^* \otimes e_{11}\,.$$

Since

$$\delta_\infty(b) s_m s_n^* = s_m b s_n^* = s_m s_n^* \delta_\infty(b)\,,$$

the C^*-morphism $[\alpha_{jk}] \to \sum_{jk} \alpha_{jk} s_j s_k^*$ extends to a C^*-morphism $\mu\colon \mathbb{K} \to \delta_\infty(\mathcal{M}(B))' \cap \mathcal{M}(B)$ and is uniquely defined by $\mu(k) \otimes e_{11} = T(1 \otimes k)T^*$.

`Better: To be shown directly with above` H:

By Remark (2), $\delta_\infty(b) := \sum_n s_n b s_n^*$ is unconditional strictly convergent for each $b \in \mathcal{M}(B)$, and δ_∞ defines a strictly continuous unital *-monomorphism from $\mathcal{M}(B)$ into $\mathcal{M}(B)$, cf. Proof of Lemma 5.1.2(i,ii), or compare the proof of the equation $\delta_\infty(b) \otimes e_{1,1} = T(b \otimes 1)T^*$ where $T \in \mathcal{M}(B \otimes \mathbb{K})$ is the isometry defined by Equation (1.3).

(b) *There exists a non-degenerate *-monomorphism* $\mu\colon \mathbb{K} \to \mathcal{M}(B)$, *where* $\mathbb{K} := \mathbb{K}(\ell_2(\mathbb{N}))$, *with the properties* $\mu(\mathbb{K}) \subseteq \delta_\infty(B)' \cap \mathcal{M}(B)$ *such that* $\delta_\infty(b)\mu(k) \in B$ *for* $b \in B$ *and* $k \in \mathbb{K}$ and *such that the unique C^*-morphism* $\psi\colon B \otimes \mathbb{K} \to B$ *with* $\varphi(b \otimes k) = \delta_\infty(b)\mu(k)$ *is a *-isomorphism from* $B \otimes \mathbb{K}$ *onto* B.

The above defined isomorphism $\varphi\colon B \otimes \mathbb{K} \to B$, with $H = \mathcal{M}(\varphi)^{-1}$, $\psi := \varphi^{-1} = H|B$, $T(b \otimes k)T^* = (\delta_\infty(b)\mu(k)) \otimes e_{11}$ and $H(b) = T^*(b \otimes e_{1,1})T$, does the job if μ is defined by $\mu(k) \otimes e_{1,1} := T(1 \otimes k)T^*$.

(c) *The non-degenerate *-monomorphism* $\mu\colon \mathbb{K} \to \mathcal{M}(B)$ *has the property* $\mu(\mathbb{K})' \cap \mathcal{M}(B) = \delta_\infty(\mathcal{M}(B))$. *In particular,* $\delta_\infty(\mathcal{M}(B))$ *is closed in* $\mathcal{M}(B)$ *with respect to the strict topology of* $\mathcal{M}(B)$.

This can be seen by using the isomorphism $\mathcal{M}(\varphi)\colon \mathcal{M}(B \otimes \mathbb{K}) \to \mathcal{M}(B)$ from $\mathcal{M}(B \otimes \mathbb{K})$ onto $\mathcal{M}(B)$.

(d) *The strictly continuous extension* $\mathcal{M}(\mu)\colon \mathcal{M}(\mathbb{K}) \cong \mathcal{L}(\ell_2) \to \mathcal{M}(B)$ *of* μ *is a strictly continuous unital *-monomorphism, has image in* $\delta_\infty(\mathcal{M}(B))' \cap \mathcal{M}(B)$ *and* $\mathcal{M}(\mu)(\mathcal{L}(\ell_2))$ *is closed in the strict topology of* $\mathcal{M}(B)$.

`Next new version of proof ?`

The natural extension $\theta\colon \mathcal{M}(B) \to B^{**}$ of the unital *-monomorphism $\eta_B\colon B \to B^{**}$ from $\mathcal{M}(B)$ into the W*-algebra B^{**} is continuous with respect to the strict topology on $\mathcal{M}(B)$ and the *-ultra-strong topology on B^{**}.

If $h\colon A \to \mathcal{M}(B)$ is any non-degenerate *-morphism, then μ extends uniquely to a unital and strictly continuous map $\mathcal{M}(h)\colon \mathcal{M}(A) \to \mathcal{M}(B)$. Then $\mathcal{M}(h)(1) = 1$ and $\mathcal{M}(h)(\mathcal{M}(A))$ is in $\mathcal{M}(B)$ the strict closure of $h(A)$. Since $\theta\colon \mathcal{M}(B) \to B^{**}$ is continuous with respect to the strict topology on $\mathcal{M}(B)$ and the *-ultra-strong topology on B^{**}, it follows that the *-ultra-strong closure of $\theta(h(A))$ in B^{**} contains

$\theta(\mathcal{M}(h)(A))$. In particular, the *-ultra-weak closure of $h(A)$ contains the unit $1 := 1_{B^{**}}$ of B^{**}.

If M is a von-Neumann algebra and $\Phi\colon \mathcal{L}(\ell_2) \cong \mathcal{M}(\mathbb{K}) \to M$ is a C^*-morphism such that the unit 1_M of M is contained in the *-ultra-weak closure of $\Phi(\mathbb{K})$ then Φ is normal on $\mathcal{L}(\ell_2)$, i.e., is a unital W*-algebra isomorphism from $\mathcal{L}(\ell_2)$ onto the *-ultra-weak closure of $\Phi(\mathbb{K})$.

In particular, $\Phi(\mathcal{M}(\mathbb{K}))$ is closed in the *-ultra-strong topology of B^{**}, and the topology induced from this topology on $\mathcal{M}(\mathbb{K}) \cong \mathcal{L}(\ell_2)$ is the same as the *-ultra-strong topology on $\mathcal{L}(\ell_2)$.

Now take $\mathbb{K}$ and $\mu\colon \mathbb{K} \to \mathcal{M}(B)$ in place of A and h above. Let $\Psi := \theta \circ \mathcal{M}(\mu)$, then we get that the restriction of the strict topology on $\mathcal{M}(B)$ to $\mathcal{M}(\mu)(\mathcal{M}(\mathbb{K}))$ is finer than the topology induced from the *-ultra-strong topology on $\mathcal{M}(\mathbb{K})$. Since $\mathcal{M}(\mu)\colon \mathcal{M}(\mathbb{K}) \to \mathcal{M}(B)$ is strictly continuous with respect to the strict topology on $\mathcal{M}(\mathbb{K})$ and on $\mathcal{M}(B)$, it follows that the topology induced on $\mathcal{M}(\mathbb{K})$ by $\mathcal{M}(\mu)^{-1}$ is equal to or coarser than the strict topology on $\mathcal{M}(\mathbb{K})$. So it is between the *-ultra-strong topology and the strict topology on $\mathcal{L}(\ell_2) \cong \mathcal{M}(\mathbb{K})$. It is easy to see - by the definitions and by the remark in Part (i) – that the latter both coincides on bounded parts of $\mathcal{M}(\mathbb{K})$.

Thus, on bounded parts of $\mathcal{M}(\mathbb{K})$ the topology induced from the strict topology on $\mathcal{M}(B)$ via $\mathcal{M}(\mu)^{-1}$ coincide.

The image $\mathcal{M}(\mu)(\mathcal{M}(\mathbb{K}))$ is strictly closed, because θ is continuous with respect to the strict and *-ultra-strong topology, and $\theta(\mathcal{M}(\mu)(\mathcal{M}(\mathbb{K})))$ is *-ultra-strongly closed in B^{**}.

If one uses the isomorphism $\mathcal{M}(\varphi)$ from $\mathcal{M}(B \otimes \mathbb{K})$ onto $\mathcal{M}(B)$, then one can see that $\mathcal{M}(\mu)(\mathcal{L}(\ell_2))$ is the isomorphic image of $1 \otimes \mathcal{L}(\ell_2) \subseteq \mathcal{M}(B \otimes \mathbb{K})$.

It is not difficult to see that $1 \otimes \mathcal{L}(\ell_2)$ is strictly closed in $\mathcal{M}(B \otimes \mathbb{K})$ and that the induced topology on $\mathcal{M}(\mathbb{K}) \cong \mathcal{L}(\ell_2)$ coincides on bounded parts of $\mathcal{L}(\ell_2)$ with the *-strong topology.

Indeed, if $e \in B_+$ is a strictly positive positive contraction, then $C^*(e) \otimes \mathbb{K}$ is a non-degenerate C^*-subalgebra of $B \otimes \mathbb{K}$ and $1 \otimes \mathcal{M}(\mathbb{K})$ is naturally contained in $\mathcal{M}(C^*(e) \otimes \mathbb{K}) \subseteq \mathcal{M}(B \otimes \mathbb{K})$ and the representation $T \in \mathcal{M}(\mathbb{K}) \mapsto 1 \otimes T \in$ is strictly continuous, because it extends a non-degenerate representation of $\mathbb{K}$. Thus, the topology on $\mathcal{M}(\mathbb{K})$ induced from $T \mapsto 1 \otimes T$ is coarser than the strict topology on $\mathcal{M}(\mathbb{K})$. Let $\chi\colon C^*(e) \to \mathbb{C}$ a character. It defines a *-epimorphism λ from $C^*(e) \otimes \mathbb{K}$ onto $\mathbb{K}$. Then $\mathcal{M}(\lambda)\colon \mathcal{M}(C^*(e) \otimes \mathbb{K}) \to \mathcal{M}(\mathbb{K})$ is strictly continuous, and its restriction to $1 \otimes \mathcal{M}(\mathbb{K})$ is continuous with respect to the strict topology on $\mathcal{M}(C^*(e) \otimes \mathbb{K})$ defined by $C^*(e) \otimes \mathbb{K}$.

The strict topology on $\mathcal{M}(C^*(e) \otimes \mathbb{K})$ coming from $C^*(e) \otimes \mathbb{K}$ coincides on bounded parts with the restriction to $\mathcal{M}(C^*(e) \otimes \mathbb{K})$ of the strict topology on $\mathcal{M}(B \otimes \mathbb{K})$, because on bounded parts the strict topology can be defined by the semi-norms $d \in \mathcal{M}(B \otimes \mathbb{K}) \mapsto \|d(e \otimes k_1)\| + \|(e \otimes k_2)d\|$ with $k_1, k_2 \in \mathbb{K}_+$ of finite rank. In particular this topologies coincide on bounded parts of $1 \otimes \mathcal{M}(\mathbb{K})$.

Summing up, we get strictly continuous C^*-morphisms $\mathcal{M}(\mu) \colon \mathcal{M}(\mathbb{K}) \to 1 \otimes \mathcal{M}(\mathbb{K}) \subseteq \mathcal{M}(C^*(e) \otimes \mathbb{K}) \subseteq \mathcal{M}(B \otimes \mathbb{K})$ and $\mathcal{M}(\lambda) \colon \mathcal{M}(C^*(e) \otimes \mathbb{K}) \to \mathcal{M}(\mathbb{K})$ such that the strict topology on bounded parts of $\mathcal{M}(C^*(e) \otimes \mathbb{K})$ coincides with the topology induced from the strict topology of $\mathcal{M}(B \otimes \mathbb{K})$. Moreover $\mathcal{M}(\lambda) \circ \mathcal{M}(\mu) \colon \mathcal{M}(\mathbb{K}) \to \mathcal{M}(\mathbb{K})$ is a strictly continuous isomorphism of $\mathcal{M}(\mathbb{K})$ Thus it is given by an inner automorphism of $\mathcal{M}(\mathbb{K})$. It follows that all the induced strict topologies are the same on bounded parts of $\mathcal{M}(\mathbb{K})$.

The topology on $\mathcal{L}(\ell_2) \cong \mathcal{M}(\mathbb{K})$ induced from the strict topology on $\mathcal{M}(\mathbb{K})$ is on bounded parts the same as the *-strong topology on $\mathcal{L}(\ell_2)$.

Thus, the topology induced by $\mathcal{M}(\mu)^{-1}$ on $\mathcal{L}(\ell_2)$ is on bounded parts the same as the *-strong topology on $\mathcal{L}(\ell_2)$.

Since the unit-ball of $\mathcal{L}(\ell_2)$ is complete in the *-strong topology, it follows that $\mathcal{M}(\mu)(\mathcal{M}(\mathbb{K}))$ is closed in $\mathcal{M}(B)$ with respect to the *strict* topology on $\mathcal{M}(B)$.

By Lemma 5.1.2(i,ii), all infinite repeats δ_∞ are unitarily equivalent in $\mathcal{M}(B)$. Therefore we need only to verify the observations by choosing case by case a suitable "fitting" infinite repeat δ_∞.

The isomorphism ψ from $B \otimes \mathbb{K}$ onto B extends uniquely to a strictly continuous *-isomorphism $\mathcal{M}(\psi)$ from $\mathcal{M}(B \otimes \mathbb{K})$ onto $\mathcal{M}(B)$. The natural *-monomorphism $\lambda \colon \mathbb{K} \to \mathcal{M}(B \otimes \mathbb{K})$ with $\lambda(k_1)(b \otimes k_2) = b \otimes k_1 k_2$ is non-degenerate and extends to a strictly continuous unital *-monomorphism $\mathcal{M}(\lambda)$ from $\mathcal{M}(\mathbb{K})$ into $\mathcal{M}(B \otimes \mathbb{K})$.

Since there is an isomorphism ι from $\mathbb{K} \otimes \mathbb{K}$ onto $\mathbb{K}$, given by an isomorphism $\ell_2 \cong \ell_2 \otimes_2 \ell_2$, there exists isometries $t_1, t_2, \ldots \in \mathcal{M}(\mathbb{K})$ such that $\sum_n t_n t_n^*$ strictly convergent to 1, and that the commutant $\delta_\infty(\mathbb{K})' \cap \mathcal{M}(\mathbb{K})$ of $\delta_\infty(\mathbb{K})$ contains a non-degenerate copy $H(\mathbb{K})$ of $\mathbb{K}$, that satisfies $\delta_\infty(k_1)H(k_2) = \iota(k_1 \otimes k_2)$ where $\delta_\infty(k) := \sum_n t_n k t_n^*$.

Let $s_n := \mathcal{M}(\psi) \circ \mathcal{M}(\lambda)(t_n)$. Then $s_1, s_2, \ldots$ is a sequence of isometries in $\mathcal{M}(B)$ such that $\sum_n s_n s_n^*$ converges strictly to 1.

And $\delta_\infty(b) := \sum_n s_n b s_n^*$ is a non-degenerate C^*-morphism, such that $\mu \colon \mathbb{K} \to \delta_\infty(B)' \cap \mathcal{M}(B)$ (given by $\mu(k) := \mathcal{M}(\psi)(H(k))$) satisfies that $\delta_\infty(b)\mu(k) \in B$. It follows that there is a (new) C^*-morphism φ from $B \otimes \mathbb{K}$ into B that satisfies $\varphi(J \otimes \mathbb{K}) = J$ for all closed ideals of B and defines an isomorphism from $B \otimes \mathbb{K}$ onto B that is considerably different from the above defined by an arbitrary isomorphism of B and some $C \otimes \mathbb{K}$.

In particular, the unique strictly continuous extension $\mathcal{M}(\mu) = \mathcal{M}(\psi) \circ \mathcal{M}(H) \colon \mathcal{M}(\mathbb{K}) \to \mathcal{M}(B)$ of $\mu \colon \mathbb{K} \to \mathcal{M}(B)$ is a unital *-monomorphism from $\mathcal{L}(\ell_2)$ into $\mathcal{M}(B)$, and has the property that $\delta_\infty(\mathcal{M}(B))$ and $\mathcal{M}(\mu)(\mathcal{L}(\ell_2))$ commute and the C^*-algebra generated by $\delta_\infty(B) \cdot \mu(\mathbb{K})$ is strictly dense in $\mathcal{M}(B)$.

NEXT old or new ???

There exists isometries $t_1, t_2, \ldots$ in $\delta_\infty(\mathcal{M}(B))' \cap \mathcal{M}(B)$ such that $\sum_n t_n t_n^*$ converges strictly to 1. This is because $\delta_\infty(\mathcal{M}(B))' \cap \mathcal{M}(B)$ is strictly closed and there is a non-degenerate *-monomorphism $\mu\colon \mathbb{K}(\ell_2) \to \mathcal{M}(B)$ with image in $\delta_\infty(\mathcal{M}(B))' \cap \mathcal{M}(B)$. Then $\mathcal{M}(\mu)\colon \mathcal{M}(\mathbb{K}) \cong \mathcal{L}(\ell_2) \to \mathcal{M}(B)$ is strictly continuous, unital and has image in $\delta_\infty(\mathcal{M}(B))' \cap \mathcal{M}(B)$.

(9): Recall that a C^*-morphism $h\colon A \to \mathcal{M}(B)$ is *non-degenerate* if and only if the linear span of $h(A)B$ is dense in B. The Cohen factorization theorem shows that this is equivalent to $B = h(A) \cdot B$ (as set of products $h(a)b$).

It follows that non-degenerate h satisfies $h(A)(h(A)+B) \subseteq h(A)+B$ and that $h(A)(h(A)+B)$ is norm-dense in the C^*-subalgebra $h(A)+B$ of $\mathcal{M}(B)$.

Indeed, if $a \in A$, $b \in B$ and $\varepsilon > 0$ are given, then let $\gamma := \varepsilon/(3 + \|b\|)$ We find $f \in A$ with $\|b - h(f)b\| < \gamma$. There exists a positive contraction $e \in A_+$ with $\|f - ef\| < \gamma$ and $\|a - ea\| < \gamma$. Straight calculation shows that $\|(h(a) + b) - h(e)(h(a) + b)\| < \varepsilon$.

Let $H\colon A \to \mathcal{M}(h(A)+B)$ the C^*-morphism with $H(e)(h(a)+b) := h(e)(h(a)+b)$ for $a, e \in A$ and $b \in B$. The elements $t_n := \mathcal{M}(h)(s_n) \in \mathcal{M}(B)$ (respectively $t_n := \mathcal{M}(H)(s_n) \in \mathcal{M}(B)$ are isometries in $\mathcal{M}(h)(\mathcal{M}(A)) \subseteq \mathcal{M}(B)$ (respectively in $\mathcal{M}(H)(\mathcal{M}(A)) \subseteq \mathcal{M}(h(A) + B)$), and $\sum t_n t_n^*$ converges strictly to 1 in $\mathcal{M}(B)$ (respectively in $\mathcal{M}(h(A)+B)$), because $\mathcal{M}(h)$ (respectively $\mathcal{M}(H)$) is strictly continuous and unital by Part (1).

It follows that B and $h(A)+B$ are stable by Part (8). □

LEMMA 5.1.2. *Suppose that B is a stable and σ-unital C^*-algebra, and let $s_1, s_2, \ldots \in \mathcal{M}(B)$ a sequence of isometries such that $\sum_n s_n s_n^*$ converges strictly to 1 in $\mathcal{M}(B)$, – see Remark 5.1.1(8) for the existence of $\{s_1, s_2, \ldots\}$.*

(i) *The map $\delta_\infty\colon \mathcal{M}(B) \to \mathcal{M}(B)$ is a strictly continuous unital *-monomorphism. If $\delta'_\infty\colon \mathcal{M}(B) \to \mathcal{M}(B)$ comes from another sequence $t_1, t_2, \ldots$ of isometries in $\mathcal{M}(B)$ such that $\sum t_n t_n^*$ converges strongly to 1, then δ'_∞ is unitarily equivalent to δ_∞. In particular, δ_∞^2 is unitarily equivalent to δ_∞.*

The algebra $\delta_\infty(\mathcal{M}(B))' \cap \mathcal{M}(B)$ is strictly closed and contains a sequence of isometries $q_1, q_2, \ldots$ such that $\sum q_n q_n^*$ converges strictly to 1.

(ii) *$\delta_\infty(\mathcal{M}(B))' \cap \mathcal{M}(B)$ contains a copy of $\mathcal{O}_2$ (with canonical generators r_1, r_2) unitally, and $\delta_\infty \oplus_{r_1,r_2} \mathrm{id}_{\mathcal{M}(B)}$ is unitarily equivalent to δ_∞.*

(iii) *Let $D := \mathcal{O}_2 \otimes \mathbb{K}$ denote the stabilized Cuntz algebra $\mathcal{O}_2$, $q_1 \le q_2 \le \ldots$ an increasing sequence of projections in D and p_0 is a nonzero projection in D.*

Then there exists norm-continuous maps $t \mapsto U(t)$ from $\mathbb{R}_+$ into the set of unitaries in $1 + D \subseteq \mathcal{M}(D)$ such that $U(0) = 1$ and $q_n \le U(t)^* p_0 U(t)$ and $q_n \ne U(t)^* p_0 U(t)$ for $t \ge n$.

If, in addition, $q_n \neq q_{n+1}$ *for* $n = 1, 2, \ldots$, *then one can find the path* $t \mapsto U(t) \in \mathcal{M}(D)$ *such that* $q_n \leq U(t)^* p_0 U(t) \leq q_{n+3}$ *and* $U(t)^* p_0 U(t) \notin \{q_n, q_{n+3}\}$ *for* $t \in [n+1, n+2]$.

(iv) *There are isometries* $S, T \in \delta_\infty(\mathcal{M}(B))' \cap \mathcal{M}(B)$ *with* $SS^* + TT^* = 1$ *and a norm-continuous map* $t \in [0, \infty) \mapsto U(t) \in \delta_\infty(\mathcal{M}(B))' \cap \mathcal{M}(B)$ *into the unitaries of* $\mathcal{M}(B)$, *such that the norm-continuous maps*

$$S_0, T_0 \colon t \in \mathbb{R}_+ \mapsto S_0(t), T_0(t) \in \delta_\infty(\mathcal{M}(B))' \cap \mathcal{M}(B)$$

given by $S_0(t) := U(t)^* S U(t)$ *and* $T_0(t) := U(t)^* T U(t)$ *for* $t \in \mathbb{R}_+$ *satisfy* $\lim_{t\to\infty} S_0(t)^* b = 0$ *and* $\lim_{t\to\infty} T_0(t)^* b = b$ *for every* $b \in B$.

(v) *Let* C *a separable* C^**-subalgebra of* $\mathcal{M}(B)$, $T \colon C \to \mathcal{M}(B)$ *a completely positive contraction, and suppose that there exists a contraction* $g \in \mathcal{M}(B)$ *with* $g^* c g - \delta_\infty(T(c)) \in B$ *for every* $c \in C$.

Then there exists a norm-continuous map $t \in \mathbb{R}_+ \mapsto S(t) \in \mathcal{M}(B)$ *into the contractions in* $\mathcal{M}(B)$ *such that* $S(t)^* c S(t) - \delta_\infty(T(c)) \in B$ *for every* $t \in \mathbb{R}_+$, *and* $\lim_{n\to\infty} \|\delta_\infty(T(c)) - S(t)^* c S(t)\| = 0$ *for all* $c \in C$.

If, moreover, $1_{\mathcal{M}(B)} \in C$ *and* T *is unital then* $t \mapsto S(t)$ *can be found such that, moreover,* $S(t)^* S(t) = 1$ *for* $t \in \mathbb{R}_+$.

(vi) *Suppose that* $1_{\mathcal{M}(B)} \in C \subseteq \mathcal{M}(B)$, C *is separable, and that* T *is a unital* C^**-morphism such that there exists a contraction* $g \in \mathcal{M}(B)$ *with* $g^* c g - \delta_\infty(T(c)) \in B$ *for every* $c \in C$. *Then* id_C *asymptotically absorbs* T, *i.e.,* $\mathrm{id}_C \oplus T$ *and* id_C *are unitarily homotopic in the sense of Definition 5.0.1.*

(vii) *If* $f \in \mathcal{M}(B)$ *and if* $e \in B_+$ *is a strictly positive element, then the norm closures* B_0 *of* $f^* B f$ *and* B_1 *of* $\delta_\infty(f^*) B \delta_\infty(f)$ *are* σ*-unital with strictly positive elements* $f^* e f$, *respectively with* $\delta_\infty(f^*) e \delta_\infty(f)$.

There is a natural isomorphism ψ *from* B_1 *onto* $B_0 \otimes \mathbb{K}$, *that is given by*

$$\psi(b) := [s_j^* b s_k]_{jk} \in B_0 \otimes \mathbb{K} \subseteq M_\infty(B_0)\,.$$

PROOF. (i): The strict convergence of the n-th partial sums of $\sum s_n d s_n^*$ for $d \in \mathcal{M}(B)$ and then of $\delta_\infty(d_\tau)$ to $\delta_\infty(d)$ for a strictly convergent bounded net in $\{d_\tau\} \subseteq \mathcal{M}(B)$ with strict limit $d \in \mathcal{M}(B)$ can be seen from the argument in Remark 5.1.1(2). Since $\sum_n s_n s_n^* = 1$ (strictly), the map δ_∞ is unital. It is clear that δ_∞ is an isometric and completely positive map. It is multiplicative because

$$\delta_\infty(d)\delta_\infty(e) s_n s_n^* = s_n d s_n^* s_n e s_n^* = \delta_\infty(de) s_n s_n^*\,.$$

The sum $\sum s_n t_n^* =: U$ is strictly convergent to a unitary because the strong convergence of U and that of U^* can be seen by the argument in Remark 5.1.1(2). This also shows that $U \in \mathcal{M}(B)$ is unitary and $U^* \delta_\infty(d) U = \delta'_\infty(d)$ for $d \in \mathcal{M}(B)$.

The sufficient criterium in Remark 5.1.1(2) shows that $\sum_{n,m} s_n s_m (s_n s_m)^*$ converges unconditional strictly to $1_{\mathcal{M}(B)}$. Thus, δ_∞^2 is an infinite repeat of $\mathrm{id}_{\mathcal{M}(B)}$.

Compare Remark 5.1.1(8)
and use $\rho(e_{jk}) := s_j s_k^*$????

''It is clear that'' ???????

The map $T \in \mathcal{M}(B) \mapsto ST - TS \in \mathcal{M}(B)$ is strictly continuous for each $S \in \mathcal{M}(B)$, thus with $S := \delta_\infty(d)$ we get that $\{\delta_\infty(d)\}' \cap \mathcal{M}(B)$ is strictly closed for every $d \in \mathcal{M}(B)_+$. It implies that $\delta_\infty(\mathcal{M}(B))' \cap \mathcal{M}(B)$ is strictly closed as intersection of strictly closed C^*-subalgebras. It contains a non-degenerate copy of $\mathbb{K}(\ell_2)$ by Remark 5.1.1(8). Therefore, there is a strictly continuous unital *-monomorphism $\rho \colon \mathcal{M}(\mathbb{K}) \cong \mathcal{L}(\ell_2) \to \mathcal{M}(B)$ such that the image of ρ commutes with $\delta_\infty(\mathcal{M}(B))$.

If $t_1, t_2, \ldots$ is a sequence of isometries in $\mathcal{M}(B)$ (with $\sum t_n t_n^* = 1$ strictly) then $\rho(t_1), \rho(t_2), \ldots$ are isometries in $\delta_\infty(\mathcal{M}(B))' \cap \mathcal{M}(B)$ (with $\sum \rho(t_n)\rho(t_n)^* = 1$ strictly).

(ii): Let the isometries $s_1, s_2, \ldots \in \mathcal{M}(B)$ the generators of a copy of $\mathcal{O}_\infty$ as established in Remark 5.1.1(8). By part (i), there exists a unital *-monomorphism Λ from $\mathcal{L}(\ell_2) \cong \mathcal{M}(\mathbb{K})$ into $\delta_\infty(\mathcal{M}(B))' \cap \mathcal{M}(B)$. Take isometries $R_1, R_2 \in \mathcal{L}(\ell_2)$ with $R_1R_1^* + R_2R_2^* = 1$ and let $r_k := \Lambda(R_k) \in \mathcal{M}(B)$ for $k = 1, 2$. Then $C^*(r_1, r_2)$ is a copy of $\mathcal{O}_2$ in $\delta_\infty(\mathcal{M}(B))' \cap \mathcal{M}(B)$ that contains $1_{\mathcal{M}(B)}$.

The map $\delta_\infty \oplus_{r_1,r_2} \mathrm{id}_{\mathcal{M}(B)}$ is an infinite repeat $\delta'_\infty(b) := \sum_n t_n b t_n^*$ of the identity map $\mathrm{id}_{\mathcal{M}(B)}$ of $\mathcal{M}(B)$ that is given by the sequence of isometries $t_1 := r_2$, $t_{n+1} := r_1 s_n$ for $n = 1, 2, \ldots$, because the series $\sum t_n t_n^* = r_2 r_2^* + r_1(\sum s_n s_n^*) r_1^*$ converges strictly to 1. It follows that $\delta_\infty \oplus_{r_1,r_2} \mathrm{id}_{\mathcal{M}(B)}$ is unitarily equivalent to δ_∞ by (i).

(iii): We use here (and only here !) the notation $p < q$ for projections if $p \leq q$ and $p \neq q$.

Where next is really used? For what?

Let $p_0 := 1 \otimes e_{11} \in D$ and a $p \in D := \mathcal{O}_2 \otimes \mathbb{K}$ non-zero projection. Since D has an approximate unit consisting of projections we find projections $r, s \in D$ and a unitary $v_1 \in \mathcal{U}_0(D + \mathbb{C} \cdot 1)$ in the connected component of 1 inside the unitaries in $D + 1$ such that $p_0 < r < s$, $p < r < s$, $v_1(1 - s) = (1 - s)$ and $v_1^* p_0 v_1 = p$.

Is r really necessary for something above?

Let $p, q, r, s \in D$ with $p < q < s$ and $p < r < s$. Then there exists a continuous map $t \in [0, 1] \mapsto v(t) \in D$ with $v(t)^*v(t) = v(t)v(t)^* = v(0) = s - p$ and $v(1)^* q v(1) = r$.

Use below that $\mathcal{O}_2$ has property (sq), because $\mathcal{O}_2 = \mathcal{E}_2/\mathbb{K}$.
It implies: $\mathcal{O}_2$ is K_1-bijective.

Every projection in $\mathcal{O}_2$ is properly infinite,
and
δ_2 is homotopic to id.
(Implies $\mathrm{K}_*(\mathcal{O}_2) = 0$.

This happens because, by [**172**], any two projections $P, Q \in \mathcal{O}_2 \setminus \{0,1\}$ are unitarily equivalent in $\mathcal{O}_2 \cong (s-p)D(s-p)$, and $\mathcal{U}(\mathcal{O}_2) = \mathcal{U}_0(\mathcal{O}_2)$.

The unitary equivalence of non-trivial projections in $\mathcal{O}_2$ implies that all non-zero projections in $D = \mathcal{O}_2 \otimes \mathbb{K}$ are MvN-equivalent, thus $(s-p)D(s-p)$ is isomorphic to $\mathcal{O}_2$, and we can pass from $\mathcal{O}_2$ to $(s-p)D(s-p)$.

If there is $n_0 \in \mathbb{N}$ such that $q_n = q_{n_0}$ for all $n \geq n_0$, then we find projections $r, s \in D$ and a continuous map $t \mapsto w(t) \in D + 1$ into the unitaries of $D + 1$ such that $w(0) = 1$, $q_{n_0} < r < s$ and $q := w(1)^* p_0 w(1) < s$.

Thus $0 < r < s$ and $0 < q < s$, and there is a continuous map $t \mapsto v(t) \in D$ with $v(t)^* v(t) = v(t)v(t)^* = v(0) = s$ and $v(1)^* q v(1) = r$. Let $U(t) := w(t)(v(t) + (1-s))$ for $t \in [0,1]$ and $U(t) = U(1)$ for $t > 1$. The map $t \mapsto U(t)$ is a continuous path in the $\mathcal{U}_0(D + \mathbb{C}1) \cap (1 + D)$ of the desired type.

If the sequence $q_1 \leq q_2 \leq \ldots$ becomes not stationary, than we may assume that $0 < q_n < q_{n+1}$ for all $n \in \mathbb{N}$, – simply by re-indexing the non-equal q_n and changing the parameter $t \in \mathbb{R}$. Therefore we find continuous maps $t \in [0,1] \mapsto v_n(t) \in D$ into the partial unitaries of D such that $v_n(t)^* v_n(t) = v_n(t) v_n(t)^* = v_n(0) = q_{n+3} - q_n$ and $v_n(1)^* q_{n+1} v_n(1) = q_{n+2}$.

We find a projection $s \in D$ with $0 < q_3 < s$ and a continuous map $t \mapsto w(t)$ from $[0,1]$ into the unitaries of $D + 1$, such that $q := w(1)^* p_0 w(1) < s$, $w(0) = 1$. Then there is a continuous map $t \mapsto v_0(t) \in D$ with $v_0(t)^* v_0(t) = v_0(t) v_0(t)^* = v_0(0) = s$ and $v_0(1)^* q v_0(1) = q_3$.

Let $U(t) := w(t)(v_0(t) + (1-s))$ for $t \in [0,1]$ and, by induction, $U(n+t) := U(n)(q_{n+2} + v_{n+1}(t) + (1 - q_{n+4}))$ for $t \in [0,1]$ and $n = 1, 2, \ldots$. Then $t \mapsto U(t)$ is a continuous map from $\mathbb{R}_+$ to the unitaries in $D + 1$, with $U(0) = 1$, $U(n)^* p_0 U(n) = q_{n+2}$ and $q_n \leq U(t)^* p_0 U(t)$ and $U(t)^* p_0 U(t) \neq q_n$ for $t \in [n, n+1]$.

(iv): As noticed in Remark 5.1.1(8) (combined with part (i)), there is a *non-degenerate* *-monomorphism $\psi\colon \mathbb{K} \to \mathcal{M}(B)$ such that $\mathcal{M}(\psi)\colon \mathcal{M}(\mathbb{K}) \to \mathcal{M}(B)$ is a unital strictly continuous *-monomorphism with image in $\delta_\infty(\mathcal{M}(B))' \cap \mathcal{M}(B)$. We identify $\mathcal{M}(\mathbb{K})$ with such a copy $\mathcal{M}(\psi)(\mathcal{M}(\mathbb{K}))$ of $\mathcal{M}(\mathbb{K})$ in $\delta_\infty(\mathcal{M}(B))' \cap \mathcal{M}(B)$.

Since $\ell_2 \otimes_2 \ell_2 \cong \ell_2$ there is a non-degenerate copy D of $\mathcal{O}_2 \otimes \mathbb{K}$ contained in $\mathcal{M}(\mathbb{K}) = \mathcal{L}(\ell_2)$, i.e., $\overline{D\mathbb{K}} = \mathbb{K}$ and the inclusion $\mathcal{M}(D) \subseteq \mathcal{M}(\mathbb{K})$ is unital. $p_0 := 1_{\mathcal{O}_2} \otimes p_{11}$ is in D, but is not in $\mathbb{K}$. There exists an increasing sequence of projections $q_0 < q_1 < q_2 < \cdots$ in $1_{\mathcal{O}_2} \otimes \mathbb{K} \subseteq D$ with $q_0 \leq q_1$, $q_1 - q_0 \neq 0$, $q_1 - q_2 \neq 0$, and $\lim_{n\to\infty} \|q_n k - k\| = 0$ for every $k \in \mathbb{K}$. It follows that (q_n) converges strictly to $1 \in \mathcal{M}(B)$.

By (iii) there is a norm-continuous map $t \mapsto U(t)$ into the unitaries of $D + 1 \subseteq \mathcal{M}(\mathbb{K})$ such that $q_n \leq U(t)^* p_0 U(t)$ for $t \geq n$.

In $\mathcal{M}(\mathbb{K}) = \mathcal{L}(\ell_2)$ there are isometries T and S with $p_0 T = p_0$, $TT^* = q_1$, $SS^* = 1 - q_1$, because $1 - p_0$, $q_1 - p_0$ and $1 - q_1$ are not in $\mathbb{K}$ (recall: $D \cap \mathbb{K} = \{0\}$). Let $S_0(t) := U(t)^* S U(t)$ and $T_0(t) := U(t)^* T U(t)$. Then $q_n S(t) = q_n (U(t)^* p_0 U(t)) U(t)^* S U(t) = q_n U(t)^* p_0 \, S U(t) = 0$ and $q_n T(t) =$

$q_n(U(t)^*p_0\,U(t))U(t)^*TU(t) = q_n(U(t)^*p_0\,U(t)) = q_n$ for $t > n$, and the maps $t \to S_0(t), T_0(t) \in \mathcal{M}(\mathbb{K}) \subseteq \mathcal{M}(B)$ are norm-continuous.

Thus, $\lim_{t\to\infty} S_0(t)^*q_nb = 0$ and $\lim_{t\to\infty} T_0(t)^*q_nb = q_nb$ for every $b \in B$ and $n \in \mathbb{N}$.

The desired result follows, because $\bigcup_n(q_nB)$ is dense in B.

(v): Let $S(t) := gS_0(t)$ where $S_0(t) \in \delta_\infty(\mathcal{M}(B))' \cap \mathcal{M}(B)$ is as in (iv). Then $t \mapsto S(t)$ is a norm-continuous map from $[0,\infty)$ into the contractions in $\mathcal{M}(B)$,

$$(\delta_\infty \circ T)(c) - S(t)^*cS(t) = S_0(t)^*(\delta_\infty(T(c)) - g^*cg)S_0(t) \in B$$

for $t \in \mathbb{R}_+$, and $\lim_{t\to\infty} \|S(t)^*cS(t) - \delta_\infty(T(c))\| = 0$.

If $1 \in C$ and $T(1) = 1$, then $1 - S(t)^*S(t) = S_0(t)^*(\delta_\infty(T(1)) - g^*1g)S_0(t)$ is in B and tends to zero in norm. Since the norm-limit of $S(t)^*S(t)$ is 1, there is $t_0 \geq 0$ such that $S(t)^*S(t)$ is invertible for every $t \geq t_0$. Then $t \to (S(t_0+t)^*S(t_0+t))^{-1/2} \in B$ is norm-continuous, $S'(t) := S(t_0+t)(S(t_0+t)^*S(t_0+t))^{-1/2}$ is norm-continuous and satisfies $S'(t)^*S'(t) = 1$, $S'(t)^*cS'(t) - \delta_\infty(T(c)) \in B$ and $\lim S'(t)^*cS'(t) = \delta_\infty(T(c))$ for $c \in C$.

(vi): The statement is independent of the chosen copy and generators $\{s_1, s_2\}$, $\{t_1, t_2\}$ of $\mathcal{O}_2$ in $\mathcal{M}(B)$, because the unital completely positive map $\mathrm{id}_C \oplus_{s_1,s_2} T$ is unitarily equivalent to $\mathrm{id}_C \oplus_{t_1,t_2} T$ by the unitary $w = t_1s_1^* + t_2s_2^*$. In the following $\oplus$ is formed with help of the same generators of $\mathcal{O}_2 \subseteq \mathcal{M}(B)$. Let $V := \delta_\infty \circ T$. By (ii), there is a unitary $U_0 \in \mathcal{M}(B)$ with $U_0^*V(\cdot)\,U_0 = T \oplus V$. If we have found a norm-continuous map $t \mapsto U_1(t)$ into the unitaries of $\mathcal{M}(B)$ with $V(c) \oplus c - U_1(t)^*c\,U_1(t) \in B$ and $\lim_{n\to\infty} \|V(c) \oplus c - U_1(t)^*c\,U_1(t)\| = 0$ for all $c \in C$, then

$$U(t) := U_1(t)(U_0 \oplus 1)U_d(1 \oplus U_1(t)^*)$$

is as desired, where U_d is a unitary in $\mathcal{U}_0(\mathcal{O}_2)$ with $U_d^*(a \oplus b) \oplus c)U_d = a \oplus (b \oplus c)$ as in Proposition 4.3.2(iv).

Thus, it is enough to prove the existence of $U(t)$ for $V = \delta_\infty \circ T$ (in place of T). By (iv) there exists a norm continuous map $t \in \mathbb{R}_+ \mapsto S(t) \in \mathcal{M}(B)$ into the isometries of $\mathcal{M}(B)$ such that $S(t)^*c\,S(t) - V(c) \in B$ for every $t \in \mathbb{R}_+$, and $\lim_{n\to\infty} \|V(c) - S(t)^*c\,S(t)\| = 0$ for all $c \in C$. The relative commutant of $V(C)$ in $\mathcal{M}(B)$ contains a copy of $\mathcal{O}_2$ unitally, by Part (ii).

Now we prove a **more general result** than stated in Part (vi):
Suppose that C is a C^*-subalgebra $C \subseteq \mathcal{M}(B)$ with $1_{\mathcal{M}(B)} \in C$ and that V is a unital C^*-morphism $V\colon C \to \mathcal{M}(B)$ such that there are a unital copy of $\mathcal{O}_2$ in $V(C)' \cap \mathcal{M}(B)$ and a norm-continuous map $t \mapsto S(t)$ from $\mathbb{R}_+$ into the contractions of $\mathcal{M}(B)$ with $S(t)^*c\,S(t) - V(c) \in B$ and $V(c) = \lim S(t)^*c\,S(t)$. Then there is a norm-continuous map $t \mapsto U(t)$ from $\mathbb{R}_+$ into the unitaries of $\mathcal{M}(B)$ such that $c \oplus V(c) - U(t)^*c\,U(t) \in B$ for every $t \in \mathbb{R}_+$ and

$$\lim_{t\to\infty} \|\, c \oplus V(c) \;-\; U(t)^*c\,U(t)\,\| = 0 \qquad \text{for } c \in C\,.$$

By $\mathrm{C_b}(\mathbb{R}_+, \mathcal{M}(B))$ we denote the bounded continuous maps from $\mathbb{R}_+$ into $\mathcal{M}(B)$. We let $E := \mathrm{C_b}(\mathbb{R}_+, \mathcal{M}(B))/\mathrm{C_0}(\mathbb{R}_+, B)$ and consider $\mathcal{M}(B)$ as a subalgebra of E. Then the assumptions imply that $C \hookrightarrow E$ dominates the C^*-morphism $V: C \to E$ and that $V(C)' \cap E$ contains a copy of $\mathcal{O}_2$ unitally. Thus, by Proposition 4.3.5(i) there is a unitary $u \in E$ such that $u^*cu = c \oplus V(c)$ for $c \in C$.

Let $t \mapsto W(t)$ a contraction in $\mathrm{C_b}(\mathbb{R}_+, \mathcal{M}(B))$ which represents u. Then $1 - W(t)^*W(t)$ and $1 - W(t)W(t)^*$ are in B, $\lim \|1 - W(t)W(t)^*\| = 0$, $\lim \|1 - W(t)^*W(t)\| = 0$. Thus there exists $t_0 \geq 0$ with $\|1 - W(t)^*W(t)\| \leq 1/2$ and $\|1 - W(t)W(t)^*\| \leq 1/2$ for $t \geq t_0$. Let $U(t) := W(t+t_0)(W(t+t_0)^*W(t+t_0))^{-1/2}$ for $t \geq 0$. Then $t \mapsto U(t)$ is as desired.

(vii): Let $g := \delta_\infty(f)$, $p_k := s_k s_k^*$ and $q_n := \sum_{k \leq n} p_k$. Recall $B_0 := \overline{f^*Bf}$ and $B_1 := \overline{g^*Bg}$. We have $p_k g = g p_k = s_k f s_k^*$, $p_k B_1 \subseteq B_1$ $B = s_j^*(s_j B s_k^*) s_k \subseteq s_j^* B s_k \subseteq B$, and $p_j g B g p_k = s_j f^* s_j^* B s_k f s_k^* = s_j f^* B f s_k^*$. Thus, $p_j B_1 p_k = s_j B_0 s_k^*$ and $s_j^* B_1 s_k = B_0$. Since $q_n g = g q_n$, $\|q_n g^* b g - g^* b g\| \leq \|g\|^2 \|(q_n b - b) g\| \to 0$ for $n \to \infty$ and $b \in B$, we get $q_n B_1 + B_1 q_n \subseteq B_1$ and $\lim_{n\to\infty} \|q_n b q_n - b\| = 0$ for all $b \in B_1$.

Let $\psi(b) := [s_j^* b s_k]_{j,k} \in \mathcal{M}_\infty(B_0)$. The restriction of ψ to $q_n B_1 q_n$ defines a *-isomorphism from $q_n B_1 q_n$ onto $M_n(B_0)$. It follows that ψ is a *-isomorphism from B_1 onto $B_0 \otimes \mathbb{K} \subseteq M_\infty(B_0)$ because $\lim_{n\to\infty} \|q_n b q_n - b\| = 0$ for all $b \in B_1$.

Let $\rho \colon B \to \mathbb{C}$ a positive state with $\rho(f^*ef) = 0$. Since $b \mapsto \rho(f^*bf)$ is a positive functional on B and e is strictly positive, we get $\rho(f^*Bf) = \{0\}$ and $\rho(B_0) = \{0\}$, i.e., f^*ef is a strictly positive element of B_0. In the same way one gets that g^*eg is strictly positive in B_1. □

2. Some properties of corona C^*-algebras

HERE STARTS DISCUSSION ON σ-sub-Stonean C^*-algebras:

DEFINITION 5.2.1. A C^*-algebra E is **sub-Stonean** (also called **SAW*-algebra**) if, for each positive contractions $a, b \in E_+$ with $ab = 0$, there exists a positive contraction $c \in E_+$ with $ca = a$ and $bc = 0$ ([6]).

???? Wrong Definition ?:

The C^*-algebra E is a **σ-sub-Stonean** C^*-algebra if $A' \cap E$ is sub-Stonean for every *separable* C^*-subalgebra A of E.

????

My comment:

This (!) is an other property than given in my original definition in [**448**, def. 1.4].

This original definition seems to be at least formally “stronger”? It is unclear if they are equivalent.

[6] In particular, for each $e \in E_+$ there exist a positive contraction $f \in E_+$ with $fe = e = ef$.

"Recall" that a C^*-algebra C is an SAW*-algebra if any two σ-unital C^*-subalgebras A and B of C are "orthogonal" (i.e., $A \cdot B = \{0\}$) if and only if they are "separated" (i.e., there exists positive contractions $e, f \in C$ with $ef = 0$, $A = eAe$ and $B = fBf$. $\Leftarrow$ is perhaps not the original definition of SAW*-algebras?

This applies to $E := C^*(e)$ and $F := C^*(f)$. It causes that there exists contractions $g, h \in C_+$ with $gh = 0$, $F = gFg$ and $G = hGh$. It implies that $\rho_\varphi \cdot \varphi(f) \leq g$ for each $\varphi \in \mathrm{C}_0(0,1]_+$ with suitable $\rho_\varphi \in (0,1]$. Does it imply that there exists a positive contraction $T \in \overline{gCg}$ with $Tf = f = fT$?

What is it the correct Definition of sub-Stonean C^*-algebras? (Look to Pedersen and others?)

???? Definition ???? A C^*-algebra C is an SAW*-algebra if any two σ-unital subalgebras A and B of C are "orthogonal", if and only if, they are "separated".

Original ?: positive f, g?: [**292**, def. 2.9]

My Definition [**448**, def. 1.4] in "green":

We call a C^*- algebra C σ-sub-Stonean if for every separable C^*-subalgebra $A \subseteq C$ and every $b, c \in C_+$ with $bc = 0$ and $bAc = \{0\}$ there are positive contractions $f, g \in A' \cap C$ with $fg = 0$, $fb = b$ and $gc = c$.

Definition [**292**, def. 2.9]:

A C^*-algebra C is σ-sub-Stonean if for every separable subalgebra A of C and all positive b and c in C such that $bAc = \{0\}$ there are contractions f and g in $A' \cap C$ such that $fg = 0$, $fb = b$ and $gc = c$.

Gives $fb = b$ and $fc = 0$, $f^*fg = 0$, $f^*fc = 0$ and $fP_b = P_b$.

Missing:

$bc = 0$ (becomes stronger, because of weaker assumptions)

and

Positivity of f, g (becomes weaker conclusion).

Therefore difficult to compare!

Is it really equivalent to my Def?

(Implies: $fc = 0$, $f = v(f^*f)^{1/2}$, $(f^*f)^{1/2}g = 0$, $v(f^*f)^{1/2}P_b = P_b$???? . f^*f has properties: $f^*fg = 0$, $fP_b = P_b$. Is $g^*c = c$? $gP_c = P_c$ with P_c support of c.

Can here replace A by $C^*(A, b)$ then it covers partly our Definition ... but I can not see that one can deduce from [**292**, def. 2.9] that the commutant $A' \cap C$ is again σ-sub-Stonean as it is in our Definition ...

The definition [**292**, def. 2.9] is not identical to my Definition:

A C^*-algebra C is σ-sub-Stonean if, for every separable subalgebra A of C and all positive b and c in C such that $bAc = \{0\}$, there are contractions f and g in $A' \cap C$ such that $fg = 0$, $fb = b$ and $gc = c$.

Definitions [**292**, def. 2.5] of Farah and Hart:

Two subalgebras A, B of an algebra C are **orthogonal** if $ab = 0$ for all $a \in A$ and $b \in B$.

They are **separated** if there is a positive element $c \in C$ such that $cac = a$ for all $a \in A$ and $cb = 0$ for all $b \in B$.

My definition [**448**, def. 1.4] is stated here again ([7]):

DEFINITION 5.2.2. We call a C^*-algebra C **σ-sub-Stonean** if for every separable C^*-subalgebra $A \subset C$ and every $b, c \in C_+$ with $bc = 0$ and $bAc = \{0\}$ there are positive contractions $f, g \in A' \cap C$ with $fg = 0$, $fb = b$ and $gc = c$.

My comments:

Obviously, if C is σ-sub-Stonean, then C is sub-Stonean (case $A := \{0\}$), and $B' \cap C$ is σ-sub-Stonean for every separable C^*-subalgebra B of C (consider $C^*(B, A)$ in place of A in the definition).

It is easy to see, that if D is a hereditary C^*-subalgebra of C, then D is σ-sub-Stonean, if and only if, for every $d \in D_+$ there is a positive contraction $e \in D$ with $ed = d$.

Proof of last:
There is a positive contraction e in D with $eb = b$, $ec = c$ and $ea = a$ for all $a \in A$. Then $bC^*(A, e)c = \{0\}$. If f', g' are positive contractions in C that commute with $C^*(A, e)$ and satisfy $f'g - 0$, $fb = b$ and $g'c = c$, then $f := f'e$ and $g = g'e$ in I_+ are as desired.

In particular, $\mathrm{Ann}(d, C)$ is σ-sub-Stonean for every $d \in C_+$ if C is σ-sub-Stonean.

Further, if C is σ-sub-Stonean and $I \triangleleft C$ is a σ-sub-Stonean closed ideal of C, then C/I is σ-sub-Stonean. (An exercise.)

Proof of last:
Let $A \subset C/I$ separable, $b, c \in (C/I)_+$ with $bc = 0$ and $bAc = \{0\}$, $A_1 \subset C$ separable with $\pi_I(A_1) = A$, $f \in C$ a self-adjoint contraction with $f = b^{1/2} - c^{1/2}$, d a strictly positive element of $C^*(f_+ A_1 f_-) \subset I$. Let $e \in I$ a positive contraction with $ed = d$, and let $b' := f_+(1-e)f_+, c' := f_-(1-e)f_- \in C_+$. Then $b'A_1c' = \{0\}$, $b'c' = 0$ and $\pi_I(b') = b$, $\pi_I(c') = c$. Since C is σ-sub-Stonean there are $f', g' \in A_1' \cap C$ with $f'b' - b'$ and $g'c' = c'$. $f := \pi_I(f')$ and $g := \pi_I(g')$ are as desired.

If C is sub-Stonean, then C satisfies almost a sort σ-variant for this for given:

There are always contractions $g, h \in C_+$ with $gh = 0$ that are "quasi-invariant" under the unitaries in $A + \mathbb{C} \cdot 1 \subseteq \mathcal{M}(C)$, – in the sense that e.g. $u^*gu \in \overline{gCg}$ for all $u \in \mathcal{U}(A + \mathbb{C} \cdot 1)$ and satisfy $b \in \overline{gCg}$ and $c \in \overline{hCh}$.

Definition of Farah and Hart ([**292**, def. 2.9]):

[7] It was modified or wrongly displayed in [**292**, def. 2.9] to something that ?????? seems to be even not equivalent to [**448**, def. 1.4].

A C^*-algebra C is σ-sub-Stonean if for every separable subalgebra A of C and all positive b and c in C such that $bAc = \{0\}$ there are contractions f and g in $A' \cap C$ such that $fg = 0$, $fb = b$ and $gc = c$.

My question: Each SAW*-algebra (Def.???) has this property?

Let B the separable C^*-algebra generated by AcA and $e \in B_+$ a strictly positive contraction in B. Then $be = 0$ and there are positive contractions $f, g \in C_+$ with $fg = 0$, $bf = b$ and $ge = e$. It follows $gbc = bc$ for all $b \in B$

Definition 5.2.3. The algebra E is σ_2**-sub-Stonean** if for every separable C^*-subalgebra A of E, every positive contraction $e \in A' \cap E$ and every sequence $g_1, g_2, \ldots$ of positive contractions with $eg_n = 0$, $g_{n+1}g_n = g_n$ and $\lim_n \|g_n a - a g_n\| = 0$ for all $a \in A_+$ there exists a positive contraction $f \in A' \cap E$ with $fg_n = g_n$ for all $n \in \mathbb{N}$ and $fe = 0$.

`Next blue argument not clear !`

(If one can take a subsequence $h_k = g_{n_k}$ and then takes $g := \sum 2^{-n} g_n$ or $G := \sum_k 2^{-n_k}(h_{k+1} - h_k)$, then $ge = 0$ and $Ge = 0$, the proposed positive contraction $f \in A' \cap E$ satisfies $fg = g$ – which is equivalent to $fg_n = g_n$ for each $n = 1, 2, \ldots$ –, and each $a \in A$ derives $D = \overline{gEg}$ into D:

$$ageg - gega = (ag - ga)eg + (gaeg - geag) + (ge(ag - ga)) \ \in D$$

for each $a \in A$ and $e \in E$, because for all $a \in A$ $ga = \sum_n 2^{-n} g_n a \in D$ by $\lim_k \|(g_n a - a g_n) g_k\|$.)

A C^*-algebra C has **AA-CRISP** (**asymptotically abelian, countable Riesz separation property**) if the following holds:

Assume a_n, b_n, for $n \in \mathbb{N}$, are positive elements of C such that

$$a_n \leq a_{n+1} \leq b_{n+1} \leq b_n$$

for all n. Furthermore assume that D is a separable *subset* of C such that for every $d \in D$ we have

$$\lim_n \|[a_n, d]\| = 0 .$$

Then there exists a positive $c \in C$ such that $a_n \leq c \leq b_n$ for all n and $[c, d] = 0$ for all $d \in D$.

The algebra E satisfies **Kasparov's technical property** (**KTP**) if E has the following property:

If B_1 and B_2 are σ-unital C^*-subalgebras of E with $B_1 \cdot B_2 = \{0\}$ and $\Delta \subset E$ is a separable subspace with $xb - bx \in B_1$ for all $x \in \Delta$ and $b \in B_1$, then there exists a positive contraction $f \in E_+$ such that $f \cdot B_1 = \{0\}$, $(1 - f) \cdot B_2 = \{0\}$ and $fx = xf$ for all $x \in \Delta$.

We say that a C^*-algebra M has **KTP** if the following holds:
Assume A, B, and C are subalgebras of M such that $A \perp B$ and C derives B. Furthermore assume A and B are σ-unital and C is separable. Then there is a

positive element $d \in M$ such that $d \in C' \cap M$, the map $x \mapsto xd$ is the identity on B, and the map $x \mapsto dx$ annihilates A.

Every derivation of a separable subalgebra of M is of the form δ_b for some $b \in M$.

(Latter is Part of Definition? Is it ∂_b?)

Kasparov's Technical Theorem: [**73**, thm.12.4.2]

Let J be a σ-unital C^*-algebra. Let A_1 and A_2 be σ-unital C^*-subalgebras of $\mathcal{M}(J)$, and Δ a separable subspace of $\mathcal{M}(J)$. Suppose $A_1 \cdot A_2 \subseteq J$, and that Δ derives A_1. Then there are $M, N \in \mathcal{M}(J)$ such that

$$0 \leq M \leq 1,\ \ N = 1 - M,\ \ M \cdot A_1 \subseteq J,\ \ N \cdot A_2 \subseteq J,\ \ \text{and}\ \ [M, \Delta] \subseteq J\,.$$

The result can fail if A_1 and A_2 are not σ-unital, even if B_1? and B_2? are commutative and $\Delta = 0$ [Choi and Christensen 1983]:

Kasparov's Technical Theorem [**73**, thm.12.4.2] says – in an equivalent formulation – that $E := \mathrm{Q}(A) := \mathcal{M}(A)/A$ has "Kasparov's Technical Property" if A is σ-unital.

If B_1 and B_2 are orthogonal σ-unital C^*-subalgebras of E with $B_1 \cdot B_2 = \{0\}$ and Δ a separable subspace with $[x, b] \in B_2$ for all $b \in B_2$ and $x \in \Delta$. Then we can find strictly positive contractions $e_1 \in B_1$ and $e_2 \in B_2$ and we get $[x, b] \in \overline{e_1 E e_1}$ for all $x \in \Delta$ and $b \in B_1$.

The algebras B_1 and B_2 can not be completely re-discovered from (e_1, e_2, Δ). But if we find a positive contraction $T \in E_+$ with $Te_2 = e_2$ and $Te_1 = 0$, and $[T, d] = 0$ for all $d \in \Delta$ then $f := T$ satisfies Kasparov's technical property for (B_1, B_2, Δ).

We can conversely consider two positive $e_1, e_2 \in E_+$ with $e_1 e_2 = 0$ and a countable subset X of E with the property that $[x, e_1] \in \overline{e_1 E e_1}$ for all $x \in X$. (E.g. by taking strictly positive contractions $e_1 \in A_1$ and $e_2 \in A_2$).

If we find a contraction $T \in E_+$ with $Tx = xT$ for all $x \in X$, $Te_2 = e_2$ and $Te_1 = 0$. Then T has the required properties.

In fact it suffices to find $T \in C^*(X)' \cap E$, $\|T\| \leq 1$, $T \geq 0$ and $Te_1 = 0$, $Te_2 = e_2$.

If $e_1, e_2 \in E_+$ with $e_1 e_2 = 0$ and a countable subset X of E with the property that $[x, e_1] \in \overline{e_1 E e_1}$ for all $x \in X$ are given, then one can consider the C^*-algebras $B_2 := C^*(e_2)$ and define Δ as the linear span of X. A C^*-algebra B_1 can be defined as closure of $\bigcup_n B_{1,n}$, where the $B_{1,n}$ are inductively defined by $B_{1,1} := C^*(e_1)$, $B_{1,n+1} := C^*(B_{1,n}, [y, x], x \in X, y \in ???)$.

Then e_1 is a strictly positive element of B_1 and $[B_1, y] \subseteq B_1$ for all y in the linear span of X.

Assuming that E satisfies the Kasparov technical property, we get a contraction $f \in E_+$ with $f \cdot B_1 = \{0\}$, $f \in C^*(X)' \cap E$ and $fe_1 = e_1$.

A C^*-algebra C has AA-CRISP (asymptotically abelian, countable Riesz separation property) if the following holds:

Assume a_n, b_n, for $n \in \mathbb{N}$, are positive elements of C such that $a_n \leq a_{n+1} \leq b_{n+1} \leq b_n$ for all $n \in \mathbb{N}$. Furthermore assume D is a separable subset of C such that for every $d \in D$ we have

$$\lim_n \|[a_n, d]\| = 0\,.$$

Then there exists a positive $c \in C$ such that $a_n \leq c \leq b_n$ for all n and $[c, d] = 0$ for all $d \in D$.

So far we have not seen examples that separate the stronger definitions from the sub-Stonean C^*-algebras. For abelian C^*-algebras the definitions are equivalent.

(But compare the study [**292**] of I. Farah and B. Hart in the case of corona algebras.:

" We present unified proofs of several properties of the corona of σ-unital C^*-algebras such as $AA-CRISP$, SAW^*, being sub-σ-Stonean in the sense of Kirchberg, and the conclusion of Kasparov's Technical Theorem.

Although our results were obtained by considering C^*-algebras as models of the logic for metric structures, the reader is not required to have any knowledge of model theory of metric structures (or model theory, or logic in general). The proofs involve analysis of the extent of model-theoretic saturation of corona algebras.

Countable saturation of corona algebras Ilijas Farah, Bradd Hart,
arXiv:1112.3898v2 (revised 17 Oct 2012)

Related properties of coronas of σ-unital stable C^*-algebras A is given in the following proposition.

PROPOSITION 5.2.4. *Let A a stable σ-unital C^*-algebra, $D \subset A$ a σ-unital hereditary C^*-subalgebra.*

(i) *D is unitary homotopic to a corner of A.*
(ii) *The corona $\mathrm{Q}(A) := \mathcal{M}(A)/A \cong \mathrm{Q}^{\mathrm{s}}(A)$ is is a σ_2-sub-Stonean C^*-algebra (in sense of Definition 5.2.3).*

PROOF. (i): `To be filled in` **??** (ii): It is essentially Kasparov's lemma. □

QUESTION 5.2.5. Let B a sub-Stonean C^*-algebra (in the sense that for each self-adjoint contraction $c \in B$ there exists a self-adjoint contraction $d \in B$ such that $dc = |c|$ (equivalently expressed: for $c_1, c_2 \in B_+$ with $c_1c_2 = 0$ exist contractions $d_1, d_2 \in B_+$ with $d_1d_2 = 0$ and $d_kc_k = c_k$ for $k \in \{1, 2\}$.)

Let $e \in B_+$ a positive contraction, $D := \overline{eBe}$ and define the (two-sided) **normalizer** of D in B by

$$\mathcal{N}(D) := \{b \in B\,;\; bD \cup Db \subseteq D\}\,.$$

It is easy to see that $\mathcal{N}(D)$ is a C^*-subalgebra of B and that $\psi_D(c)d := cd$ (for $d \in D$ and $c \in \mathcal{N}(D)$) defines a natural C^*-morphism $\psi_D \colon \mathcal{N}(D) \to \mathcal{M}(D)$ from $\mathcal{N}(D)$ into the (abstract two-sided) multiplier algebra $\mathcal{M}(D)$ of D. It is unital, because there exists a contraction $f \in B_+$ with $fe = e$.

Is $\psi_D(\mathcal{N}(D))$ sub-Stonean?

Clearly, the kernel of ψ_D is equal to the two-sided annihilator

$$\mathrm{Ann}(D) := \mathrm{Ann}(B, D) := \{b \in B\,;\; bD = Db = \{0\}\,\}$$

of D in B, which is a sub-Stonean hereditary C^*-subalgebra of B.

The interesting *question* says:
Is $\psi_D \colon \mathcal{N}(D) \to \mathcal{M}(D)$ surjective?

I.e., $\mathcal{M}(D)/D \cong \mathcal{N}(D)/\,\mathrm{Ann}(D)$ in a natural way.

It would give a nice new characterization of sub-Stonean C^*-algebras.

QUESTION 5.2.6. Let B a sub-Stonean C^*-algebra. A special case of Question 5.2.5 is the following question:

Let $b_1, b_2, \ldots \in B_+$ a sequence of mutually orthogonal contractions.

Does B_+ contain an contraction $c \in B_+$ such that c is contained in the in $\mathcal{N}(D)$ for $D := \overline{dBd}$ with $d := \sum_n 2^{-n} b_n$ and $c(b_n - (b_n - 1/2)_+) = (b_n - 1/2)_+$ for all $n \in \mathbb{N}$?

It seems (!) that Question 5.2.5 is equivalent to the following question:

QUESTION 5.2.7. Let B a sub-Stonean C^*-algebra and $a \in B_+$. Let $D := \overline{aBa}$. Suppose that $d_1, d_2, \ldots \in D_+$ are mutually orthogonal and such that $d_1 + d_2 + \cdots$ converges strictly to an element in $T \in \mathcal{M}(D)_+$.

Something more elaborate is needed ?

Does there exist an element $b \in B_+$ that satisfies $bD \cup Db \subseteq D$ and

$$\lim_n \|b(a - (1 - 1/n))_+ a - \sum_{k \le n} d_n (a - (1 - 1/n))_+ a\| = 0\,?$$

3. Functions that respect quasi-central approximate units

If we want to verify in applications the estimates that appear in the assumptions of the Parts (2)-(6) of Remark 5.1.1, then the below given Proposition 5.3.1 and its consequence, the Lemma 5.3.2, are useful, despite the fact that also the arguments in the proof of [**43**, thm. 2] can be used without controlling bound. This argument of Arveson in [**43**] is in essence the following:

Let K a convex subset of the positive contractions in A that contains an approximate unit of A, and $\varphi_1, \varphi_2, \ldots \in \mathrm{C}_0(0, 1]_+$ a given sequence of continuous function.

We need an element $e \in K$ with $\|y - ey\| \leq \varepsilon\|y\|$ for y in a given finite-dimensional subspace $Y \subseteq A$ that satisfies at the same time the commutation properties $\|[e,x]\| \leq \varepsilon\|x\|$ and $\|[\varphi_k(e),x]\| \leq \varepsilon\|x\|$ for $x \in X$ and $k = 1,\ldots,n$, where $X \subseteq \mathcal{M}(A)$ is a finite-dimensional linear subspace. This can be done by solving following inequalities by an inductive selection procedure with n^{th} step as follows:

First choose for each given $\varepsilon > 0$, n_0 and the considered continuous function $\varphi_k(\lambda)$ with $\varphi_k(0) = 0$, $k \leq n$, a polynomial $P_k(\lambda)$ with $P_k(0) = 0$ and $|\varphi_k(\lambda) - P_k(\lambda)| < \varepsilon/2$ for $\lambda \in [0,1]$ and then select from before constructed approximate units e_n with $e_n e_m = e_{\min m,n}$ a finite convex combination e of elements $e_{n_1},\ldots,e_{n_k}$ ($n_0 < n_1 < n_2 < \ldots < n_k$) such that $\|[e,x]\| \leq \eta\|x\|$ for x in a given finite-dimensional subspace $X_k \subseteq \mathcal{M}(A)$ in a (before chosen) filtration of A or of some separable subspace, where η can be taken e.g. as $\eta := \varepsilon/(2\max_{1\leq k\leq n}\{1 + Q_k'(1)\})$ with polynomials $Q_k(\lambda)$ build from $P_k(\lambda)$ by replacing all coefficients of P_k by its absolute values and $Q_k' := d/d\lambda\, Q_k$ is the derivative of Q_k. Those estimates are not perfect.

See [**11**, lem. 10.3] for the case of the polynomials $P(\lambda) := \lambda^n$.

Notice also that by [**11**, lem. 10.4], $T^* = T$, $\|T\| < 1$ and bounded X:

$$\|(1-T^2)^{1/2}X - X(1-T^2)^{1/2}\| \leq (\|T\| \cdot \|XT - TX\|)/(1 - \|T\|^2)^{1/2}\,.$$

Unfortunately we have to consider the case where $\|T\|$ is near to 1.

In our application we need a construction that produces a sufficiently fast commutation property such that sub-selections satisfy automatically better commutation and approximate-unit properties, i.e., we need to check estimates of commutator-norms for commutators of elements in given different convex subsets of an algebra. This must be used later to verify the quadratic unconditional strict convergence of some series build by selections from given sequences of elements in the multiplier algebra.

A control of such general estimate is possible by the above described inductive selection. But we need a general control of the commutators for all needed functions f itself, e.g. by suitable bounds for the – with respect to $t \in [0,1]$ non-decreasing – function

$$G(f,\cdot)\colon\ [0,1] \ni t \mapsto G(f,t) \in [0,\infty]\,,$$

defined by

$$G(f,t) := \sup\{\, \|[x,f(a)]\|\,;\ (a,x) \in P(t)\,\}$$

for the set of pairs

$$P(t) := \{\,(x,a)\,;\ x,a \in \mathcal{L}(\ell_2),\ \|x\| \leq 1,\, 0 \leq a \leq 1,\, \|xa - ax\| \leq t\,\}\,.$$

Here f is a given non-decreasing continuous real function on $[0,1]$. The definition shows that $t \mapsto G(f,t)$ is the minimal function that satisfies for given f the inequalities

$$\|[x,f(a)]\| \leq G(f,\|[x,a]\|)$$

for all contractions $x, a \in \mathcal{L}(H)$ with $a \geq 0$. Below we observe that it suffices to consider only self-adjoint contractions $x = x^*$ to define $G(f,t)$.

`Where` $G_u(f,t)$ `is used?`

`Where` $G_u(f,t)$ `is used?` To get applicable estimates of $G(f,t)$ it could be useful to consider also the functions $G_u(f,t)$ defined by

$$G_u(f,t) := \sup\{ \|u^* f(a) u - f(a)\| \,;\ (a,u) \in PU(t) \}$$

where $PU(t)$ is defined as the set of pairs

$$PU(t) := \{ (u,a) \,;\ u, a \in \mathcal{L}(H) \ \text{with}\ u^*u = 1 = uu^*, 0 \leq a \leq 1, \|[a,u]\| \leq t \},$$

i.e., it considers only differences $\|f(b) - f(a)\|$ of functions of unitary transformations $b := u^* a u$. Those have often easier estimates if the function f is operator monotone, e.g. for $f(t) = t^{1/2}$ it is easy to see that $\|f(b) - f(a)\| \leq f(\|b - a\|)$.

Always $\|[b,x]\| \leq \|[b_-, x]\| + \|[b_+, x]\| \leq 2\|x\|(\|b_-\| + \|b_+\|)$ for all $x \in \mathcal{L}(H)$

Is always $\|[b,x]\| \leq \|x\|\|b\|$ and each positive $b \in \mathcal{L}(H)$?

It implies that for $b \in \mathcal{L}(H)_+$ and $x \in \mathcal{L}(H)$ holds that

$$\|[b,x]\| \leq \inf_{t \in \mathbb{R}_+} \|[(b-t)_-, x]\| + \|[(b-t)_+, x]\| \,.$$

Is $\|[b,x]\| \leq \|x\|\|b\|$ for $b \in \mathcal{L}(H)_+$ and any $x \in \mathcal{L}(H)$ by the following estimates ??:

For each $\delta > 0$ there are vectors $\theta, \xi \in H$ with norm $= 1$ such that $\langle [b,x]\theta, \xi \rangle \geq 0$ and $\|[b,x]\| \leq \delta + \langle [b,x]\theta, \xi \rangle$. Notice that $\langle [b,x]\theta, \xi \rangle = \langle b\theta, x^*\xi \rangle - \langle x\theta, b\xi \rangle \geq 0$

It is a non-negative difference of two complex numbers of norm $\leq \|x\|\|b\|$. It follows that it is also a non-negative difference of two real numbers of norm $\leq \|x\|\|b\|$. (Still it could be $= 2\|x\|\|b\|$.)

If P is the orthogonal projection onto the linear span of $\{\theta, \xi, x\theta, x^*\xi\}$ then $\langle [b,x]\theta, \xi \rangle = \langle bP\theta, P^2 x^* P\xi \rangle - \langle P^2 x P\theta, bP\xi \rangle \geq 0$. The latter is equal to $\langle [PbP, PxP]\theta, \xi \rangle \leq \|[PbP, PxP]\|$.

Thus $\|[b,x]\| \leq \delta + \|[PbP, PxP]\|$ and we can reduce all to the case of $H = \mathbb{C}^4$.

Can suppose that $0 \in \operatorname{Spec}(PbP)$.

Let $P \in \mathcal{L}(H)$ an orthogonal projection that commutes with b and satisfies $Pb = b_+$ and $(1-P)b = b_-$. Then $[b,x] = bPx - xPb + b(1-P)x - x(1-P)b$ ...

??? says $b_+x - xb_+ + b_-x - xb_- = [b,x]$

and then ????? used where ???

`check above and next again:`

This ????????? can be seen by restriction to the case of self-adjoint contractions $X^* = X$ and $B \geq 0$, if we replace b by $B := \operatorname{diag}(\gamma + b, \gamma + b) \in M_2(\mathcal{L}(H)) \cong \mathcal{L}(H)$ with $\gamma := \|b_-\|$ and replace x by $X := \operatorname{diag}(x^*, x) \cdot Z \in M_2(\mathcal{L}(H))$, where $Z^* = Z := [\zeta_{jk}] \in M_2$ is defined by $\zeta_{jk} := 1 - \delta_{jk}$ and satisfies $Z^2 = 1$, $Z \operatorname{diag}(y,z) =$

$\mathrm{diag}(z,y)Z$. Thus, $ZBZ = B$, $ZX = \mathrm{diag}(x,x^*)$, $XZ = \mathrm{diag}(x^*,x)$. and $X^* = Z \cdot \mathrm{diag}(x,x^*) = X$.

It follows that $G(f,\cdot)$ restrict to the case of self-adjoint contractions $X = X^*$, because Then $\|[x,b]\| = \|[X,B]\|$ and $\|[x,f(b)]\| = \|[X,f(B)]\|$.

$B\,\mathrm{diag}(x^*,x) = \mathrm{diag}((\gamma+b)x^*, (\gamma+b)x)$,

$ZBX = \mathrm{diag}((\gamma+b)x, (\gamma+b)x^*)$,

$ZB = Z\,\mathrm{diag}((\gamma+b),(\gamma+b)) = \mathrm{diag}((\gamma+b),(\gamma+b))Z = BZ$,

$Z(XB - BX) = \mathrm{diag}(x,x^*)\cdot \mathrm{diag}(\gamma+b,\gamma+b) - \mathrm{diag}((\gamma+b)x,(\gamma+b)x^*)$ is the diagonal matrix with entries $x(\gamma+b)-(\gamma+b)x$ and $x^*(\gamma+b)-(\gamma+b)x^*$. Thus $\|XB - BX\| = \|x(\gamma+b)-(\gamma+b)x\| = \|[b,x]\|$ if $b^* = b$, $\gamma := \|b_-\|$ and $X := \mathrm{diag}(x^*,x)\cdot Z = X^*$.

Since one can X replace here again by $X + \|X_-\| \geq 0$ without changing the norms, it shows that all estimates can be done using positive operators in $\mathcal{L}(\ell_2)$.

In particular it suffices to consider self-adjoint contractions x and positive a if we want to find an estimate for $G(f,t)$.

`Check next arguments again`

Always $G(f,0) = 0$, because $f(a)$ commutes with x if $a = a^*$ commutes with x and $f(t)$ is a function on the spectrum of a. Moreover, if $t_1 > t_2 > \cdots$ we find (a_n,x_n) with $\|[x_n,a_n]\| \leq t_n$ and $G(f,t_n) - 2^{-n} < \|[x_n,f(a_n)]\| \leq G(f,t_n)$. The elements $a := (a_1,a_2,\ldots) + c_0(\mathcal{L}(H))$ and $x := (x_1,x_2,\ldots) + c_0(\mathcal{L}(H))$ of $\ell_\infty(\mathcal{L}(H))/c_0(\mathcal{L}(H))$ generate a C^*-subalgebra $C^*(a,x)$ that can be faithfully represented as a C^*-subalgebra of $\mathcal{L}(H)$, then $\|[x,a]\| \leq t_\infty := \lim_n t_n$ and $\|[x,f(a)]\| = \limsup_{n\to\infty} G(f,t_n) = \lim_n G(f,t_n)$. Since $t \mapsto G(f,t)$ is increasing, and $\|[x,f(a)]\| \leq G(f,t_\infty) \leq G(f,t_n)$, it follows that the monotone increasing function $t \mapsto G(f,t)$ is continuous from the right side.

(i.e., is upper semi-continuous ?) What about the left side?

If f is continuous, then $t \mapsto G(f,t)$ is continuous, i.e., is also continuous from the left side: Let $t_1 < t_2 < \ldots$ in $[0,1]$ and $t_\infty := \lim_n t_n$. Suppose $G(f,t_\infty) > \sup_n G(f,t_n)$ and let $0 < \varepsilon < G(f,t_\infty) - \sup_n G(f,t_n)$.

By definition of $G(f,t_\infty)$, there exists $(a,x) \in P(t_\infty)$ with $G(f,t_\infty) - \varepsilon < \|[x,f(a)]\| \leq G(f,t_\infty)$. If f is continuous on $[0,1]$, then $\lim_{\delta\to 0} \|f((1-2\delta)(a+\delta 1)) - f(a)\| = 0$.

Since $[x,(1-2\delta)(a+\delta 1)] = (1-2\delta)[x,a]$, and $G(f,(1-2\delta)t_\infty) \leq \sup_n G(f,t_n)$ and

$$\|[x,f((1-2\delta)(a+\delta 1))]\| \leq \sup_n G(f,t_n) \leq G(f,t_\infty) - \varepsilon \leq G(f,t_\infty)\,.$$

If we suppose that f is continuous, then $\|f((1-2\delta)(a+\delta 1)) - f(a)\| \to 0$ for $0 < \delta \to 0$. Thus, $\sup_n G(f,t_n) = G(f,t_\infty)$. This implies that $t \in [0,1] \mapsto G(f,t) \in [0,1]$ is continuous on $[0,1]$. The continuity implies – by the Lemma of Dini on automatic uniform convergence from below applied to $G(f,\cdot)$ on $[0,1]$ – that the value $G(f,t)$ is determined by the pairs (a,x) in $P(t)$ with a and b operators of finite rank.

Some words about lower bounds for $G(f,\cdot)$:

It is easy to check that $f(t) \leq G(f,t)$, e.g. $a(t) := ts_2s_2^* + s_3s_3^*$ and $x := s_1s_2^*$ of $\mathcal{O}_\infty = C^*(s_1,s_2,\ldots) \subseteq \mathcal{L}(\ell_2)$ satisfy $\|x\| = 1$, $\|a(t)\| = 1$, $a(t) \geq 0$ and $\|[x, f(a(t))]\| = f(t)$, $\|[x,a(t)]\| = t$. This shows that $f(t) \leq G(f,t)$ for all $t \in [0,1]$. Alternatively one can take elements $a := \mathrm{diag}(0,t,1) \in M_3$ and $x := [\xi_{jk}] \in M_3$ with $\xi_{13} := 1$ and $\xi_{jk} = 0$ for $(j,k) \neq (1,3)$.

If we allow in case of M_2 also the case with $\|a\| < 1$, then $a(t) := \mathrm{diag}(t,0)$ and the above defined self-adjoint orthogonal matrix $Z \in M_2$ again satisfy $\|[Z, f(a(t))]\| = f(t)$ and $\|[Z,a(t)]\| = t$ for $t \in [0,1]$.

The above reduction to the case of self-adjoint $x = x^*$ and $b \geq 0$ shows also that $\|xb - bx\| \leq \|x\|(\|b_+\| + \|b_-\|)$ for each $b^* = b = b_+ - b_-$, and any $x \in \mathcal{L}(\ell_2)$, because for $x^* = x$ and $b^* = b$ the element $T := i(bx - xb)$ is self-adjoint and its norm is given by the supremum of $|\langle Tv, v\rangle| = |\langle xv, bv\rangle - \langle bv, xv\rangle|$ for $v \in H := \ell_2$ with $\|v\| = 1$. To see that $|\langle Tv, v\rangle| \leq \|x\|\|b\|$, consider the orthogonal projection $P \in \mathbb{K}$ of rank ≤ 2 from H onto the linear span of v and xv. Then

$$|\langle Tv, v\rangle| = |\langle PxPv, bPv\rangle - \langle bPv, PxPv\rangle| = |\langle (PbPxP - PxPbP)v, v\rangle|\,.$$

This reduces the claim to the case where b and x are in M_2: If $\mathrm{rank}(P) = 1$ we get $\langle Tv, v\rangle = 0$, and otherwise PbP is positive and PxP is self-adjoint in $p(\mathbb{K})p \cong M_2$. It is easy to see that $\|bx - xb\| \leq 1$ for contractions $b, x \in M_2$ with $b \geq 0$, because one can reduce the general case to the case where b is diagonal and x has zero diagonal.

If we allow both of b and x to be non-positive but self-adjoint contractions, then $x := Z$ with $Z \in M_2$ as above defined and $b := \mathrm{diag}(1,-1)$ are self-adjoint contractions that satisfy $\|[x,b]\| = \|x\|(\|b_-\| + \|b_+\|) = 2$.

Since one can for positive $a \in M_2$ and $f \geq 0$ reduce the considerations to the case of diagonal a and $x = \mathrm{diag}(\alpha,\beta)\cdot Z$, one gets that $\|[x, f(a)]\| \leq f(\|[x,a]\|)$ for all contractions $x, a \in M_2(\mathbb{C})$ with $a \geq 0$ and any continuous non-decreasing f on $[0,1]$ with $f(0) \geq 0$.

Def. of P and ?

$\|[x, f(a)]\| = i\langle xv,\ f(a)v\rangle = i\langle PxPv, f(a)Pv\rangle \geq \|[PxP, Pf(a)P]\|$
for $P = P^*P$, $Pv = v$, $Pxv = xv$???
and $\|[PxP, Pf(a)P]\| \leq$??? if $Pf(a)P \geq f(PaP)$?

Some determination of $G(f,t)$ should be possible in other cases because one can restrict the definition to $a, x \in M_n(\mathbb{C})$ and get $G_n(f,t) \leq G(f,t)$ and $G(f,t) = \sup_n G_n(f,t)$ with uniform convergence by the Lemma of Dini. This reduction to M_n can be seen as follows:

The positive contractions in $c_0 \subseteq \mathbb{K}(\ell_2)$ contain a approximate unit (e_n) of $\mathbb{K}$ that is (in norm) quasi-central for $\mathcal{L}(\ell_2)$, i.e., for each separable subset of $X \subset$

$\mathcal{L}(\ell_2)$ there exists a suitable sub-sequence that approximately commutes with the elements of X and has the following properties: If $0 \leq e_n \leq 1$ satisfy $e_n e_m = e_m$ for $1 \leq m < n$ (that implies that each e_n is automatically of finite rank) and $e_n \to 1$ strictly in $\mathcal{M}(\mathbb{K}) \cong \mathcal{L}(\ell_2)$ and $\|[e_n, a]\| + \|[e_n, f(a)]\| \to 0$ for $n \to \infty$, then $\|[a, e_n x e_n]\| \to \|[a, x]\|$ and $\|[f(a), e_n x e_n]\| \to \|[f(a), x]\|$ for $n \to \infty$.

Thus, it suffices to consider self-adjoint contractions $x = x^* \in \mathbb{K}$ of finite rank to determine the value of $F(f, t)$. After this reduction we can modify the approximate unit (e_n) such that in addition $e_n x = x = x e_n$ for all n, and get $[e_n a e_n, x] = e_n [a, x] e_n$ and $\lim_n \|f(e_n a e_n) - f(a e_n^2)\| = 0$, $\lim_n \|f(e_n a e_n) - f(e_n^2 a)\| = 0$, $\lim_n \|f(e_n a e_n) - f(a e_n^2)\| = 0$, $\lim_n \|f(a e_n^2) x - f(a) x\| = 0$ and $\lim_n \|x f(a e_n^2) - x f(a)\| = 0$, but $[f(e_n a e_n), x] = [e_n^2 f(a) e_n^2, x]$ and $\|e_n^2 a^2 e_n^2 - (e_n a e_n)^2\| \to 0$ for $n \to \infty$. We obtain finally the convergences $\|[f(e_n a e_n), x]\| \to \|[f(a), x]\|$ and $\|[e_n a e_n, x]\| \to \|[a, x]\|$. Together with the continuity of $t \mapsto F(f, t)$ this shows that $F(f, t) = \lim_n F_n(f, t)$.

T.A. Loring and F. Vides study in [**541**] among others the special case of $f(t) = t^{1/2}$ and get good reason for the *conjecture* that $G(f, t) = t^{1/2}$ for $f(t) = t^{1/2}$, that was also suggested by G.K. Pedersen in [**619**]. Related results up to a (there not explicitly given) constant can be obtained from results of A.B. Aleksandrov and V.V. Peller, e.g. in [**11, 12**]. An estimate by Pedersen was given in [**619**, cor. 6.3]: If $0 \leq a \leq 1$ and $\|b\| = 1$, then $\|[a, b]\| \leq \varepsilon \leq 1/4$ implies $\|[a^{1/2}, b]\| \leq (1.25)\varepsilon^{1/2}$.

We give explicit estimates in the following Proposition 5.3.1, that are likely not the best possible, but its proof can be obtained easily by elementary observations.

PROPOSITION 5.3.1. *Let H a Hilbert space, and suppose that $\varphi(t)$ a continuous function on $[0, \infty)$ that is operator-monotone in $(0, \infty)$ and satisfies $\varphi(0) \geq 0$.*

For all positive $a, b \in \mathcal{L}(H)$,

$$\|\varphi(b) - \varphi(a)\| \leq \varphi(\|b - a\|) .$$

If $u \in \mathcal{L}(H)$ is unitary and $a \geq 0$, then

$$\| [u, \varphi(a)] \| \leq \varphi(\|[u, a]\|) . \tag{3.1}$$

If $a, x \in \mathcal{L}(H)$ are contractions with $a \geq 0$, then

$$\| [x, \varphi(a)] \| \leq 3\varphi(\| [x, a] \|) . \tag{3.2}$$

In particular, for all $a \geq 0$, every contraction x and each $\beta \in [1, \infty)$,

$$\|[x, a^{1/\beta}]\| \leq 3\|[x, a]\|^{1/\beta} .$$

PROOF. It suffices to consider $a_\varepsilon := (1 - 2\varepsilon)(\varepsilon + a)$ in place of a, because

$$x a_\varepsilon - a_\varepsilon x =: [x, a_\varepsilon] = (1 - 2\varepsilon)[x, a] ,$$

and $\varphi(\|[x, a]\|) = \lim_{\varepsilon \to 0} \varphi(\|[x, a_\varepsilon]\|)$ by continuity of φ on $[0, \infty)$, and it implies $[x, \varphi(a)] = \lim_{\varepsilon \to 0} [x, \varphi(a_\varepsilon)]$ by uniform continuity of φ on bounded subsets of $[0, \infty)$.

Notice that $\mathrm{Spec}(a_\varepsilon) \subseteq [(1-2\varepsilon)\varepsilon, \infty) \subset (0,\infty)$. Therefore we can use the variant of the Löwner theorem given by F. Hansen [**356**, thm. 4.9, rem. 5.3]:

For every positive operator monotone function φ, defined in the positive half-line $(0,\infty)$, there is a unique bounded positive measure μ on the closed interval $[0,1]$ such that for $t \in (0,\infty)$, $\lambda \in [0,1]$ and the functions

$$f_\lambda(t) := (\lambda + (1-\lambda)t)^{-1}t = \big(1 - \big(1 + ((1-\lambda)/\lambda)t\big)^{-1}\big)/\big(1-\lambda\big)$$

holds

$$\varphi(t) = \int_0^1 f_\lambda(t)\,\mathrm{d}\mu(\lambda) \quad \text{for } t > 0\,.$$

Any function given by such a measure is operator monotone, and the measure μ is a probability measure if and only if $\varphi(1) = 1$. The functions $f_\lambda \colon t \mapsto f_\lambda(t)$ are easily seen operator monotone, in particular the f_λ are monotone.

Let $\eta > 0$ and $a, b \in \mathcal{L}(\ell_2)_+$ such that $\eta \le a$ and $\eta \le b$ and let $\gamma := \|b-a\|$. Since f_λ is operator monotone and $b \le a + \gamma$, we get $f_\lambda(b) \le f_\lambda(a+\gamma)$. Moreover f_λ has the property $f_\lambda(t+\gamma) \le f_\lambda(t) + f_\lambda(\gamma)$ for $\gamma > 0$, because the function $x \to x/(1+x)$ is sub-additive for $x \in [0,\infty)$. Thus we get

$$f_\lambda(b) \le f_\lambda(a+\gamma) \le f_\lambda(a) + f_\lambda(\gamma)\,.$$

If we interchange here a and b it implies together that $\|f_\lambda(b) - f_\lambda(a)\| \le f_\lambda(\gamma)$. If we use the above integral representations of $\varphi(a)$ and $\varphi(b)$, we obtain the estimate

$$\|\varphi(b) - \varphi(a)\| \le \int_0^1 f_\lambda(\gamma)\,\mathrm{d}\mu(\lambda) = \varphi(\gamma) = \varphi(\|b-a\|)\,.$$

To get that $\|\varphi(b) - \varphi(a)\| \le \varphi(\|b-a\|)$ for arbitrary positive $a, b \in \mathcal{L}(\ell_2)$, we can consider $\delta + a$ and $\delta + b$ for $\delta > 0$ and then use that φ is uniformly continuous on bounded parts of $[0,\infty)$, e.g. that

$$\lim_{0<\delta\to 0} \|\varphi(a) - \varphi(\delta + a)\| = 0\,.$$

If u is unitary and $a \ge 0$, then $u\varphi(a)u^* = \varphi(uau^*)$ can be seen easily with help of uniform approximation of φ by polynomials on the interval $[0, \|a\|]$. For $b := u^*au$ holds $\|ua - au\| = \|b - a\|$ and $\|u\varphi(a) - \varphi(a)u\| = \|\varphi(b) - \varphi(a)\|$. This implies inequality (3.1).

To find an estimate of $\|[x,\varphi(a)]\|$ for a contraction x and $a \ge 0$ by $\|[x,a]\|$, we can replace a by the positive element $A := \mathrm{diag}(a,a) \in M_2(\mathcal{L}(\ell_2))$ and x by the self-adjoint contraction $X := \mathrm{diag}(x, x^*) \cdot Z \in M_2(\mathcal{L}(\ell_2))$, because then $\|[X,A]\| = \|[x,a]\|$ and $\|[X,\varphi(A)]\| = \|[x,\varphi(a)]\|$ ([8]).

Let $x^* = x$, $b \in \mathcal{L}(\ell_2)$ with $\|x\| < 1$ and $b \ge 0$. The **Cayley transformation** of $x \in \mathcal{L}(\ell_2)$ with $\|x\| < 1$ and $x^*x = xx^*$ is defined as the continuous operator-valued function

$$u(\lambda) := (\lambda + x)(1 + \lambda x^*)^{-1}$$

for $\lambda \in \mathbb{C}$ with $|\lambda| \le 1$, cf. [**616**, p. 4]. Then $u(\lambda)$ is analytic for $|\lambda| < 1$, $u(0) = x$, $u(e^{is})$ is unitary for $s \in [0, 2\pi]$.

[8] Here $Z \in M_2$ has entries $z_{j,k} := 1 - \delta_{j,k}$.

Is this next blue general study useful here?

The general Cayley transformation is given for all $x \in \mathcal{L}(\ell_2)$ with $\|x\| < 1$ and $\lambda \in \mathbb{C}$ with $|\lambda| \le 1$ by

$$u(\lambda) := (1 - xx^*)^{-1/2}(\lambda 1 + x)(1 + \lambda x^*)^{-1}(1 - x^*x)^{1/2}.$$

Then $u(\lambda)$ is unitary for $|\lambda| = 1$ and $x = u(0)$. Moreover $\|u(\lambda)\| < 1$ for all $|\lambda| < 1$ (the latter by maximum modulus principle). See [**222**] or [**402**, ex. 10.5.5].

As in the considerations below, we get for $v_1, v_2 \in \mathcal{H} := \ell_2$ and $\rho(y) := \langle yv_1, v_2\rangle$ that

$$\rho([x,b]) = (2\pi)^{-1} \int_0^{2\pi} \rho([u(e^{is}), b]) \, \mathrm{d}s.$$

??????

Since $2\pi u(0) = \int_0^{2\pi} u(e^{is}) \, \mathrm{d}s$, we get

$$[x,b] = (2\pi)^{-1} \int_0^{2\pi} [u(e^{is}), b] \, \mathrm{d}s.$$

It implies $(2\pi) \cdot \|[x,b]\| \le \int_0^{2\pi} \|[u(e^{is}), b]\| \, \mathrm{d}s$. Hence, $\|[x,b]\| \le \sup_s \|[u(e^{is}), b]\|$.

If we let here $b := \varphi(a)$ then inequality (3.1) implies that

$$\|[x, \varphi(a)]\| \le \sup\{ \varphi(\|[u(e^{is}), a]\|) \,;\; s \in [0, 2\pi] \}.$$

We let $v(\lambda) := (\lambda + x)$ and $w(\lambda) := (1 + \lambda x^*)^{-1} = \sum_{n=0}^{\infty} (\lambda x^*)^n$. Then $u(\lambda) = v(\lambda)w(\lambda)$, and, for all $b \in \mathcal{L}(\ell_2)$, $[b, v(\lambda)] = [b, x]$, $[b, w(\lambda)] = -\lambda w(\lambda)[b, x^*]w(\lambda)$ and

$$[b, u(\lambda)] = [b, x]w(\lambda) + \lambda u(\lambda)[b, x^*]w(\lambda).$$

Since $u(\lambda)$ is unitary if $|\lambda| = 1$ we get for $x = x^*$ the estimate

$$\|[u(e^{is}), b]\| \le 2\|[x, b]\| \|w(e^{is})\|.$$

The inequality $\|e^{is}x^*\| = \|x\| < 1$ implies $\|w(e^{is})\| \le (1 - \|x\|)^{-1}$. Thus,

$$\varphi(\|[u(e^{is}), a]\|) \le \varphi((1 - \|x\|)^{-1} 2\|[x, a]\|),$$

and for all $x^* = x$ with $\|x\| < 1$,

$$\|[x, \varphi(a)]\| \le \varphi((1 - \|x\|)^{-1} 2\|[x, a]\|).$$

Since the latter formula holds for all $x = x^*$ with norm $\|x\| < 1$, we can replace x by $3^{-1}x$ and get by monotony of φ the estimate

$$\|[x, \varphi(a)]\| \le 3\varphi(\|[x, a]\|).$$

□

Compare next blue with above given similar remarks!!

A particular case is the operator monotone function $\varphi(t) := t^{1/2}$, where the estimate shows that $\|[x, a]\|^2 \le 9\|[x, a^2]\|$. It gives that the above defined and discussed continuous function $G(t) := G(\varphi, t) \le 3t^{1/2}$ for $\varphi(t) := t^{1/2}$ – defined as the "minimal" function with $G(\|[a,x]\|) \geq \|[a^{1/2},x]\|$ for contractions $x, a \in \mathcal{L}(\ell_2)$ with $a \geq 0$ – satisfies

$$t^{1/2} \leq G(t) \leq 3t^{1/2}\,.$$

Numerical methods indicate (but do not prove) that in this special case it could be possible to improve the constant 3 down to 1 by other methods, compare [**541**]. This is in accordance with a suggestion of G.K. Pedersen in [**619**].

The following lemma gives for explicit estimates of unconditional strict convergence at least some useful upper bounds (that are perhaps not minimal).

LEMMA 5.3.2. *Let $x, y \in A$ and $a, b \in A_+$ contractions and $\gamma > 0$. Suppose that*

$$\max(\,\|[x,a^2]\|\,,\,\|[x,b^2]\|\,) \leq \gamma \quad \textit{and} \quad \|y - b^2y\| + \|y^* - b^2y^*\| \leq \gamma\,.$$

Then we get the estimates

$$\|[x,(1-b)a]\| \leq 6\gamma^{1/2} \quad \textit{and} \quad \|y - by\| + \|y^* - by^*\| \leq \gamma\,.$$

PROOF. Let $a, b \in A_+$ and $x \in A$ contractions. We get from Proposition 5.3.1 that

$$\max(\,\|[x,a]\|\,,\,\|[x,b]\|\,)^2 \leq 9\max(\|[x,a^2]\|, \|[x,b^2]\|) \leq 9\gamma\,.$$

This implies by $[(1-b)a,x] = (1-b)[a,x] - [b,x]a$ that

$$\|[(1-b)a,x]\| \leq \|[a,x]\| + \|[b,x]\| \leq 3\|[a^2,x]\|^{1/2} + 3\|[b^2,x]\|^{1/2} \leq 6\gamma^{1/2}\,.$$

The estimates for y follows from $e := (1-b)^2 \leq (1-b^2)^2 =: f$ if $0 \leq b \leq 1$, because e.g. $\|y - by\|^2 = \|y^*ey\| \leq \|y^*fy\| = \|y - b^2y\|^2$. □

4. A "tautologic" Weyl–von Neumann type result

We prove a very general "tautologic" version of the classical Weyl–von Neumann theorem: the below stated Proposition 5.4.1.

Applications will be obtained later by verifying in some special cases the validity of assumptions (α) and (β) given in Proposition 5.4.1. The assumptions are sufficient but are not necessary for some derived properties e.g. as in Part (iii) of Proposition 5.4.1. Applications consider cases where the C^*-algebra C does not contain an element h with the property (α) required in Proposition 5.4.1 or is not unital. But often one can build a larger algebra C_1 and a suitable extension T_1 of T that contains an element h that satisfies the required Conditions (α) and (β) with C_1 and T_1 in place of C and T. But this extension, e.g. to an outer unitization is not always possible and needs some care. Here is a warning concerning application in the theory of extension groups $\mathrm{Ext}(\mathcal{C}\,;\,C, B)$: The nontrivial part in those applications – by trying to establish the assumptions of Proposition 5.4.1 – consists in showing that condition (β) still holds also for the *extended* T_1 on the bigger C^*-algebra C_1.

Adjoining a unit to C is only possible if the considered c.p. map T on C satisfies that $\pi_B \circ T$ is "zero-absorbing", i.e., if $\pi_B \cdot T$ "dominates zero" in the more precise sense, as discussed in Chapter 4.

`Does the Elliott-Kucerovsky result follow??` – from the special case where $C = C^*(E, d)$, with $d \in B$ strictly positive, and $\pi_B(E)$ separable, $T(d) = 0$ and $[T] \colon \pi_B(C) \to \mathcal{M}(B)$ has the property that, for each $a \in B_+$, the map $e \in E \mapsto a[T](\pi_B(e))a$ or the map $f \in \pi_B(E) \mapsto a[T](f)a$ is nuclear?

I.e.: When does it satisfy moreover the Condition (β)?? (That we can then apply Prop. 5.4.1 to it.)

PROPOSITION 5.4.1. *Let B a σ-unital C^*-algebra, C a separable C^*-subalgebra of $\mathcal{M}(B)$, and $T \colon C \to \mathcal{M}(B)$ a linear map with $\|T\| \leq 1$ that satisfies the following Conditions (α) and (β):*

- (α) *There exists $h \in C_+$ with $T(h) = 0$ and $h^{1/n}d \to d$ if $n \to \infty$ for every $d \in B$.*
- (β) *For every $a \in B_+$, every finite subset $X \subset C_+$ of contractions, and every $\varepsilon > 0$ there exists $d \in \mathcal{M}(B)$ with $\|d^*cd - aT(c)a\| < \varepsilon$ for $c \in X$.*

Then the contraction $T \colon C \to \mathcal{M}(B)$ with this properties is completely positive and has following properties:

- (i) *There exists a sequence S_n of contractions in $\mathcal{M}(B)$ such that, for all $c \in C$ and $k \in \mathbb{N}$, and, for all $m, n \in \mathbb{N}$,*

$$S_n^* c S_m - \delta_{m,n} T(c) \in B \qquad \textit{and} \qquad \lim_{n \to \infty} \| \delta_{k,0} T(c) - S_n^* c S_{n+k} \| = 0 \,.$$

- (ii) *If B is* stable *then the completely positive contraction $V := \delta_\infty \circ T$ satisfies again Conditions (α) and (β) (with V there in place of T) and there is a norm-continuous map $t \in \mathbb{R}_+ \mapsto S(t) \in \mathcal{M}(B)$ into the contractions of $\mathcal{M}(B)$ such that, for $s, t \in \mathbb{R}_+$, $k \in \mathbb{Z}_+ = \mathbb{N} \cup \{0\}$ and $c \in C$ holds*

$$S(s)^* c\, S(t) - \delta_{s,t} T(c) \in B \quad \textit{and} \quad \lim_{t \to \infty} S(t+k)^* c\, S(t) = \delta_{k,0} \cdot T(c) \,. \qquad (4.1)$$

- (iii) *If in addition to the properties in (ii) T is a C^*-morphism and $T(C)B$ is dense in B, then the monomorphism $\eta_C \colon c \in C \ni c \mapsto c \in \mathcal{M}(B)$ asymptotically absorbs T, i.e., the C^*-morphisms $(\mathrm{id}_C \oplus T) \colon C \to \mathcal{M}(B)$ and η_C are unitarily homotopic in the sense of Definition 5.0.1 modulo B.*
- (iv) *If B is stable, $1_{\mathcal{M}(B)} \in C$ and $T(1) = 1$, or if $\pi_B \circ T$ "dominates zero" in the sense of Definition 4.3.3 ([9]), then the path $t \to S(t)$ in Part (ii) can be modified such that Properties (4.1) still hold, but that $S(t)$ has the additional property that $\pi_B(S(t))$ is an isometry for all $t \in \mathbb{R}_+$.*

  If the operators $\pi_B(S(t))$ are isometries, $\pi_B \circ T$ is a C^*-morphism and $(\pi_B \circ T)(C)' \cap (\mathcal{M}(B)/B)$ contains a copy $C^*(s_1, s_2)$ of $\mathcal{O}_2$ unitally,

[9] Compare also Lemma 4.3.4(i,iv).

then there exists a unitary $U \in \mathcal{M}(B)/B$ *with*

$$U^*\pi_B(c)U \;=\; \pi_B(c) \oplus_{s_1,s_2} \pi_B(T(c)) \quad \textit{for all } c \in C\,.$$

(v) *The contractions* S_n *in Part (i), respectively the* $S(t)$ *in Part (ii), can be chosen as isometries if* $1_{\mathcal{M}(B)} \in C$ *and* T *is unital.*

Collection of remarks:

General remarks:

Check and reorganize the proof !!!

Items have been changed !!!

Condition (α) is satisfied by some $h \in C_+$ with $T(h) = 0$ if $B = R$ for the closed right ideal $R := \{d \in B\,;\ \lim_n h^{1/n}d = d\}$. In particular it suffices to check this for d in a subset of B that generates B as a closed right ideal.

It suffices for Condition (β) to check the existence of $d_a \in \mathcal{M}(B)$ with

$$\|d_a^* c d_a - aT(c)a\| < \varepsilon \quad \text{for each} c \in X_\gamma$$

and for each $a \in B_+$ in an approximate unit for B and a family $\{X_\gamma\}$ of finite subsets $X_\gamma \subset B_+$ that have the property that the linear spans $L(X_\gamma)$ build an upward directed net of linear subspaces of B with $\bigcup_\gamma L(X_\gamma)$ dense in B. This implies then that T is a point-wise approximately inner completely positive map.

Are there weaker formulation of Condition (β) possible? e.g. :

(New β): For every $a \in B_+$, every pair of positive contractions $c_1, c_2 \in C_+$ and every $\varepsilon > 0$ there exists $d \in \mathcal{M}(B)$, – depending on $(a, c_1, c_2, \varepsilon)$ – with

$$\|d^* c_j d - aT(c_j)a\| < \varepsilon \quad \text{for } j \in \{1, 2\}$$

We can replace the element $d \in \mathcal{M}(B)$ in Condition (New β) or in Condition (β) by some $d \in B$, because $aT(c)a \in B$ for $a \in B_+$, $de_\lambda \in B$ and

$$\lim_\lambda \|aT(c)a \;-\; e_\lambda aT(c)ae_\lambda\| = 0$$

for any quasi-central approximate unit $\{e_\lambda\} \subseteq B_+$ of B ([10]).

Now we use Condition (α) and the positivity of T. They imply the following:

For any $\varphi, \psi \in \mathrm{C}_0(0,1]$ and each $c \in C$ we have that

$$T((1-\varphi(h))c(1-\psi(h))) = T(c),$$

i.e., $T(\varphi(h)c) = 0$ for all $c \in C$ and $\varphi \in \mathrm{C}_0(0,1]$.

For any finite subset $X \subseteq C_+$, $\varepsilon > 0$ and contraction $\varphi \in \mathrm{C}_0(0,1]_+$ there exists for each $x \in X$ an element $d_x \in B$ with $\|d_x^*(1-\varphi(h))x(1-\varphi(h))d_x - aT(x)a\| \,<\, \varepsilon\,.$

Since $\overline{hBh} = B$ by Condition (α), it implies that we can find a sequence of mutually orthogonal positive contractions $e_n \in C*(h)_+ \subseteq C \subset \mathcal{M}(B)$ such that,

[10] Quasi-central approximate units of B exist in B_+ for every C^*-algebra B.

for each $a \in B_+$ and $x \in C_+$, there exists a sequence of elements $d_k \in B$ and numbers $n_k \in \mathbb{N}$ such that

$$\|d_k^* e_{n_k} x e_{n_k} d_k - aT(x)a\| < 2^{-k} .$$

Unfortunately this seems only to work for each single element of finite subsets $X \subset C_+$.

Condition (α) implies that there exists a contraction $h \in C_+ \subseteq \mathcal{M}(B)$ with the property that for any given ??????

Question:

Is it enough to require in place of (β) for every $a \in B_+$, every pair contraction $c_1, c_2 \in C_+$ and every $\varepsilon > 0$ there exists $d \in \mathcal{M}(B)$ with $\|d^* c_k d - aT(c_k)a\| < \varepsilon$?

Could it be that Condition (α) allows to use a kind of an approximate induction procedure:

Suppose we have verified (β) for all finite subsets $X \subset C_+$ with cardinality $\leq n$ (with fixed $n \geq 2$) and all $\varepsilon > 0$. Is it possible to derive then that (β) also holds for X with cardinality $\leq n+1$.

CONCERNING PASSAGE TO THE STABLE CASE:

We show first that the conditions (α) and (β) on a linear map $T : C \to \mathcal{M}(B)$ of norm $\|T\| \leq 1$ imply that T is completely positive (and $T = 0$ is possible).

Then each of the maps

$$T_1 : C \otimes 1 \ni c \otimes 1 \mapsto T(c) \otimes 1 \in \mathcal{M}(B \otimes \mathbb{K})$$

– where here 1 means the unit element $1_{\mathcal{M}(\mathbb{K})}$ of $\mathcal{M}(\mathbb{K})$ –, and

$$T_2 : C \otimes \mathbb{K} \ni c \mapsto (T \otimes \mathrm{id}_{\mathbb{K}})(c) \in \mathcal{M}(B) \otimes \mathbb{K} \subseteq \mathcal{M}(B \otimes \mathbb{K})$$

satisfy again the Condition (α) with $h \otimes 1 \in C \otimes 1$ for T_1 and for T_2 e.g. with $h \otimes q$ in place of h, where $q := \sum_n n^{-2} p_{nn}$.

Notice that T_1 is unitary equivalent to its infinite repeat, but T_2 is usually not, but the quotient C^*-morphism $\pi_{B\otimes\mathbb{K}} \circ T_2 : C \otimes \mathbb{K} \to \mathrm{Q}^{\mathrm{s}}(B)$ dominates zero (in sense of Definition 4.3.3).

The elements $a \in (B \otimes \mathbb{K})_+$ can be approximated in norm by elements in $(b_0 \otimes q)(B \otimes \mathbb{K})_+(b_0 \otimes q)$ with a strictly positive element $b_0 \in B_+$.

In case of $T_2 : C \otimes \mathbb{K} \to \mathcal{M}(B \otimes \mathbb{K})$ it is enough to consider finite sets $X \subset C \otimes \mathbb{K}$ containing only tensors $c \otimes p$ with $c \in C_+$ and $p \in \mathbb{K}$ a projection.

It follows that it suffices to check the Condition (β) for completely positive maps T_1 or T_2 (in place of T) only on those finite subsets $X \subseteq (C \otimes 1)_+$ that contain finitely many elements $c \otimes 1$ with $c \in C_+$ in case of T_1, and those finite subsets $X \subseteq (C \otimes \mathbb{K})_+$ that contain only elements $c \otimes p$ with $c \in C_+$ and $p \in \mathbb{K}$ in case of T_2 .

????? the elements $(b_0 \otimes q)^{1/n}$ in place of the required arbitrary elements $a \in (B \otimes \mathbb{K})_+$ in the test criterium for Condition (β).

The linear span of the elements $c \otimes p$ with $c \in C_+$ and $p \in \mathbb{K}$ a rank-one projection in $\mathbb{K}$ is dense in $X \subseteq (B \otimes \mathbb{K})_+$.

For every $a \in B_+$, every finite subset $X \subset C_+$ of contractions and every $\varepsilon > 0$ there exists $d \in \mathcal{M}(B)$ with $\|d^*cd - aT(c)a\| < \varepsilon$ for $c \in X$.

$h \otimes (\sum_n n^{-2} p_{nn}) \in B \otimes \mathbb{K}$

in place of B,

??? map from $T \otimes \mathrm{id}_{\mathbb{K}}$ also the properties (α) and (β) for $B \otimes \mathbb{K}$ in place of B with $h \otimes (\sum_n n^{-2} p_{nn})$ in place of h and $d \otimes 1$ in place of d?

If we can shown that $\|T \otimes \mathrm{id}_{\mathbb{K}}\| \leq 1$, then it suffices to consider stable B.

We have anyway $\|T \otimes 1_{\mathcal{M}(\mathbb{K})}\| \leq 1$, because $\|c \otimes 1\| = \|c\|$.

Desire / hope more:

Ad(i): $S_k^* S_\ell = 0$?? Perhaps at least sufficient that only $S_k^* S_\ell \in B$ for $k \neq \ell$?

The strong hope is that (moreover) $S_1, S_2, \ldots$ can be found such that:

$S_j^* S_k = 0$ for $j \neq k$

Or at least: $S_j^* S_k \in B$ and $\lim_n S_{n+k}^* S_n = 0$ for $j \neq k$, $k \geq 1$. ??

Could be related to extendability to unital case $\tilde{T}$??

Reality check to (i):

Contractions $S_1, S_2, \ldots$.

$S_j^* c S_k \in B$ for all $c \in C$ (Suffices: $S_j^* c S_k - \delta_{jk} T(c) \in B$ For each $c \in L_m$ and $m \in \mathbb{N}$.

For each $m \in \mathbb{N}$ and $\varepsilon > 0$ there exist $n := n(m, \varepsilon)$ such that $\|S_j^c S_k\| \leq \varepsilon \|c\|$ for all $j, k \geq n$ and $c \in L_m$.

and, for all $c \in C$ and $n, m \in \mathbb{N}$,

$$S_n^* c S_m - \delta_{n,m} T(c) \in B \qquad \text{and} \qquad \lim_{n \to \infty} \|\delta_{k,0} \cdot T(c) - S_{n+k}^* c S_n\| = 0\,.$$

In the special case where $S_n^* S_{n+1} = 0$, let $\alpha(t) := t - n + 1$ for $t \in [n-1, n]$ and

$$S(t) := \alpha(t) S_{n+1} + (1 - \alpha(t)^2)^{1/2} S_n\,.$$

Calc: $S(t)^* S(t) = \alpha^2 S_n^* S_n + (1 - \alpha^2) S_{n+1}^* S_{n+1} + 0$ if $S_n^* S_{n+1} = 0$.

If $S_{n+1}^* c S_n \in B$ and $\|S_{n+1}^* c S_n\| \leq 2^{-(n+1)} \|c\|$ and $\|S_n^* c S_n - T(c)\| \leq 2^{-n} \|c\|$ and $\|S_{n+1}^* c S_{n+1} - T(c)\| \leq 2^{-(n+1)} \|c\|$ for $c \in L_n$, then we get:

$S(t)^* c S(t) = \alpha^2 S_n^* c S_n + (1 - \alpha^2) S_{n+1}^* c S_{n+1} + \alpha(1 - \alpha^2)^{1/2} S_n^* c S_{n+1} + \alpha(1 - \alpha^2)^{1/2} S_{n+1}^* c S_n$

It has estimates $\|S(t)^* c S(t) - T(c)\| \leq \|c\| \cdot \big(\alpha^2 2^{-n} + (1 - \alpha^2) 2^{-(n+1)} + \alpha(1 - \alpha^2)^{1/2} 2^{-n}\big) \leq 2^{-n}$

The map $t \in \mathbb{R}_+ \mapsto S(t)$ is norm-continuous path in the contractions in $\mathcal{M}(B)$ and satisfies for $s, t \in \mathbb{R}_+$ and $c \in C$,

$$S(s)^* c S(t) - \delta_{s,t} T(c) \in B \qquad \text{and} \qquad \lim_{t\to\infty} \|\delta_{s,0} T(c) - S(t+s)^* c S(t)\| = 0.$$

Indeed: Let $s \in [m-1, m]$ and $t \in [n-1, n]$, $\beta := s - m + 1$, $\alpha := t - n + 1$, $S(s) = \beta S_m + (1 - \beta^{1/2})^{1/2} S_{m+1}$, $S(t) := \alpha S_n + (1-\alpha^2)^{1/2} S_{n+1}$. If $c \in \mathcal{M}(B)$, then $S(s)^* c S(t) = \alpha\beta S_m^* c S_n + \alpha(1-\beta^{1/2})^{1/2} S_{m+1}^* c S_n +$

$(1-\alpha^2)^{1/2} \beta S_m^* c S_{n+1} + (1-\alpha^2)^{1/2}(1-\beta^{1/2})^{1/2} S_{m+1}^* c S_n$.

To (ii): requires to distinguish the unital, non-unital, or stable case ??

It seems that second part of (ii) is not so different to the case of NON-STABLE B. Compare all with Part (iv) !!!

Ad (iii): ''$\pi_B \circ T$ is a C*-morphism'' enough?? The unital, non-unital, or stable can give different results??

Addition in (iii) requires that $\pi_B(S_n)$ resp. $\pi_B(S(t))$ is an isometry and that $\mathcal{O}_2$ is unitally contained in $\pi_B(T(C))' \cap \mathrm{Q}(B)$.

General remark to proof: Notice that for a verification of assumption (β) it suffices to consider only positive contractions $a := a_m$ in a given approximate unit $(a_m)_{m\in\mathbb{N}}$ of B.

Proof. The following are elementary consequences of assumptions (α) and (β): If $Y = \{y_1, \ldots, y_n\} \subset C$ is any finite subset of contractions in C, then we can pass to the finite set $X := \{x_{1,1}, \ldots, x_{1,4}, \ldots, x_{n,1}, \ldots, x_{n,4}\}$ of the at most $4n$ positive contractions $x_{k,1}$, $x_{k,2}$, $x_{k,3}$, $x_{k,4}$, given by the polar decompositions $x_{k,1} - x_{k,2} = 2^{-1}(y_k^* + y_k)$ and $x_{k,3} - x_{k,4} = i2^{-1}(y_k^* - y_k)$ of the real and imaginary parts of the $y_k \in Y$. An application of Condition (β) to X gives that there is $d \in \mathcal{M}(B)$ with $\|d^* y_k d - aT(y_k)a\| < 4\varepsilon$ for $k = 1, \ldots, n$.

If we apply this observation to the set $Y := \{c_{1,1}, c_{1,2}, \ldots, c_{nn}\}$ of entries $c_{j,k}$ of a positive contraction $[c_{j,k}] \in M_n(C)_+$ and take $a \in \{e_m\}$ for an approximate unit $e_m \in B_+$ of B, then we can see – with help of Condition (β) with $\varepsilon/(4n^2)$ in place of ε –, that there exists $d_m \in \mathcal{M}(B)$ for each $a := e_m$ and $\varepsilon := 1/m$ such that in $M_n(B)$ holds

$$\| (d_m \otimes 1_n)^* [c_{j,k}]_{n,n} (d_m \otimes 1_n) - (e_m \otimes 1_n)[T(c_{j,k})]_{n,n}(e_m \otimes 1) \| < m^{-1} .$$

In particular, the matrix $[T(c_{j,k})]$ is positive in $M_n(\mathcal{M}(B))$ for each positive matrix $[c_{j,k}] \in M_n(C)_+$, i.e., we get that *the map* $T\colon C \to \mathcal{M}(B)$ *is a completely positive contraction.*

Therefore, we can tensor it with $\mathrm{id}_{\mathbb{K}}$ and get a c.p. contraction $T_s := T \otimes \mathrm{id}_{\mathbb{K}}$ from $C \otimes \mathbb{K}$ into $\mathcal{M}(B) \otimes \mathbb{K} \subseteq \mathcal{M}(B \otimes \mathbb{K})$. Let $e := \sum 2^{-n} p_{nn} \in \mathbb{K}$.

The c.p. contraction $T_s \colon C \otimes \mathbb{K} \to \mathcal{M}(B \otimes \mathbb{K})$ satisfies again the conditions (α) and (β) with $C \otimes \mathbb{K}$, $B \otimes \mathbb{K}$ and $h \otimes e$ in places of C, B and h, but now with the estimate

$$\|T_s(c) - (d \otimes e^{1/n})^* c(d \otimes e^{1/n})\| < \varepsilon ,$$

where d comes from condition (β) for suitably chosen $n \in \mathbb{N}$.

It is clear that $T_s(h \otimes e) = 0$ and $\lim (h \otimes e)^{1/n} c = c$ for each $c \in B \otimes \mathbb{K}$.

We can replace the d in Condition (β) by $da^\gamma \in B$ for sufficiently small $\gamma > 0$. Thus, the element $d \in \mathcal{M}(B)$ in the inequality of Condition (β) for a given finite set $X \subset C_{s.a.}$ of selfadjoint contractions $x = x_+ - x_-$ in C and $a \in B_+$ can be always chosen such that $d \in B$.

It follows for fixed $a \in B_+$ that the c.p. map $c \in C \mapsto aT(c)a \in B$ is "approximately 1-step inner" in the strict topology of $\mathcal{M}(B)$ as a map from $C \subseteq \mathcal{M}(B)$ into B by assumption (β), and we can apply Lemma 3.1.8 by Remark 3.1.7 to this approximately 1-step inner map. It gives an element $d \in B$ that satisfies condition (β) with norm $\|d\| \leq \|a\|$, because the c.p. map $c \in C \mapsto aT(c)a \in B$ has norm $\|a\|^2 \|T\| \leq \|a\|^2$.

If $b \in B$ is not positive, then $a := (bb^*)^{1/4}$, $b_0 := a^{-1}b := \lim_n (bb^* + 1/n)^{-1/4} b$ with norms $\|a\| = \|b\|^{1/2} = \|b_0\|$ and there exists $d_0 \in B$, depending on a, X and $\varepsilon > 0$, with $\|d_0\| \leq \|a\|$ and $\|d_0^* x d_0 - aT(x)a\| < \gamma := \varepsilon/(1 + \|b\|^{1/2})$ for $x \in X$. Thus $d := d_0 b_0$ satisfies $\|d^* x d - b^* T(x) b\| \leq \|b\|^{1/2}\gamma \leq \varepsilon$ and $\|d\| \leq \|b\|$.

Hence, we can use in the following also the c.p. maps $b^* T(\cdot) b$ with non-selfadjoint $b \in B$ in place of $aT(\cdot)a$ in Condition (β), and find the element $d \in B$ with $\| d^* c\, d - b^* T(c) b \| < \varepsilon$ for $c \in X$ with $\|d\| \leq \|b\|$ and $d \in B \cdot b$.

Now we bring Condition (α) into play:
If $\varphi \in \mathrm{C}_0(0,1]_+$ is any non-negative continuous function with $\varphi(0) = 0$ and $\|\varphi\| \leq 1$, then we can find moreover an element $d \in B$ depending on X, $b \in B$, φ and ε, such that $\|d\| \leq \|b\|$ and

$$\| d^*(1 - \varphi(h)) x (1 - \varphi(h)) d - b^* T(x) b \| < \varepsilon \quad \text{for all } x \in X . \tag{4.2}$$

This holds because the assumption $T(h) = 0$ from Condition (α) and the positivity of T imply $T(c\varphi(h)) = 0$ for $c \in C$ and $\varphi \in \mathrm{C}_0(0,1]$, which gives that

$$T((1 - \varphi(h)) c (1 - \varphi(h))) = T(c) \quad \text{for all } c \in C . \tag{4.3}$$

To get the requested element d from Condition (β) – with a replaced by our non-selfadjoint b (as discussed above) –, we replace $X = \{x_1, \ldots, x_n\}$ by

$$gXg := \{ g x_1 g, \ldots, g x_n g \} ,$$

where we let $g := 1 - \varphi(h)$, and use Equation (4.3). We find some $d \in B$ depending on X, b and ε, with $\|d\| \leq \|b\|$ such that d solves the Inequality (β) for gXg and b in place of X and a, i.e., d solves the Inequality (4.2).

We can go one step further and consider the specific elements $h_n := \psi_n(h)$ for increasing pice-wise linear functions $\psi_n \in \mathrm{C}_c(0,1]$, as e.g. defined by

$$h_n := \psi_n(h) \quad \text{for} \quad \psi_n(t) := \min(1, \max(0, 2^n t - 1))\,. \tag{4.4}$$

Notice that the positive contractions $h_{n+1}h_n = h_n$ for all $n \in \mathbb{N}$. Above considerations show that we can use in place of the before considered general $\varphi(h)$ any of the h_n.

This allows to choose another solutions $d \in B$ of the inequality in assumption (β) in the following manner:
Let $n_0 \in \mathbb{N}$, and X a finite set of selfadjoint contractions $x^* = x \in C$, an element $b \in B$ and $\varepsilon > 0$. Moreover we suppose that there is given an element $f \in B$ and let $\delta \in (0, \varepsilon)$, e.g. let $\delta := \varepsilon/(2 + 2\|b\|)$. Condition ($\alpha$) implies that

$$\lim_n h_n b = \lim_n h^{1/n} b = b \quad \text{for all} \quad b \in B\,. \tag{4.5}$$

It implies that the decreasing sequence $\{(1 - h_m)^2\}$ converges strictly to zero in $\mathcal{M}(B)$. Thus, there is a number $m_1 := m(f, \delta) > n_0$ with $\|f - h_m f\| < \delta$ and $\|xf - h_m xf\| < \delta$ for each $m \geq m_1$ and $x \in X$.

We can replace for $m > m_1 > n_0$ the finite set X of selfadjoint contractions by the set $(1 - h_m)X(1 - h_m)$ and apply Equation $T((1 - h_m)c(1 - h_m)) = T(c)$ for $c \in C$ – coming from Equation (4.3) – and find $d \in B$ with $\|d\| \leq \|b\|$ such that for $x \in X$ and $\varepsilon > 0$ holds

$$\| \, d^*(1 - h_m)x(1 - h_m)d \, - \, b^*T(x)b \, \| \, < \, \varepsilon/2\,. \tag{4.6}$$

The new element $d \in B$ depends from X, b, $m \in \mathbb{N}$ and ε. Moreover our choice of $m \in \mathbb{N}$ ensures that $\|d^*(1 - h_m)xf\| < \delta\|b\|$ for $x \in X$ and $\|d^*(1 - h_m)f\| < \delta\|b\|$.

Let $\delta \in (0, \varepsilon/(4 + 4\|d\|))$ and let $f \in B$. The elements $(1 - h_m)d$ and xf are in B. Therefore we find by Equation (4.5) a number $n \in \mathbb{N}$ such that $n > m + 2$, $\| \, h_n(1 - h_m)d - (1 - h_m)d \, \| \, < \, \delta$ and $\| \, h_n xf - xf \, \| \, < \, \delta$ for $x \in X$.

Then element $d_0 := h_n(1 - h_m)d$ satisfies $\|d_0\| \leq \|d\| \leq \|b\|$, and for $x \in X$,

$$\| \, d_0^* x d_0 - d^*(1 - h_m)x(1 - h_m)d \, \| \leq \, 2\delta\|b\| < \varepsilon/2$$

and

$$\|d_0^* xf - d^*(1 - h_m)xf\| \leq \|b\| \cdot \|h_n(1 - h_m)xf - (1 - h_m)xf\| \leq \delta\|b\| < \varepsilon/2\,.$$

It implies that h_n, h_m, $d, b \in B$ and all $x \in X$ satisfy following inequalities

$$\| \, (h_n(1 - h_m)d)^* x (h_n(1 - h_m)d) \quad - \quad b^*T(x)b \, \| \, < \, \varepsilon\,, \tag{4.7}$$

$$\|(h_n(1 - h_m)d)^* xf\| \quad < \quad \varepsilon/2\,. \tag{4.8}$$

and $\|(h_n(1 - h_m)d)^* xf\| \, \leq \, \|d\| \cdot \|xf - h_m xf\| \, < \varepsilon/2$ for $x \in X$.

This describes the idea for an induction procedure if $b_1, b_2, \ldots \in B$, a zero-sequence $\varepsilon_1 > \varepsilon_2 > \cdots > 0$ (or finite sequence) and an increasing sequence of finite subsets $X_1 \subseteq X_2 \subseteq \cdots$ of the selfadjoint contractions in C are given.

To explain in more detail the proposed induction procedure that is indicated by the above observations, we rename above considered $b, f \in B$, $X \subseteq C$, $\varepsilon > 0$, and the from them defined $d \in B$, $m < n \in \mathbb{N}$ by b_1, f_1, X_1, ε_1, d_1, $m_1 + 2 < n_1$.

The f_1, i.e., in the above side condition involving f, was an "additional" information, e.g. we can put $f_1 := f := 0$ for $n := 1$. In the induction step (from $k-1$ to k) it will be *defined* below more generally by

$$f_k := \big(\sum_{j=1}^{k-1}(h_{n_j}(1-h_{m_j})d_j)(h_{n_j}(1-h_{m_j})d_j)^*\big)^{1/2}\,. \tag{4.9}$$

Let $X_1 \subseteq X_2 \subset C$ finite sets of contractions, $b_2 \in B$ an arbitrary element and $\varepsilon_2 \in (0, \varepsilon_1)$ given. Take from the former step d_1 and $n_1 > m_1 + 2$ in $\mathbb{N}$. Define $f_2 := \big(h_{n_1}(1-h_{m_1})d_1 d_1^*(1-h_{m_1})h_{n_1}\big)^{1/2}$ and find $m_2 > n_1 + 2$ such that

$$\|h_{m_2} x f_2 - x f_2\| < \varepsilon_2/2$$

for all $x \in X_2$. Notice that automatically $h_{m_2} f_2 = f_2$ because $h_{m_2} h_{n_1} = h_{n_1}$.

We find $d_2 \in B$ with $\|d_2\| \leq \|b_2\|$ such that, for $x \in X_2$,

$$\|\, d_2^*(1-h_{m_2})x(1-h_{m_2})d_2 \;-\; b_2^* T(x) b_2 \,\| \;<\; \varepsilon_2\,.$$

Let $\delta_2 := \varepsilon_2/(2+2\|b_2\|)$. After we have selected d_2 we apply the above consideration and find a suitable number $n_2 > m_2 + 1$ such that, for $x \in X_2$,

$$\|\, h_{n_2}(1-h_{m_2})d_2 - (1-h_{m_2})d_2 \,\| \;<\; \delta_2 \quad\text{and}\quad \|\, h_{n_2} x f_2 - x f_2 \,\| \;<\; \delta_2\,.$$

From now on we use the new notation $h[m,n] := h_n(1-h_m) = h_n - h_m$ for $m < n$ that avoids iterated indices and seems to be more transparent ([11]). The $h[n,m]$ are positive contractions that satisfy the identities $h[\ell,p]^\alpha h[m,n] = h[m,n]$, $h[m,n]h[p,q] = 0$, and $h[m,n] + h[n,p] = h[m,p]$ for $\alpha \in (0,1]$ and $\ell, m, n, p \in \mathbb{N}$ with $\ell < m < n < p < q$. Then we get for $x \in X_2$ and $h[m_2,n_2] = h_{n_2}(1-h_{m_2})$ that

$$\|\, (h[m_2,n_2]d_2)^* x (h[m_2,n_2]d_2) \;-\; b_2^* T(x) b_2 \,\| \;<\; \varepsilon_2\,,$$

$(h[m_2,n_2]d_2)^*(h[m_1,n_1]d_1) = 0$ by $m_2 > n_1$, and

$$\|\, (h[m_2,n_2]d_2)^* x f_2 \,\| \;<\; \varepsilon_2\,.$$

If we repeat this arguments for given contractions $b_1, b_2, \ldots, b_k, \ldots \in B$, selfadjoint contractions $c_1 := 1, c_2 = h, c_3, \ldots, c_k, \ldots \in C_+$ and a given decreasing zero sequence $\varepsilon_1 > \varepsilon_2 > \cdots > 0$, then we obtain by the above described method for each $k \in \mathbb{N}$ and $X_k := \{c_1, \ldots, c_k\}$, suitable positive integers with $\ell_1 := 1$, $\ell_k < m_k < n_k < \ell_{k+1}$ (with $\ell_1 := 1$ and element $d_k \in B$ with $\|d_k\| \leq \|b_k\|$ that satisfy the general Inequalities:

$$\|\, (h[m_k,n_k]d_k)^* x (h[m_k,n_k]d_k) \;-\; b_k^* T(x) b_k \,\| \;<\; \varepsilon_k \quad \text{for all } x \in X_k\,. \tag{4.10}$$

and $\|(h[m_k,n_k]d_k)^* x (h[m_{j-1},n_{j-1}]d_{j-1})\| < \varepsilon_k$ for $x \in X_k$ and $1 \leq j < k$.

[11] Observe here and in some later proofs that the expressions $[m,n]$ denote pairs of indices and *not* any sort of commutators!

What happens with $j = k-1$??? Perhaps we have to replace in Equation (4.10) $(h[m_k, n_k]d_k)^* x(h[m_k, n_k]d_k) - b_k^* T(x) b_k$ simply by $(h[m_k, n_k]d_k)^* x(h[m_j, n_j]d_j) - \delta_{jk} \cdot b_k^* T(x) b_k$ for $1 \leq j \leq k$

The latter inequalities follow from $\| (h[m_k, n_k]d_k)^* \, x \, f_n \| < \varepsilon_k$ for f_n as defined in Equation (4.9). We have automatically $(h[m_k, n_k]d_k)^*(h[m_j, n_j]d_j) = 0$ for $j = 1, \ldots, k-1$ by $h[m_k, n_k]h[m_j, n_j] = 0$ for $j < k$. This can be sees also from the equations $h[m_k, n_k]h[\ell_k, \ell_{k+1}] = h[m_k, n_k]$, for the suitable chosen sequence $1 := \ell_0 < \ell_1 < \ell_2 < \ldots$ in $\mathbb{N}$ with $\ell_k < m_k < n_k < \ell_{k+1}$. Such a sequence exists because we have chosen $m_{k+1} > 1 + n_k$.

In particular, for a given finite set $X \subseteq C$ of selfadjoint contractions in C, and given elements $b_1, b_2, \ldots, b_k \in B$ and $\varepsilon > 0$, we find elements $d_1, \ldots, d_k \in B$ with $\|d_j\| \leq \|b_j\|$ that satisfy

$$\|d_i^* x d_j - \delta_{i,j} b_i^* T(x) b_j\| < \varepsilon$$

for $1 \leq i, j \leq k$ and $x \in X$, i.e., we get the following observation:

Observation (1):
Given contractions $b_1, \ldots, b_n$ and $X \subset C$ a finite subset of the selfadjoint contractions, then, for every $\varepsilon > 0$, there exists contractions $d_1, \ldots, d_n \in B$ such that $d_j^* d_k = 0$ for $j < k$ and

$$\| \, d_j^* x d_k \, - \, \delta_{j,k} b_k^* T(x) b_k \, \| \, < \, \varepsilon / n^2 \quad \text{for } k, j = 1, \ldots, n, \text{ and } x \in X \, . \tag{4.11}$$

The Inequality (4.11) implies the approximate 1-step innerness of the c.p. map $\sum_{k=1}^n b_k^* T(\cdot) b_k :=$ `NAME? S ????????` with respect to the strict topology on $\mathcal{M}(B)$, i.e., the element $d := d_1 + d_2 + \cdots + d_n \in B$ and all $x \in X$ satisfy the Inequality

$$\| \, d^* x d \, - \, \sum_{k=1}^{n} b_k^* \, T(x) \, b_k \, \| \, < \, \varepsilon \, . \tag{4.12}$$

Proof of Part(i):

We are going to choose the following objects μ, X_n, f_k and S_n to make the rest of the proof transparent and almost "constructive" – in a certain sense:

(A) A bijection μ form $\mathbb{N} \times \mathbb{N}$ onto $\mathbb{N}$ such that

$$\mu((k,1)) \, = \, \min \mu(\{k\} \times \mathbb{N}) \, < \, \mu((n,1))$$

for $k < n$ in $\mathbb{N}$. It can be used to define a (disjoint) decomposition $\bigcup_k M_k$ of $\mathbb{N}$ given by bijective and *order preserving* maps $\nu_k \colon \mathbb{N} \to \mathbb{N}$ with $k \leq \nu_k(1) < \nu_n(1)$ for $k < n$ in $\mathbb{N}$. Here $M_k = \nu_k(\mathbb{N}) = \mu(\{k\} \times \mathbb{N})$. We have $\nu_1(n) = n$ for all $n < \nu_2(1) = \min M_2$, $\nu_1(n) > n$ for $n \geq \nu_2(1)$, and $\nu_k(1) > k$ for all $k > 1$. It follows that $\nu_k(n) \geq k + n$ for $k > 1$, $n \in \mathbb{N}$ and $\nu_1(n) \geq n + 1$ for $n \in \mathbb{N}$.

(B) Filtration X_n of C and quasi-central approximate unit (e_n) for $V(X_n)$ defined from strictly positive contraction $e \in B_+$.

(C) By induction:
Find solutions m_k, n_k, d_k, and the such defined elements $h[m_k, n_k]d_k =: g_k$ of (4.10) for $b_k := e_k^{1/2}$, with $\varepsilon_k := 4^{-n}$ and from them f_k defined by Equation (4.9).

(D) The S_n are then (suitable) Γ-sums for the in (A) defined maps $\nu_n \colon \mathbb{N} \to \mathbb{N}$,

$$S_n := \Gamma_n(g_{\nu_k(1)} \, , g_{\nu_k(2)} \, , \ldots) \, ,$$

with $\Gamma_n(\cdot)$ defined by the $x^{(n)}$ and $y^{(n)}$ as where x_n and y_n have the components

components ?????????????

We use the above considerations concerning the inductive solutions of the Inequalities (4.10) and Part (3) of Remarks 5.1.1 to define a filtration of C given by linear spans $L_n := \mathrm{span}(X_n)$ with $X_n := \{c_1, \ldots, c_{k_n}\}$, defined from a sequence of selfadjoint contractions $c_1, c_2, \ldots \in C$ that is dense in the unit ball of the self-adjoint part $C_{s.a.}$ of C.

Let $e \in B_+$ a strictly positive contraction. We find a sequence of functions $f_n \in \mathrm{C}_0((0,1])_+$ such that $e_n := f_n(e)$ build an approximate unit of B that is quasi-central with respect to finite subsets $X_n \cup T(X_n)$ of $\mathcal{M}(B)$. See Part (3) of Remarks 5.1.1 for more details. We take the there defined adjustment of the sequence e_n, – in particular in relation to $T(X_n)$ – such that, for each (contraction) $x \in X_n$ and $m > n$,

$$\| \, [e_n, T(x)] \, \| \; + \; \| [(e_m - e_n)^{1/2}, T(x)] \, \| \; < \; 4^{-n} \, .$$

It follows for infinite subsets $M_1, M_2 \subseteq \mathbb{N}$ with $\min M_1 < \min M_2$ and order preserving bijective maps λ_j from $\mathbb{N}$ onto M_j, $\lambda_j \colon \mathbb{N} \to M_j$, that

`NEXT give good estimate:`

$$\|\Gamma_{j,k}(T(x), T(x), \ldots) - \delta_{j,k} T(x)\| \leq ?????$$

and $\Gamma_{j,k}(T(x), T(x), \ldots) - \delta_{j,k} T(x) \in B$ for $x \in X_n$ and $j,k \in \{1,2\}$. Here $\Gamma_{j,k}(a_1, a_2, \ldots)$ for $j,k \in \{1,2\}$ is defined as in Remark 5.1.1(2) with $y_1 := e^{1/2}_{\lambda_j(1)}$, $y_{n+1} := (e_{\lambda_j}(n+1) - e_{\lambda_j}(n))^{1/2}$ $x_1 := e^{1/2}_{\lambda_k(1)}$, and $x_{n+1} := (e_{\lambda_k}(n+1) - e_{\lambda_k}(n))^{1/2}$.

We define by induction successive elements

$$g_1 := h[m_1, n_1]d_1 \, , \;\; g_2 := h[m_2, n_2]d_2 \, , \;\; \ldots \in B$$

and a sequence $p_1 < p_2 < \ldots$ in $\mathbb{N}$ with $p_k + 1 < m_k$, $m_k + 1 < n_k$, $n_k + 1 < p_k$ such that

$$\|g_k^* x g_\ell \; - \; \delta_{k,\ell} e_k^{1/2} T(x) e_k^{1/2}\| \leq ???$$

for $x \in X_k$, $\ell \leq k$, and that $p_k ???? g_k = g_k$.

Let $M \subseteq \mathbb{N}$ an infinite subset, and let $\lambda \colon \mathbb{N} \to M$ the unique bijective order-preserving map from $\mathbb{N}$ onto M, as described in Part (i,A).

allow to make the following observations (?0.1) - (?0.4):

????

such that corresponding $\varphi_{k_n}(h)(1 - \varphi_{\ell_n}(h))d_n$

with $n_k > 2 + m_k$, next $m_{k+1} > 2 + n + k$????

can be used in place of d_n for

$$\|d_m^* x d_n - \delta_{n,m} g_n(e) T(x) g_n(e)\| < 2^{-\max m,n} \|x\| .$$

NEXT:

The sequences (φ_n) and $h_1, h_2, \ldots$ can be defined by Equation (**??**).

(1.) $h_1, h_2, \ldots \in C^*(h)_+ \subseteq C$.

" suitably " (TO BE MADE PRECISE!!)

positive contractions with $h_{n+1} h_n = h_n$, $h_n \to 1_{\mathcal{M}(B)}$ strictly, using that hB is dense in B by condition (α).

`Define a nice sequence of` φ_n.
`Such that` $h[m_k, n_k] d_k$ `with` $n_k > 2 + m_k$, `next` $m_{k+1} > 2 + n + k$
`can be used in place of` d_n `for`
$\|d_n^* x d_n - g_n(e) T(x) g_n(e)\| < 2^{-n} \|x\|$

(2.) $f_n \in C^*(e)_+ \subseteq B$ for a strictly positive contraction $e \in B_+$ with $f_{n+1} f_n = f_n$ and $\lim_n \|e - f_n e\| = 0$.

Since $A := C^*(e, C, T(C))$ is a separable C^*-subalgebra of $\mathcal{M}(B)$ we find for every linear filtration of A by finite-dimensional linear subspaces $K_1 \subseteq K_2 \subseteq \ldots$ of A with $\bigcup_n K_n$ dense in the rational convex hull of $\{f_1, f_2, \ldots\}$ an approximate unit $e_1, e_2, \ldots$ with $e_{n+1} e_n = e_n$ and $\|[e_n, y]\| \leq 4^{-n} \|y\|$ for $y \in K_n$. Compare Remark 5.1.1(3,4).

We can manage that K_n contains $L_n \cup T(L_n)$ from a before defined linear filtration $L_1 \subseteq L_2 \subseteq \ldots$ of C, given by $L_n := \operatorname{span}(X_n)$, $X_n := \{ c_1, c_2, \ldots, c_n \}$.

Thus, can find an approximate unit $e_1, e_2, \ldots$, with $\| [(e_{n+1} - e_n)^{1/2}, c] \| \leq 3(2^{-n}) \sqrt{2} \, \|c\|$

`Compare next with above given definition of` $h[m,n]$
`without taking roots!`

We define

$$h[j,k] := (h_k - h_j) = (h_k(1 - h_j))$$

for $k > j$. Notice that $h[j+1, k-1](h_k - h_j) = h_k - h_j$ and $h[j_1, k_1] h[j_2, k_2] = 0$ if $k_1 < j_2$.

Find $d_1, d_2, \ldots \in B$ and $m_1 < n_1 < m_2 < n_2 < \cdots$ in $\mathbb{N}$ with the properties:

(1.) $m_{k+1} > n_k + 3$

(2.) $\|d_n\| \leq 1$,

$$\|d_n^* c d_n - e_{n+1} T(c) e_{n+1}\| \leq 8^{-n} \|c\|$$

for all $c \in L_n$, e_n, e_{n+1} well-commute with $c \in L_n$ and with $T(\, c\,)$ if $c \in L_n$.

(3.) $d_k = (h_{n_k} - h_{m_k}) d_k$, in particular $d_k^* d_\ell = 0$ for $\ell \neq k$.

(4.) $\|(h_{n_{k+1}} - h_{m_{k+1}}) c \, d_k\| \leq 8^{-n} \| c \|$ for all $c \in L_n$.

(5.) In particular ???, $\|c\, d_k - h_{m_{k+1}} c\, d_k\|$ <?????.

`That is not clear !!!`

(6.) The contractions S_n should be defined as some $S_n = S_{\mu,\nu}$, where

$$S_{\mu,\nu} := \sum_{\ell} d_{\nu(\ell)} (e_{\mu(\ell+1)} - e_{\mu(\ell)})^{1/2}$$

for suitable injective maps $\nu\colon \mathbb{N} \to \mathbb{N}$ and $\mu\colon \mathbb{N} \to \mathbb{N}$.

(6.0) We take a bijective map $\lambda\colon \mathbb{N} \to \mathbb{N}\times\mathbb{N}$ such that $\lambda^{-1}(n,1) < \lambda^{-1}(n+1,1)$ and $\lambda^{-1}(n,1) = \min \lambda^{-1}(\{n\} \times \mathbb{N})$ for all $n \in \mathbb{N}$. E.g. take λ defined by the order on $\mathbb{N} \times \mathbb{N}$ given by $(1,1) < (1,2) < (2,1) < (1,3) < (2,2) < (3,1) < (1,4) < \ldots$, which comes from $\gamma\colon (m,n) \to k := m+n-1 \in \mathbb{N}$, $\gamma^{-1}(k)$ lexicographic ordered as e.g. $\gamma^{-1}(1) = \{(1,1)\}$, $\gamma^{-1}(2) = \{(1,2) < (2,1)\}$, and so on. Then λ defines a decomposition of $\mathbb{N}$ into countably many pairwise disjoint infinite subsets $M_n := \lambda^{-1}(\{n\} \times \mathbb{N})$, such that $k_n := \min M_n$ satisfies $k_n < k_{n+1}$.

The natural maps order preserving bijections $\mu_n\colon \mathbb{N} \to M_n$ satisfy $\mu_1(k) = k$ for $k = 1, \ldots, \mu_2(1) - 1$ and $\mu_n(k) > k$ for all other pairs $(n,k) \in \mathbb{N} \times \mathbb{N}$.

`find more flexible formulation by working with finite subsets!`
??

For each $\ell, m, n \in \mathbb{N}$, each finite-dimensional linear subspace ??? $L \subseteq C$??? of C, contractions $b_k \in B$, $\gamma_k \in (0,1)$, $k = 1, \ldots, \ell$ there exist ???? $L \subseteq C$????

(i) numbers $m(j,k)$, and $n(j,k)$, $j = 1, \ldots, m$, with $n+2 < m(j,k)$, $m(j,k) + 2 < n(j,k)$, $n(j,k) + 2 < m(j+1,k)$, $n(m,k) + 2 < m(1,k+1)$.

(ii) Contractions $d_{j,k} \in B$, $j = 1, \ldots, m$; $k = 1, \ldots, \ell$, with

$$\|d_{i,k}^* x d_{j,k} - b_k^* x b_k\| < \gamma_k\,, \quad \text{and} \quad \|d_{j,k}^* x d_{i,k'}\| < \gamma_{\min(k',k)}\,.$$

(iii) a number $\nu \in \mathbb{N}$ depending on $d_{j,k} \in B$, $j = 1, \ldots, m$, $k = 1, \ldots, \ell$,
numbers $n < n_1 < n_2$ <???
Let $b_1, b_2, \ldots \in B$, $\gamma_1, \gamma_2, \ldots \in (0,1)$ finite or infinite sequence,
?????

Consider the functions

$$\varphi_n(\xi) := \min\big(1, \max(0, 2^n\xi - 1)\big) = (2^n\xi - 1)_+ - (2^n\xi - 2)_+\,,$$

and let $h_n := \varphi_n(h)$ for $n = 1, 2, \ldots$.

The elements $h_n \in \mathcal{M}(B)_+$ are positive contractions with $h_m h_n = h_m$ for $n > m$ and $\|h_n h - h\| \leq 2^{1-n}$. Since $h^{1/k}$ converges strictly to 1 in $\mathcal{M}(B)$ by (β), the sequence $h_1, h_2, \ldots$ tends to 1 unconditional strictly in $\mathcal{M}(B)$, because $\|(1-h_n)h^{1/k}\| \leq 2^{(1-n)/k}$.

We define rational numbers $\gamma_k > 0$, $k = 1, 2, \ldots, n$ and select by induction elements $f_1, f_2, \ldots, f_{n-1}$ and $g_1, g_2, \ldots, g_n$ from the above defined increasing sequence $\mathcal{S} := \{h_1, h_2, \ldots\} \subset C^*(h)_+ \subset \mathcal{M}(B)$, and choose simultaneously contractions $d_1, \ldots, d_n \in B$ such that they fulfill together following equations and inequalities, where we let $g_1 := h_1$ at the first step:

(1.1) Find contractions $d_k \in B$ that fulfill inequality (4.13) for the given b_k, $x \in X$ and given $g_k \in \mathcal{S} := \{h_1, h_2, \ldots\}$:

$$\| d_k^*(1-g_k)x(1-g_k)d_k - b_k^* T(x) b_k \| < \gamma_k . \tag{4.13}$$

(1.2) Find $f_k \in \mathcal{S}$ with $f_k g_k = g_k$, $\|(1-f_k)d_k\| < \gamma_k$ and $\|(1-f_k)xd_k\| < \gamma_k$ for $x \in X$, where g_k, d_k, X are given.

(1.3) Take $g_{k+1} \in \mathcal{S}$ with $g_{k+1}f_k = f_k$ for given $f_k \in \mathcal{S}$ (if $k < n$).

We have seen above the possibility to find the contraction $d_k \in B$ (for given X, γ_k, b_k and g_k) that satisfies the inequality (4.13). The existence of f_k and g_{k+1} follow immediately from the properties of the sequence $\mathcal{S}$.

We apply the conditions on the inductively selected b_k, g_k and f_k to find an estimate:

Conditions (1.3) and (1.2) on g_k and f_k imply that $g_{k+1} \geq f_k \geq g_k$, and by induction that $g_\ell \geq f_k$ and $(1-g_\ell)(1-f_k) = (1-g_\ell)$ for all $\ell > k$. The elements d_ℓ and $(1-g_k)$ are contractions by condition (1.2), and we get from condition (1.2) that

$$\|d_\ell^*(1-g_\ell)x(1-g_k)d_k\| \leq \|(1-f_k)x(1-g_k)d_k\| < \gamma\,.$$

If we combine this with Inequalities (4.13) and (4.18) we get that the element $D := (1-g_1)d_1 + \ldots + (1-g_n)d_n \in B$ satisfies

$$\|D^*xD - V(x)\| < \varepsilon \quad \text{for all } \; x \in X\,,$$

because

$$\|D^*xD - \sum_k b_k^* V(x) b_k\| < n^2\delta = \varepsilon/2$$

by $\|d_\ell^*(1-g_\ell)x(1-g_k)d_k\| < \delta$ for $k \neq \ell$, and by the Inequalities (4.13).

Hence, $V := \delta_\infty \circ T \colon C \to \mathcal{M}(B)$ satisfies also condition (β).

Notice that $\delta_\infty \circ V = \delta_\infty^2 \circ T$ is unitarily equivalent to V by a unitary in $u \in \mathcal{M}(B)$ by Lemma 5.1.2(i), and that $T = s_k^* V(\cdot) s_k$ for each $k \in \mathbb{N}$ if $\delta_\infty(b) = \sum_k s_k b s_k^*$.

`Next assumption necessary?`
`It becomes relevant in Part (ii), where` B `is stable,`
`And not here!!!`

We suppose from now on that T is unitary equivalent to $\delta_\infty \circ T$. ????

`Begin of a bit revised old text:`

It seems better to define first the needed universal sequences of $e_k \in B$ and $d_k \in B$ with the "good" properties with respect to a given filtration L_n of C. And then select the corresponding $h_{n(k)} - h_{m(k)}$.

Then define S and more general S_n only with help of this sequences!

We define below a contraction $S \in \mathcal{M}(B)$ with the property $S^*cS - T(c) \in B$ for all $c \in C$.

The element S is defined as the sum of an unconditional strictly convergent series by

$$S := \sum_n (f_{n+1} - f_n)^{1/2} d_n (e_{n+1} - e_n)^{1/2}$$

where the $f_n = h_{k_n} \in \mathcal{S} := \{h_1, h_2, \ldots\}$ have to be suitably chosen, and $\{e_1, e_2, \ldots\} \subset B_+$ is an approximate unit of B that is quasi-central with respect of the C^*-subalgebra $A := C^*(e, C, T(C)) \subseteq \mathcal{M}(B)$ build from a strictly positive contraction $e \in B_+$ of B and contractions $d_n \in B$. They are "suitably chosen" in the sense that the series S converges strictly and unconditional to a contraction in B, $\|S\| \leq 1$, and

??????

$$\sum_{m,n} \|d_n^*(f_{n+1} - f_n)^{1/2} c (f_{m+1} - f_m)^{1/2} d_m \; - \; \delta_{n,m} e_{n+2} f_{n+2} c f_{n+2} e_{n+2}\| \; < \; \infty \, .$$

By assumption, B is σ-unital, i.e., there exists a strictly positive element $e \in B_+$ with $\|e\| = 1$.

Steps:

Choose:

(0) strictly positive contraction $e \in B_+$, $\|e\| = 1$.

(1) linear filtration of $C^*(e, C, T(C))$ by taking a sequence in the unit ball of $C^*(e, C, T(C))_+$ that contains a sub-sequence $c_1, c_2, \ldots$ that is dense in the positive part of the unit ball of C (notation: $C_+^{\leq 1}$???)

the positive rational convex combinations of the $\varphi_n(e)$,

$\mathcal{S} := \{h_1, h_2, \ldots\}$, $\varphi_n(h_k)$,

and with ????

defining a filtration $Y_1 \subset Y_2 \subset \ldots$ of $A := C^*(e, C, T(C))$ such that

Y_n contains e, $X_n := \{h, h_n, c_1, \ldots, c_n\}$, $T(X_n)$ and $y_1, \ldots, y_n$ of a dense sequence in the positive parts $C_+^{\leq 1}$ and $A_+^{\leq 1}$ of the unit balls of C_+ and of A_+.

The strict convergence of $\mathcal{S} := \{h_1, h_2, \ldots\}$ to $1_{\mathcal{M}(B)}$ implies that we can find for each linear subspace $Y \subseteq B$ of finite dimension and $\varepsilon > 0$ a number $m := m(Y, \varepsilon) \in \mathbb{N}$ such that $\|(1 - h_m)y\| + \|y(1 - h_m)\| < \varepsilon \|y\|$ for all $y \in Y$.

A reformulation of conditions (α) and (β) together says:

Let $L \subset C$ a finite-dimensional subspace of C, $m \in \mathbb{N}$, $a \in B$ a positive contraction and $\varepsilon > 0$ then there exists $d := d(L, \varepsilon) \in B$ with $\|d\| \leq 1$ and

$$\|d^*(1 - h_m)c(1 - h_m)d - aT(c)a\| \leq \varepsilon \|c\| \quad \forall\, c \in L \, .$$

And, given any $d \in B$ and $m \in \mathbb{N}$, $\gamma > 0$ we find $n \in \mathbb{N}$ with $n > m + 1$ such that $\|(1 - h_n)d\| < \gamma$, $\|(1 - h_n)cd\| < \gamma$ and $\|(1 - h_n)c(1 - h_m)d\| < \gamma$ for all $c \in L$.

We take a dense sequence in the positive contractions $c_1, c_2, \ldots \in C_+$ and denote by L_n the linear span of $\{h, h_{n+2}, c_1, \ldots, c_n\}$.

Find positive $e_1, e_2, \ldots \in C^*(e)_+ \subset B_+$ with $e_n e_m = e_{\min(m,n)}$ and $\|[e_n, T(x)]\| < 4^{-(n+1)}$ for $x \in L_n$, $\|x\| \leq 1$.

Then $\|[e_n^{1/2}, T(x)]\| < 2^{-n}$ for $x \in L_n$, $\|x\| \leq 1$, $\|[(e_n - e_m), T(x)]\| < 4^{-(n+1)} + 4^{-(m+1)}$ and $\|[(e_n - e_m)^{-1/2}, T(x)]\| < 2^{-\min(n,m)}$ for $x \in L_n$, $\|x\| \leq 1$.

The positive contractions $e_n := \varphi_n(e) \in B$ with above ???

???? the above defined functions φ_n satisfy ???$e'_n e'_m = e'_m$ for $m < n$ build an approximate unit of B, i.e., the sequence (??e'_1, ??$e'_2, \ldots$) converges unconditional strictly to 1 in $\mathcal{M}(B)$.

If we build elements e_n $(n = 1, 2, \ldots)$ by convex combinations of $e'_{k_n}, \ldots, e'_{l_n}$ with $k_n < l_n < k_{n+1}$ then again $e_n e_m = e_m$ for $m < n$ and $\lim e_n b = b$ for all $b \in B$.

By Remark 5.1.1(3)

– applied

to the ??? of the separable C^*-subalgebra $A := C^*(T(C) \cup C \cup \{1\}) \supset C$ of $\mathcal{M}(B)$, and to a dense sub-sequence $y_1, y_2, \ldots$ of the positive contractions in A – Let $x_1, x_2, \ldots$ a dense sequence in the positive contractions of C.

Let L_n and K_n the linear span of $X_n := \{h, h_n, x_1, \ldots, x_n\} \subset C$ respectively of $X_n \cup T(X_n) \cup \{y_1, \ldots, y_n\}$. Thus $L_n \cup T(L_n) \subseteq K_n$.

By Remarks **??**(??,???) we can find positive contractions $e_1, \ldots, e_n, \ldots \in \mathrm{C}_0(e)_+$ that satisfy $e_n e_m = e_{\min(m,n)}$, $\lim_n e_n = 1_{\mathcal{M}(B)}$ and that the commutators $[e_n, x] = e_n x - x e_n$ for $x \in K_n$ satisfy $\|[e_n, x]\| \leq 8^{-n}\|x\|$?????? $[e_n, x]$ and $[e_n, (1 - x^2)^{1/2}]$ for each $x \in K_n$

have norms

$$\max\{\, \|[e_n, x]\| \,,\ \|[e_n, (1 - x^2)^{1/2}]\|\,\} < 8^{-2n} \quad \text{for all } x \in K_n\,,\ \|x\| \leq 1\,.$$

`Convergence proof needs explicit dependence !!`

By Lemma 5.3.2 we get the desired estimates of $[e_n^{1/2}, x]$, $[(1 - e_n)^{1/2}, x]$ and $[(e_{n+k} - e_n)^{1/2}, x]$.

If $1 \leq k_1 < k_2 < \ldots$ is any sequence $\Sigma \subseteq \mathbb{N}$, and $c \in C$, then, – with $e_{k_0} := 0$ –, the series

$$T_\Sigma(c) := \sum_{k=0}^{\infty} (e_{k_{n+1}} - e_{k_n})^{1/2} T(c) (e_{k_{n+1}} - e_{k_n})^{1/2}$$

is unconditional strictly convergent in $\mathcal{M}(B)$ for each $c \in C$, and its "sum" $c \mapsto T_\Sigma(c)$ defines a c.p. contraction $T_\Sigma \colon C \to \mathcal{M}(B)$ with the property $T_\Sigma(c) - T(c) \in B$ for all $c \in C$

...?

Moreover $\|T_\Sigma(c) - T(c)\| \leq$??????? for $c \in L_n$.

Indeed, let $y_n := x_n := (e_{k_{n+1}} - e_{k_n})^{1/2}$ in Remark 5.1.1(2), then $\sum_n x_n^2 = 1 = \sum y_n^2$, the there defined map Γ corresponding to

??? $Y := X := [x_1, x_2, \ldots]$??? `look this up in 5.1.1(2) ???`

is a strictly continuous unital c.p. map from $\ell_\infty(\mathcal{M}(B)) = \mathcal{M}(c_0(B))$ into $\mathcal{M}(B)$ and $T_\Sigma(c) = \Gamma(T(c), T(c), \ldots)$ for $c \in C$ defines a c.p. contraction from C into $\mathcal{M}(B)$.

If ?????? ???????

Again by functional calculus – this time applied to the element h in condition (α), we find a sequence of contractions $h'_1, h'_2, \ldots \in C^*(h)_+ \subseteq C_+$ such that $h'_n h'_m = h'_m$ for $m < n$ and $\|(1 - h'_n)e_n\| < 8^{-n}$. Thus $\|h'_n b - b\| \to 0$ if $n \to \infty$ for each $b \in B$.

`Why not` h_n `(or` g_n, f_n`) in place of` h'_n`?`

If we use that T is positive, $h \geq 0$ and $T(h) = 0$ by assumption (α), we get $T(h'_n) = 0$, $T(c\,h'_n) = 0$, $T(h'_n\,c) = 0$ and

$$T(c) = T((1 - h'_n)c(1 - h'_n)), \quad \forall\, c \in C\,,\ \forall\, n \in \mathbb{N}\,.$$

Combining this with condition (β) we get the existence of contractions $g_{n,k} \in B$ $(k, n \in \mathbb{N})$ that satisfy, for $c \in L_n$,

$$\|\,(g_{n,k})^*(1 - (h'_k)^2)^{1/2}c(1 - (h'_k)^2)^{1/2}g_{n,k} - e_{n+3}T(c)e_{n+3}\,\| \leq 8^{-n-k}\,\|c\|\,. \quad (4.14)$$

We define the desired contractions $S_{n,p}$ as the sum of strictly converging series of the kind

$$(h'_{\ell(n)} - h'_{m(n)})g_{2n,m(n)}e_n^{1/2} + \sum_{k>n}(h'_{\ell(k)} - h'_{m(k)})g_{2k,m(k)}(e_k - e_{k-1})^{1/2}\,,$$

where $m(k) < \ell(k) < m(k+1) < \ell(k+1)$ with choice depending from $p \in \mathbb{N}$. Huge gaps between $\ell(k)$ and $m(k+1)$ can be used to make the $S_{n,p}$ orthogonal modulo B, i.e., $S^*_{n,p}S_{n,q} \in B$ and even such that $S^*_{n,p}cS_{n,q} \subset B$ for $c \in C$ and

$$\lim_{n\to\infty} \|S^*_{n,p}cS_{n,q} - \delta_{p,q}T(c)\| = 0\,.$$

More precisely, we select inductively a subsequence $h_n := h'_{k(n)}$ and finite subsequences $h_{n,m} := h'_{\ell(n,m)}$, $m = 1, \ldots, n$, from the above selected sequence $h'_1, h'_2, \ldots$ with following properties :

(1) $k(0) = 1$,
(2) $k(n) < \ell(n,m) < \ell(n, m+1) \leq k(n+1)$ for $m = 1, 2, \ldots, n-1$.
(3) $\|(1 - h'_{\ell(n,m+1)})g_{n,\ell(n,m)}\| < 8^{-n}$,
(4) $\|(1 - h'_{k(n+1)})g_{n,k(n)}\| < 8^{-n}$,
(5) $\|(1 - h'_{k(n+1)})c(1 - h'_{k(n)})g_{n,k(n)}\| < 8^{-n}$ and $\|(1 - h_{n+1})c(h_{j+1} - h_j)g_{j,k(j)}\| < 8^{-n}$ for $c \in X_{n+1}$, $j = 1, \ldots, n-1$, $n = 1, 2, \ldots$, and
(6) $(h_{\ell(n,m+1)} - h_{\ell(n,m)})(h_{n+1} - h_n) = h_{\ell(n,m+1)} - h_{\ell(n,m)}$, and then $(h_{\ell(n_1,m+1)} - h_{\ell(n_1,m)})(h_{\ell(n_2,m+3)} - h_{\ell(n_2,m+2)}) = 0$

Notice that $(1-h_k)(1-h_n) = 1-h_n$ for $k < n$, and $(h_{k+1}-h_k)(h_{n+1}-h_n) = 0$ for $k+1 < n$. Let

$$t_{n,m} := (h_{n+2,m} - h_n)g_{n,k(n)}e_{n+2}$$

for all $n \in \mathbb{N}$ and $m \leq n$.

Then the $t_{n,m}$ are contractions with $t^*_{n,m}t_{n,m} \leq e^2_{n+2}$, $t^*_{n,m_1}t_{k,m_2} = 0$ and $\|t^*_{n,m(2)}ct_{k,m(1)}\| < 8^{-n+1}2$ for $k+1 < n$, $c \in X_k$. We get $(h_{n+2} - h_{n-1})^{1/2}t_{n,m} = t_{n,m}$ for $n = 1, 2, \ldots$, $m \leq n$.

It follows

$$\|t^*_{k,m(1)}ct_{n,m(2)} - \delta_{k,n}e_{n+2}T(c)e_{n+2}\| < 8^{-n}3\|c\|$$

for $c \in L_n$, because $\|t_{n,m} - (1-h_n)g_{n,k(n)}e_{n+2}\| < 8^{-n}$.

This follows from the definitions and the inequality $\|(1-h_{n+2,m})g_{n,k(n)}\| < 8^{-n}$, because $h_{n+2,m} = h'_{\ell(n+2,m)}$ and $\|(1-h'_{\ell(n+2,m)})g_{n,k(n)}\| < 8^{-n}$.

The latter inequality is a consequence of the following properties of h'_n and $g_{n,k(n)}$:
The inequality $\|(1-h'_{k(n+1)})g_{n,k(n)}\| < 8^{-n}$ is property (3) of $h'_{k(n)}$ and $g_{n,k(n)}$, and that $k(n+1) < k(n+2) < \ell(n+2,m)$ follows from property (2) of $k(n)$ and $\ell(n,m)$. Then $0 \leq h'_nh'_m = h'_m \leq 1$ for $m < n$ by construction of h'_n. It follows that

$$0 \leq h'_{k(n+1)} = h'_{k(n+1)}h'_{\ell(n+2,m)} \leq h'_{\ell(n+2,m)} \leq 1\,,$$

It implies $(1-h'_{\ell(n+2,m)})^2 \leq (1-h'_{k(n+1)})^2$ and, therefore

$$\|(1-h'_{\ell(n+2,m)})g_{n,k(n)}\| \leq \|(1-h'_{k(n+1)})g_{n,k(n)}\| < 8^{-n}\,.$$

The definition of $S_{n,p}$ is justified by the unconditional strict convergence of the sum at the right hand side. The strict convergence can be seen with the argument mentioned in Remark 5.1.1(2):

We define $S_{n,p} \in \mathcal{M}(B)$ for $n \in \mathbb{N}$ and $p \leq n$ by

$$S_{n,p} := t_{2n,\min(p,2n)}e_n^{1/2} + \sum_{k>n} t_{2k,\min(p,2k)}(e_k - e_{k-1})^{1/2}.$$

We must show now:

(I) The series

$$\sum_{k>n} t_{2k,\min(p,2k)}(e_k - e_{k-1})^{1/2}$$

is unconditional strictly convergent, ...????

(II) $\lim_{n\to\infty} \|S_{n,p}\| = 1$, and $S^*_{n,p}cS_{n,q} - \delta_{p,q}T(c) \in B$ for all $c \in C$ and $n, p, q \in \mathbb{N}$, and

$$\lim_{n\to\infty} \|S^*_{n,p}cS_{n,q} - \delta_{p,q}T(c)\| = 0\,.$$

`Old version:`

because one can express $S_{n,p}$ as product RDC of the bounded row matrix

$$R := [h_{2n+2}^{1/2}, (h_{2(n+1)} - h_{2(n-1)})^{1/2}, (h_{2(n+2)} - h_{(n+1)-2})^{1/2}, \ldots]$$

the contractive diagonal matrix

$$D := \operatorname{diag}(\alpha_1, \alpha_2, \ldots)$$

with diagonal entries $\alpha_1 := t_{2n,m}$ and $\alpha_\ell := t_{2(\ell+n),m}$, and the bounded column matrix C with transposed row

$$C^\top := [e_n^{1/2}, (e_{n+1} - e_n)^{1/2}, (e_{n+2} - e_{n+1})^{1/2}, \ldots] .$$

Moreover, Remark 5.1.1(2) shows that the $S_{n,p}$ are contractions.

It is not difficult to see that $?S_{k,m} - ?S_{n,m} \in B$ and, therefore

$$?S^*_{k,m} c S_{k,m} - ?S^*_{n,m} c S_{n,m} \in B$$

for every $c \in C$.

Now let $c \in X_m$ and, for $n > m$ let

$$a_m := e_m^{1/2} t^*_{2m} c t_{2m} e_m^{1/2} - T(c) e_m, \tag{4.15}$$
$$b_n := (e_n - e_{n-1})^{1/2} t^*_{2n} c t_{2n} (e_n - e_{n-1})^{1/2} - T(c)(e_n - e_{n-1}), \tag{4.16}$$
$$d_{m,n} := (e_n - e_{n-1})^{1/2} t^*_{2n} c t_{2m} e_m^{1/2} + e_m^{1/2} t^*_{2m} c t_{2n} (e_n - e_{n-1})^{1/2} , \tag{4.17}$$

and, for $i < j$,

$$f_{i,j} := (e_j - e_{j-1})^{1/2} t^*_{2j} c t_{2i} (e_i - e_{i-1})^{1/2} + (e_i - e_{i-1})^{1/2} t^*_{2i} c t_{2j} (e_j - e_{j-1})^{1/2} .$$

Then from $d^{1/2} T(c) d^{1/2} - T(c) d = (d^{1/2} T(c) - T(c) d^{1/2}) d^{1/2}$ we get $\|a_k\| < 8^{-2m} 3 + 8^{-k}$, $\|b_n\| < 8^{-2n} 3 + 8^{-n}$, $\|d_{m,n}\| < 8^{-2n+1} 2$ and $\|f_{i,j}\| < 8^{-2j+1} 2$ for $m < n$, $m < i < j$.

Since $e_m + (e_{m+1} - e_m) + \ldots = 1$ strictly, for $c \in X_m$,

$$S^*_m c S_m - T(c) = a_m + \sum_{n=m+1}^{\infty} b_n + \sum_{n=m+1}^{\infty} d_{m,n} + \sum_{m<i<j} f_{i,j} .$$

The right hand side are absolutely convergent series in B. The sums of the norms can be estimated by by $8^{-m} 4$.

It follows that $\|S^*_{k,m} c S_{k,m} - T(c)\| < 2^{-k}$ and that $S^*_{k,m} c S_{k,m} - T(c) \in B$ for $c \in X_k$. Since $S^*_k c S_k - S^*_n c S_n \in B$, we get that $S^*_{n,m} c S_{n,m} - T(c) \in B$ for each $n = 1, 2, \ldots$ and every element c of our dense sequence in the unit ball of C.

Thus, $S^*_{n,m} c S_{n,m} - T(c) \in B$ and $\lim_n \|S^*_{n,m} c S_{n,m} - T(c)\| = 0$ for every $c \in C$.

`Our desire was to deepen the results by proving orthogonality modulo` B `for the` S_n `...`

`still to check:`

We have $S^*_{n,m_1} c S_{n,m_2} \in B$ for $m_1 \neq m_2$ and $\|S^*_{n,m_1} c S_{n,m_2}\| \to 0$ for $n \to \infty$ if $c \in C$ or $c = 1$.

(ii): Recall that B is stable if and only if $\mathcal{M}(B)$ contains a sequence of isometries $s_1, s_2, \ldots$ such that $\sum_k s_k s_k^* = 1$, cf. Remark 5.1.1(8). Then $\delta_\infty(b) := \sum_k s_k b s_k^*$ converges unconditional strictly for $b \in \mathcal{M}(B)$, is a strictly continuous unital *-endomorphism and $\delta_\infty(\mathcal{M}(B))' \cap \mathcal{M}(B) = \delta_\infty(B)' \cap \mathcal{M}(B)$ contains a copy of $\mathcal{O}_2$ unitally by Remark 5.1.1(8).

The contractive c.p. map $V := \delta_\infty \circ T$, i.e., $V(\cdot) := \sum_k s_k T(\cdot) s_k^*$ again satisfies Conditions (α) and (β):

Clearly V satisfies condition (α), because $V(h) = \delta_\infty(T(h)) = 0$.

Let $X \subseteq C_+$ a finite subset of the contractions in C_+, $b \in B$ a contraction and $\varepsilon > 0$.

There exists $q \in \mathbb{N}$ with

$$\| (1 - P_q) b \| < \varepsilon/4$$

for the projection $P_q := \sum_{k=1}^q s_k s_k^*$, because $\sum_k s_k s_k^*$ converges strictly to $1 \in \mathcal{M}(B)$.

It implies for $x \in X$ and the contractions $b_k := s_k^* b \in B$ that

$$\| b^* V(x) b - \sum_{k=1}^{q} b_k^* T(x) b_k \| < \varepsilon/2 \,. \tag{4.18}$$

We have seen at the end of the general observation, cf. Inequality (4.12), that, for finite $X \subset C_+$, $b_1, \ldots, b_q \in B$ and $\varepsilon > 0$, there exists an element $d \in B$ with

$$\|d^* x d - \sum_{k=1}^{q} b_k^* T(x) b_k\| < \varepsilon/2$$

Thus $d \in B$ solves the inequalities $\|d^* x d - b^* V(x) b\| < \varepsilon$ $(x \in X)$ for given finite $X \subseteq C_+$, $b \in B$, $\varepsilon > 0$ and $V := \delta_\infty \circ T$.

This confirms that $\delta_\infty \circ T$ satisfies also the Condition (β).

NEXT TO BE SORTED WITH NEW INSIGHT.

By Part (i), there exists a contraction $g \in \mathcal{M}(B)$ with $V(c) - g^* c g \in B$ for all $c \in C$.

Apply ???? Part (i) to $V =: \delta_\infty \circ T$ and C. Let $g := S_1$ with S_1 as in Part (i).

We use Lemma 5.1.2(v). Let $t \mapsto S'(t)$ the map for $V = \delta_\infty \circ T$ in Part (v) of Lemma 5.1.2, and let $s_1, s_2, \ldots$ be the generators of a unital copy of $\mathcal{O}_\infty$ in $\mathcal{M}(B)$ with $\sum_n s_n s_n^* = 1$ (strictly convergent) such that $\delta_\infty = \sum_n s_n(\,\cdot\,) s_n^*$, cf. Remark 5.1.1(8). Then $t \mapsto S(t) := S'(t) s_1$ is as desired for T.

Now notice that ?????????? ...

When $S(t)$ is an isometry ? E.g. if $S'(t)$ is a contraction with $S'(t)^* S(t) \geq s_1 s_1^*$ and $s_1^* s_1 = 1$??

When absorption happens?

(iii): If $1_{\mathcal{M}(B)} \in C$, then T is unital, because $T(C)B$ is dense in B.

By Part (ii), $V := \delta_\infty \circ T$ satisfies (α) and (β). Moreover $V(C)' \cap \mathcal{M}(B) \subset \delta_\infty(\mathcal{M}(B))' \cap \mathcal{M}(B)$ contains a copy of $\mathcal{O}_2$ unitally.

By Part (i), there exists a contraction $g \in \mathcal{M}(B)$ with $V(c) - g^*cg \in B$ for all $c \in C$. The existence of $U(t)$ now follows from Lemma 5.1.2(vi).

If $1_{\mathcal{M}(B)}$ is *not* in C, then let $\widetilde{C} := C + \mathbb{C}1_{\mathcal{M}(B)}$ and $\widetilde{T}(c + z1) := T(c) + z1$ for $c \in C$ and $z \in \mathbb{C}$.

Then $\widetilde{T}$ is a unital C^*-morphism, and $\widetilde{C}$ and $V := \delta_\infty \circ \widetilde{T}$ again satisfy (α) and (β) (in place of C and T there).

Indeed: $V(h) = \delta_\infty(T(h)) = 0$ gives (α).

We show (β) for the *unital* C^*-morphism $V : \widetilde{C} \to \mathcal{M}(B)$:
It suffices to check the condition (β) for V on sets of the form $X \cup \{1\}$ and $a \in B_+$, where $\|a\| \le 1$ and X is a finite set of contractions in C.

By assumption, $T(C)B$ is dense in B. The set $\delta_\infty(B)B$ is dense in B, because δ_∞ is a unital and strictly continuous endomorphism of $\mathcal{M}(B)$. It follows that the set $V(C)B$ is dense in B, because $V(C)\delta_\infty(B)B = \delta_\infty(T(C)B)B$.

Let X be a finite subset of the contractions in C, $a \in B_+$ a contraction and $\varepsilon > 0$.

There exists a contraction

`e was used as strictly positive in B`

$e \in C_+$ with $\|V(e)a - a\| < \varepsilon/4$ and $\|ece - c\| < \varepsilon/4$ for $c \in X$, because V is multiplicative and $V(C)B$ is dense in B.

`(β) of V was shown above from (β) of T`

By assumption, $V|C = \delta_\infty \circ T$ satisfies (β).

Thus, there exists a *contraction* $d_1 \in B$ such that $\|d_1^* x d_1 - aV(x)a\| < \varepsilon/2$ for $x \in eXe \cup \{e^2\}$, cf. proof of part (i).

Let $d := ed_1 \in B$. Then $\|d^*cd - aV(c)a\| < \varepsilon$ for $c \in X \cup \{1\}$.

(iv): See the argument at the end of the proof of Part (v) of Lemma 5.1.2. □

`What are (α) and (β) in case T := 0 or`
`if T(c) := ρ(c)·1 for a (pure) state ρ on C with ρ(C ∩ B) = {0}?`

REMARK 5.4.2. *Desirable !!! is the following version for countably generated Hilbert D-modules and with a finite group action:*

Let G a finite group, D a σ-unital C^*-algebra with a G-action $\tau_D : G \to \mathrm{Aut}(D)$, E a countably generated right Hilbert D-module with an isometric G-action $\tau_E : G \to \mathrm{Iso}(E)$ into the linear isometries on E that is compatible with τ_D in the sense that, for $e \in E$, $g \in G$, ??? and

$$\tau_E(g)(e) \cdot \tau_D(g)(d) = \tau_E(g)(e \cdot d)$$

Now let C a separable C^*-algebra with a G-action $\tau_C\colon G \to \mathrm{Aut}(C)$, and suppose that $H_k\colon C \to \mathcal{L}(E)$, $k \in \{1,2\}$, are G-equivariant C^*-morphisms.

If they are both in general position, and generate the same m.o.c cone, then they should be unitarily homotopic ??

COROLLARY 5.4.3. *Suppose that B is σ-unital and stable, A is separable, and that $H_1, H_2\colon A \to \mathcal{M}(B)$ are C^*-morphisms, such that $\delta_\infty \circ H_k$ are non-degenerate for $k \in \{1,2\}$.*

Then $\delta_\infty \circ H_1$ and $\delta_\infty \circ H_2$ are unitarily homotopic, if and only if, for every contraction $b \in B$, H_j dominates weakly approximately inner the c.p. map $b^* H_k(\cdot) b$ for $j,k \in \{1,2\}$ in sense of Definition 3.10.1.

I.e., $\delta_\infty \circ H_1$ and $\delta_\infty \circ H_2$ are unitarily homotopic if, and only if, the (point-norm closed) m.o.c. cones $\mathcal{C}(H_1)$ and $\mathcal{C}(H_2)$ in $\mathrm{CP}(A,B)$ corresponding to H_1 and H_2 are identical.

Recall here that, by definition, the m.o.c. cone $\mathcal{C}(H_k) \subseteq \mathrm{CP}(A,B)$ is generated by $\{b^* H_k(\cdot) b\,;\ b \in B\}$ and is point-norm closed.

We can weaken the requirement of non-degeneracy of $\delta_\infty \circ H_k$ by supposing only that $\delta_\infty \circ H_k$ is *unitarily homotopic* to a non-degenerate C^*-morphism from A into $\mathcal{M}(B)$. Notice that this is a property of $\delta_\infty \circ H_k$ that is *not* the same as as the property that $\delta_\infty \circ H_k$ non-degenerate.

PROOF. The condition implies that H_1 and H_2 have the same kernel. Thus, w.l.o.g. we can assume that H_1 and H_2 are faithful.

Let $e \in B_+$ a strictly positive element of B, $F_j := \delta_\infty(H_j(A))$ and $C_j := C^*(F_j, e)$ for $j = 1,2$. Since $F_j \cap B = \{0\}$, there is a *unique* C^*-morphism T_j from C_j onto F_i (for $i \neq j \in \{1,2\}$) with $T_j(e) = 0$ and $T_j(\delta_\infty(H_j(a))) = \delta_\infty(H_i(a))$ for $a \in A$.

The C^*-morphism $\delta_\infty \circ T_j$ is unitarily equivalent to T_j, because δ_∞^2 is unitarily equivalent to δ_∞ by Lemma 5.1.2(i) and H_j is uniquely defined up to unitary equivalence.

C_j and T_j satisfy assumption (α) of Proposition 5.4.1 with $h := e$.

We show that (C_j, T_j) satisfies also condition 5.4.1(β):
Let $s_1, s_2, \ldots$ a sequence of isometries in $\mathcal{M}(B)$ such that $\sum_n s_n (s_n)^*$ strictly converges to $1_{\mathcal{M}(B)}$, and let $a \in B_+$, X a finite subset of C_j and $\varepsilon > 0$ given. Then there are finite subsets $Y \subseteq A_+$ and $Z \subseteq B$ such that X is a subset of $\{\delta_\infty(H_j(y)) + z\colon y \in Y, z \in Z\}$. Our assumptions imply that there are $b_1, \ldots, b_n \in B$ such that

$$\|a(\delta_\infty)^2(H_i(y))a - \sum_{1\le k\le n} b_k^* H_j(y) b_k\| < \varepsilon/2\,.$$

Since $\sum_n s_n(s_n)^*$ strictly converges to $1_{\mathcal{M}(B)}$, there is $m \in \mathbb{N}$ such that $\|d^* z d\| < \varepsilon/2$ for $z \in Z$ and $d := s_{m+1} b_1 + \ldots + s_{m+n} b_n$. Thus $\|a V_j(x) a - d^* x d\| < \varepsilon$ for $x = \delta_\infty(H_j(y)) + z$ in X.

By assumption, $T_j(C_j)B = \delta_\infty(H_i(A))B$ is dense in B. Thus Proposition 5.4.1(iii) applies to (C_j, T_j) and yields that H_1, $H_1 \oplus H_2$ and H_2 are mutually unitarily homotopic. □

COROLLARY 5.4.4. *Suppose that B is σ-unital and stable, A is separable, and that $\mathcal{S}$ is a countably generated matrix operator-convex cone of completely positive maps V from A into B (cf. Definition 3.2.2), such that $\mathcal{S}$ is* non-degenerate *in the following sense: For every $b \in B_+$ and $\varepsilon > 0$, there exists $a \in A_+$ and $V \in \mathcal{S}$ such that $(b-\varepsilon)_+$ is in the closed ideal of B that is generated by $V(a)$.*

Then there is a non-degenerate *C^*-morphism $H_0 \colon A \to \mathcal{M}(B)$ with following properties (i)–(iii):*

(i) *H_0 is unitary equivalent to $\delta_\infty \circ H_0$ by a unitary in $\mathcal{M}(B)$.*
(ii) *For every $V \in \mathcal{S}$ there exists a sequence $b_1, b_2, \ldots \in B$ such that, for every $a \in A$,*
$$\lim_{n\to\infty} b_n^* H_0(a) b_n = V(a)\,.$$
(iii) *For every $b \in B$ there exists a sequence $V_1, V_2, \ldots \in \mathcal{S}$ such that, for every $a \in A$,*
$$\lim_{n\to\infty} V_n(a) = b^* H_0(a) b\,.$$

H_0 is determined by (i)–(iii) up to unitary homotopy (cf. Definition 5.0.1).

H_0 is injective, if and only if, $\mathcal{S}$ is separating *for A, i.e., for every non-zero positive $a \in A_+ \setminus \{0\}$, there is $V \in \mathcal{S}$ with $V(a) \neq 0$.*

The example with $B := A := \mathcal{O}_2 \otimes \mathbb{K}$, $\mathcal{S} = \mathrm{CP}(A, B)$, $H_0(a) := a$ shows that H_0 is *not* determined by (ii) and (iii) of Corollary 5.4.4 alone.

PROOF. The uniqueness up to unitary homotopy follows from Corollary 5.4.3.

Let $a \in A_+$. By (ii) and (iii), $H_0(a) = 0$ if and only if $V(a) = 0$ for every $V \in \mathcal{S}$. In particular, H_0 is a monomorphism if and only if $a \in A_+$ and $V(a) = 0$ for all $V \in \mathcal{S}$ imply $a = 0$.

By assumption there exists a countable sequence $V_1, V_2, \ldots \in \mathcal{S}$ such that $\mathcal{S}$ is contained in the point-norm closure of the matrix operator-convex cone generated by $\{V_1, V_2, \ldots\}$. We can suppose that every V_n appears infinitely times in this sequence.

Kasparov–Stinespring dilations lead to Hilbert B-modules $\mathcal{H}_n$ and and C^*-morphisms $D_n \colon A \to \mathcal{L}(\mathcal{H}_n)$ such that for $b \in B$ and $c \in A$ there is $x \in \mathcal{H}_n$ with $\langle x, D_n(a)x\rangle = b^* V_n(c^*ac)b$ for $a \in A$, and that $a \in A \mapsto \langle y, D_n(a)y\rangle \in B$ is in the point-norm closure of the matrix operator-convex cone generated by V_n. (Recall here that $\mathcal{H}_n$ is a completion of a quotient of the algebraic tensor product $A \odot B$, and that the B-valued Hermitian form is given there by
$$\langle x, y\rangle := \sum_{j,k} b_j^* V(a_j^* c_k) d_k$$

for representatives $\sum_j a_j \otimes b_j$ of x and $\sum_k c_k \otimes d_k$ of y. We take it anti-linear in the first variable.)

Let $\mathcal{H} := \mathcal{H}_1 \oplus \mathcal{H}_2 \oplus \ldots$ and $D\colon A \to \mathcal{L}(\mathcal{H})$ denote the Hilbert B-module sum, respectively of the corresponding ℓ_∞-sum of the C^*-morphisms D_n.

Since every completely positive map V_n appears infinitely often in our sequence $(V_1, V_2, \ldots)$, the maps $W_y\colon a \in A \mapsto \langle y, D(a)y\rangle \in B$ for $y \in \mathcal{H}$ build a *convex* cone $\mathcal{S}_0$ of completely positive maps from A into B, which is then automatically matrix operator-convex. The map W_y is in the point-norm closure of $\mathcal{S}$ for every $y \in \mathcal{H}$, and every V_n is in the point-norm closure of $\mathcal{S}_0$, i.e., $\mathcal{S}_0$ and $\mathcal{S}$ have the same point-norm closure in $\mathrm{CP}(A, B)$. (Here we use the existence of approximate units in A and B.)

Since $\mathcal{H}_n$ and (therefore) $\mathcal{H}$ are countably generated over B and since B is σ-unital and stable, the Kasparov trivialization theorem leads to the Hilbert B-module isomorphisms $\mathcal{H} \oplus \mathcal{H}_B \cong \mathcal{H}_B \cong B$.

Thus there is a (degenerate) C^*-morphism $h\colon A \to \mathcal{M}(B)$ that satisfies properties (ii) and (iii) (with H_0 replaced by h).

Let B_0 denote the closed span of $\delta_\infty(h(A))B\delta_\infty(h(A))$, and let $e \in B_+$, $f \in A_+$ strictly positive elements. B_0 is a stable hereditary C^*-subalgebra of B and $\delta_\infty(h(f))e\delta_\infty(h(f))$ is a strictly positive element of B_0, cf. Lemma 5.1.2(vii). B is the closure of the linear span of $Bh(A)B$, because h satisfies property (ii) (with H_0 replaced by h). $Bh(A)B$ is contained in the closed span of BB_0B.

Thus, by a variant of the stable isomorphism theorem of L.G. Brown [**107**] (cf. Corollary 5.5.6) there is an isomorphism ψ from B onto $B_0 \subseteq B$, which is approximately unitary equivalent to the id_B by unitaries in $\mathcal{M}(B)$. $H(a)b := \psi^{-1}(\delta_\infty(h(a))\psi(b))$ defines a non-degenerate C^*-morphism from A into $\mathcal{M}(B)$.

Since ψ is approximately unitary equivalent to id_B, we get that that H satisfies (ii) and (iii). Thus $H_0 := \delta_\infty \circ H$ satisfies (i)–(iii) by Lemma 5.1.2(i). □

Remark 5.4.5. A "converse" of Corollary 5.4.4 holds obviously if A is separable and B is σ-unital:

For every non-degenerate C^*-morphism $h\colon A \to \mathcal{M}(B)$, the set $\mathcal{S}_h$ of maps

$$V_{h,b}\colon a \in A \mapsto b^*\delta_\infty(h(a))b \in B$$

is a singly generated matrix operator-convex cone of completely positive maps, and $V_{h,e}$ is a generator of $\mathcal{S}_h$ if e is a strictly positive element of B. The corresponding H_0 is given by $H_0 := \delta_\infty \circ h$.

Corollary 5.4.6. *Suppose that B is σ-unital and stable, A is separable and unital, $\mathcal{C} \subset \mathrm{CP}(A, B)$ a countably generated non-degenerate and faithful point-norm closed operator-convex cone. Let $H_0\colon A \to \mathcal{M}(B)$ the non-degenerate *-monomorphism from $A \to \mathcal{M}(B)$ as defined in Corollary 5.4.4. Further let $W\colon A \to \mathcal{M}(B)$ be a unital completely positive map with $b^*W(\cdot)b \in \mathcal{C}$ for all $b \in B$.*

Then $H_0(1) = 1$*, and there are isometries* $S, T \in \mathcal{M}(B)$ *with* $SS^* + TT^* = 1$ *and* $W(a) - S^* H_0(a) S \in B$ *for all* $a \in A$*.*

PROOF. Since A is unital and H_0 is non-degenerate, we get $H_0(1) = 1$. Property (i) in Corollary 5.4.4 implies $H_0(A) \cap B = \{0\}$.

Let $e \in B_+$ a strictly positive contraction, and let $C := C^*(e, H_0(A)) \subset \mathcal{M}(B)$. Then $C/(C \cap B) \cong H_0(A)$. Thus, there is a unique *-morphism $\psi \colon C \to A$ with $\psi(e) = 0$ and $\psi \circ H_0 = \mathrm{id}_A$. Let $V(c) := W(\psi(c))$ for $c \in C$. Then V is unital and $(C, h := e, V)$ satisfy the condition (α) of Proposition 5.4.1.

We have $C = (C \cap B) + H_0(A)$. Let $c_j = b_j + H_0(a_j)$ $(j = 1, \ldots, n)$ and $\varepsilon > 0$, $\delta := \varepsilon/3$. Since $V \circ H_0 = W$ and since $b^* W(\cdot) b \in \mathcal{C}$, there is $d_1 \in B$ with $\|d_1^* H_0(a_j) d_1 - W(a_j)\| < \delta$ for $j = 1, \ldots, n$. By Lemma 5.1.2(iv) there exists

$$t \mapsto S_0(t) \in \delta_\infty(\mathcal{M}(B))' \cap \mathcal{M}(B) \subset H_0(A)' \cap \mathcal{M}(B)$$

with $\lim_{t\to\infty} b S_0(t) = 0$ for $b \in B$. There is $t \in \mathbb{R}_+$ with $\|d_1^* S_0(t)^* b_j S_0(t)(t) d_1\| < \delta$ for $j = 1, \ldots, n$. Thus $\|d^* c_j d - W(c_j)\| < \varepsilon$ for $j = 1, \ldots, n$. Hence, for every $b \in B$, the map $c \mapsto b^* V(c) b \in B$ is approximately 1-step inner, i.e., condition (β) of Proposition 5.4.1 is satisfied.

Thus $C \subset \mathcal{M}(B)$, $h := e$ and $V \colon C \to \mathcal{M}(B)$ satisfy the assumptions of Proposition 5.4.1(i,iv). It gives an isometry $S_1 \in \mathcal{M}(B)$ with $S_1^* H_0(a) S_1 - W(a) \in B$ for all $a \in A$.

By Lemma 5.1.2(iv), there exist isometries $s, t \in H_0(A)' \cap \mathcal{M}(B)$ with $ss^* + tt^* = 1$. Let $S := sS_1$, then $S^* H_1(\cdot) S = S_1^* H_1(\cdot) S_1$, $tt^* \leq 1 - SS^*$ and $[1 - SS^*] = [1]$ in $\mathrm{K}_0(\mathcal{M}(B))$. By Lemma 4.2.6(ii), there is an isometry T with $TT^* = 1 - SS^*$. $\square$

DEFINITION 5.4.7. The quotient $\mathrm{Q^s}(B) := \mathcal{M}(B \otimes \mathbb{K})/(B \otimes \mathbb{K})$ is called **stable corona** of the C^*-algebra B.

If B itself is stable, i.e., $B \cong B \otimes \mathbb{K}$, we write instead $\mathrm{Q}(B)$ for $\mathcal{M}(B)/B \cong \mathrm{Q^s}(B)$. But the notation $\mathrm{Q}(B)$ for $\mathcal{M}(B)/B$ will also be used if B is non-unital and not stable, i.e., it does not indicate that B is stable.

In Section 9 we define extension groups (depending on operator-convex cones $\mathcal{C} \subset \mathrm{CP}(A, B)$) by

$$\mathrm{Ext}(\mathcal{C}\,;\, A, B) := G(\pi_B \circ H_0\,;\; A, \mathrm{Q}(B))$$

where $\mathcal{C}$ is separating and satisfies the requirements of Corollary 5.4.4 and $H_0 \colon A \to \mathcal{M}(B)$ is as in Corollary 5.4.4. The following Corollary 5.4.9 describes its elements.

LEMMA 5.4.8. *Let* $\mathcal{S} \subset \mathrm{CP}(A, J)$ *a point-norm closed operator-convex cone,* $T \colon A \to C/J$ *a c.p. contraction, and* $V \colon A \to C$ *a c.p. lift of* T*, i.e.,* $\pi_J \circ V = T$*, such that* $c^* V(\cdot) c \in \mathcal{S}$ *for every* $c \in J$*.*

If A *is separable, then there is a c.p. contraction* $W \colon A \to C$ *in the point-norm closure of the operator convex hull* $\mathcal{C}(V) \subset \mathrm{CP}(A, C)$ *of* V *in* $\mathrm{CP}(A, C)$ *with* $\pi_J \circ W = T$*. In particular,* $c^* V(\cdot) c \in \mathcal{S}$ *for every* $c \in J$*.*

If, in addition, A, C and T are unital, and if $\mathcal{S}$ is non-degenerate ([12]), *then there are a positive contraction $e \in C_+$ and $\chi \in \mathcal{S}$ such that such that $\chi(1) = 1 - eV(1)e \in J_+$. Then $W = \chi(\cdot) + eV(\cdot)e$ is unital, $\pi_J \circ W = T$ and $c^*W(\cdot)c \in \mathcal{S}$ for all $c \in C$.*

Proof. Suppose that A is separable and that $e \in A_+$ is a strictly positive contraction. Let $g_\delta(t) := \min(t^\delta, t^{-1})$ for $t \in (0, \infty)$ and $g_\delta(0) := 0$, where $\delta \in (0, 1]$. For $\delta \in (0, 1]$ and $a \in A + \mathbb{C} \cdot 1$ let

$$V_\delta(a) := g_\delta(V(e^{2\delta})V(e^\delta a e^\delta)g_\delta(V(e^{2\delta}))\,,$$

and

$$T_\delta(a) := (T(e^{2\delta})^\delta T(e^\delta a e^\delta)(T(e^{2\delta}))^\delta\,,$$

Then $\pi_J \circ V_\delta = T_\delta$, $V_\delta \in \mathcal{C}(V)$, and $\|V_\delta\| = \|V_\delta(1)\| \leq 1$, because $V_\delta(1) = g_\delta(c)^2 c$ has norm ≤ 1 for $c = V(e^{2\delta}) \in C_+$. Let D the hereditary C^*-subalgebra of C/J generated by $T(e^2)$, i.e., D is the closure of $T(e^2)DT(e^2)$. The span of eA_+e is dense in A and $0 \geq T(eae) \leq T(e^2)$. Thus $T(A) \subset D$, and $T(e^2)^\delta \leq T(e^{2\delta})^\delta \in D_+$, and $f_\delta := T(e^{2\delta})^\delta$ is an increasing approximate unit for D_+. Since $e^\delta a e^\delta \to a$ if $\delta \searrow 0$, it follows, that $T_\delta(a) \to T(a)$ for $a \in A$ if $\delta \searrow 0$. Hence, T is in the point-norm closure of the c.p. maps $\pi_J \circ V_\delta$ where the $V_\delta \in \mathcal{C}(V)$ are contractions.

The set $\mathcal{C}(V)_1$ of contractions in $\mathcal{C}(V)$ is an operator-convex set, in the sense that $a^*V_1(\cdot)a + b^*V_2(\cdot)b$ is a contraction in $\mathcal{C}(V)$ for $a, b \in C$ with $\|a^*a + b^*b\| \leq 1$ and contractions $V_1, V_2 \in \mathcal{C}(V)$). Therefore one can "perturb" ([13]) the elements of the sequence $\{V_{1/n}\}$ inside $\mathcal{C}(V)_1$ to a sequence $W_n \in \mathcal{C}(V)_1$ that converges in point-norm to an element $W \in \mathrm{CP}(A, C)$ such that $c^*W(\cdot)c \in \mathcal{S}$ for every $c \in C$.

Suppose now that A, C and T are unital. Then $1 - g_1(V(1)) \in J_+$ and $d_1 := 1 - V(1)g_1(V(1)) \in J_+$. Let $e_1 := g_1(V(1))^{1/2}$. There exists $\chi_0 \in \mathcal{S}$ with $\chi_0(1) \geq (d_1 - 1/4)_+$. There is a contraction $f \in J$ with $f^*\chi_0(1)f = (d_1 - 1/2)_+$, cf. Lemma 2.1.9. Let $\chi_1 := f^*\chi_0(\cdot)f$. Then $\chi_1 \in \mathcal{S}$, $\chi_1(1) + e_1V(1)e_1 = (d_1 - 1/2)_+ + 1 - d_1 =: h \geq 1/2$. Now let $e := e_1h^{-1/2} \in C^*(d_1, 1) \subset C$ and $\chi := h^{-1/2}\chi_1(\cdot)h^{-1/2} \in \mathcal{S}$. Then $\pi_J(e) = 1$ and $W := \chi + eV(\cdot)e$ is unital with $c^*W(\cdot)c \in \mathcal{S}$ for all $c \in J$. □

Corollary 5.4.9. *Suppose that A is separable, that B is stable and σ-unital, and that $\varphi\colon A \to \mathrm{Q}(B) = \mathcal{M}(B)/B$ is a C^*-morphism.*

Let $e \in B_+$ denote a strictly positive contraction in B and let $\mathcal{S} \subset \mathrm{CP}(A, B)$ countably generated non-degenerate operator-convex cone. Consider the non-degenerate $H_0\colon A \to \mathcal{M}(B)$ as defined in Corollary 5.4.4 for $\mathcal{S}$, and let $h_0 := \pi_B \circ (H_0 \oplus 0)$. Then:

(i) $[h_0] + [h_0] = [h_0]$,
(ii) *The unitary equivalence class $[\varphi]$ of φ is in $S(h_0;\, A, \mathrm{Q}(B))$ (= the semi-group introduced in Section 4 of Chapter 4), if and only if, there is a*

[12] I.e., for every $e \in J_+$ and $\varepsilon > 0$ there are $\chi \in \mathcal{S}$ and $a \in A_+$ with $(e - \varepsilon)_+ \leq \chi(a)$

[13] By "controlled" perturbations on a compact subset $\Omega \subset A$ with $\mathrm{span}(\Omega)$ dense in A, cf. e.g. the proof of the existence of nuclear lifts in [**43**].

completely positive map $W\colon A \to \mathcal{M}(B)$ *with* $\pi_B \circ W = \varphi$ *such that* $b^*W(\cdot)b$ *in the point-norm closure of* $\mathcal{S}$ *for every* $b \in B$ ([14]).

(iii) $[\varphi \oplus 0] = [\varphi] + [0]$ ([15]) *is in* $G(h_0;\, A, \mathrm{Q}(B)) = [h_0] + S(h_0;\, A, \mathrm{Q}(B))$, (*cf. Chapter 4, Section 4*), *if and only if, there is completely positive contraction* $W\colon A \to \mathcal{M}(B)$ *with* $\pi_B \circ W = \varphi$ *such that*

(a) $b^*W(\cdot)b$ *in the point-norm closure of* $\mathcal{S}$ *for every* $b \in B$, *and,*

(b) *for each* $V \in \mathcal{S}$, *there is a sequence of elements* $d_1, d_2, \ldots \in B$ *such that* $\lim_n d_n^* e d_n = 0$ *and* $\lim_n d_n^* W(a) d_n = V(a)$ *for all* $a \in A$.

Proof. (i): The commutant $h_0(A)' \cap \mathrm{Q}(B)$ contains a copy of $\mathcal{O}_2$ unitally, because H_0 is unitarily equivalent to $\delta_\infty \circ H_0$, $\delta_\infty(\mathcal{M}(B))' \cap \mathcal{M}(B)$ contains a copy of $\mathcal{L}(\ell_2)$ unitally, and because $\mathcal{L}(\ell_2)$ contains a copy of $\mathcal{O}_2 \otimes \mathcal{O}_2$ unitally. Thus the semigroup $S(h_0\,; A, \mathrm{Q}(B))$ is well-defined and is the set of unitary equivalence classes (by unitaries in $\mathrm{Q}(B)$) of C^*-morphisms $\psi\colon A \to \mathrm{Q}(B)$ dominated by h_0 (cf. Definition 4.3.3).

(ii): Let $\mathcal{D}$ denote the point-norm closure of $\mathcal{S}$.

Suppose that $W\colon A \to \mathcal{M}(B)$ is a completely positive map with $\pi_B \circ W = \varphi$ such that $b^*W(\cdot)b \in \mathcal{D}$ for every $b \in B$. The c.p. lift W of φ can be modified that it becomes *contractive*, cf. Lemma 5.4.8. It can be taken unital if A and $\varphi\colon A \to \mathrm{Q}(B)$ unital, because $W'(a) := d^{1/2} H_0(a) d^{1/2} + cW(a)c$ is as desired, if $c \in \mathcal{M}(B)_+$ with $0 \le c \le 1$, $1 - c \in B$ and $d := 1 - cV(1)c \in B$.

Let $J \subset A$ denote the kernel of $H_0\colon A \to \mathcal{M}(B)$ and let $H_1 = \delta_\infty \circ H_0$. H_1 is unitarily equivalent to H_1 (by condition (i) of Corollary 5.4.4) and, obviously, $\pi_B \circ H_1$ has the same kernel as H_0. $W(J) = \{0\}$, because $b^*W(\cdot)b \in \mathcal{D}$ for every $b \in B$ and H_0 satisfies (ii). Thus, there is a completely positive contrcaction $[W]_J\colon A/J \to \mathcal{M}(B)$ with $W = [W]_J \circ \pi_J$. Let $C := C^*(e, H_1(A))$, and define $V\colon C \to \mathcal{M}(B)$ by $V(c) := [W]_J(\Gamma^{-1}(\pi_B(c)))$, where $\Gamma\colon A/J \to \pi_B(H_1(A))$ is the isomorphism from A/J onto $\pi_B(H_1(A))$ with $\Gamma(a + J) := \pi_B(H_1(a))$. Note that $C \cap B = \overline{eCe}$, $C = (C \cap B) + \delta_\infty(H_0(A))$ and that $V(H_1(y) + z) = V(H_1(y)) = W(y)$ for $y \in A$ and $z \in C \cap B$.

Then $V(e) = 0$ and $e^{1/n} d \to d$ if $n \to \infty$ for every $d \in B$. In particular, $V(C \cap B) = \{0\}$. If $b \in B_+$, $\varepsilon > 0$ and if X is a finite subset of C_+, then there are $f \in B$ and finite subsets $Y \subset A$, and $Z \subset C \cap B$ such that $X \subset \{H_1(y) + z :\ y \in Y, z \in Z\}$ and $\|f^* H_0(y) f - bW(y)b\| < \varepsilon/2$ for $y \in Y$. The latter holds by property (ii) of H_0 in Corollary 5.4.4, because $bW(\cdot)b \in \mathcal{D}$. Since $\delta_\infty(g) = \sum_n s_n g s_n^*$ for all $g \in \mathcal{M}(B)$ with some sequence $s_1, s_2, \ldots$ of isometries in $\mathcal{M}(B)$ with $\sum_n s_n s_n^*$ strictly convergent to 1 in $\mathcal{M}(B)$, there is $m \in \mathbb{N}$ such that $\|f^* s_m^* z s_m f\| < \varepsilon/2$ for $z \in Z$. It follows $\|d^* x d - bV(x)b\| < \varepsilon$ for $x \in X$ and $d := s_m f$. Thus Proposition 5.4.1(i) applies: There is a contraction $g \in \mathcal{M}(B)$ such that $g^* c g - V(c) \in B$ for every $c \in C$. In particular, $g^* H_1(a) g - W(a) \in B$

[14]This particular c.p. lifts W of φ can be taken contractive. W can be chosen unital if A and φ are unital.

[15]Note that, in general, $[\varphi] + [0] \neq [\varphi]$ and $[\varphi] + [0] \neq [\varphi] + [h_0]$.

and $\pi_B(g)^*\pi_B(H_1(a))\pi_B(g)^* = \varphi(a)$ for $a \in A$. Since H_0 is unitarily equivalent to H_1 by property (i) of Corollary 5.4.4, and since $h_0 := \pi_B \circ H_0 \oplus 0$ (trivially) dominates zero, it follows from Proposition 4.3.6(ii) that h_0 dominates φ. This means $[\varphi] \in S(h_0, A, \mathrm{Q}(B))$.

Conversely, if φ is dominated by $h_0 = \pi_B \circ H_0 \oplus 0$ in $\mathrm{Q}(B) = \mathcal{M}(B)/B$, then there is a contraction $g \in \mathcal{M}(B)$ with $\pi_B(g^*H_0(\cdot)g) = \varphi$. For every $b \in B$, the map $W\colon a \in A \mapsto b^*g^*H_0(a)gb$ is in $\mathcal{D}$ by property (iii) of Corollary 5.4.4, i.e., $W := g^*H_0(\cdot)g$ is as desired.

We have seen that (i) is equivalent to $[\varphi] \in S(h_0, A, \mathrm{Q}(B))$.

But $[\varphi] \in S(h_0, A, \mathrm{Q}(B))$ implies $[\varphi \oplus 0] = [\varphi] + [0] \in S(h_0, A, \mathrm{Q}(B))$, because (trivially) $[0] \in S(h_0, A, \mathrm{Q}(B))$ and $S(h_0, A, \mathrm{Q}(B))$ is a semigroup by Proposition 4.4.2(i). Since $\varphi \oplus 0$ trivially dominates φ, $[\varphi] + [0] \in S(h_0, A, \mathrm{Q}(B))$ if and only if $[\varphi] \in S(h_0, A, \mathrm{Q}(B))$.

By Proposition 4.3.5(i), $[\varphi]+[0] \in G(h_0, A, \mathrm{Q}(B)$, i.e., $[\varphi]+[0] = [\varphi]+[0]+[h_0]$, if and only if $\varphi \oplus 0$ dominates h_0.

Suppose that $[\varphi]+[0]$ is in $G(h_0, A, \mathrm{Q}(B))$. Then there are contractions $g_1, g_2 \in \mathcal{M}(B)$ such that $\pi_B(g_1^*H_0(a)g_2) = \varphi(a)$ and $g_2^*g_1^*H_0(a)g_1g_2 - H_1(a) \in B$ for all $a \in A$ and $H_1 := \delta_\infty \circ H_0$, because H_1 is unitarily equivalent to H_0. Let $W(a) := g_1^*H_0(a)g_1$, then W satisfies (i), as we have seen above.

Let $V \in \mathcal{D}$, there is a sequence of elements $b_1, b_2, \ldots \in B$ such that $\lim_n b_n^*H_0(a)b_n = V(a)$ for all $a \in A$ (by property (ii) of H_0 in Corollary 5.4.4). One can see, with help of an approximate unit of A, that one manage that $\|b_n\|^2 \leq \|V\|$. Then $d_n := g_2s_nb_n$ satisfies $\lim_n d_n^*W(a)d_n = V(a)$ for all $a \in A$ and $\lim_n \|d_n^*ed_n\| \leq \|V\| \lim \|s_n^*(g_2^*eg_2)s_n\| = 0$, i.e., W satisfies also (ii).

Conversely, let $W\colon A \to \mathcal{M}(B)$ a contractive and completely positive lift of φ with (i) and (ii).

Then $[\varphi \oplus 0] \in S(h_0, A, \mathrm{Q}(A))$ by (i), as we have seen above. Since h_0 and $\varphi \oplus 0$ both dominate zero and since H_0 is unitarily equivalent to $H_1 = \delta_\infty \circ H_0$, it suffices to find a contraction $g \in \mathcal{M}(B)$ with $g^*W(a)g - H_0(a) \in B$ for all $a \in A$, to get that $\varphi \oplus 0$ dominates h_0 (cf. Proposition 4.3.6(ii)).

There is an isomorphism ψ from $\varphi(A)$ onto $H_0(A)$ such that $\psi(\varphi(a)) = H_0(a)$ for $a \in A$, because $W(a) \in B$ if and only if $H_0(a) = 0$: Indeed, above we have seen that $H_0(a) = 0$ implies $H_0(a^*a) = 0$ and $0 \leq W(a)^*W(a) \leq W(a^*a) = 0$. $W(a) \in B$ implies $\varphi(a^*a) = 0$, i.e., $W(a^*a) \in B$, and, by (ii), that $V(a^*a) = 0$ for all $V \in \mathcal{D}$, i.e., $H_0(a) = 0$ by property (iii) of H_0 in Corollary 5.4.4.

Let $C := C^*(e, W(A))$ and $V(c) := \psi(\pi_B(c))$. Then C is separable, $C \cap B = \overline{eCe}$, $C = (C \cap B) + W(A)$, $V(e) = 0$, $\lim_n e^{1/n}b = b$ for $b \in B$, $V(C \cap B) = \{0\}$, $V(W(a)) = H_0(a)$ for $a \in A$, and $\delta_\infty \circ V$ is unitarily equivalent to V, because H_0 is unitarily equivalent to $H_1 := \delta_\infty \circ H_0$. Moreover, $V\colon C \to \mathcal{M}(B)$ is a non-degenerate C^*-morphism.

If $b \in B_+$, $X \subset A$ and $Y \subset C \cap B$ are finite and $\varepsilon > 0$, then there is $d \in B$ with $\|d^* y d\| < \varepsilon/2$ and $\|d^* V(x) d - bH_0(x)b\| < \varepsilon/2$ by property (ii) of W, because $bH_0(\cdot)b \in \mathcal{D}$. Thus, Proposition 5.4.1 applies to C and V: There is a contraction $g \in \mathcal{M}(B)$ with $g^* c g - V(c) \in B$ for all $c \in C$, in particular $g^* W(a) g - H_0(a) \in B$ for all $a \in A$. □

Corollary 5.4.10. *Suppose that A is separable, B is σ-unital, $D \subset \mathcal{M}(B)$ is a*

`Is ``simple'' necessary?`

simple, stable and σ-unital C^*-subalgebra of $\mathcal{M}(B)$ such that DB is dense in B.

*Let $H\colon A \to \mathcal{M}(D) \subset \mathcal{M}(B)$ a non-degenerate *-monomorphism with $H(A) \cap D = \{0\}$ such that $H_d\colon A \ni a \mapsto d^* H(a) d \in D$ is nuclear for all $d \in D$.*

Then

(i) *$H_0 := \delta_\infty \circ H$ satisfies properties (i)–(iii) of Corollary 5.4.4 for the operator-convex cone $\mathcal{S} := \mathrm{CP}_{\mathrm{nuc}}(A, B)$.*
(ii) *H and H_0 are unitarily homotopic if $D \cong \mathbb{K}$ or if D is purely infinite.*

Proof. (i): Let $s_1, s_2, \ldots$ a sequence of isometries in $\mathcal{M}(D)$ such that $\sum s_n (s_n)^*$ converges strictly to 1. Then H_0 is unitarily equivalent to H_1 given by $H_1(a) := \sum s_n H(a) s_n^*$, and H_1 is unitarily equivalent to $\delta_\infty \circ H_1$, cf. Lemma 5.1.2(i). Let $q_m := \sum_{n \le m} s_n s_n^*$, $e \in D_+$ strictly positive, $b \in B$. Then

$$a \in A \to b^* e^{1/n} q_m H_1(a) q_m e^{1/m} b = \sum_{1 \le k \le m} b^* e^{1/m} s_k H(a) s_k^* e^{1/m} b$$

is nuclear, because $H\colon A \to \mathcal{M}(D)$ is weakly nuclear. It implies that $V_b := b^* H_1(\cdot) b$ is a nuclear map from A into B, because $\lim_m \|q_m e^{1/m} b - b\| = 0$ for $b \in B$. Hence $H_0 = U^* H_1(\cdot) U$ satisfies condition (i) and (iii) of Corollary 5.4.4 for the m.o.c. cone $\mathcal{S} := \mathrm{CP}_{\mathrm{nuc}}(A, B)$.

The proof of Corollary 5.4.4 shows: Since H_1 is unitarily equivalent to $\delta_\infty \circ H_1$ and is non-degenerate, we get that the maps $V_b\colon a \mapsto b^* H_1(a) b$ build an operator-convex cone $\mathcal{C} \subset \mathrm{CP}_{\mathrm{nuc}}(A, B)$ (that is generated by V_f for a strictly positive element $f \in B_+$).

Let $a \in A_+$ with $\|a\| = 1$, $b \in B_+$ and $\varepsilon > 0$. Then there is $m \in \mathbb{N}$ such that $\|e^{1/m} H(a) e^{1/m}\| > 1/2$, and $\|b(1 - e^{1/m}) b\| < \varepsilon/2$, because $\|H(a)\| = 1$ and because DB is dense in B. Let $c := e^{1/m} H(a) e^{1/m} \in D$. Since D is simple, there are $f_1, \ldots, f_k \in D$ such that $\|e^{1/m} - \sum f_j^* c f_j\| < \varepsilon/2$. Now let $d := \sum_{1 \le j \le k} s_j^* e^{1/m} f_j b \in B$. Then $\|d^* H_1(a) d - b^2\| < \varepsilon$. Thus, Lemma 3.2.7 applies, and every nuclear map $V\colon A \to B$ is in the point-norm closure of $\mathcal{C}$. Hence, H_0 satisfies condition (ii) of Corollary 5.4.4 for $\mathcal{S} := \mathrm{CP}_{\mathrm{nuc}}(A, B)$.

(ii): Since $\delta_\infty(H(a)) = \sum s_n a s_n^*$ is (up to unitary equivalence) independent from the sequence of isometries $s_1, s_2, \ldots$ with $\sum s_n s_n^* = 1$ (strictly), and since $\mathcal{M}(D) \to \mathcal{M}(B)$ is unital and strictly continuous, it suffices to consider the case, where $B = D$. Let $e \in D_+$ a strictly positive contraction, and let $C := C^*(H(A), e)$, $e \in C \cap B =: J \triangleleft C$ and there is a (unique) *-morphism $\psi \colon C \to A$ with $\ker(\psi) = C \cap B$ and $\psi \circ H = \mathrm{id}_A$. Let $V := H_0 \circ \psi = \delta_\infty \circ T$ (for $T := H \circ \psi$). Then $V \colon C \to \mathcal{M}(D)$ is a non-degenerate *-morphism with $V(e) = 0$. The map V is weakly nuclear, because $H_0 \colon A \to \mathcal{M}(B)$ is weakly nuclear.

For $b \in D = B$ the map $V_b \colon c \in C \mapsto b^* V(c) b \in D$ is nuclear and $V_b(C \cap D) = \{0\}$. It follows from Proposition 3.2.13(i) that V_b is approximately 1-step inner if D is purely infinite.

If $D \cong \mathbb{K}$, then $[V_b] \colon C/(C \cap D) \to D$ is necessarily nuclear. Then the map V_b is approximately 1-step inner by Remark 3.2.14. It follows that $(C, V, e, B = D)$ satisfy also condition (β) of Proposition 5.4.1 in both cases. Then $H_0 = \delta_\infty \circ H = H \oplus \delta_\infty \circ H$ is unitarily homotopic to H by Proposition 5.4.1(iii). □

QUESTIONS:

Suppose A separable (unital or stable), B σ-unital and stable.

Let $H_0 \colon A \to \mathrm{Q}(B)$ a C^*-morphism, e.g. is defined by the universal bi-module of all nuclear maps form A to B.

Is it next?

If we use that $B \otimes \mathbb{K} \cong B$, then this is given by $H_0 := \pi_B \circ \delta_\infty \circ (1 \otimes h)$ the infinite repeat of any faithful representation $h \colon A \to \mathcal{M}(\mathbb{K})$.

Now describe all $H \colon A \to \mathrm{Q}(B)$ that absorb H_0. ...???

Define $\mathcal{S}'(H)$ as the set of "u.c.p. maps $V \colon A \to B$" (??) with the property that there exists a sequence of contractions in $T_n \in \mathrm{Q}(B)$ such that

$$\pi_B(\delta_\infty \circ V(a)) - T_n^* H_o(a) T_n \to 0\,.$$

Let $W \colon A \to \mathcal{M}(B)$ a c.p. contraction.

Does H dominate $\pi \circ W$ if $b^* W(\cdot) b \in \mathcal{C}(\mathcal{S}'(H))$ for all $b \in B$?

The point is:

What happens with infinite strictly convergent sums

$$T(\cdot) = \sum_n b_n^* V_n(\cdot) b_n$$

with $V_n \in \mathcal{C}(\mathcal{S}'(H))$?

Cases $A = \mathbb{C}$, $A = \mathrm{C}_0(0,1]$?

What happens in unital/non-unital cases?

Check next blue text again!!

REMARK 5.4.11. G. Elliott and D. Kucerovsky, [**264**], have used – together with their own proof – the following older version of Proposition 5.4.1:

Let C be a unital separable C^*-algebra and let B be an essential closed two-sided ideal of C, so that we may view C as a unital subalgebra of $\mathcal{M}(B)$:

$$B \subseteq C \subseteq \mathcal{M}(B); \quad 1 \in C\,.$$

Let $T\colon C \to \mathcal{M}(B)$ be a completely positive map which is zero on B, and suppose that, for every $b \in B$, the map

$$b^*T(\cdot)b\colon\ C \to B,$$

given by $c \mapsto b^*T(c)b$, can be approximated (on finite subsets of C) by the maps

$$c \mapsto d^*cd,\ \ d \in B\,.$$

It follows that there exists a sequence $S_n \in \mathcal{M}(B)$ such that

$$T(c) - S_n^*cS_n \in B,\ \text{ for all, } c \in C\,,$$

and $\lim_n S_n^*cS_n = T(c)$ for all $c \in C$.

This can be seen from Proposition 5.4.1, if one takes for the element $h \in C_+$ in Condition (α) of Proposition 5.4.1 a strictly positive contraction of B. The approximation condition implies Condition (β).

Comments to it: Find out the ingredients!!

Let B a σ-unital C^*-algebra, C a separable C^*-subalgebra of $\mathcal{M}(B)$, and $T\colon C \to \mathcal{M}(B)$ a linear map with $\|T\| \leq 1$ that satisfies the following Conditions *(α)* and *(β)*:

(α) There exists $h \in C_+$ with $T(h) = 0$ and $h^{1/n}d \to d$ if $n \to \infty$ for every $d \in B$.

(β) For every $a \in B_+$, every finite subset $X \subset C_+$ of contractions and every $\varepsilon > 0$ there exists $d \in \mathcal{M}(B)$ with $\|d^*cd - aT(c)a\| < \varepsilon$ for $c \in X$.

Question 5.4.12. Let A separable, B stable and σ-unital, $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ a countably generated operator convex cone, e.g. $\mathcal{C} := \mathrm{CP}_{\mathrm{nuc}}(A, B)$ (which is singly generated).

Is there a characterization of those $H\colon A \to \mathrm{Q}(B)$ that absorbs each $\pi_B \circ \delta_\infty \circ h\colon A \to \mathrm{Q}(B)$ with $h\colon A \to \mathcal{M}(B)$ that satisfies $b^*h(\cdot)b \in \mathcal{C}$ for all $b \in B$?

In the case of [**264**] it is

In case of $\mathcal{C} := \mathrm{CP}_{\mathrm{nuc}}(A, B)$ a necessary and sufficient criteria for absorbing was given by G. Elliott and D. Kucerovsky [**264**], cf. [**310**] for the non-unital case.

Has to consider as $C \subset \mathcal{M}(B)$ some separable C^*-subalgebra of $\mathcal{M}(B)$ with the properties that $\pi_B(C) = H(A)$ and that $C \cap B$ contains $e \in C \cap B$ that is strictly positiv in B. Then use $B \cong B \otimes \mathbb{K}$ and take a faithful representation $\rho\colon A \to \mathcal{M}(\mathbb{K}) \subseteq \mathcal{M}(B \otimes \mathbb{K})$ in "general position", i.e., ρ unitary equivalent to its infinite repeat.

To get absorbed it is necessary that H is faithful.

Then let $T(c) := \rho(H^{-1}\pi_B(c))$. Let $h := e$ for (α) a strictly positive element of $B \otimes \mathbb{K}$.

Check (β) ... for C, T ...

5. Ψ-equivariant Stability of extensions

We deduce from Proposition 5.4.1 some results concerning stability and a Ψ-equivariant version (respectively m.o.c. cone equivariant version) of L.G. Brown's stable isomorphism theorem [**107**, thm.2.8].

Recall that a hereditary C^*-subalgebra D of a C^*-algebra B is **full** if the linear span of BDB is dense in B, and that D is called a **corner** if there exists a (unique) projection $p \in \mathcal{M}(B)$ with $D = pBp$.

The following Corollary of the tautological Weil–von-Neumann type result Proposition 5.4.1 gives an alternative proof of the stability criteria for σ-unital C^*-algebras of Hjelmborg and Rørdam [**373**, thm. 2.1, prop. 2.2(b)].

Corollary 5.5.1. *Suppose that B is a non-zero σ-unital and stable C^*-algebra, and that D is a* full corner *of B, i.e., there is a projection $p \in \mathcal{M}(B)$ with $pBp = D$ and* span BDB *is dense in B.*

(i) *If, for every $g \in D_+$ and $\delta > 0$, there exist $b \in D$ with $\|b^*b - g\| < \delta$, and $\|b^*gb\| < \delta$, then there exists an isometry $S \in \mathcal{M}(B)$ with $SS^* = p$.*
(ii) *The isometry S of Part (i) defines an isomorphism φ from B onto D by $\varphi(b) := SbS^*$ for $b \in B$, and φ satisfies*

$$\varphi(J) = D \cap J \quad \textit{for all } J \in \mathcal{I}(B)\,.$$

(iii) *If $S_1, S_2 \in \mathcal{M}(B)$ are isometries in $\mathcal{M}(B)$ such that the maps $\varphi_k := S_k(\,\cdot\,)S_k^*$, $k \in \{1,2\}$, from B onto $D \subseteq B$ coincide (i.e., $\varphi_1 = \varphi_2$), then there exists a unitary U in the center of $\mathcal{M}(B)$ with $S_1 \cdot U = S_2$.*
(iv) *The isometries $S \in \mathcal{M}(B)$ with $SBS^* = D$ can be obtained from the polar decompositions $d := S(d^*d)^{1/2} = (dd^*)^{1/2}S$, of any element $d \in B$ with the property that d^*d is strictly positive in B and dd^* is a strictly positive element of D.*

Proof. The idea of our proof is different from that in [**373**], because our proof is based on the fact that full properly infinite projections are MvN-equivalent if they have the same class in K_0 (an observation of J. Cuntz, cf. proof of Lemma 4.2.6(ii)). We combine this with the "tautological" Weyl–von-Neumann type result in Proposition 5.4.1 to get Part (i). The other parts follow then by straight calculation.

(In fact all this conclusions of Proposition 5.4.1 are almost trivial elementary applications, consisting only in notational problems.)

(i):

TO BE SHOWN:

Let $p \in \mathcal{M}(B)$ a projection, and let $D := pBp$. Suppose that span BDB is dense in B, and that for every $g \in D_+$ and $\delta > 0$, there exist $b \in D$ with $\|b^*b - g\| < \delta$, and $\|b^*gb\| < \delta$.

Then there exists an isometry $S \in \mathcal{M}(B)$ with $SS^* = p$.

Recall that $\mathrm{K}_*(\mathcal{M}(B)) = 0$ because δ_∞ is unitarily equivalent to $\delta_\infty \oplus \mathrm{id}$, cf. Lemma 5.1.2(ii).

By Lemma 4.2.6(ii), it suffices to show that there is an isometry I in $\mathcal{M}(B)$ with $II^* \leq p$, because then p and $q := 1$ are both projections that majorize orthogonal ranges of two isometries in $\mathcal{M}(B)$ and have same class $[p] = [q]$ in $\mathrm{K}_0(\mathcal{M}(B)) = 0$. By Lemma 4.2.6(ii), the projections p and $q = 1$ are MvN-equivalent in $\mathcal{M}(B)$, i.e., there is an isometry $S \in \mathcal{M}(B)$ with $SS^* = p$.

(In fact, the existence of an operator $S_0 \in \mathcal{M}(B)$ with $x := 1 - S_0^*pS_0 \in B$ would be enough, because the stability of B causes the existence of an isometry $S_1 \in \mathcal{M}(B)$ with $\|S_1^*xS_1\| \leq 1/2$. Then $I := pS_0S_1(S_1^*S_0^*pS_0S_1)^{-1/2}$ is an isometry with $II^* \leq p$.)

We apply Proposition 5.4.1(i) to prove the existence of needed isometry I:

Take a strictly positive contraction $e \in B_+$ and let C denote the unital commutative C^*-subalgebra of $\mathcal{M}(B)$, which is generated by the commuting elements 1, p, pep and $(1-p)e(1-p)$. The intersection $C \cap B$ contains the strictly positive contraction $h := pep + (1-p)e(1-p) = 2^{-1}((1-2p)e(1-2p) + e)$ of B.

The projection $p \in \mathcal{M}(B)$ is not contained in B, because otherwise $p \in pBp = D$ and the assumptions in part (i) propose the existence of $b \in D$ (i.e., $b \in pBp$) with $pb = b = bp$, $\|b^*pb\| < 1/4$ and $\|b^*b - p\| < 1/4$, which is impossible for a non-zero projection p.

Let χ denote the (unique) character of C with $\chi(C \cap B) = 0$ and $\chi(p) = 1$. It satisfies $\chi(y) = \chi(pyp)$ for all $y \in C$, in particular, $\chi((1-p) + pep) = 0$.

The map $T(a) := \chi(a)1$ is a C^*-morphism from C into $\mathcal{M}(B)$. Obviously, $T(p) = T(1) = 1$ and T has the same kernel $T^{-1}(0) = C \cap B + \mathbb{C} \cdot (1-p)$ as $\chi \colon C \to \mathbb{C}$ has. In particular $T(h) = 0$ for the strictly positive element h of B. The strict positivity implies that $b = \lim h^{1/n}b$ for all $b \in B$.

Thus, C, T and h satisfy condition (α) of Proposition 5.4.1.

(β): For every $a \in B_+$, every finite subset $X \subset C_+$ and every $\varepsilon > 0$ there exists $d \in \mathcal{M}(B)$ with $\|d^*cd - aT(c)a\| < \varepsilon$ for $c \in X$.

`Part to be checked:`

We show that T satisfies also condition (β) of Proposition 5.4.1:

Let $a \in B_+$, X a finite subset of C_+ for $C := C^*(1, p, pep, (1-p)e(1-p))$ and $\varepsilon > 0$. We define $\gamma := \max\{\|c\| \colon c \in X\}$ and $\delta := \varepsilon/(4 + 4\gamma)$.

Notice that $pCp = C^*(pep) + \mathbb{C} \cdot p$, because $c = pcp + (1-p)c(1-p)$ for all $c \in C$.

The kernel of T is identical with the kernel $(1-p)C + p(C \cap D)$ of χ.

It follows that $\chi(C \cap D) \subseteq \chi(C \cap B) = \{0\}$ and $\chi(1-p) = 0$

In particular $pcp - \chi(c)p$ is in $C \cap D$ for $c \in C_+$.

Since $c = pc+(1-p)c = pcp+(1-p)c(1-p)$ for all $c \in C$ and since $\chi(1-p) = 0$ and $\chi(C \cap B) = \{0\}$, we get that

$pcp - \chi(c)p$ is in $C \cap D$ for $c \in C_+$. Thus, if $b \in pB$, then, for $c \in C_+$,

$$b^*cb = \chi(c)b^*b + b^*(pcp - \chi(c)p)b\,.$$

Since $pcp - \chi(c)p$ is selfadjoint,

$$\|b^*(pcp - \chi(c)p)b\| \leq \|b^*|(pcp - \chi(c)p)|b\|\,.$$

We consider the sum f of the absolute values $|pcp - \chi(c)p|$:

$$f := \sum_{c\in X} |pcp - \chi(c)p| \in C \cap D_+\,. \tag{5.1}$$

Then, for $c \in X$ and $b \in pB$,

$$\|b^*cb - aV(c)a\| \leq |\chi(c)|\|b^*b - a^2\| + \|b^*fb\|\,.$$

Thus, to verify (β), it suffices to find $b \in pB$ with $\|b^*b - a^2\| < 2\delta$ and $\|b^*fb\| < 2\delta$ for the f defined in Equation (5.1).

Since D is full, there exists $b_1, \ldots, b_m \in pB$ with $\|\sum b_j^*b_j - a^2\| < \delta$. Let $\rho := \delta/m(1+\|a\|^2+\delta)$. There is a contraction $g \in D_+$, such that $\|b_j^*gb_j - b_j^*b_j\| < \rho$ for $j = 1, \ldots, m$. By induction, the assumption on D implies that, for every $f, g \in D_+$, $m \in \mathbb{N}$, and $\rho > 0$, there exist $d_1, \ldots, d_m \in D$, such that $\|d_i^*d_j - \delta_{ij}g\| < \rho$ and $\|d_i^*fd_j\| < \rho$ for $i, j = 1, \ldots, m$. Let $b := \sum d_jb_j$. Then $\|b^*fb\| < m\cdot(\|a\|^2+\delta)\cdot\rho$ and $\|b^*b - \sum b_j^*b_j\| < m\cdot(1 + \|a\|^2 + \delta)\cdot\rho$. Thus $\|b^*fb\| < \delta$, $\|b^*b - a^2\| < 2\delta$, and $V = \delta_\infty \circ T$ satisfies also condition (β) of Proposition 5.4.1.

We are now in position to apply Parts (i) and (iv) of Proposition 5.4.1, and find an element S_1 in $\mathcal{M}(B)$, such that $\|S_1^*pS_1 - 1\| < 1$.

The element $I := pS_1(S_1^*pS_1)^{-1/2}$ is an isometry in $\mathcal{M}(B)$ with $II^* \leq p$.

Thus p is full and properly infinite in $\mathcal{M}(B)$.

(ii): The isometry $S \in \mathcal{M}(B)$ with $SS^* = p$ defines obviously an injective C^*-morphism $\varphi(b) := SbS^*$ $(b \in B)$ from B into $D = pBp$. It is surjective because $\varphi(SdS^*) = d$ for $d \in D$.

The hereditary C^*-subalgebra D of B is full in B. Therefore, the map $J \in \mathcal{I}(B) \mapsto D \cap J \in \mathcal{I}(B)$ is a bijective map. Since $S \in \mathcal{M}(B)$ we get that $SJS^* \subseteq D \cap J$. If $d \in D \cap J$, then $S^*dS \in J$ and $\varphi(S^*dS) = d$. Thus, $\varphi(J) = D \cap J$.

(iii):

If $\varphi(b) = S_1bS_1^* = S_2bS_2^*$ for isometries $S_1, S_2 \in \mathcal{M}(B)$ and $b \in B$, then we obtain that $S_1S_1^* = S_2S_2^* =: p$ from $S_1eS_1^* = S_2eS_2^*$ for for $e \in B$ in an approximate unit of B. Thus, $U := T^*S \in \mathcal{M}(B)$ is a unitary with $Ub = bU$ for all $b \in B$. Now use that B is strictly dense in $\mathcal{M}(B)$ the unitary U is in the center of $\mathcal{M}(B)$. Clearly $TU = S = UT$.

(iv): If $d \in B$ has the property that d^*d is strictly positive in B and dd^* is a strictly positive element of D, then the partial isometry $v \in B^{**}$ in the polar decomposition with $d := v(d^*d)^{1/2} = (dd^*)^{1/2}v$ satisfies, – by definition of the unique polar-decomposition in the W*-algebra B^{**} –, that v^*v is the open support projection $= 1$ of d^*d in B^{**} and vv^* is the support projection p of dd^* in B^{**}. Thus, $vv^* = p$, $v^*v = 1$.

Above formulas imply $B = \overline{(d^*d)^{1/2}B}$, $\overline{dB} = pB$ and $\overline{B(dd^*)^{1/2}} = Bp$. Using this equations, then we get $vB = \overline{dB} = pB \subseteq B$ from $d = v(d^*d)^{1/2}$, and $Bv = Bpv = \overline{Bd} \subseteq B$ from $(dd^*)^{1/2}v = d$.

Thus, v is an isometry in $\mathcal{M}(B)$ and can deserve as one of the above considered $S \in \mathcal{M}(B)$. □

(StC) looks strange? Better notation?

Corollary 5.5.2 ([**373**]). *A non-zero σ-unital C^*-algebra A is stable, if and only if, satisfies the following "stability criterium"* (StC)*:*

(StC) *For every $a \in A_+$ and $\varepsilon > 0$ there exists $d \in A$ such that $\|a - d^*d\| < \varepsilon$ and $\|d^*ad\| < \varepsilon$.*

Proof. Let $a \in A_+$ and $\varepsilon > 0$. If A is stable and $t_1, t_2, \ldots$ is a sequence of isometries in $\mathcal{M}(A)$ with $\sum t_k t_k^*$ strictly convergent to $1_{\mathcal{M}(A)}$, then there exists $n \in \mathbb{N}$ with $\|t_n^* a t_n\| < \varepsilon/(1 + \|a\|)$. If we let $d := t_n a^{1/2}$, then $d^*d = a$ and $\|d^*ad\| < \varepsilon$.

Conversely suppose that each for $a \in A_+$ and $\varepsilon > 0$, there exists $d \in A$ with $\|d^*ad\| < \varepsilon$ and $\|d^*d - a\| < \varepsilon$. Let $B := A \otimes \mathbb{K}$ and $D := A \otimes e_{11}$.

Then the corner D of the σ-unital stable C^*-algebra B satisfies the assumptions of Corollary 5.5.1. Thus, A is isomorphic to the stable algebra B. □

If A is σ-unital, then A/J is σ-unital. If $A_1 \subseteq A_2 \subseteq \cdots \subseteq A$ are σ-unital C^*-subalgebras with $\bigcup_n A_n$ dense in A, then A is σ-unital: $e = \sum_n 2^{-n} e_n$ is strictly positive in A if e_n is strictly positive in A_n. This together implies that $\mathrm{indlim}(h_n \colon A_n \to A_{n+1})$ is σ-unital if each A_n is σ-unital.

It is easy to see that A satisfies the criteria of Corollary 5.5.2 if A is the inductive limit of an (arbitrary upward directed) family of C^*-algebras A_τ that satisfy the criteria (STC) if the inductive limit is still σ-unital, e.g. if the directed diagram of morphisms h_n is countable. Thus we get:

Corollary 5.5.3 ([**373**]). *The inductive limit of a* sequence *of σ-unital stable C^*-algebras is σ-unital and stable.*

A generalization of the Zhang's dichotomy [**846**] for simple purely infinite σ-unital C^*-algebras, is the following, cf. [**462**, thm. 4.24].

COROLLARY 5.5.4 (Generalized Zhang dichotomy). *A σ-unital purely infinite C^*-algebra B is stable if and only if B has no unital quotient.*

PROOF. Quotients of stable C^*-algebras are zero or stable. Thus B can not have a unital quotient if B is stable.

For the *non-trivial* direction suppose that B is p.i. and has no unital quotient. Let $0 \neq a \in B_+$, $0 < \varepsilon < 1$ and $\delta = \varepsilon/(1 + \|a\|)$.

The closed ideal J of B which is generated by the non-zero (!) annihilator $D := \mathrm{Ann}((a-\delta)_+, B)$ of $(a-\delta)_+$ in B is equal to B, because – otherwise – B/J is unital, $\mathrm{Spec}(\pi_J(a)) \subset \{0\} \cup [\delta/2, \|a\|]$ and $\pi_J(a)$ is a strictly positive element of B/J, cf. Lemma 2.5.14(i,ii) for more details. Since, by assumption, B has no unital quotient, it follows that $D = \mathrm{Ann}((a-\delta)_+, B)$ is a full hereditary C^*-subalgebra of B. Thus, there are $c_1, \ldots, c_n \in D_+$ and $e_1, \ldots, e_n \in B$ with $\|a - \sum e_k^* c_k e_k\| < \delta/2$. By the definition of p.i. algebras there is $f \in B$ with $\|a - f^*cf\| < \delta$, where $c := c_1 + \ldots + c_n \in D_+$. Let $d := c^{1/2} f$. Then $\|d^*d - a\| < \delta < \varepsilon$, $d^*ad = d^*(a - (a-\delta)_+)d$ and $\|d^*ad\| \leq \delta(\|a\| + \delta) < \varepsilon$. Thus, B satisfies the criteria (STC) of Corollary 5.5.2 and is stable. □

REMARK 5.5.5.

(i) Corollary 5.5.4 implies Zhang's dichotomy [**846**] for simple purely infinite algebras:

A σ-unital simple purely infinite C^*-algebra is unital or is stable.

(ii) Proposition 2.2.1, Brown's stable isomorphism theorem and the dichotomy together immediately imply that every hereditary C^*-subalgebra D of a simple purely infinite C^*-algebra A has an approximate unit consisting of projections. By a theorem of Brown and Pedersen, [**113**], this property is equivalent to the property that the real rank of A is zero, i.e., every selfadjoint element can be approximated by selfadjoint elements of A with finite spectra.

Thus *every simple purely infinite C^*-algebra has real rank zero.* See also the proof of Proposition 2.2.1(x).

(iii) We don't use for our results on classification that simple purely infinite algebras A have zero real rank. ($rr(A) = 0$ can be seen also by the asymptotic methods in Chapter 7 or immediately from Theorem B.)

The following Corollary 5.5.6 is implicitly contained in the proofs of [**107**]. `more precise ref` We derive it from Corollary 5.5.1.

COROLLARY 5.5.6 (Ψ-equivariant Brown stable isomorphism). *Suppose that D is a stable σ-unital hereditary C^*-subalgebra of a stable σ-unital C^*-algebra B, such that BDB is dense in B.*

Then there exists $d \in B$, such that

(i) *d^*d is a strictly positive element of B,*
(ii) *dd^* is a strictly positive element of D,*

(iii) *the polar decomposition* $v(d^*d)^{1/2}$ *of* d *in* B^{**} *defines an isomorphism* $\varphi := v(\cdot)v^*$ *from* B *onto* $D \subset B$*, such that*

(iv) $\varphi\colon B \to B$ *is unitarily homotopic to* id_B*, in particular* $\varphi(J) = D \cap J$ *for* $J \in \mathcal{I}(B)$*.*

It follows: if D_1 *is a* σ*-unital hereditary* C^**-subalgebra of a* σ*-unital* C^**-algebra* B_1*, which is not contained in a closed ideal* $J \neq B_1$*, then there exists a* **-isomorphism* ψ *from* $D_1 \otimes \mathbb{K}$ *onto* $B_1 \otimes \mathbb{K}$ *such that, for* $J \in \mathcal{I}(B_1)$*,*

$$\psi((D_1 \cap J) \otimes \mathbb{K}) = J \otimes \mathbb{K}.$$

Proof. Let t and s isometries in $\mathcal{M}(B)$ with $t^*s = 0$, and let E denote the hereditary C^*-subalgebra of B which is generated by $F := sDs^* + tBt^*$. Then $\mathrm{id}\,|F$ is a non-degenerate *-monomorphism from F into E. It extends to a unital strictly continuous *-monomorphism $H := \mathcal{M}(\mathrm{id}\,|E)$ from $\mathcal{M}(F) \cong \mathcal{M}(sDs^*) \oplus \mathcal{M}(tBt^*)$ into E. It follows that sDs^* and tBt^* generate a corner of E. But both are hereditary C^*-subalgebras of B, which generate B as closed ideal.

Thus, sDs^* and tBt^* are corners of E that generate E as closed ideal.

F is stable, because sDs^* and tBt^* are stable, indeed: If $s_1, s_2, \ldots$ is a sequence of isometries in $\mathcal{M}(F)$, such that $\sum_n s_n s_n^*$ converges strictly to 1, then $H(s_1), H(s_2), \ldots$ has the same property for E. Thus, E is stable by Remark 5.1.1(8).

Since $sDs^* \cong D$, tBt^* and and E are stable, Corollary 5.5.2 implies that the pairs $sDs^* \subset E$ and $tBt^* \subset E$ satisfy the assumptions of Corollary 5.5.1 (in place of the pair $D \subset B$). It follows, that there are elements $d_1, d_2 \in E$, such that $d_1^*d_1$ and $d_2^*d_2$ are strictly positive elements of E, $d_1d_1^*$ is a strictly positive element of sDs^* and $d_2d_2^*$ is a strictly positive element of tBt^*. Then $d := s^*d_1d_2^*t$ satisfies that d^*d is a strictly positive element of B and dd^* is a strictly positive element of D. Let $v(d^*d)^{1/2}$ be the polar decomposition. By Remark 2.3.1, $\varphi(a) = vav^*$ is an isomorphism from B onto D, and $\varphi^{-1} : D \to B$ is given by $a \mapsto v^*av$.

By Lemma 5.1.2(iv) there exists a norm-continuous map $t \in [1, \infty) \mapsto S_0(t)$ into the isometries in $\mathcal{M}(B)$ with $\lim_{t\to\infty} S_0(t)b = 0$ for $b \in B$. Let $G := \mathrm{C_b}([1,\infty), \mathcal{M}(B))/\,\mathrm{C_0}([1,\infty), B) \supset B$. Then $\mathcal{M}(B) \subset G$ naturally and G contains a copy of $\mathcal{O}_2$ unitally. Let $h_1, h_2\colon B \to E$ given by $h_1(b) := b \in F$??? or G and $h_2(b) := h_1(\varphi(b))$ for $b \in B$. Now consider the isometry $s := \{S_0(t)\}_{1 \le t < \infty} + \mathrm{C_0}(\mathbb{R}_+, B)$ in G which corresponds to $S_0 \in \mathrm{C_b}([0,\infty), \mathcal{M}(B))$, and the contraction $y \in G$ with representative $Y(t) := d^*(dd^* + 1/t)^{-1/2}$ for $t \in [0, \infty)$.

Then $s^*h_j(\cdot)s = 0$ for $j = 1, 2$, $y^*h_1(\cdot)y = h_2$ and $yy^*h_1(\cdot)yy^* = h_1$ Thus Proposition 4.3.6(iii) applies: there is a unitary u in F with $u^*h_1(\cdot)u = h_2$.

The unitary u comes from a continuous map $U(t)$ from $[0, \infty)$ into the unitaries of $\mathcal{M}(B)$ such that $u = \{U(t)\}_{t\in[0,\infty)} + \mathrm{C_0}(\mathbb{R}_+, B)$, cf. proof of Lemma 5.1.2(vi).

Since the unitary group of $\mathcal{M}(B)$ is (norm-) connected ([**180**]), one can choose such that $t \mapsto U(t)$ such that $U(0) = 1$. Clearly, $u^*h_1(\cdot)u = h_2$ means that

$\lim_{t\to\infty} \|U(t)^* bU(t) - \varphi(b)\| = 0$ for $b \in B$, i.e., that id_B and φ are unitarily homotopic.

It follows $\varphi(J) \subset D \cap J$ and $\varphi^{-1}(D \cap J) \subset J$, which means $\varphi(J) = D \cap J$ for $J \in \mathcal{I}(B)$. □

next Lemma is the old Lemma 7.15,
which is now n o t cited in Chapter 7

LEMMA 5.5.7. *Suppose that A is a* full *hereditary C^*-subalgebra of B (i.e., $ABA = A$ and $\overline{\mathrm{span}(BAB)} = B$), and that A and B are both σ-unital and stable. Then there exist x in B and an isomorphism φ from B onto A such that x^*x is strictly positive in B, xx^* is a strictly positive element in A and $\varphi(b) = ubu^*$ where u can be chosen as any contraction in B^{**} that satisfies $u^*x = (x^*x)^{1/2}$ and $xu^* = (xx^*)^{1/2}$.*

Moreover, $\varphi \colon B \to A \subset B$ is unitarily homotopic to id_B.

PROOF. The proof is implicitly contained in the proofs of Corollaries 5.5.1 and 5.5.6:
It is enough to find an $x \in B$ with x^*x strictly positive in B and xx^* strictly positive in A. We proceed as in [**107**]. Let $D \subset M_2(B)$ be the hereditary C^*-subalgebra which is generated by $\mathrm{diag}(e, f)$ where e is a strictly positive element of B and f is a strictly positive element of A. Then $F = \mathrm{diag}(A, B) \cong B \oplus A$ is naturally a C^*-subalgebra of D such that D is the closure of FDF. It follows that $\mathcal{M}(F)$ is unitally and strictly continuous contained in $\mathcal{M}(D)$. F is stable because A and B are stable. Thus there exists a copy C of $\mathbb{K}$ in $\mathcal{M}(F)$ with $\overline{CF} = F = \overline{FC}$. Then $C \subset \mathcal{M}(D)$ and $\overline{CD} = \overline{CFDF} = \overline{FDF} = D$ and similarly $\overline{DC} = D$. Then $\mathcal{M}(C) \subset \mathcal{M}(D)$ by a strictly continuous inclusion map such that $1_{\mathcal{M}(C)} \mapsto 1_{\mathcal{M}(D)}$. It follows that D is isomorphic to $p_{11}Dp_{11} \otimes \mathbb{K}$ where p_{11} is a rank one projection in C. To see this, we take $b_i \in \mathcal{M}(D)$ with $b_i^* b_j = \delta_{ij} p_{11}$ and with C the strict closure of the span of the $b_j b_i$ $(i, j = 1, 2, 3, \ldots)$. Since $\{\sum_{i=1}^n b_i b_i^*\}$ converges strictly to $1_{\mathcal{M}(D)}$, $d \mapsto (b_j^* d b_i)_{ji}$ defines a *-isomorphism from D onto $(p_{11}Dp_{11}) \otimes \mathbb{K}$. Since F is isomorphic to $B \oplus A$, $1_{\mathcal{M}(B)} \oplus 0$ and $0 \oplus 1_{\mathcal{M}(A)}$ define projections p, $q \in \mathcal{M}(D)$ with $p + q = 1$ and p, $q \in C'$. By definition of F we have that p, $q \in M_2(B)^{**} = M_2(B^{**})$ are given by $p = \mathrm{diag}(1, 0)$ and $q = \mathrm{diag}(0, r)$ where r is the open support projection of A. Since p, q are in C' it follows that under the isomorphism $D \cong (p_{11}Dp_{11}) \otimes \mathbb{K}$ (defined by C) p, q define $\bar{p} = pp_{11}$, $\bar{q} = qp_{11}$ in $\mathcal{M}(p_{11}Dp_{11})$ with $\bar{p} + \bar{q} = 1$. Furthermore one gets $p \cong \bar{p} \otimes 1_{\mathcal{M}(\mathbb{K})}$ and $q \cong \bar{q} \otimes 1_{\mathcal{M}(\mathbb{K})}$. ($\mathcal{M}(D) \cong \mathcal{M}(p_{11}Dp_{11}) \otimes \mathbb{K}$ is described in $\mathrm{Mat}_\infty(p_{11}Dp_{11})$ again by $T \in \mathcal{M}(D) \mapsto (b_j^* T b_i)_{ij}$ and we get $p \mapsto (b_j^* p b_i) = (b_j^* b_i p) = (\delta_{ij} p_{11} p) \otimes 1_{\mathcal{M}(\mathbb{K})}$. Similarly q maps to $p_{11} p \otimes 1_{\mathcal{M}(\mathbb{K})}$. $\bar{p}(p_{11}Dp_{11}\bar{p}$ generates $p_{11}Dp_{11}$ as a closed ideal because $(\bar{p} \otimes 1)(p_{11}Dp_{11} \otimes \mathbb{K})(\bar{p} \otimes 1) \cong pDp$ and pDp generates D as a closed ideal. A similar argument shows that $\bar{q}p_{11}Dp_{11}\bar{q}$ generates $p_{11}Dp_{11}$ as a closed ideal, i.e., $\bar{p}$ and $\bar{q}$ are full projections and $\bar{p} + \bar{q} = 1$).

Since D contains a strictly positive element, $p_{11}Dp_{11}$ also contains one. Thus the conditions of [**107**, lem. 2.5] are fulfilled and we get isometries $\bar{v}$, $\bar{w}$ in $\mathcal{M}(p_{11}Dp_{11} \otimes \mathbb{K})$ with $\bar{v}^*\bar{v} = \bar{w}^*\bar{w} = 1$ and $\bar{v}\bar{v}^* = \bar{p} \otimes 1_{\mathcal{M}(\mathbb{K})}$, $\bar{w}\bar{w}^* = \bar{q} \otimes 1_{\mathcal{M}(\mathbb{K})}$. In particular $\bar{p} \otimes 1_{\mathcal{M}(\mathbb{K})}$ and $\bar{q} \otimes 1_{\mathcal{M}(\mathbb{K})}$ are Murray- von Neumann equivalent in $\mathcal{M}(p_{11}Dp_{11} \otimes \mathbb{K})$. Now we use the isomorphism to $\mathcal{M}(D)$ and get a partial isometry $v \in \mathcal{M}(D)$ with $v^*v = p$ and $vv^* = q$. If we consider v as an element in $M_2(B^{**}) \supset \mathcal{M}(D)$ we get $v^*v = \operatorname{diag}(1,0)$, $vv^* = \operatorname{diag}(0,r)$. Let $y = v\operatorname{diag}(e,0)$, then y satisfies $y \in D$, $y^*y = \operatorname{diag}(e^2,0)$ is strictly positive in $pDp \cong B \oplus 0$, $yy^* = v\operatorname{diag}(e^2,0)v^*$ is strictly positive in $qDq \cong 0 \oplus A$. Thus we get that $y = (a_{ij})_{ij} \in M_2(B)$ with only a_{12} nonzero. Let x be a_{12} and $\varphi(b) = ubu^*$ for any u in B^{**} with $u^*x = (x^*x)^{\frac{1}{2}}$, $xu^* = (xx^*)^{\frac{1}{2}}$ and $\|u\| \leq 1$ (e.g. coming from the polar decomposition of x). Since φ is a completely positive contraction, it is sufficient to check that φ is multiplicative on the dense subset x^*Bx of B and here we only need that $xx^* = xu^*ux^*$ holds.

Similarly one checks that φ maps all onto the closure A of $(xx^*)^{1/2}B(xx^*)^{1/2}$, and that $\psi(a) := u^*au$ for $a \in A$ is the inverse of φ, cf. Remark **??**. □

REMARK 5.5.8. *Extensions E (given by an exact sequence $0 \to B \to E \to A \to 0$) of stable separable algebras A by stable separable algebras B are in general not stable.* E.g. there is an extension E of $A := \mathbb{K}$ by $B := C(\mathcal{Z}, \mathbb{K})$ for the Tychonoff product $\mathcal{Z}$ of countably many copies of the 2-dimensional sphere S^2, cf. [**685**].

We show that every extension E of a separable stable C^*-algebra A by a purely infinite σ-unital stable B is stable.

This follows from some more general stability criteria that we discuss now.

Notice that it it suffices to consider the case $A := \mathrm{C}_0(\mathbb{R}_+, \mathbb{K})$ by Remark 5.1.1(9).

LEMMA 5.5.9. *Suppose that B is stable and σ-unital, and that D is σ-unital. Let $\mathrm{Q}(B) := \mathcal{M}(B)/B$ and suppose that $h_1, h_2 \colon D \to \mathrm{Q}(B)$ are unitarily equivalent C^*-morphisms. Then:*

- (o) *$\mathcal{M}(B)$ and $\mathrm{Q}(B)$ have property* (sq) *of Definition 4.2.14 (and are K_1-bijective by Lemma 4.2.6(v) and Proposition 4.2.15).*
- (i) *$\mathrm{K}_*(\mathcal{M}(B)) = 0$ and $\mathcal{U}_0(\mathcal{M}(B)) = \mathcal{U}(\mathcal{M}(B))$.*
- (ii) *$E := \mathrm{Q}(B)$ contains a copy of $\mathcal{O}_2$ unitally, and is K_1-bijective, i.e., the natural map $\mathcal{U}(E) \to \mathrm{K}_1(E)$ defines an isomorphism $\mathcal{U}(E)/\mathcal{U}_0(E) \cong \mathrm{K}_1(E) \cong \mathrm{K}_0(B)$.*
- (iii) *If h_1 dominates zero in the sense of Definition 4.3.3 then there is a unitary $U \in \mathcal{U}(\mathcal{M}(B))$ such that $\pi_B(U)^*h_1(\cdot)\pi_B(U) = h_2(\cdot)$.*

  In particular, h_1 and h_2 are unitary equivalent by a unitary in $\mathcal{U}_0(E)$.

PROOF. (i): The triviality $\mathrm{K}_*(\mathcal{M}(B)) = 0$ easily follows from the unitary equivalence of δ_∞ and $\delta_\infty \oplus \mathrm{id}$.
The equation $\mathcal{U}_0(\mathcal{M}(B)) = \mathcal{U}(\mathcal{M}(B))$ was found by J. Cuntz and N. Higson [**180**],

see also [**557**] in case that B contains a full projection. Modification of an observation in [**180**] leads to a slightly stronger observation in Lemma A.23.1, which implies that $\mathcal{M}(B)$ satisfies the "squeezing" property (sq) of Definition 4.2.14, cf. Proposition 4.2.15. Thus, $\mathcal{M}(B)$ and, for every C^*-algebra A, every C^*-algebra quotient of $\mathcal{M}(B) \otimes^{\max} A$ is K_1-bijective by Proposition 4.2.15.

(ii): $\mathcal{O}_2 \subset \mathcal{L}(\mathcal{H}) = \mathcal{M}(\mathbb{K}) \subseteq \mathcal{M}(B)$ unitally. Thus, $E := \mathcal{M}(B)/B$ contains a copy of $\mathcal{O}_2$ unitally. E is K_1-surjective by Lemma 4.2.6(v) and is K_1-injective by Part (i). This follows also from Proposition 4.2.15.

(iii): The maps $h_1, h_2 \colon D \to E$ satisfy the requirements of Proposition 4.3.6(iv,d) by Part (ii): There exists $W \in \mathcal{U}(E)$ with $W^* h_1(\cdot) W = h_2$. The C^*-morphism h_1 dominates zero in the sense of Definition 4.3.3 if and only if there exists an isometry $s \in E$ with $s^* h_1(D) s = \{0\}$. Then $V := \big(sW^*s^* + (1 - ss^*)\big)W$ is a unitary in $\mathcal{U}(E)$ with $V^* h_1(\cdot) V = h_2$ and $0 = [V] \in \mathrm{K}_1(E)$. Thus, $V \in \mathcal{U}_0(E)$ by the K_1-injectivity of $E = \mathrm{Q}(B) = \mathcal{M}(B)/B$. Since V is in $\mathcal{U}_0(\mathcal{M}(B)/B)$ it is a finite product of exponentials $\exp(t_k)$, of $-t_k^* = t_k \in \mathcal{M}(B)/B$, $k = 1, \ldots, n$. There are $T_k = -T_k^*$ in $\mathcal{M}(B)$ with $\pi_B(T_k) = t_k$. Thus, $V = \pi_B(U)$ for the unitary $U := \exp(T_1) \cdot \ldots \cdot \exp(T_n)$ in $\mathcal{M}(B)$. □

The following Lemma 5.5.10 summarizes consequences of Proposition 4.3.6 and of the generalized Tietze extension theorem of Akemann, Pedersen and Tomiyama in the σ-unital case (see [**616**, prop. 3.12.10] for the *separable case*).

LEMMA 5.5.10. *Suppose that A and B are σ-unital, and that $h \colon A \to \mathcal{M}(B)/B$ is a C^*-morphism. Let J denote the kernel of h, and define*

$$\mathcal{M}(A, J) := \{T \in \mathcal{M}(A)\,;\; TA \cup AT \subset J\}\,.$$

Further, let $C := h(A)$, and let $\mathcal{N}(C) \subset \mathcal{M}(B)/B$ the normalizer algebra of C in $\mathcal{M}(B)/B$, i.e., $\mathcal{N}(C) := \{b \in \mathcal{M}(B)/B\,;\; bC \cup Cb \subset C\}$, and let $\mathrm{Ann}(C) :=$ *$\{b \in \mathcal{M}(B)/B \;\; bC = 0 = Cb\}$ denote the (two-sided) annihilator of C in $\mathcal{M}(B)/B$. Define $L \colon \mathcal{N}(C) \to \mathcal{M}(C)$ by $L(b)(c) := bc$ for $c \in C$ and $b \in \mathcal{N}(C)$.*

Then L is a C^*-morphism, and the following properties are valid:

(i) *h extends naturally to an epimorphism $\mathcal{M}(h)$ from $\mathcal{M}(A)$ onto $\mathcal{M}(C)$ with kernel $\mathcal{M}(A, J)$ (generalized Tietze extension).*
(ii) *If, in addition, h has a non-degenerate lift to a C^*-morphism $h_1 \colon A \to \mathcal{M}(B)$, then $\pi_B(\mathcal{M}(h_1)(\mathcal{M}(A))) \subset \mathcal{N}(C)$, and $\mathcal{M}(h) = L \circ \pi_B \circ \mathcal{M}(h_1)$.*
(iii) *The natural C^*-morphism L from the normalizer $\mathcal{N}(C) \subset \mathcal{M}(B)/B$ of C into the multiplier algebra $\mathcal{M}(C)$ of C is an epimorphism. The kernel of L is* $\mathrm{Ann}(C)$.
(iv) *If h dominates zero, cf. Def. 4.3.3, and if S is any isometry in $\mathcal{M}(C)$, then there exists a unitary U in the connected component of* 1 *in the unitaries of $\mathcal{M}(B)$, such that $\pi_B(U)^* h(\cdot) \pi_B(U) = Sh(\cdot)S^*$.*

PROOF. (i): The morphism $h \colon A \to C$ is non-degenerate, because h is a *-epimorphism from A onto C. Thus, there is a unique unital strictly continuous

C^*-morphism $\mathcal{M}(h)$ from $\mathcal{M}(A)$ into $\mathcal{M}(C)$. By definition of $\mathcal{M}(h)$, $\mathcal{M}(h)(T) = 0$, if and only if, $h(TA \cup AT) = \{0\}$.

The morphism $\mathcal{M}(h)$ is an epimorphism, because A is σ-unital. Indeed: This is, — in the separable case —, the generalized Tietze extension theorem [**616**, prop. 3.12.10]. If A is not separable — but σ-unital —, then one can reduce the proof to the separable case ([16]), as follows:
Let $c \in \mathcal{M}(C)_+$, let $e \in A_+$ a strictly positive element of A and take $b \in A$ with $h(b) = c \cdot h(e)$, by using that $h\colon A \to C$ is surjective. Then the separable C^*-subalgebras $F := C^*(b, e) \subseteq A$, and $G := h(F) \subseteq C$ satisfy $\mathcal{M}(F) \subseteq \mathcal{M}(A)$ and $c \in \mathcal{M}(G) \subseteq \mathcal{M}(C)$, $\mathcal{M}(h)|\mathcal{M}(F) = \mathcal{M}(h|F)$ and $\mathcal{M}(h|F)(\mathcal{M}(F)) = \mathcal{M}(G)$.

(ii): Let $b \in \mathcal{M}(A)$, $c \in C$ and $a \in A$ with $\pi_B(h_1(a)) = h(a) = c$. Then $\mathcal{M}(h)(b)c = h(ba) = \pi_B(h_1(ba))$, and $\pi_B(\mathcal{M}(h_1)(b))c = \pi_B(\mathcal{M}(h_1)(b)h_1(a))$.

(iii): It is obvious that $\mathrm{Ann}(C) \subset \mathcal{N}(C)$, and that the natural C^*-morphism L from $\mathcal{N}(C)$ into $\mathcal{M}(C)$ has kernel $\mathrm{Ann}(C)$.

We show that $\mathcal{N}(C) \to \mathcal{M}(C)$ is surjective:

Consider $D := (\pi_B)^{-1}(C)$ and the *-epimorphism $k := \pi_B|D$. Since C has a strictly positive element $d = h(e)$, and B has a strictly positive element p, the element $p + q$ is a strictly positive element of D, if $q \in D_+$ is such that $k(q) = d$.

By part (i), $\mathcal{M}(k)$ is an epimorphism from $\mathcal{M}(D)$ onto $\mathcal{M}(C)$.

The lifted C^*-morphism $k_1 := \mathrm{id}\,|D$ of k is non-degenerate, because $B \subset D$. Thus, $\mathcal{M}(k_1)$ is a unital map from $\mathcal{M}(D)$ into $\mathcal{M}(B)$, and $\pi_B(\mathcal{M}(k_1)(\mathcal{M}(D))) \subset \mathcal{N}(C)$.

By part (ii), the image of the natural C^*-morphism $\mathcal{N}(C) \to \mathcal{M}(C)$ contains the image of $\mathcal{M}(k)$, i.e., $\mathcal{N}(C) \to \mathcal{M}(C)$ is an epimorphism.

(iv): Let $h_2 := Sh(\cdot)S^*$. Then h_2 is a C^*-morphism from A into $h(A) = C \subset \mathcal{M}(B)/B$. By assumption, h dominates zero, i.e., there exists an isometry $V \in \mathcal{M}(B)/B$ such that $V^*h(A)V = \{0\}$. Thus, $V^*h_2(\cdot)V = 0$.

There exists a contraction y in $\mathcal{N}(C)$ such that $L(y) = S$ by part (ii). It follows $y^*h_2(\cdot)y = h$ and $yh(\cdot)y^* = h_2$.

By Proposition 4.3.6(iii), h_2 and h are unitarily equivalent by a unitary $u_1 \in \mathcal{M}(B)/B$. By Proposition 4.3.6(iv,c) the unitary equivalence can be realized by

---

[16] There is a direct argument: Since $\mathcal{M}(h)(\mathcal{M}(A))$ contains C, it suffices to show that for a given contraction $c \in \mathcal{M}(C)_+$ there exist $d \in \mathcal{M}(A)_+$ with $\mathcal{M}(h)(d) - c \in C$. Let $e \in A_+$ be a strictly positive element of A with $\|e\| = 1$, and let $d := h(e)$. By Remark 5.1.1(3), there exist continuous functions $0 \leq f_n \leq 1$, with $f_n(0) = 0$, $f_{n+1}f_n = f_n$, such that $\lim f_n(t) = 1$ for $t \in (0, 1]$ and that the commutator norms $\|[g_n(d), c]\|$ are less than 2^{-n}, where $g_1 = f_1^{1/2}$, and $g_n := (f_{n+1} - f_n)^{1/2}$ for $n > 1$. Let $b_n \in A_+$ contractions with $h(b_n) = f_{n+2}(d)cf_{n+2}(d)$. By Remark 5.1.1(4), $s := \sum g_n(a)b_ng_n(a)$ and $t := \sum g_n(d)cg_n(d)$ are strictly convergent series in $\mathcal{M}(A)$ and $\mathcal{M}(C)$, respectively. Then $\mathcal{M}(h)(s) = t$ and $c - t \in C$, because $h(g_n(e)b_ng_n(e)) = g_n(d)cg_n(d)$, $\mathcal{M}(h)$ is strictly continuous, and $c - t$ is the sum of the norm-convergent series $\sum x_n$, where with $x_n := g_n(d)[g_n(d), c] \in C$.

a unitary $u = \pi_B(U)$ in $\pi_B(\mathcal{U}_0(\mathcal{M}(B))) = \mathcal{U}_0(M(B)/B)$, because $V^*(h(a) + h_2(a))V = 0$ for $a \in A$. □

LEMMA 5.5.11. *Suppose that A and B are σ-unital and let $h\colon A \to \mathrm{Q^s}(B)$ a C^*-morphism.*

Choose an isomorphism $\psi\colon \mathbb{K} \otimes \mathbb{K} \to \mathbb{K}$ from $\mathbb{K} \otimes \mathbb{K}$ onto $\mathbb{K}$.

Let γ denote the natural isomorphism from $(B \otimes \mathbb{K}) \otimes \mathbb{K}$ onto $B \otimes (\mathbb{K} \otimes \mathbb{K})$, i.e., with $\gamma((b \otimes k_1) \otimes k_2) = b \otimes (k_1 \otimes k_2)$ for $b \in B$, $k_1, k_2 \in \mathbb{K}$, and let

$$\Phi_1\colon \mathcal{M}(B \otimes \mathbb{K}) \otimes \mathbb{K} \to \mathcal{M}(B \otimes \mathbb{K})$$

the non-degenerate monomorphism, is defined by

$$\Phi_1 := \mathcal{M}((\mathrm{id}_B \otimes \psi) \circ \gamma) | \mathcal{M}(B \otimes \mathbb{K}) \otimes \mathbb{K}.$$

(i) *There are isometries $s_0, t_0 \in \mathcal{M}(\mathbb{K})$ and a norm-continuous map $\tau \in (0,1] \mapsto I_\tau \in \mathcal{M}(\mathbb{K})$ into the isometries in $\mathcal{M}(\mathbb{K}) \cong \mathcal{L}(H)$, such that, for $b \in \mathbb{K}$,*

$$\begin{aligned} s_0 s_0^* + t_0^* t_0 &= 1, \\ \mathcal{M}(\psi)(1_{\mathcal{M}(\mathbb{K})} \otimes p_{11}) &= s_0 s_0^*, \\ s_0^* \psi(k \otimes p_{11}) s_0 &= k, \\ (I_\tau)^* \mathcal{M}(\psi)(1_{\mathcal{M}(\mathbb{K})} \otimes b) I_\tau &\in \mathbb{K}, \quad \text{and} \\ \lim_{\tau \to 0} \|(I_\tau)^* \mathcal{M}(\psi)(1_{\mathcal{M}(\mathbb{K})} \otimes b) I_\tau\| &= 0\,. \end{aligned}$$

(ii) *Let $r_1 \in \mathcal{M}(\mathrm{C}_0((0,1], \mathbb{K}))$ be the isometry, which is defined by $(r_1 f)(\tau) := I_\tau f(\tau)$ and $(r_1 f)(0) = 0$ for $f \in \mathrm{C}_0((0,1], \mathbb{K})$, $\tau \in (0,1]$. Let e a strictly positive element of B with $\|e\| = 1$, and let μ the non-degenerate C^*-morphism from $\mathrm{C}_0((0,1])$ into B with $\mu(g_0) = e$, where $g_0(\tau) := \tau$. Now define $r = \mathcal{M}(\mu \otimes \mathrm{id}_{\mathbb{K}})(r_1)$.*

Then Φ_1 and the isometries $s := 1_{\mathcal{M}(B)} \otimes s_0$, $t := 1_{\mathcal{M}(B)} \otimes t_0$ and r in $\mathcal{M}(B \otimes \mathbb{K})$ satisfy, for $b \in \mathcal{M}(B \otimes \mathbb{K})$,

$$\begin{aligned} ss^* + tt^* &= 1, \\ ss^* &= \mathcal{M}(\mathrm{id}_B \otimes \psi)(1_{\mathcal{M}(B)} \otimes (1_{\mathcal{M}(\mathbb{K})} \otimes p_{11})), \\ \Phi_1(b \otimes p_{11}) &= sbs^*, \\ r^* \Phi_1(\mathcal{M}(B \otimes \mathbb{K}) \otimes \mathbb{K}) r &\subset B \otimes \mathbb{K}, \quad \text{and} \\ \Phi_1((B \otimes \mathbb{K}) \otimes \mathbb{K}) &= B \otimes \mathbb{K}. \end{aligned}$$

(iii) $\Phi := [\Phi_1]\colon \mathrm{Q^s}(B) \otimes \mathbb{K} \to \mathrm{Q^s}(B)$ *is a monomorphism, which dominates zero and satisfies $\Phi(b \otimes p_{11}) = S^* b S$ with $S := \pi_{B \otimes \mathbb{K}}(s)$. The range projection of S is $SS^* = \Phi(1 \otimes p_{11})$.*

(iv) *h is unitarily equivalent to $\Phi(h(\cdot) \otimes p_{11})$ if and only if h dominates zero in the sense of Definition 4.3.3. If this is the case, then the unitary equivalence can be given by a unitary in the image of the unitaries in $\mathcal{M}(B \otimes \mathbb{K})$.*

(v) $\Phi \circ (h \otimes \mathrm{id}_{\mathbb{K}})$ *is the Busby invariant of the stable extension*

$$0 \to (B \otimes \mathbb{K}) \otimes \mathbb{K} \to E \otimes \mathbb{K} \to A \otimes \mathbb{K} \to 0,$$

where we identify $B \otimes \mathbb{K}$ *and* $(B \otimes \mathbb{K}) \otimes \mathbb{K}$ *naturally by* $(\mathrm{id}_B \otimes \psi) \circ \gamma$, *and define*

$$0 \to B \otimes \mathbb{K} \to E \to A \to 0,$$

as the extension corresponding to $h\colon A \to \mathrm{Q^s}(B)$.

(vi) *If* A *is stable, then* $\Phi(h(\cdot) \otimes p_{11})$ *is the Busby invariant of a stable extension.*

Proof. (i): $p := \mathcal{M}(\psi)(1_{\mathcal{M}(\mathbb{K})} \otimes p_{11})$ and $1 - p$ are infinite projections in $\mathcal{M}(\mathbb{K}) \cong \mathcal{L}(H)$. Thus, there are isometries $s_1, t_0 \in \mathcal{M}(\mathbb{K})$ with $s_1 s_1^* = p$ and $t_0 t_0^* = 1 - p$. Then $b \in \mathcal{M}(\mathbb{K}) \mapsto s_1^* \mathcal{M}(\psi)(b \otimes p_{11}) s_1$ is a unital weakly continuous *-endomorphism on $\mathcal{M}(\mathbb{K})$. Its image contains the corner $\psi(\mathbb{K} \otimes p_{11})$ of $\mathbb{K}$. Therefore, it is an isomorphism of $\mathcal{M}(\mathbb{K})$, and there exist a unitary $u \in \mathcal{M}(\mathbb{K})$ with $ubu^* = s_1^* \mathcal{M}(\psi)(b \otimes p_{11}) s_1$ for $b \in \mathcal{M}(\mathbb{K})$. Let $s_0 := s_1 u$, then s_0 and t_0 have the desired properties.

The construction of I_τ goes as follows. We let

$$\begin{aligned} p_n &:= \sum_{j=1}^{n} p_{jj} \\ q_n &:= \mathcal{M}(\psi)(p_n \otimes (1 - p_n)) \\ e_n &:= \mathcal{M}(\psi)(p_{n+2} \otimes (1 - p_n)). \end{aligned}$$

Then, $q_n \leq e_n$, $q_{n+1} \leq e_n$, and q_n, $e_n - q_n$, $e_n - q_{n+1}$ are infinite projections. It follows that there exists a unitary v commuting with e_n, such that $vq_nv^* = q_{n+1}$. Since $\mathcal{M}(\mathbb{K})$ is isomorphic to the von-Neumann algebra $\mathcal{L}(H)$, there is a $T \in \mathcal{M}(\mathbb{K})_+$ such that T commutes with e_n and $v = e^{iT}$.

Let I an isometry in $\mathcal{M}(\mathbb{K})$ with $II^* = q_n$. Then $I_\tau := e^{iT(\tau)}v$, with $T(\tau) := ((n+1) - (n+1)n\tau)T$, defines a norm-continuous map from $[1/(n+1), 1/n]$. into the isometries of $\mathcal{M}(\mathbb{K})$, such that $I_{1/n} = I$, $I_{n+1} I_{n+1}^* = q_{n+1}$ and $I_\tau I_\tau^* \leq e_n$ for $\tau \in (1/(n+1), 1/n)$.

By induction we get the norm-continuous map

$$\tau \in (0, 1] \mapsto I_\tau \in \mathcal{M}(\mathbb{K})$$

into the isometries of $\mathcal{M}(\mathbb{K})$ with the desired properties.

(ii): The properties of Φ_1, s and t can be seen by simple calculations on the level of elementary tensors. Then use that all the maps in question are strictly continuous, to get the general result.

On the property of r: It suffices to show that $r^*(1 \otimes \mathcal{M}(\psi)(1 \otimes \mathbb{K}))r$ is contained in $C^*(e) \otimes \mathbb{K}$.

The properties of $\tau \mapsto I_\tau$ in part (i) mean that $(r_1)^*(1 \otimes \mathcal{M}(\psi)(1 \otimes \mathbb{K}))r_1$ is contained in $\mathrm{C}_0((0, 1], \mathbb{K})$. Now apply $\mathcal{M}(\mu \otimes \mathrm{id}_{\mathbb{K}})$.

(iii): With $R := \pi_{B\otimes\mathbb{K}}(r)$ we have $R^*R = 1$ and $R^*\Phi(\cdot)R = 0$ by (ii), i.e., Φ dominates zero. The rest are straight calculations.

(iv): Since Φ dominates zero by (ii), also $\Phi(h(\cdot)\otimes p_{11}) = Sh(\cdot)S^*$ dominates zero. Thus, if h is unitarily equivalent to $h_2 := \Phi(h(\cdot)\otimes p_{11})$, then h dominates zero.

Conversely, if $V^*h(\cdot)V = 0$ for some isometry $V \in \mathrm{Q^s}(B)$, and $h_2 = Sh(\cdot)S^*$, then $W^*h_2(\cdot)W = 0$ for the isometry $W := SVS^* + (1 - SS^*)$. Thus, by Proposition 4.3.6(iii), there is a unitary u with $u^*h(\cdot)u = h_2$, because $h_2 = Sh(\cdot)S^*$, $h = S^*h_2(\cdot)S$. By Lemma 5.5.9(iii) the unitary equivalence can be realized by a unitary $u = \pi_B(U)$ in $\pi_B(\mathcal{U}_0(\mathcal{M}(B)/B))$.

(v): Straightforward calculations.

(vi): Let D be a σ-unital C^*-algebra, and let φ an isomorphism from $D\otimes\mathbb{K}$ onto A. Let $h_1 := h\circ\varphi$.

Let $\psi\colon \mathbb{K}\otimes\mathbb{K}\to\mathbb{K}$ be the isomorphism from $\mathbb{K}\otimes\mathbb{K}$ onto $\mathbb{K}$, and let $s_0 \in \mathcal{M}(\mathbb{K})$ an isometry with $s_0bs_0^* = \psi(b\otimes p_{11})$ for $b\in\mathbb{K}$, see part (i).

Let γ denote the natural isomorphism from $(D\otimes\mathbb{K})\otimes\mathbb{K}$ onto $D\otimes(\mathbb{K}\otimes\mathbb{K})$.

We define an isomorphism λ from $D\otimes\mathbb{K}$ onto $(D\otimes\mathbb{K})\otimes\mathbb{K}$ by $\lambda := \gamma^{-1}\circ(\mathrm{id}_D\otimes\psi^{-1})$.

Then $\nu(b) := \lambda^{-1}(b\otimes p_{11})$, for $b\in D\otimes\mathbb{K}$, defines a *-endomorphism of $D\otimes\mathbb{K}$, such that $\nu(d\otimes b) := d\otimes\psi(b\otimes p_{11})$ for $d\in D$, $b\in\mathbb{K}$. It follows, that $s_2 := 1_{\mathcal{M}(D)}\otimes s_0$ is an isometry in $\mathcal{M}(D\otimes\mathbb{K})$, such that $s_2bs_2^* = \nu(b)$ for $b\in D\otimes\mathbb{K}$.

Let $h_2 := \Phi\circ(h_1\otimes\mathrm{id}_{\mathbb{K}})\circ\lambda$ and $h_3 := \Phi(h_1(\cdot)\otimes p_{11})$. Then $h_3 = h_1\circ\nu$. The h_2 and h_3 both dominate zero, because Φ dominates zero.

It suffices to show, that h_2 and h_3 are unitarily equivalent, by a unitary $v = \pi_B(U)$ for some unitary U of $\mathcal{M}(B\otimes\mathbb{K})$, because the extension with Busby invariant $\Phi\circ(h\otimes\mathrm{id}_{\mathbb{K}})$ is stable, by part (v).

Let $C := h_2(D\otimes\mathbb{K})$. $S := \mathcal{M}(h_2)(s_2)$ is an isometry in $\mathcal{M}(C)$, such that $h_3 = Sh_2(\cdot)S^*$. Since h_3 dominates zero, by Lemma 5.5.10(iv), there exists a unitary $U\in\mathcal{M}(B)$ with $v^*h_2(\cdot)v = h_3$ for $v := \pi_B(U)$. □

Proposition 5.5.12 (Stability of extensions). *Suppose that*

$$0\to B\to E\to A\to 0$$

is an extension of A by B, where A and B are σ-unital and stable C^*-algebras.

Let $\iota\colon B\to E$, $\eta\colon E\to A$ and $\varphi\colon A\to\mathcal{M}(B)/B\cong\mathrm{Q^s}(B)$ denote the the defining morphisms of the above short-exact sequence, i.e., the corresponding monomorphism, respectively epimorphism, and the Busby invariant of E.

Further let θ denote an (arbitrary) isomorphism θ from B onto $B\otimes\mathbb{K}$, and $\Theta\colon \mathrm{Q}(B)\to\mathrm{Q^s}(B) := \mathrm{Q}(B\otimes\mathbb{K})$ is the isomorphism that is induced by the isomorphism θ.

Then following properties (i)–(vi) are equivalent.

(i) *The extension E is a stable C^*-algebra.*
(ii) *The Busby invariant φ dominates zero.*
(iii) *For every $a \in \mathcal{M}(B)_+$ with $\pi_B(a) \in \varphi(A)$, $b \in B_+$ and $\varepsilon > 0$, there exists $d \in B$ with $\|d^*ad\| < \varepsilon$ and $\|d^*d - b\| < \varepsilon$.*
(iv) *$\Theta \circ \varphi$ and $\Phi(\Theta \circ \varphi(\cdot) \otimes p_{11})$ are unitarily equivalent, where Φ denotes the natural monomorphism from $\mathrm{Q^s}(B) \otimes \mathbb{K}$ into $\mathrm{Q^s}(B)$ defined in Lemma 5.5.11(iii).*
(v) *There is an isomorphism λ from $E \otimes \mathbb{K}$ onto E, such that $B = \lambda(B \otimes \mathbb{K})$, and that $b \in B \mapsto \lambda(b \otimes p_{11})$ and $a \in A \mapsto [\lambda](a \otimes p_{11})$ are approximately inner in B respectively in A, where $[\lambda](a \otimes p) := \eta(\lambda(f \otimes p))$ for $a \in A$, $f \in \eta^{-1}(a)$ and $p \in \mathbb{K}$.*
(vi) *$1_{\mathcal{M}(E)}$ is properly infinite in $\mathcal{M}(E)$, i.e., the multiplier algebra $\mathcal{M}(E)$ of E contains two isometries with orthogonal ranges.*

The criteria (ii) and (vi) are not obvious, and (iii) is useful for applications. Criterium (iii) was established by J. Hjelmborg and M. Rørdam in [**373**].

Compare also proof of [**499**, thm. 2.4].

Compare ?????

Proof. The implications (v)⇒(i) and (i)⇒(vi) are trivial. (i)⇒(iv) follows from Lemma 5.1.2(ii).

(vi)⇒(iii): The natural C^*-morphism $h_1 \colon E \to \mathcal{M}(B)$ with $h_1(f)b = \iota^{-1}(f\iota(b))$ (for $f \in E$, $b \in B$) satisfies $\varphi \circ \eta = \pi_B \circ h_1$ for the Busby invariant $\varphi \colon A \to \mathrm{Q}(B)$ of the extension. This can be seen by the natural Busby isomorphism:

$$E \cong E_\varphi := A \oplus_{\varphi, \pi_B} \mathcal{M}(B) \subset A \oplus \mathcal{M}(B)\,,$$

that is given by $f \mapsto (\eta(f), h_1(f))$.

Let $C := \varphi(A) = \pi_B(h_1(E))$, and let $a \in \mathcal{M}(B)_+$ with $\pi_B(a) \in C$, $b \in B_+$, $\varepsilon > 0$ and let $\delta := \varepsilon/(2(\|a\| + \|b\| + 1))$.

By Lemma 5.5.10(i) and (ii) (with E in place of A), the epimorphism $h := \pi_B \circ h_1 \colon E \to C$ extends uniquely to a strictly continuous epimorphism $\mathcal{M}(h) \colon \mathcal{M}(E) \to \mathcal{M}(C)$.

By assumption there are isometries $T_1, T_2 \in \mathcal{M}(E)$ with $(T_2)^*T_1 = 0$. Thus $r_j := \mathcal{M}(h)(T_j)$ for $j = 1, 2$ are isometries in $\mathcal{M}(C)$ with orthogonal ranges.

Since A is stable, its image $C = \varphi(A)$ by φ is again stable: $A \cong D \otimes \mathbb{K}$ implies that D has a closed ideal J such that $C \cong (D \otimes \mathbb{K})/(J \otimes \mathbb{K}) \cong (D/J) \otimes \mathbb{K}$.

Let $s_1, s_2, \ldots$ a sequence of isometries in $\mathcal{M}(C)$ such that $\sum_n s_n(s_n)^*$ strictly converges to 1. Then there is $m \in \mathbb{N}$ with $\|s_m^* \pi_B(a) s_m\| < \delta$. Since $\mathcal{M}(C)$ contains a copy of $\mathcal{O}_2$ unitally, there is a unitary v in $\mathcal{M}(C)$, such that $vr_1 = s_m$. The unitary group of $\mathcal{M}(C)$ is (norm-)contractible by [**180**]. Hence, there is a unitary $U \in \mathcal{M}(E)$ with $\mathcal{M}(h)(U) = v$.

The C^*-morphism $h_1 \colon E \to \mathcal{M}(B)$ is non-degenerate, because $h_1(\iota(B)) = B$. Thus h_1 uniquely extends to a strictly continuous unital C^*-morphism $\mathcal{M}(h_1) \colon \mathcal{M}(E) \to \mathcal{M}(B)$.

By Lemma 5.5.10(ii), $\pi_B(\mathcal{M}(h_1)(\mathcal{M}(E))) \subset \mathcal{N}(C)$ and $\mathcal{M}(h) = L \circ \pi_B \circ \mathcal{M}(h_1)$ for the natural epimorphism L from $\mathcal{N}(C)$ onto $\mathcal{M}(C)$ with kernel $\mathrm{Ann}(C)$. Thus the isometry $I := \mathcal{M}(h_1)(UT_1) \in \mathcal{M}(B)$ satisfies $\pi_B(I) \in \mathcal{N}(C)$ and $\mathrm{dist}(I^*aI, B) = \|\pi_B(I^*aI)\|$.

It follows $\pi_B(I^*aI) = (L \circ \pi_B)(I^*aI) == \mathcal{M}(h)(UT_1)^* \pi_B(a) \mathcal{M}(h)(UT_1) = s_m^* a s_m$, and, therefore, there is $g = g^* \in B$ with $\|I^*aI - g\| < \delta$.

Now let $t_1, t_2, \ldots$ a sequence of isometries in $\mathcal{M}(B)$ such that $\sum t_n(t_n)^*$ strictly converges to 1 (exists, because B is stable). There is $k \in \mathbb{N}$ such that $\|t_k^* g t_k\| < \delta$. Let $d := I t_k b^{1/2} \in B$, then $d^*d = b$ and $\|d^*ad\| < 2\delta\|b\| < \varepsilon$.

(iii)⇒(ii): Let $e \in A_+$ and $b \in B_+$ strictly positive elements of A and B respectively. We find $a \in \mathcal{M}(B)_+$ with $\pi_B(a) = \varphi(e)$. It is enough to find an isometry $S \in \mathcal{M}(B)$ with $S^*aS \in B$.

Let $C := C^*(a, b, 1)$ denote the unital C^*-subalgebra of $\mathcal{M}(B)$ generated by a, b and 1. Then C is the unitization $\widetilde{D}$ of the C^*-subalgebra D of C which is generated by b and a. Let $\chi \colon C \to \mathbb{C} \cong C/D$ the natural character.

The C^*-morphism $V \colon C \to \mathcal{M}(B)$, with $V(c) := \chi(c)1$ for $c \in C$, satisfies condition (α) of Proposition 5.4.1 with $h := b$.

$f := b + a$ is a strictly positive element of D, and, by assumption, for every $\delta > 0$, there is $d \in B$ with $\|d^* f^\delta d\| < \delta$ and $\|d^*d - b^\delta\| < \delta$.

Thus V and C satisfy also condition (β) of Proposition 5.4.1.

Since $\delta_\infty \circ V = V$ and $V(a) = 0$, by Proposition 5.4.1(ii) and (iv), there exists an isometry $S \in \mathcal{M}(B)$ with $S^*aS \in B$.

(ii)⇒(iv): $\Theta \circ \varphi$ dominates zero if φ dominates zero. But then $\Theta \circ \varphi$ and $\Phi((\Theta \circ \varphi)(\cdot) \otimes p_{11})$ are unitarily equivalent by Lemma 5.5.11(iv).

(iv)⇒(i): Since A is stable and σ-unital, $\Phi((\Theta \circ \varphi)(\cdot) \otimes p_{11})$ is the Busby invariant of a stable extension $0 \to B \otimes \mathbb{K} \to E_1 \to A \to 0$ by Lemma 5.5.11(vi). Since $\Phi((\Theta \circ \varphi)(\cdot) \otimes p_{11})$ is unitarily equivalent to $\Theta \circ \varphi$, it follows that this equivalence is given by a unitary in the image in $\mathcal{M}(B \otimes \mathbb{K})/(B \otimes \mathbb{K})$ of the unitaries of $\mathcal{M}(B \otimes \mathbb{K})$, cf. Lemma 5.5.11(iv). Thus, the extension E_1 is equivalent to an extension $0 \to B \otimes \mathbb{K} \to E_2 \to A \to 0$ with Busby invariant $\Theta \circ \varphi$ –

in particular, $E_2 \cong E_1$ as C^*-algebras, and

?? ????.

Since E_2 and $0 \to B \to E \to A \to 0$ are determined up to equivalence by the Busby invariants $\Theta \circ \varphi$ and φ, it follows that E_2 and E are naturally isomorphic (in particular, as C^*-algebras). Thus E is a stable C^*-algebra.

(i)⇒(v): Let $\mu\colon E\otimes\mathbb{K}\to E$ any isomorphism from $E\otimes\mathbb{K}$ onto E, and let $\iota\colon B\to E$, $\eta\colon E\to A$ the defining morphisms for the exact sequence $0\to B\to E\to A\to 0$. Then there is a closed ideal J of E such that $\mu(J\otimes\mathbb{K})=\iota(B)$ and $J\otimes\mathbb{K}$ is the kernel of $\eta\circ\mu\colon E\otimes\mathbb{K}\to A$.

We define a new isomorphism λ from $E\otimes\mathbb{K}$ onto E by

$$\lambda := \mu\circ(\mathrm{id}_B\otimes\psi)\circ\gamma\circ(\mu^{-1}\otimes\mathrm{id}_{\mathbb{K}})\,,$$

where ψ is an isomorphism from $\mathbb{K}\otimes\mathbb{K}$ onto $\mathbb{K}$, and γ is the natural isomorphism from $(E\otimes\mathbb{K})\otimes\mathbb{K}$ onto $E\otimes(\mathbb{K}\otimes\mathbb{K})$.

Then $\lambda(\iota(B)\otimes\mathbb{K})=\iota(B)$ and the *-monomorphisms

$$b\in B\mapsto \iota^{-1}(\lambda(\iota(b)\otimes p_{11}))$$

and $a\in A\mapsto[\eta\circ\lambda](a\otimes p_{11})$ are approximately inner, because even the *-endomorphisms $g\in E\otimes\mathbb{K}\mapsto(\mathrm{id}_E\otimes\psi)(\gamma(g\otimes p_{11}))$ and $f\in E\mapsto\lambda(f\otimes p_{11})$ are unitarily homotopic to $\mathrm{id}_{E\otimes\mathbb{K}}$ respectively id_E. □

Remark 5.5.13. One can the criteria 5.5.12(iii) replace by the (formally weaker) criteria:

(iii*) *There exists $k\in\mathbb{N}$, such that, for every $b,g\in B_+$, $\varepsilon>0$, $e_1,\dots,e_k\in\mathcal{M}(B)$, with $\pi_B(e_j)\in\varphi(A)$ and $e_i^*e_j=\delta_{ij}e_1^*e_1$ for $i,j=1,\dots,n$, there is $d\in B$ with $\|d^*(e_1^*e_1)d\|<\varepsilon$, $\|d^*gd\|<\varepsilon$ and $\|d^*d-b\|<\varepsilon$.*

Indeed:

(iii)⇒(iii*): Take $k:=1$, and let $a:=g+e_1^*e_1$ in (iii).

(iii*)⇒(iii): Let $C:=\varphi(A)$, $a\in\mathcal{M}(B)_+$ with $\pi_B(a)\in C$, $b\in B_+$, $\varepsilon>0$, and let $c:=\pi_B(a)$, $\delta:=\varepsilon/(2+\|b\|+\varepsilon)$.

Since A is stable, C is stable, and there are isometries $s_1,s_2,\dots$ in $\mathcal{M}(C)$, such that $\sum p_j$ strictly converges to 1, where $p_j:=s_js_j^*$. Thus there is a projection $q_1:=p_1+\ldots+p_n$ in $\mathcal{O}_\infty\subset\mathcal{M}(C)$ such that $\|q_1cq_1-c\|<\delta$. Let $q_j:=p_{(j-1)n+1}+\ldots+p_{jn}$. Then there are partial isometries v_j in $\mathcal{M}(C)$ with $v_j^*v_j=q_1$ and $v_jv_j^*=q_j$. Let $f_j:=v_j(q_1cq_1)^{1/2}$, $j=1,\dots,k$. Then $f_j\in C$ and $f_i^*f_j=\delta_{ij}q_1cq_1$. By Proposition A.8.4, there exist $e_1,\dots,e_k\in\mathcal{M}(B)$, with $\pi_B(e_j)=f_j$ and $e_i^*e_j=\delta_{ij}e_1^*e_1$ for $i,j=1,\dots,n$.

It follows, that $g:=(|a-e_1^*e_1|-\delta)_+$ is in B_+. By assumption, there is $d\in B$ with $\|d^*e_1^*e_1d\|<\delta$, $\|d^*gd\|<\delta$ and $\|d^*d-b\|<\delta$.

Since $\delta<\varepsilon$ and $a\le e_1^*e_1+|a-e_1^*e_1|$, we get $\|d^*d-b\|<\varepsilon$ and $\|d^*ad\|<\varepsilon$.

Corollary 5.5.14. *Suppose that D and B are σ-unital C*-algebras and that $\psi\colon D\to\mathcal{M}(B)/B$ is a *-monomorphism. Let $E:=\pi_B^{-1}(\psi(D))$.*

(I) *If ψ has a* non-degenerate *"split" C*-morphism $H\colon D\to\mathcal{M}(B)$ with $\psi=\pi_B\circ H$, and if D is stable, then B and E are stable.*

(II) *If E is stable, then*

(i) *B and D are stable and $\psi \oplus 0$ is unitarily equivalent to ψ by a unitary $u \in \mathcal{U}_0(\mathrm{Q}(B))$, and*

(ii) *there exists isometries $S, T \in \mathcal{M}(B)$ with $SS^* + TT^* = 1$, $S^*ES \subseteq B$ and $(1 - T)E \cup E(1 - T) \subset B$.*

Proof. Ad(I): Suppose that D is stable and that $H \colon D \to \mathcal{M}(B)$ is a non-degenerate C^*-morphism with $\psi = \pi_B \circ H$.

Then the σ-unital C^*-algebra B is stable by Remark 5.1.1(9), because $H(D)$ is a stable non-degenerate C^*-subalgebra of $\mathcal{M}(B)$, i.e., $\overline{H(D)B} = B$.

If $e \in E_+$, then there exist $b \in B$ and $d \in D$ with $e = b + H(d)$. Thus, for $\varepsilon > 0$ there exists a contraction $f \in D_+$ with

$$\|e - H(f)e\| \leq \|b - H(f)b\| + \|d - fd\| < \varepsilon\,,$$

i.e., $\overline{H(D)E} = E$ and $H(D)$ is a non-degenerate C^*-subalgebra of $\mathcal{M}(E)$. It follows that E is stable by Remark 5.1.1(9).

(II): Suppose that E is stable.

(i): The stability of E implies the stability of its ideal B and of its quotient D.

By Proposition 5.5.12(ii), the Busby invariant $\psi \colon D \to \mathcal{M}(B)/B \cong \mathrm{Q}^{\mathrm{s}}(B)$ dominates zero, i.e., there is an isometry $t \in \mathrm{Q}(B)$ with $t^*\psi(D)t = \{0\}$.

Define $\oplus := \oplus_{s_1,s_2}$. Then ψ and $\psi \oplus 0$ both dominate zero: $t^*\psi(\cdot)t = 0$ and $(t \oplus 1)^*(\psi(\cdot) \oplus 0)(t \oplus 1) = 0$.

Chose one of next:

Since B is σ-unital and stable, the stable corona $\mathrm{Q}^{\mathrm{s}}(B)$ of B is K_1-injective by Lemma 4.2.10.

Stable coronas $\mathrm{Q}^{\mathrm{s}}(B)$ of σ-unital C^*-algebras B have Property *(sq)* and are therefore K_1-bijective by Proposition 4.2.15.

If B is stable, then $\mathrm{Q}(B)$ is K_1-surjective by Lemma 5.5.9.

It follows that ψ and $\psi(\cdot) \oplus 0$ are unitary equivalent with a unitary $u \in \mathcal{U}_0(\mathrm{Q}^{\mathrm{s}}(B))$ by last conclusion in Parts (iii) and (iv,b) of Proposition 4.3.6.

Prop./Lem./Rem. in Chp. 4

??

????????????????? **??**

Since B is stable, there exist isometries $S_1, S_2 \in \mathcal{M}(B)$ with $S_1S_1^* + S_2S_2^* = 1$. Let $s_j = \pi_B(S_j)$. By Lemma 4.2.6(iii) there is a unitary u_1 in $\mathrm{Q}(B)$ with $u_1s_2 = ss_2$, because $t_1 := ss_1s_2$ and $t_2 := ss_2$ and $r_1 := s_1s_2$ and $r_2 := s_2$ are pairs of isometries (t_1, t_2) and (r_1, r_2) with orthogonal ranges and the property that $1 - (t_1t_1^* + t_2t_2^*) \geq ss_1^2(ss_1^2)$ and $1 - (r_1r_1^* + r_2r_2^*) = s_1^2(s_1^2)^*$ are full and properly infinite projections in $\mathrm{Q}(B)$.

What is the application?

Then $\psi = u_1^*\psi(\cdot)u_1$ and $\psi_2 := \psi(\cdot) \oplus_{s_1,s_2} 0$ have the property $\psi_j(D)s_2 = 0$ for $j = 1, 2$.

Since B is stable, $\mathrm{Q}(B)$ is K_1-injective by Lemma 5.5.9.

`Better refer to Lemma for property` *sq* `in 4 ?`

By Proposition 4.3.6(iv,a ???), there exists a a unitary $V \in \mathcal{U}_0(\mathrm{Q}(B))$ with

??? **??** Proceed proof ! ???????????????

(ii): By the proof of part (ii) of Lemma 5.5.9, there exist isometries $S_1, S_2, T_1 \in \mathcal{M}(B)$ with $\pi_B(S_1) = s\pi_B(S_2)$ and $S_1S_1^* + T_1T_1^* = 1$. Thus, $\pi_B(S_1^*ES_1) = \pi_B(S_2)^*s^*\psi(D)s\pi_B(S_2) = \{0\}$. It follows $\pi_B(S_1(1-T_1)S_1^*E) = \{0\} = \pi_B(ES_1(1-T_1)S_1^*)$.

Now let $P := T_1T_1^* = 1 - S_1S_1^*$, $T := P + S_1T_1S_1^*$ and $S := S_1^2$. Then $T^*T = 1 = S^*S$, $TT^* = P + S_1PS_1^* = 1 - SS^*$ and $1 - T = S_1(1-T_1)S_1^*$. Hence, $S^*ES \subset B$ and $(1-T)E \cup E(1-T) \subset B$. □

Corollary 5.5.15. *Suppose that Y is a σ-compact locally compact space, that B is a σ-unital stable C^*-algebra and that C is a σ-unital C^*-subalgebra of the ideal $\mathrm{Q}(Y,B) := \mathrm{C_b}(Y,B)/\,\mathrm{C_0}(Y,B)$ of $\mathrm{Q}(\mathrm{C_0}(Y,B)) = \mathcal{M}(\mathrm{C_0}(Y,B))/\,\mathrm{C_0}(Y,B)$.*

(i) *There are isometries S and T in $\mathrm{C_b}(Y,\mathcal{M}(B)) \subset \mathcal{M}(\mathrm{C_0}(Y,B)) = \mathcal{M}(\mathrm{C_b}(Y,B))$ such that $SS^* + TT^* = 1$, and that $s := S + \mathrm{C_0}(Y,B) \in \mathrm{Q}(\mathrm{C_0}(Y,B))$ and $t := T + \mathrm{C_0}(Y,B) \in \mathrm{Q}(\mathrm{C_0}(Y,B))$ satisfy $s^*Cs = \{0\}$ and $(1-t)C = \{0\} = C(1-t)$.*

(ii) *If D is a σ-unital stable C^*-algebra, and $0 \to \mathrm{C_0}(Y,B) \to E_\varphi \to D \to 0$ is an extension which has Busby invariant $\varphi\colon D \to \mathrm{Q}(\mathrm{C_0}(Y,B))$ with image $\varphi(D)$ in $\mathrm{C_b}(Y,B)/\,\mathrm{C_0}(Y,B) \subset \mathrm{Q}(\mathrm{C_0}(Y,B))$, then E_φ is* stable.

(iii) *If f is a contraction in $\mathrm{C_b}(Y,B)$, then there is an isometry T in $\mathrm{C_b}(Y,\mathcal{M}(B))$ such that $g^*ag = t^*at$ for all $a \in C$, where $g := f + \mathrm{C_0}(Y,B)$ and $t := T + \mathrm{C_0}(Y,B)$.*

(iv) *There is an *-monomorphism $\rho\colon C \otimes \mathbb{K} \hookrightarrow \mathrm{C_b}(Y,B)/\,\mathrm{C_0}(Y,B)$ with $\rho(c \otimes p_{11}) = c$ for $c \in C$.*

Proof. (i): We use that $B \cong B \otimes \mathbb{K}$, and replace B by $B \otimes \mathbb{K}$. Since Y is σ-compact, there is a strictly positive function $\gamma \in C_0(Y)$ with $0 \le \gamma(y) \le 1$. Since $\gamma \in C_0(Y)_+$ is strictly positive, the subsets $Y_n := \gamma^{-1}[1/n, 1] \subset Y$ are compact and $Y = \bigcup_n Y_n$. Let $g \in C_+$ a strictly positive contraction for C. There is $f \in \mathrm{C_b}(Y, B \otimes \mathbb{K})_+$ with $g = f + \mathrm{C_0}(Y, B \otimes \mathbb{K})$ and $\|f(y)\| \le 1$. There are projections $p_n \in \mathbb{K}$ with $\|f(y)(1 \otimes p_n) - f(y)\| < 1/(n+1)$ for all $y \in Y_{n+1}$ for $n = 0, 1, 2, \ldots$. This can be seen, because $f|Y_n$ is in $\mathrm{C}(Y_n, B \otimes \mathbb{K}) \cong \mathrm{C}(Y_n, B) \otimes \mathbb{K}$. If we take linear interpolations $p(t) := (n-t)p_{n-1} + (t+1-n)p_n$ for $t \in [n-1, n]$, then we get a norm-continuous path $t \in [0,\infty) \mapsto p(t) \in \mathbb{K}$ from $\mathbb{R}_+$ into the positive contractions of $\mathbb{K}$ such that $\|f(y)(1 \otimes p(t)) - f(y)\| < 1/n$ for all $y \in Y_n$ and $t \ge n-1$. Thus, $\|f(y)(1 \otimes p(\gamma(y)^{-1})) - f(y)\| \le \gamma(y)$ for all $y \in Y$. Note that

$p(t) \leq q_n := \bigvee_{1\leq k\leq n} p_k \in \mathbb{K}$, $p(t) = p(t)q_n$ and $p(t)r_n - p(t) = p(t)(q_n r_n - q_n)$ for $t \leq n$.

There is a non-degenerate *-representation $\lambda\colon D := \mathcal{O}_2 \otimes \mathbb{K} \to \mathcal{L}(\ell_2) \cong \mathcal{M}(\mathbb{K})$. We identify $d \in D$ with $\lambda(d)$ and $\mathcal{M}(\mathbb{K})$ with $\mathcal{L}(\mathcal{H})$ (for simplicity of notations).

Then we find projections $r_n \in D$ with $0 \neq r_1 \leq r_2 \leq \cdots$, $r_n \neq r_{n+1}$ and $\|q_n r_n - q_n\| < 1/n$ for $t \leq n$ because $q_n \in \mathbb{K}$. By Lemma 5.1.2(iii), there exists a *norm*-continuous path $t \mapsto U(t)$ from $\mathbb{R}_+$ into the unitaries in $1 + D \subset \mathcal{M}(\mathbb{K})$ such that $U(t)r_1U(t)^* \geq r_{n+1}$ for $t \geq n$.

Since r_1 and $1 - r_1 \geq r_2 - r_1 \in D \setminus \{0\}$ are properly infinite projections in $\mathcal{M}(\mathbb{K})$, there are isometries $S_0, T_0 \in \mathcal{M}(\mathbb{K})$ with $S_0S_0^* = 1 - r_1$ and $T_0T_0^* = r_1$. It follows $\|p(t)U(t)S_0\| \leq \|p(t)-p(t)r_{n+1}\|+\|r_{n+1}U(t)S_0\| < 1/n + 1$ for $t \in [n, n+1]$, because $r_{n+1}U(t)(1 - r_1) = 0$ for $t \geq n$. Thus, $\|p(\gamma(y)^{-1})U(\gamma(y)^{-1})S_0\| \leq \gamma(y)$.

We define a norm-continuous map $y \mapsto V(y)$ from Y into the unitary elements of $1 \otimes \mathcal{M}(\mathbb{K}) \subset \mathcal{M}(B \otimes \mathbb{K})$ by $V(y) := 1 \otimes U(\gamma(y)^{-1})$ for $y \in Y$. Then $S_1(y) := V(y)(1\otimes S_0)$ and $T_1(y) := V(y)(1\otimes T_0)$ define isometries $S_1, T_1 \in \mathrm{C_b}(Y, \mathcal{M}(B\otimes\mathbb{K}))$ with $S_1S_1^* + T_1T_1^* = 1$ and, for $y \in Y$,

$$\|f(y)S_1(y)\| \leq \|f(y)(1 \otimes p(\gamma(y)^{-1})) - f(y)\| + \|p(\gamma(y)^{-1})U(\gamma(y)^{-1})S_0\| \leq 2\gamma(y)\,.$$

Thus, $fS_1 \in \mathrm{C_0}(Y, B\otimes\mathbb{K})$, i.e., $gs_1 = 0$ and $s_1^*Cs_1 = \{0\}$ for $s_1 := S_1+\mathrm{C_0}(Y, B\otimes\mathbb{K})$.

Now we proceed as in the proof of Proposition 5.5.14: The isometries $S := S_1^2$, $T := T_1T_1^* + S_1T_1S_1^*$ and $s := S + \mathrm{C_0}(Y, B \otimes \mathbb{K})$ are as stipulated.

(ii): By (i) with $C := \varphi(D)$, Proposition 5.5.12 applies to φ, because φ dominates zero.

(iii) follows from (i) by Proposition 4.3.6(ii), with $\mathrm{C_b}(Y, \mathcal{M}(B))/\,\mathrm{C_0}(Y, B)$ in place of E.

(iv): Let $S, T \in \mathrm{C_b}(Y, \mathcal{M}(B))$ the isometries from part (i), and let $s := S + \mathrm{C_0}(Y, B)$,

$t := T + \mathrm{C_0}(Y, B)$, $t_1 := t$ and $t_n := st^n$ for $n = 2, 3, \ldots$. Then s, t, t_n are isometries in $\mathrm{C_b}(Y, \mathcal{M}(B))/\,\mathrm{C_0}(Y, B)$ with $t^*s = 0$, $t_m^*t_n = 0$ for $m < n$, and $t_1ct_1^* = tct^* = c$ for all $c \in C$. There is a *-morphism $\rho\colon C \otimes \mathbb{K} \to \mathrm{C_b}(Y, B)/\,\mathrm{C_0}(Y, B)$ with $\rho(c\otimes p_{jk}) = t_jct_k^*$ for canonical matrix units p_{jk} in $\mathbb{K}$. We get $\rho(c\otimes p_{11}) = tct^* = c$ for $c \in C$. □

`Compare here also [499, thm. 2.4.]:` Let A and B be separable C^*-algebras such that $B\otimes\mathbb{K}$ has the CFP (= Corona Factorization Property). Suppose that there is an extension of C^*-algebras of the form $0 \to B \to E \to A \to 0$. Then E is stable if and only if A and B are stable.

(E.K.: It is clear that A and B must be stable if $E \cong E \otimes \mathbb{K}$. Does Prop. 5.5.12(iii) apply in the opposite direction?
Implies "B is s.p.i. and σ-unital" that $B \otimes \mathbb{K}$ has the CFP?)

COROLLARY 5.5.16. *Extensions $0 \to B \to E \to A \to 0$ of stable σ-unital C^*-algebras A by σ-unital purely infinite stable C^*-algebras B are stable.*

PROOF. Suppose that B is a stable, σ-unital and purely infinite C^*-algebra, that A is a stable σ-unital C^*-algebra, and that $\varphi\colon A \to \mathrm{Q}(B)$ is a C^*-morphism, i.e., is the Busby invariant of an extension of A by B.

We show that the criterion (iii) of Proposition 5.5.12 is satisfied:

Let $C := \varphi(A)$, $E := \pi_B^{-1}(C)$, $a \in E_+$, $b \in B_+$ a strictly positive contraction in B, let $\varepsilon \in (0,1)$, and put $\delta := \varepsilon/5$. The annihilator $D := \mathrm{Ann}((a-\delta)_+)$ of $(a-\delta)_+$ in E generates a closed ideal J of E, such that $J = E$ or E/J is unital and $\pi_J(a)$ is invertible. Then $E/(J+B) \cong C/\pi_B(J)$ is a quotient of C. It is isomorphic to $A/\varphi^{-1}(\pi_B(J))$ and is unital (if non-zero). Since A is stable it has no unit. Thus $\varphi(A) = \pi_B(J)$, i.e., $J + B = E$ and $B/(B \cap J) \cong E/J$ is unital or zero. Since B is stable and E/J is unital we get $B = B \cap J \subset J$.

The hereditary C^*-subalgebra $D \cap B$ generates $B \cap J = B$ as a closed ideal of B, because B is an ideal of E. Therefore, there exist $d_1, \ldots, d_n \in B$ with $\|b - \sum d_j^* d_j\| < \delta$ and $d_j d_j^* \in (D \cap B)$. Let $c := \sum d_j d_j^*$, $g := d_j^* d_j$. Since B is purely infinite, there exist $f \in B$ with $\|f^* c f - g\| < \delta$. It follows, that $d := c^{1/2} f$ satisfies $\|d^* d - b\| < 2\delta < \varepsilon$ and $\|d^* a d\| < \|d\|^2 \delta < \varepsilon$, i.e., the stability criterion (iii) of Proposition 5.5.12 applies. □

REMARK 5.5.17. Suppose that A and B are stable and σ-unital, and that $\varphi\colon A \otimes \mathcal{O}_2 \to \mathrm{Q}(B)$ is a *-monomorphism. The above results contain the following observations: (i) The extension $E := \pi_B^{-1}(\varphi(A \otimes \mathcal{O}_2))$ is stable if and only if $E_0 := \pi_B^{-1}(\varphi(A \otimes 1))$ is stable.

(This is because $\varphi(A \otimes 1)$ is orthogonal to the range of an isometry in $\mathcal{M}(B)/B$ if and only if $\varphi(A \otimes \mathcal{O}_2)$ is orthogonal to it. Recall that E is always stable if B is purely infinite by Corollary 5.5.16.)

(ii) If E is stable, then there is a copy of $\mathcal{O}_2$ unitally contained in $\mathcal{M}(B)$, such that, for $a \in A$ and $c \in \mathcal{O}_2$,

$$\varphi(a \otimes 1)\pi_B(c) = \varphi(a \otimes c) = \pi_B(c)\varphi(a \otimes 1)\,.$$

(Indeed, then $\mathcal{M}(E)$ contains a unital copy of $\mathcal{O}_2 = C^*(s_1, s_2)$, and the epimorphism $\lambda := \varphi^{-1}\pi_B|E\colon E \to A \otimes \mathcal{O}_2$ extends to an epimorphism $\mathcal{M}(\lambda)$ from $\mathcal{M}(E)$ *onto* $\mathcal{M}(A \otimes \mathcal{O}_2)$, because λ is surjective and E and $A \otimes \mathcal{O}_2$ are both σ-unital, i.e., one can apply Proposition **??**.

(find precise cite! But it is also easy to check...) Pedersen Thm.: $\mathcal{M}(A) \to \mathcal{M}(A/J)$ surjective if A is σ-unital.

There is a unitary $V \in \mathcal{M}(A \otimes \mathcal{O}_2)$ with $V(1 \otimes s_k) = \mathcal{M}(\lambda)(s_k)$. Since the unitary group of $\mathcal{M}(A \otimes \mathcal{O}_2)$ is connected by Remark **??**,

Cuntz-Higson Theorem:
$\mathcal{U}(\mathcal{M}(A)) = \mathcal{U}_0(M(A))$ if A stable and σ-unital

there is a unitary $U \in \mathcal{M}(E) \subset \mathcal{M}(B)$ with $\mathcal{M}(\lambda)(U) = V$. One can see, that $C^*(U^*s_1, U^*s_2) \cong \mathcal{O}_2$ is a copy of $\mathcal{O}_2$ in $\mathcal{M}(B)$ with the desired property.)

(iii) If E_0 is stable and $\varphi_0(a) := \varphi(a \otimes 1)$, then (ii) is equivalent to $[\varphi_0] = [\varphi_0] + [\varphi_0]$ in $[\mathrm{Hom}(A, \mathrm{Q}(B)]$, i.e., φ_0 is unitarily equivalent to $\varphi_0 \oplus \varphi_0$ by a unitary in $\mathrm{Q}(B)$.

QUESTION 5.5.18. Is every extension

$$0 \to B \to E \to \mathrm{C}_0((0,1], \mathcal{O}_2 \otimes \mathbb{K}) \to 0$$

stable if B is stable and separable? (Compare Remark 5.5.17(i).)

6. W-vN type results for weakly nuclear maps

We deduce from Propositions 5.4.1 and 4.3.5(i) a proof of Kasparov's more general version, cf. Corollary 5.6.1, of Voiculescu's generalized Weyl–von Neumann theorem. It is implicitly contained in [**404**], but is not explicitly stated there. Voiculescu's generalization of the Weyl-von Neumann theorem reads now as a special case of Kasparov's generalization. The proof of Corollary 5.6.1 shows that we could deduce Corollary 5.6.1 as a logical sum of Voiculescu's generalized Weyl–von Neumann theorem and of Theorem 5.6.2.

Let A a (non-zero) *separable* C^*-algebra and B a stable σ-unital C^*-algebra. We have seen in Chapter 3 that the universal *-monomorphism $H_{\mathcal{C}} \colon A \to \mathcal{M}(B)$ for the matrix operator-convex cone $\mathcal{C} := \mathrm{CP}_{\mathrm{nuc}}(A, B)$ of completely positive nuclear maps from A into B is given up to unitary homotopy by the following universal construction:

Let $d \colon A \to \mathcal{M}(\mathbb{K}) \cong \mathcal{L}(\ell_2)$ any faithful *non-degenerate* *-representation of A, in sense of Remark 5.1.1(i).

We apply the infinite repeat δ_∞ of Remark 5.1.1(8) to d, i.e., replace d by $\delta_\infty \circ d$ to make sure that d is in general position, i.e., that $d(A) \cap \mathbb{K} = \{0\}$ and that $d(A)\mathbb{K} = \mathbb{K}$. A crucial property is that this "general position" implies that d and $\delta_\infty \circ d$ are unitarily homotopic.

The *-representation d is unital if A is unital. If A is not unital, then the extension given by the Busby invariant

$$\beta_0 := \pi_{\mathbb{K}} \circ d \colon A \to \mathcal{M}(\mathbb{K})/\mathbb{K}$$

dominates zero in sense of Definition 4.3.3. Since B is stable there is up to unitary equivalence (and up to unitary homotopy) a unique non-degenerate *-monomorphism $H_0 \colon \mathbb{K} \to \mathcal{M}(B)$

Hilbert B-module that the generating

COROLLARY 5.6.1 (Kasparov,Voiculescu,Weyl–von-Neumann). *Suppose that B is a σ-unital C^*-algebra, $I \colon \mathcal{M}(\mathbb{K}) \to \mathcal{M}(B)$ a strictly continuous unital *-monomorphism and $C \subset \mathcal{M}(B)$ a separable C^*-subalgebra such that $C \subset I(\mathcal{M}(\mathbb{K}))$.*

Let $T \colon C \to \mathcal{M}(B)$ be a completely positive contraction, such that

(α') $T(C \cap I(\mathbb{K})) = 0$,

(β') *the completely positive contraction* $T' \colon C/(C \cap I(\mathbb{K})) \to \mathcal{M}(B)$ *is* weakly nuclear*, and*

(γ) $T(c) = 1$ *for* $c \in C \cap (1 + I(\mathbb{K}))$ *(if* $1_{\mathcal{M}(B)} \in C + I(\mathbb{K})$*).*

Then:

(i) id_C *asymptotically dominates* T *in the sense of Definition 5.0.1.*

(ii) *If, moreover,* $T \colon C \to \mathcal{M}(B)$ *is a* C^**-morphism, then* id_C *asymptotically absorbs* T*, i.e.,* $\mathrm{id}_C \oplus T \colon C \to \mathcal{M}(B)$ *and* id_C *are unitarily homotopic in the sense of Definition 5.0.1.*

Proof. To keep notations simple, we identify the elements of $\mathcal{M}(\mathbb{K})$ and $I(\mathcal{M}(\mathbb{K}))$ with help of I. (In fact, there is a σ-unital C^*-algebra A and an isomorphism λ from $A \otimes \mathbb{K}$ onto B such that $I(k) = \mathcal{M}(\lambda)(1_{\mathcal{M}(A)} \otimes k)$ for $k \in \mathbb{K}$, and C lives in $1 \otimes \mathcal{M}(\mathbb{K})$.)

The strict continuity of the unital *-monomorphism I implies that $\mathbb{K}B$ is dense in B. $\mathcal{M}(\mathbb{K})$ contains a copy of $\mathcal{O}_\infty$ with generators given by isometries $t_1, t_2, \ldots$ with $t_j^* t_k = \delta_{jk} 1$ such that $\sum t_k t_k^*$ converges strictly to $1_{\mathcal{M}(\mathbb{K})} = 1_{\mathcal{M}(B)}$. By Remark 5.1.1(8), it follows that B is stable.

The conditions (β') and (γ) allow us to reduce the proof to the case where C is unital and contains $\mathbb{K}$ and that T is unital with $T(\mathbb{K}) = 0$: By assumption (β'), $T' \colon C/(C \cap \mathbb{K}) \to \mathcal{M}(B)$ is weakly nuclear. Replace C by $C + \mathbb{K}$ if $1_{\mathcal{M}(B)} \in C + \mathbb{K}$. Then T' is unital by assumption (γ). Thus we can replace T by $T'\pi_{\mathbb{K}}$, because $(C + \mathbb{K})/\mathbb{K} \cong C/(C \cap \mathbb{K})$.

If $1_{\mathcal{M}(B)}$ is not in $C + \mathbb{K}$, then $(C + \mathbb{K} + \mathbb{C}1)/\mathbb{K}$ is naturally isomorphic to the (outer) unitization of $C/(C \cap \mathbb{K})$ and the unital extension T_1 of T' to $(C + \mathbb{K} + \mathbb{C}1)/\mathbb{K}$ is again completely positive and weakly nuclear by Lemma B.7.7(i). Thus we can replace C by $C + \mathbb{K} + \mathbb{C}1$ and T by $T_1 \pi_{\mathbb{K}}$.

Thus C and $V := \delta_\infty \circ T$ satisfy the condition (α) of Proposition 5.4.1, where we take a strictly positive element h of $\mathbb{K} \subset C$. The new C and V are now unital. Moreover, V is a unital C^*-morphism if the original $T \colon C \to \mathcal{M}(B)$ is a C^*-morphism.

Next, we shall show that C and V satisfy condition (β) of Proposition 5.4.1. Then (i) and (ii) will follow from parts (ii), (iv) and (iii) of Proposition 5.4.1.

Let $\rho \colon C/\mathbb{K} \to \mathcal{M}(\mathbb{K}) \cong \mathcal{L}(H)$ be given by a faithful unital *-representation of the separable unital C^*-algebra $C/\mathbb{K}$ over a separable Hilbert space H. We define $C_1 := \delta_\infty(\rho(C/\mathbb{K}))$ and a unital completely positive map $V_1 \colon C_1 \to \mathcal{M}(B)$ by $V_1(e) := \delta_\infty(T'(c))$ for $e \in C_1$, $c \in C/\mathbb{K}$, $e = \delta_\infty(\rho(c))$. Then, by Remark 3.1.2(iii), V_1 is weakly nuclear and $V = \delta_\infty \circ \circ T = V_1 \gamma$, where $\gamma := \delta_\infty \circ \rho \circ \pi_{\mathbb{K}}$ is a unital C^*-morphism from $C \subset \mathcal{M}(\mathbb{K})$ onto $C_1 \subset \mathcal{M}(\delta_\infty(\mathbb{K}))$ with kernel $\mathbb{K}$. Note that $\mathcal{M}(\delta_\infty(\mathbb{K})) = \delta_\infty(\mathcal{M}(\mathbb{K})) \subset \mathcal{M}(\mathbb{K})$ by our choice of $\mathcal{O}_\infty$.

By Lemma 5.1.2(ii), the commutant of $\delta_\infty(\mathcal{M}(\mathbb{K}))$ in $\mathcal{M}(B)$ contains a copy of $\mathcal{O}_2$ unitally. $D := C^*(\mathcal{O}_2 \cdot \delta_\infty(\mathbb{K})) \cong \mathcal{O}_2 \otimes \mathbb{K}$ is a simple purely infinite C^*-subalgebra of $\mathcal{M}(B)$ such that $\delta_\infty(\mathcal{M}(\mathbb{K})) \subset \mathcal{M}(D)$ and $\delta_\infty(\mathbb{K})D$ is dense in D. Thus $C_1 D \subset D$. DB contains $\delta_\infty(\mathbb{K})B$ and is therefore dense in B.

Let $c_1, \ldots, c_n$ be contractions in C and $\varepsilon > 0$. Since C_1 is a separable subalgebra of $\mathcal{M}(D) \subset \mathcal{M}(B)$ and since, for $a \in B_+$, the map $e \in C_1 \mapsto aV_1(e)a$ is nuclear, by Proposition 3.2.15(i), there exists $b \in B$ with $\|b^*\gamma(c_j)b - aV_1(\gamma(c_j))a\| < \varepsilon/3$ for $j = 1, \ldots, n$.

We find a projection $p \in \mathbb{K}$ with $6\|b - pb\| < \varepsilon/(1 + \|b\|)$, because $\mathbb{K}B$ is dense in B.

By Lemma 2.1.22, we find a partial isometry $v \in \mathbb{K}$ such that $v^*v = p$ and $3\|S(c_j) - v^*c_j v\| < \varepsilon/(\|b\|^2 + 1)$ for $j = 1, \ldots, n$, where the unital completely positive map $S\colon C \to p\mathbb{K}p \cong M_k$ is given by $S(c) := p\gamma(c)p$, $k := \mathrm{Dim}(p\ell_2)$ and satisfies $S(\mathbb{K}) = 0$. Let $d := vb$. Since $V(c_j) = V_1(\gamma(c_j))$, the triangle inequality gives that $\|d^*c_j d - aV(c_j)a\| < \varepsilon$ for $j = 1, \ldots, n$. Thus C and $V := \delta_\infty \circ T$ satisfy also condition (β) of Proposition 5.4.1. □

We study now weakly nuclear liftable semi-split essential extensions of separable C^*-algebras A by simple purely infinite σ-unital stable algebras B. The corresponding generalized Weyl–von Neumann Theorem 5.6.2 implies that the extension is split if its class in $\mathrm{Ext}_{\mathrm{nuc}}(A, B)$ is zero. The pure infiniteness and the weak nuclearity of the semi-split map is necessary in this statement, cf. Corollaries 5.7.1 – 5.7.3.

The following generalized Weyl–von Neumann Theorem 5.6.2 is in view of Proposition 5.4.1 almost equivalent to the "local" result in Corollary 3.10.14.

If B nuclear then *every* unital completely positive contraction T with $T(C \cap I(\mathbb{K})) = \{0\}$ respectively $T(C \cap D) = \{0\}$ can be considered in Corollary 5.6.1 and Theorem 5.6.2.

Our Theorem 5.6.2 is simply a corollary of Proposition 3.2.13, Proposition 5.4.1, and Lemma B.7.7 together. (We call it a theorem, because of its importance.)

THEOREM 5.6.2 (Generalized Weyl–von Neumann Theorem). *Suppose that B is σ-unital and stable, and that $D \subseteq \mathcal{M}(B)$ a*

simple purely infinite

C^*-subalgebra of $\mathcal{M}(B)$ such that DB is dense in B.

Let C be a separable C^*-subalgebra of $\mathcal{M}(B)$ with $CD \subseteq D$ and $T\colon C \to \mathcal{M}(B)$ a completely positive contraction such that

(α') *$T(C \cap D) = 0$,*
(α'') *$C \cap D$ generates a corner of D,*
(β') *$T\colon C \to \mathcal{M}(B)$ is weakly nuclear, and*
(γ) *$T(C \cap (1 + D)) \subseteq \{1_{\mathcal{M}(B)}\}$.*

Then

(i) id_C *asymptotically dominates* T *(in the sense of Definition 5.0.1).*
(ii) *If, moreover,* $T\colon C \to \mathcal{M}(B)$ *is a* C^**-morphism then* id_C *asymptotically absorbs* T*, i.e.,* $\mathrm{id}_C \oplus T\colon C \to \mathcal{M}(B)$ *and* id_C *are unitarily homotopic in the sense of Definition 5.0.1.*

Proof. The natural extension $T_1\colon d + c \mapsto T(c)$ of T to $D + C$ is still weakly nuclear by Lemma B.7.7(ii) and by assumptions (α'), (α'') and (β').

It is unital by assumption (γ), if $1_{\mathcal{M}(B)} = 1_{\mathcal{M}(D)}$ is in $C+D$. If $1_{\mathcal{M}(B)}$ is not in $C+D$, then the unital extension $T_2\colon d+z1+c \mapsto T(c)+z1$ is again weakly nuclear by Lemma B.7.7(i). The extension T_1 (respectively T_2) is a unital C^*-morphism if T is a C^*-morphism from C into $\mathcal{M}(B)$.

Thus, we can assume that C and T are unital and that the natural extension of T to $C + D$ is weakly nuclear.

Let $b \in B_+$ a strictly positive element of B. We find a sequence $d_1, d_2, \ldots$ in D_+ such that $d_n b$ tends to b, because DB is dense in B. Let $C_1 \subset C + D$ be the separable unital C^*-subalgebra of $\mathcal{M}(D)$ which is generated by C, 1 and $\{d_1, d_2, \ldots\}$, and let T_1 be the natural extension of T to C_1. Then C_1, $V := \delta_\infty \circ T_1$ and a strictly positive element h of $C_1 \cap D$ fulfills condition (α) of Proposition 5.4.1.

We show that condition (β) of Proposition 5.4.1 is also satisfied:
Since C_1 is a separable subalgebra of $\mathcal{M}(D) \subset \mathcal{M}(B)$ and since, for $a \in B_+$, the map $c \in C_1 \mapsto aV(c)a$ is nuclear, by Proposition 3.2.15(i), for $c_1, \ldots, c_n \in C_1$ and $\varepsilon > 0$, there exists $d \in B$ with $\|d^* c_j d - aV(c_j)a\| < \varepsilon$.

Thus C_1 and $V := \delta_\infty \circ T_1$ are unital and satisfy the assumptions (α) and (β) of Proposition 5.4.1 and the assumptions of Propositions 5.4.1(ii) and 5.4.1(iv). Hence (i) follows from Proposition 5.4.1(ii) and (iv).

Moreover, V is a C^*-morphism if the original $T\colon C \to \mathcal{M}(B)$ is a C^*-morphism, and (ii) follows then from Proposition 5.4.1(iii). □

We explain now the important role of exactness in our consideration, and why we need exactness at certain places as assumptions for generalized Weyl–von-Neumann theorems.

Corollary 5.6.3. *A* C^**-algebra* A *is exact if and only if, for every* σ*-unital* C^**-algebra* B*, every weakly nuclear map* $V\colon A \to \mathcal{M}(B)$ *is nuclear.*

Proof. Suppose that each weakly nuclear $V\colon A \to \mathcal{M}(B)$ is nuclear if B is σ-unital. Let $A \subset \mathcal{L}(H)$ for some Hilbert space H and $C \subset A$ a separable C^*-subalgebra of A. Then there exists a faithful *-representation $d\colon C \to \mathcal{M}(\mathbb{K}) \cong \mathcal{L}(H_1)$ of C on a separable Hilbert space H_1. Since $\mathcal{M}(\mathbb{K})$ is injective, by Arveson extension theorem, [**43**], d extends to a completely positive contraction $V\colon A \to \mathcal{M}(\mathbb{K})$. $B := \mathbb{K}$ is σ-unital and nuclear. Thus V is weakly nuclear and therefore nuclear by assumption. $d^{-1}\colon d(C) \to \mathcal{L}(H)$ extends to a completely positive contraction $T\colon \mathcal{M}(\mathbb{K}) \to \mathcal{L}(H)$ by injectivity of $\mathcal{L}(H)$. TV is nuclear and $TV(a) = a$ for $a \in C$. Thus the inclusion map $A \hookrightarrow \mathcal{L}(H)$ is nuclear. But this is equivalent to the exactness of A, cf. Remark 3.1.2(ii).

Now suppose conversely that A is exact and that B is σ-unital and $V\colon A \to \mathcal{M}(B)$ is a weakly nuclear contraction.

We can assume that A and V are unital: If A is not unital, then $V_1(a + z1) = V(a) + z1$ is a unital extension to the unitization of A. The u.c.p. mapV_1 is still weakly nuclear by Lemma B.7.7(i), and the unitization of A is again exact.

If A is unital, then we take a state ψ on A and consider $W(a) = V(a)+\psi(a)(1-V(1))$ for $a \in A$. W is unital and weakly nuclear. The tensor criteria in Remark 3.1.2(i) shows that V is nuclear if W is nuclear.

It suffices to approximate V on unital separable subalgebras C of A by unital nuclear maps. The subalgebras of A are again exact by Remark 3.1.2(ii) and by the Arveson extension theorem. Therefore, by Remark 3.1.2(ii), $H_0\colon C \to \mathcal{M}(\mathbb{K}) \subset \mathcal{M}(B \otimes \mathbb{K})$ is nuclear for a faithful unital *-monomorphism $H_0\colon C \to \mathcal{M}(\mathbb{K})$ with $H_0(C) \cap \mathbb{K} = \{0\}$, e.g. take $H_0 := \delta_\infty \circ \rho$ for some unital faithful *-representation $\rho\colon C \to \mathcal{L}(H)$.

$$c \in C \mapsto V(c) \otimes 1_{\mathcal{M}(\mathbb{K})} \subset \mathcal{M}(B \otimes \mathbb{K})$$

is still weakly nuclear. Therefore, by Corollary 5.6.1, there exists a sequence of isometries $S_n \in \mathcal{M}(B \otimes \mathbb{K})$ such that $\lim_n \|V(c) \otimes 1 - S_n^* H_0(c) S_n\| = 0$ for $c \in C$. The nuclearity of H_0 implies that $V|C$ is nuclear. Thus $V\colon A \to \mathcal{M}(B)$ is nuclear, because the nuclearity is a "local" property of V by Definition 3.1.1. □

Let A a separable C^*-algebra and $\rho\colon A \to \mathcal{L}(\mathcal{H}) \cong \mathcal{M}(\mathbb{K})$ a faithful non-degenerate *-representation in general position, i.e., $\rho(A) \cap \mathbb{K} = \{0\}$. If B is stable, the composition $H\colon A \to \mathcal{M}(B)$ of ρ with $\mathcal{M}(\mathbb{K}) \hookrightarrow \mathcal{M}(B)$ is a non-degenerate *-monomorphism with $H(A) \cap B = \{0\}$, and H is weakly nuclear. Let $H_0 := \pi_B \circ H$ the corresponding *-monomorphism from A into $\mathrm{Q}^{\mathrm{s}}(B) = \mathrm{Q}(B)$. We use the notation $[H_0]$ for the unitary equivalence class of $H_0\colon A \to \mathrm{Q}^{\mathrm{s}}(B)$ by unitaries in $\mathrm{Q}^{\mathrm{s}}(B)$.

Corollary 5.6.4 (Equivalence and Dominance in $\mathcal{M}(B)$ and $\mathrm{Q}^{\mathrm{s}}(B)$). *Suppose that B is σ-unital and stable, $D_i \subset \mathcal{M}(B)$ are σ-unital stable C^*-subalgebra with D_iB dense in B, for $i = 1, 2$, and that A is a separable C^*-algebra which is unital or is stable. Furthermore, assume that (for $i = 1, 2$) D_i is simple and purely infinite or $D_i \cong \mathbb{K}$.*

Further let H and H_0 be as above.

(i) *Let $h_1, h_2\colon A \to \mathrm{Q}^{\mathrm{s}}(B)$ be *-monomorphisms such that $h_1(A) \subset \pi_B(\mathcal{M}(D_1))$, $h_1(A) \cap \pi_B(D_1) = 0$, and that h_2 has a completely positive weakly nuclear lift $T_2\colon A \to \mathcal{M}(B)$. (Suppose in addition that that $h_i(1) = 1$ for $i = 1, 2$, if A is unital.)*

   Then h_1 dominates h_2 in $\mathrm{Q}^{\mathrm{s}}(B)$.

(ii) *Let $h_i\colon A \to \mathcal{M}(D_i) \subset \mathcal{M}(B)$ be weakly nuclear *-monomorphisms such that $h_i(A) \cap D_i = 0$ for $i = 1, 2$. (Suppose, in addition, that $h_i(1) = 1_{\mathcal{M}(B)}$ for $i = 1, 2$ if A is unital.)*

Then h_1 and h_2 are unitarily homotopic in the sense of Definition 5.0.1.

(iii) *$S(H_0, A, \mathrm{Q}^{\mathrm{s}}(B))$ is the $\oplus$-semigroup of the unitary equivalence classes of those C^*-morphisms from A into $\mathrm{Q}^{\mathrm{s}}(B)$ that have a weakly nuclear completely positive lift, and which are unital if A is unital.*

(iv) *If B itself is simple and purely infinite, then, for every *-monomorphism h from A into $\mathrm{Q}^{\mathrm{s}}(B)$, the Cuntz sum $h \oplus H_0$ is unitarily equivalent to h in $\mathrm{Q}^{\mathrm{s}}(B)$. (Here h is assumed to be unital, if A is unital.) In particular,*

$$S(H_0, A, \mathrm{Q}^{\mathrm{s}}(B)) \cap [\mathrm{Mon}(A, \mathrm{Q}^{\mathrm{s}}(B))] = G(H_0, A, \mathrm{Q}^{\mathrm{s}}(B))\,.$$

Proof. In the stable case the unitized monomorphisms are still monomorphisms. Therefore it suffices to consider the unital case.

(i): Note that $\pi_B T_2 = h_2$. Consider a unital separable $C \subset \mathcal{M}(D_1)$ such that C contains a strictly positive element of D_1 and $\pi_B(C) = h_1(A)$. Let $T := T_2 h_1^{-1} \pi_B | C$. T is weakly nuclear. Thus Theorem 5.6.2(i) or Corollary 5.6.1(i) applies. Let $s := \pi_B(S(1))$. Then s is an isometry in $\mathrm{Q}^{\mathrm{s}}(B)$ and $s^* h_1(\cdot) s = h_2$.

(ii): Let C_k the C^*-algebra which is generated by $h_k(A)$ and a strictly positive element of D_k, $(k = 1, 2)$. Then there are unique epimorphisms ψ_k from C_k onto A with $\psi_k h_k = \mathrm{id}_A$.

Let $T_1 := h_2 \psi_1$ and $T_2 := h_1 \psi_2$. Then C_k and $T_k\colon C_k \to \mathcal{M}(B)$ satisfy the assumptions of Theorem 5.6.2(ii) or of Corollary 5.6.1(ii). Thus we find norm continuous maps $t \mapsto U_k(t)$ into the unitaries of $\mathcal{M}(B)$ such that, for $a \in A$, $t \in \mathbb{R}_+$,

$$(h_k(a) \oplus T_k(h_k(a))) - U_k(t)^* h_k(a) U_k(t) \in B$$

and

$$\lim_{t \to \infty} \|(h_k(a) \oplus T_k(h_k(a))) - U_k(t)^* h_k(a) U_k(t)\| = 0.$$

Since $T_1 h_1 = h_2$ and $T_2 h_2 = h_1$, we get the desired result with the unitaries $U(t) = U_1(t) V_0 U_2(t)^*$, where V_0 is a unitary with $V_0^*(a \oplus b) V_0 = b \oplus a$.

By Chapter 4, (iii) and (iv) are special cases of (i). □

7. W-vN type results for simple p.i. algebras

The Part (ii) of below given Corollary 5.7.1 says among others that the absorption criteria of G. Elliott and D. Kucerovsky [**264**] (cf. [**310**] for the non-unital case) is satisfied for all pi-sun algebras.

Corollary 5.7.1. *Let B a nonzero σ-unital C^*-algebra and t_1, t_2 isometries in $\mathcal{M}(B \otimes \mathbb{K})$ with $t_1 t_1^* + t_2 t_2^* = 1$.*

The following conditions on B are equivalent:

(i) *B is stably isomorphic to a unital purely infinite simple C*-algebra or to* $\mathbb{C}$*;*

(ii) *For every unital separable C*-subalgebra C of $\mathcal{M}(B \otimes \mathbb{K})$ such that $C \cap (B \otimes \mathbb{K})$ contains a strictly positive element of $B \otimes \mathbb{K}$ and for every unital* weakly nuclear *map $V : C \to \mathcal{M}(B \otimes \mathbb{K})$ with $V(C \cap (B \otimes \mathbb{K})) = \{0\}$ there exists a sequence (s_n) of isometries in $\mathcal{M}(B \otimes \mathbb{K})$ with*
   (1) *$V(b) - s_n^* b s_n \in B \otimes \mathbb{K}$ for all $b \in C$,*
   (2) *$\|V(b) - s_n^* b s_n\| \to 0$ for all $b \in C$;*

(iii) *For every unital separable C*-subalgebra C of $\mathcal{M}(B \otimes \mathbb{K})$ such that $C \cap (B \otimes \mathbb{K})$ contains a strictly positive element of $B \otimes \mathbb{K}$, and for every unital weakly nuclear C*-morphism $h : C \to \mathcal{M}(B \otimes \mathbb{K})$ with $h(C \cap (B \otimes \mathbb{K})) = \{0\}$, there exists a sequence (u_n) of unitaries in $\mathcal{M}(B \otimes \mathbb{K})$ with*
   (1) *$b \oplus_{t_1,t_2} \varphi(b) - u_n^* b u_n \in B \otimes \mathbb{K}$ for all $b \in C$,*
   (2) *$\|b \oplus_{t_1,t_2} \varphi(b) - u_n^* b u_n\| \to 0$ for all $b \in C$,*

   for some pair s_1, s_2 of generators of $\mathcal{O}_2$ in $\mathcal{M}(B \otimes \mathbb{K})$.

Proof. The implication (i)⇒(ii) follows immediately from Theorem 5.6.2(i) and Corollary 5.6.1(i).

(ii)⇒(iii): If V is unital and weakly nuclear then $\delta_\infty \circ V$ is again unital and weakly nuclear and has the same kernel as V. Therefore the proof of Lemma 5.1.2(vi) can be modified to obtain a proof of the implication (ii)⇒(iii) here. One has only to replace E there by $\ell_\infty(\mathcal{M}(B \otimes \mathbb{K}))/c_0(B \otimes \mathbb{K})$ here. Then we apply Proposition 4.3.5(i) as there.

(iii)⇒(i): By Corollary 2.2.11(i), it suffices to show that the stable corona $\mathrm{Q}^{\mathrm{s}}(B) := \mathcal{M}(B \otimes \mathbb{K})/(B \otimes \mathbb{K})$ of B is simple. This follows already from Part (iii,1):

Let a be a positive element of $\mathrm{Q}^{\mathrm{s}}(B)$ with $\|a\| = 1$. We want to find an element d such that $d^* a d = 1$. This shows than that $\mathrm{Q}^{\mathrm{s}}(B)$ is not only simple but is also purely infinite.

Let χ be a character on $C^*(a)$ with $\chi(a) = 1$, $b \in \mathcal{M}(B)_+$ a contraction with $\pi_B(a)$ and $q \in B \otimes \mathbb{K}$ a strictly positive element of $B \otimes \mathbb{K}$. Now let $C := C^*(b, q)$ be the C^*-algebra generated by b and q. Then $C \cap (B \otimes \mathbb{K})$ contains q and we can apply Part(iii,1). The quotient map π from $\mathcal{M}(B \otimes \mathbb{K})$ onto $\mathrm{Q}^{\mathrm{s}}(B)$ maps C onto $C^*(a)$ Let us define $h : C \to \mathcal{M}(B \otimes \mathbb{K})$ as $h(c) = \chi(\pi(c)) \cdot 1$. Clearly h is a nuclear C^*-morphism and annihilates $C \cap (B \otimes \mathbb{K})$. Hence by Part (iii, α) there exists a unitary $u \in \mathcal{M}(B \otimes \mathbb{K})$ such that

$$b \oplus_{s_1,s_2} 1 - u^* b u \in B \otimes \mathbb{K}$$

(recall that $h(b) = 1$). Recalling the definition of $\oplus_{s_1,s_2}$, we get $s_1 b s_1^* + s_2 s_2^* - u^* b u \in B \otimes \mathbb{K}$. Hence $1 - s_2^*(u^* b u) s_2$ belongs to $B \otimes \mathbb{K}$. So, by taking $d = \pi(u s_2)$, $d^* a d = 1$ in $\mathrm{Q}^{\mathrm{s}}(B)$ as desired. □

Now we show a result that is stronger than the result pointed out in the proof of the implication (iii)⇒(i) of Corollary 5.7.1:

Corollary 5.7.2. *If B is σ-unital, simple and purely infinite and if A is a simple separable unital C^*-subalgebra of the stable corona $\mathrm{Q}^{\mathrm{s}}(B)$ such that the inclusion map $A \hookrightarrow \mathrm{Q}^{\mathrm{s}}(B)$ has a completely positive lift $T\colon A \to \mathcal{M}(B \otimes \mathbb{K})$ which is weakly nuclear, then $A' \cap \mathrm{Q}^{\mathrm{s}}(B)$ is purely infinite.*

In particular, $A' \cap \mathrm{Q}^{\mathrm{s}}(B)$ is purely infinite for every simple separable nuclear C^*-subalgebra $A \subseteq \mathrm{Q}^{\mathrm{s}}(B)$ that contains the unit element of $\mathrm{Q}^{\mathrm{s}}(B)$.

Proof. By Corollary 5.7.1(iii), id_A dominates the restriction of h_0 to $A \cong A \otimes 1$ where $h_0\colon A \otimes \mathcal{O}_2 \to \mathrm{Q}^{\mathrm{s}}(B)$ is a weakly nuclear liftable unital *-monomorphism, e.g. coming from a faithful unital *-representation $k\colon A \otimes \mathcal{O}_2 \to \mathcal{L}(H) \cong \mathcal{M}(\mathbb{K})$.

Thus $A' \cap \mathrm{Q}^{\mathrm{s}}(B)$ is not isomorphic to $\mathbb{C}$.

Let $V\colon A \to \mathcal{M}(B \otimes \mathbb{K})$ be a weakly nuclear unital completely positive map with $\pi \circ V = \mathrm{id}_A$. If C is a unital separable C^*-subalgebra of $\mathrm{Q}^{\mathrm{s}}(B)$ and $h\colon C \to A$ is a unital C^*-morphism, then $V \circ h$ is a weakly nuclear lift of h. Thus by Corollary 5.7.1(ii) there exists an isometry $s \in \mathrm{Q}^{\mathrm{s}}(B)$ with $h(c) = s^* c s$ for $c \in C$.

This shows that $A \subset \mathrm{Q}^{\mathrm{s}}(B)$ satisfies the criteria in Proposition 2.2.5(v), and, therefore, $A' \cap \mathrm{Q}^{\mathrm{s}}(B)$ must be simple and purely infinite. □

Next stable absorption theorem characterizes the unital nuclear purely infinite simple algebras B and $B = \mathbb{C}$ as the only C^*-algebras by the "naive" one-to-one generalization of the classical Weyl–von-Neumann theorem. It shows that a useful more general generalization of the WvN-theorem needs more elaborate assumptions and formulations, e.g. as ours.

Corollary 5.7.3. *For a σ-unital C^*-algebra B the following properties* (i) *and* (ii) *are equivalent:*

(i) *B is stably isomorphic to $\mathbb{C}$ or is stably isomorphic to a simple purely infinite unital* nuclear *C^*-algebra A.*
(ii) *For every unital separable C^*-algebra $C \subset \mathcal{M}(B \otimes \mathbb{K})$ and every unital C^*-morphism $h\colon C \to \mathcal{M}(B \otimes \mathbb{K})$ with $h\big(C \cap (B \otimes \mathbb{K})\big) = 0$ there exists a unitary $U \in \mathcal{M}(B \otimes \mathbb{K})$ such that $c \oplus h(c) - U^* c U \in B \otimes \mathbb{K}$ for all $c \in C$.*

Proof. (i)⇒(ii): Let $E := B \otimes \mathbb{K}$. Every C^*-morphism $k\colon F \to \mathcal{M}(E)$ is weakly nuclear, because E is nuclear. Therefore, in this special case, the composition $C + E \to (C + E)/E \cong C/(C \cap B) \to \mathcal{M}(B)$ is again weakly nuclear if $h(C \cap (B \otimes \mathbb{K})) = 0$, and we can assume w.l.o.g. that C contains a strictly positive element of E. Then (ii) follows from Corollary 5.7.1(iii,1).

(ii)⇒(i): We modify the proof of the implication (iii)⇒(i) of Corollary 5.7.1 as follows. Let $C := C^*(b, 1)$, with b as there. Then we don't use the assumption that B is σ-unital, that we have used in the proof of Corollary 5.7.1 to check the conditions in Corollary 2.2.11(i), because we can do *here* the same with *every* unital separable $C \subset \mathcal{M}(B \otimes \mathbb{K})$ by our assumptions in (ii).

By Corollary 2.2.11(i), this gives that B is σ-unital simple and purely infinite and thus is stably isomorphic to a simple purely infinite unital C^*-algebra A by [**172**] and by L.G. Brown's stable isomorphism theorem (cf. Corollary 5.5.6).

Let A unital with $A\otimes\mathbb{K} \cong B\otimes\mathbb{K}$ and let D be a separable unital C^*-subalgebra of A and $R\colon D \to \mathcal{L}(H) \cong 1_A \otimes \mathcal{M}(\mathbb{K})$ a faithful unital *-representation with $R(D) \cap \mathbb{K}(H) = 0$. Then (ii), for $C := R(D)$, implies that there is an isometry $S \in \mathcal{M}(A \otimes \mathbb{K})$ with

$$S^*(1_A \otimes R(d))S \,-\, d \otimes 1_{\mathcal{M}(\mathbb{K})} \in A \otimes \mathbb{K}\,.$$

If we use a sequence of states ψ_n on $\mathbb{K}$ which converges weakly to zero, then we get that $D \hookrightarrow A$ is a point-wise limit of the unital completely positive maps $d \mapsto (\mathrm{id}_A \otimes\psi_n)(S^*1_A \otimes R(d)S)$, which are nuclear. Here we have to extend $(\mathrm{id}_A \otimes\psi_n)\colon A \otimes \mathbb{K} \to A$ naturally to a unital completely positive map $\mathcal{M}(A \otimes \mathbb{K}) \to A$. Thus A is nuclear. □

REMARK 5.7.4. Above considerations show that the range of generalized Weyl–von Neumann theorems seems to be very limited almost to extensions by $\mathbb{K}$ or stable simple purely infinite algebras.

But if we consider special situations, i.e., additional requirements on C and V or h, then Proposition 5.4.1 allows to deduce other types of generalizations of the Weyl–von Neumann theorem in the spirit of Voiculescu's generalization of BDF-theory, e.g. some equivariant cases. Here we state a general result inspired by E. Blanchard [**89**]. We do not use directly the fundamental conditions (α) and (β) of the generalised Weyl–von-Neumann theorem but apply more comfortable assumptions that imply conditions (α) and (β):

Assume that B is σ-unital and stable and that $C \subset \mathcal{M}(B)$ is unital and separable. Let $T\colon C \to \mathcal{M}(B)$ a unital completely positive map such that:

- (α') *$T(C \cap B) = 0$ and $C \cap B$ contains a strictly positive element of B;*
- (β') *For every (non-degenerate) factorial representation $\rho\colon B \to \mathcal{L}(H)$ there exists a net W_τ of inner unital completely positive maps $W_\tau(a) = \sum d_k^* a d_k$ from $N := \rho(B)''$ into N, such that $\rho(V(c))$ is the point-wise weak limit of $W_\tau(\rho(c))$ for every $c \in C$, where we have extended ρ naturally to a weakly continuous homomorphism from $B^{**} \supset \mathcal{M}(B)$ into N.*
- (β'') *For every $b \in B_+$, $c_1, \ldots, c_m \in C$, $\varepsilon > 0$, $n \in \mathbb{N}$ there exist $s_1, \ldots, s_n \in \mathcal{M}(B)$ such that $s_i^* s_j = \delta_{ij}$ and $\|c_k s_i b - s_i c_k b\| < \varepsilon$ for $i = 1, \ldots, n$, $k = 1, \ldots, m$.*

Then the conclusions (ii), (iii) and (iv) Proposition 5.4.1 hold.

Idea of the proof: Clearly (α') implies (α) of Proposition 5.4.1.

A combination of a Hahn-Banach separation argument (which yields a tensor product characterization of approximately inner completely positive maps, cf. Chapter 3 or [**443**, appendix]) with a modification of the argument in the proof of Proposition 2.2.5(iii) shows that (β') and (β'') together imply (β) of Proposition 5.4.1 for $V := \delta_\infty \circ T$.

8. Extensions and $\mathrm{Ext}(\mathcal{C};\, A, B)$

Parts of the proofs of our theorems in Chapter 1 consists in showing that a certain *strong equivalence* of extensions (related to the theorem in question) can be deduced from – in a "formal sense" – considerably weaker equivalence relations on extensions. In particular, we have to deduce that certain extensions are actually split ([17]). It requires that the extensions that absorb certain split extensions need to be characterized with help of generalized Weyl–von-Neumann–Voiculescu theorems. This will be discussed here in this section.

We need urgently the following cases:

(1) $B = \mathcal{O}_2 \otimes \mathbb{K}$, A unital and separable (and exact), $\varphi \in \mathrm{Hom}(A, \mathrm{Q}(B))$ unital (!) and with (automatically weakly nuclear) unital c.c. split $T\colon A \to \mathcal{M}(B)$ with $\pi_B \circ T = \varphi$.

If A is exact, then T is automatically nuclear. Thus, this is then the case if $\varphi\colon A \to \mathrm{Q}(B)$ is nuclear.

Is there an "elementary way" to find a splitting by C^*-morphism?

E.g. it could be that φ extends to $A \otimes \mathcal{O}_2$, i.e., that one can find a unital copy of $\mathcal{O}_2$ in $\varphi(A)' \cap \mathrm{Q}(B)$: Then one can take a faithful unital nuclear *-representation $\rho\colon A \to \mathcal{L}(\ell_2) = \mathcal{M}(\mathbb{K})$ and define $\psi\colon A \to \mathrm{Q}(B)$ by $\psi(a) = \pi_{B\otimes\mathbb{K}}(1_{\mathcal{O}_2} \otimes \rho(a))$. ψ is again nuclear and commutes with a copy of $\mathcal{O}_2$ in $\mathrm{Q}(B)$.

Then ψ, φ 1-step dominate each other (needs a proof). It follows then from results in Chapter 4, that they are unitary equivalent in $\mathrm{Q}(B)$. This defines a unital splitting C^*-morphism for φ.

To get such things there are two ways:

Replace A by $A \otimes \mathcal{O}_2$ (covers the exact case), or try to find a way to prove that $\varphi \oplus \varphi$ is unitary equivalent to φ in $\mathrm{Q}(B)$ if A is nuclear. (this should be necessary to get the desired additional observations in case of nuclear A).

We can attempt to first use that $A = \mathcal{O}_2 \otimes \mathcal{O}_2 \otimes \cdots$ has this property (needs homotopy invariance of $\mathrm{Ext}(A, \mathcal{O}_2)$?).

We find every exact C^*-algebra as sub quotient of $\mathcal{O}_2$ in $\mathrm{Q}(B)$, such that each c.p. lift sits in a copy of $B \subseteq V(\mathcal{O}_2) \cap \mathcal{M}(B)$ for a u.c.p. map $V\colon \mathcal{O}_2 \to \mathcal{M}(B)$.

Get then unital embedding into $\mathcal{O}_2$, but first only of extensions of them by B.

Used later:

(1a) If φ and $\psi\colon A \to \mathrm{Q}(B)$ have unital splits, then ψ and φ are unitarily equivalent by a unitary in $\mathrm{Q}(B)$.

Moreover this should be the case if $B = \mathcal{O}_2 \otimes \mathbb{K}$

[17] I.e., is not only stably split after adding a certain split extension.

One should check if ψ extends to ?????

Because, by Kasparov, Voiculescu, ????

(1b) $\mathcal{U}(\mathrm{Q}(B)) = \mathcal{U}_0(\mathrm{Q}(B))$ deduced from K_1-injectivity and $\mathrm{K}_1(\mathrm{Q}(B)) = 0$. (By property (sq) of $\mathrm{Q}(B)$, $\mathrm{K}_*(\mathcal{M}(B)) = 0$ and $\mathrm{K}_*(\mathcal{O}_2) = 0$. Ref. from Chp. 4)

(2) B arbitrary σ-unital, stable strongly p.i. C^*-algebra. $\mathcal{C}$ given by

$$H_0 \colon A \to \mathcal{M}(B)$$

non-degenerate, A separable and *stable*, with the property that H_0 is unitarily homotopic to $\delta_\infty \circ H_0$.

Are δ_∞ and δ_∞^2 really unitarily homotopic?

Yes, they are, because they are unitary equivalent and each unitary equivalence causes "homotopy" in $\mathcal{M}(B)$ by a norm-continuous path of unitaries in $\mathcal{M}(B)$ if B stable and σ-unital, because then $\mathcal{U}(\mathcal{M}(B)) = \mathcal{U}_0(\mathcal{M}(B))$.

It is not clear if one can move them with a path $U(t)$ in the unitaries such that

$$U(t)^*\delta_\infty^2(H_0(a))U(t) - \delta_\infty(H_0(a)) \in B$$

for all $a \in A$.

But this should be possible if $H_0 = \delta_\infty \circ h_0$ for some $h_0 \colon A \to B$???

This could be almost possible with a "long" strictly continuous path $W(t)$ with $\lim W(t) = U$ for $W(t) = \exp(h_1(t)) \cdot \ldots \cdot \exp(h_n(t))$, $U = \exp(k_1) \cdot \ldots \cdot \exp(k_n)$, $h_\ell(t) \to k_\ell$ strictly, $h_\ell(t)^* = -h_\ell(t)$, $k_\ell^* = -k_\ell$.

In the corona it does nothing.

Busby invariants in question are:

$\varphi \colon A \to \mathrm{Q}(B)$

with c.p. splits $V \colon A \to \mathcal{M}(B)$: i.e., $b^*V(\cdot)b \in \mathcal{C}$ for each $b \in B$.

Pre-assumption in trivially graded case:

A and B stable, A separable, B σ-unital, $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ point-norm closed, countably generated, non-degenerate m.o.c. cone.

$H_{\mathcal{C}} \colon A \to B$ non-degenerate in general position, in 1-1-relation to $\mathcal{C}$, $h_0 := \pi_B \circ H_{\mathcal{C}}$.

$$\mathrm{Ext}(\mathcal{C};\, A, B) \cong \text{ kernel of } \mathrm{K}_0(h_0(A)' \cap \mathrm{Q}(B)) \to \mathrm{K}_0(\mathrm{Q}(B))\,.$$

This is, because we consider only the zero-dominating maps in $S(h_0; A, \mathrm{Q}(B))$, i.e., where the extension is stable.

Since the σ-unital B is stable, and A is stable and σ-unital, it means equivalently that we consider only *stable* extensions of A with B, by Proposition **??**.

Alternatively: Classes of projections $p \in \mathcal{M}(B)$ with $[p, h_0(a)] \in B$ for all $a \in A$, equivalence modulo B in $h_0(A)' \cap \mathrm{Q}(B)$ (alternatively: isometries T with $TT^* = p$, $T^*T = p'$, T commutes mod B with $h_0(A)$)

Unitary equivalence classes $[\varphi]$ by unitaries in $\pi_B(\mathcal{U}(\mathcal{M}(B))) = \mathcal{U}_0(\mathrm{Q}(B))$ deserve as elements as elements of $\mathrm{SExt}(\mathcal{C}; A, B)$.

$\mathrm{SExt}(\mathcal{C}; A, B) := S(\pi_B \circ H_0\,;\ A, \mathrm{Q}(B))$.

implies $\mathrm{Ext}(\mathcal{C}; A, B) \cong \mathrm{Gr}(\mathrm{SExt}(\mathcal{C}; A, B))$

Needs "absorbing elements".

Or / Respectively, other (not equivalent) definition ????:
$\mathrm{Ext}(\mathcal{C}; A, B) := [\pi_B \circ H_0] + \mathrm{SExt}(\mathcal{C}; A, B)$

The class $[\pi_B \circ H_0]$ deserves as a zero element.

The H_0 for $\mathcal{C} := \mathrm{CP}_{\mathrm{nuc}}(X; A, B)$, respectively $\mathcal{C} := \mathrm{CP}_{\mathrm{nuc}}(A, B)$, and (if A and B are both separable) $\mathcal{C} := \mathrm{CP}_{\mathrm{nuc}}(A, B)$ should be given.

(3) Specify the "nuclear cases" for A unital, exact, and separable, and B simple s.p.i., σ-unital, stable and separable.

Then $\mathrm{Q}^{\mathrm{s}}(B) = \mathcal{M}(B)/B$ is simple and p.i. If $\varphi, \psi \colon A \to \mathrm{Q}^{\mathrm{s}}(B)$ are two unital nuclear *-monomorphisms. Then there exist isometries $S, T \in \mathrm{Q}^{\mathrm{s}}(B)$ with $S^*\varphi(\cdot)S = \psi$ and $T^*\psi(\cdot)T = \varphi$.

Need that in case $B = \mathcal{O}_2 \otimes \mathbb{K}$ and separable unital $C \subseteq \mathrm{Q}^{\mathrm{s}}(B)$ that the unit of $C' \cap \mathrm{Q}^{\mathrm{s}}(B)$ is properly infinite in $C' \cap \mathrm{Q}^{\mathrm{s}}(B)$, and $\mathrm{K}_*(C' \cap \mathrm{Q}^{\mathrm{s}}(B)) = 0$.

Can follow form ????

In a first step one could consider $\mathcal{O}_2 \otimes \mathcal{O}_2 \otimes \cdots$ in place of A.

Implies that $\mathcal{O}_2 \otimes \mathcal{O}_2 \otimes \cdots$ is unitally contained in $\mathcal{O}_2$?

Need: All unital *-endomorphisms of $\mathcal{O}_2$ and of $\mathcal{O}_2 \otimes \mathcal{O}_2 \otimes \cdots$ are approximately inner.

Must be integrated in Chapter 3.

(4) Discuss:
Absorption like Elliott/Kucerovsky (+ correction by J. Gabe)

(5) Existence and uniqueness – up to unitary homotopy – of universal $H_0 \colon A \to \mathcal{M}(B \otimes \mathbb{K})$. In which cases of $\mathcal{C}$?

In case of B a pi-sun algebra, there exists only $\mathrm{CP}(A, B) = \mathrm{CP}_{\mathrm{nuc}}(A, B)$.

Then each nuclear c.p. map into $\mathrm{Q}^{\mathrm{s}}(B)$ is 1-compression of H_0 and one has to determine the $\mathrm{K}_1(\pi_{B \otimes \mathbb{K}} \circ H_0(A)' \cap \mathrm{Q}^{\mathrm{s}}(B))$.

The quickest way should be to show that $\mathcal{O}_2 \cong \mathcal{O}_2 \otimes \mathcal{O}_2 \otimes \cdots$ and that it causes that for each separable subset X of $Q := \mathrm{Q}^{\mathrm{s}}(\mathcal{O}_2 \otimes \mathcal{O}_2 \otimes \cdots)$ there exists a copy of $\mathcal{O}_2$ unitally in $X' \cap Q$.

(6??)

The definition of Elliott/Kucerovsky/Gabe of an "absorbing extension" is:

"An extension that absorbs any weakly nuclear extension"

Ell/Kuc in Pacific MJ: (Unital) "purely large" extensions absorb all (unitally) weakly nuclear extensions.

The extension $0 \to B \to E \to A \to 0$ is "purely large" (by Definition of "purely large") if for each $x \in E \setminus B$ the hereditary C^*-subalgebra $\overline{x^*Bx}$ of B contains a stable hereditary C^*-subalgebra $D \subseteq \overline{x^*Bx}$ that is full in B.

My observation:
Write $B \cong B \otimes \mathbb{K}$ for $\mathbb{K} := \mathbb{K}(\ell_2(\mathbb{N}))$ The extension E must necessarily absorb the extension given by Busby invariant $\pi_B \circ h$ where $h\colon A \ni a \mapsto 1_{\mathcal{M}(B)} \otimes \delta_\infty(d(a)) \in \mathcal{M}(B) \otimes \mathcal{L}(\ell_2) \subseteq \mathcal{M}(B \otimes \mathbb{K}) \cong \mathcal{M}(B)$.

Here, $d\colon A \to \mathcal{L}(\ell_2)$ is any faithful C^*-morphism that has the property that $d(A)\ell_2$ is *not* dense in ℓ_2.

Full hereditary stable C^*-subalgebras D of $B \otimes \mathbb{K}$ contain an in D strictly positive element $e \in D_+$ that is M-vN equivalent in $B \otimes \mathbb{K}$ to a strictly positive element $b \in (B \otimes \mathbb{K})_+$.

How to use it to show our assumptions for the absorption Theorem ??? for $A \subseteq \mathrm{Q}^{\mathrm{s}}(B)$ and $(\pi_B \circ h)\colon A \to \mathrm{Q}^{\mathrm{s}}(B)$

An (unital) extension $0 \to B \to E \to A \to 0$ is "(unitally) weakly nuclear" if there exists a (unital) weakly nuclear c.p. map $V\colon A \to E$ with the property that $\pi_B \circ V$ is the Busby invariant of the extension.

Here V is "weakly nuclear" if $A \ni a \mapsto b^*V(a)b \in B$ is nuclear for all $b \in B$.

(Kucerovsky/Ng, Houston J.Math.32, 2006): Any "full" extension by a σ-unital stable C^*-algebra B with (CFP) is "purely large".

Here "full" means that each non-zero element of $A \subseteq E/B$ is full in E/B.

Corona factorization property (CFP) (of stable C^*-algebras B):

Each full projection $P \in \mathcal{M}(B)$ is properly infinite in $\mathcal{M}(B)$. (P is range of a isometry in $\mathcal{M}(B)$?)

J. Gabe: Lemma 1.2 :

There exists non-unital purely large extension such that the unitization is not purely large.

Final Th.??

We recall some basic definitions from the theory of extensions: For every short exact sequence $0 \to B \to E \to A \to 0$ of C^*-algebras we consider the Busby diagram

$$\begin{array}{ccccccccc}
0 & \longrightarrow & B & \longrightarrow & E & \longrightarrow & A & \longrightarrow & 0 \\
 & & \| & & \downarrow & & \downarrow & & \\
0 & \longrightarrow & B & \longrightarrow & \mathcal{M}(B) & \underset{\pi}{\longrightarrow} & \mathrm{Q}(B) & \longrightarrow & 0
\end{array}$$

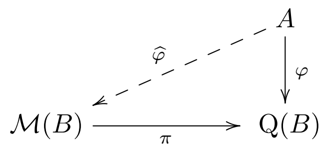
where $\mathrm{Q}(B)$ denotes the **corona algebra** $\mathcal{M}(B)/B$. The right vertical arrow $\varphi \in \mathrm{Hom}(A, \mathrm{Q}(B))$ is the **Busby invariant** of the extension. There is a natural *-isomorphism $f \in E \mapsto (\eta(f), \rho(f)) \in E_\varphi$ from E onto the pull-back

$$E_\varphi := A \oplus_{\varphi, \pi_B} \mathcal{M}(B) \subset A \oplus \mathcal{M}(B)\,,$$

where $\eta\colon E \to A$ is the defining epimorphism of the extension E and $\rho(f)b = \iota^{-1}(f\iota(b))$ for $f \in E$, $b \in B$ and the defining monomorphism $\iota\colon B \to E$ of the extension. Thus, the extension is (up to natural *-isomorphisms) uniquely determined by the Busby invariant $\varphi \in \mathrm{Hom}(A, \mathrm{Q}(B))$.

For $\varphi, \psi \in \mathrm{Hom}(A, \mathrm{Q}(B))$, we write $\varphi \approx \psi$ if $\psi(a) = \pi(u)\varphi(a)\pi(u^*)$, $a \in A$, for some unitary $u \in \mathcal{M}(B)$, and call the extensions **strongly equivalent** . Then E_ψ and E_φ are isomorphic as C^*-algebras by an isomorphism that induces the identity map on A and the automorphism $b \mapsto u^*bu$ of B. That will be applied in the proofs of Theorems A and B, and we need to establish strong equivalence in some special cases from essentially weaker definitions of equivalence.

A Busby invariant $\varphi \in \mathrm{Hom}(A, \mathrm{Q}(B))$ is called **trivial** if there exists a C^*-morphism $\hat{\varphi} \in \mathrm{Hom}(A, \mathcal{M}(B))$ such that the diagram



commutes, i.e., if φ is **liftable**. Then E_φ is a **split** extension, because the natural epimorphism η from E_φ onto A has a **split morphism** $\widehat{\eta}\colon A \to E_\varphi$ with $\eta \circ \widehat{\eta} = \mathrm{id}_A$. (We do not suppose that the lift is unital if A and φ are unital.)

Now assume that $\mathcal{M}(B)$ contains a copy $C^*(s_1, s_2)$ of $\mathcal{O}_2$ unitally. (This is the case e.g. for stable B, where $\mathcal{M}(B) \cong \mathcal{M}(B \otimes \mathbb{K})$ and $\mathrm{Q}(B) \cong \mathrm{Q}^{\mathrm{s}}(B) := \mathrm{Q}(B \otimes \mathbb{K})$.) Then $\mathrm{Q}(B)$ also contains the copy $C^*(t_1, t_2)$ of $\mathcal{O}_2$ unitally, where $t_k = \pi_B(s_k)$ $(k = 1, 2)$, and
Cuntz addition $\oplus := \oplus_{t_1,t_2}$ *is defined on the classes* $[\varphi]_\approx$:
see Proposition 4.3.2 and notice that only canonical generators $r_1, r_2 \in \mathrm{Q}(B)$ with property $t_1 r_1^* + t_2 r_2^* \in \pi_B(\mathcal{U}(\mathcal{M}(B)))$ are considered.

We write $\varphi \sim \psi$ if there exist trivial elements $\tau_1, \tau_2 \in \mathrm{Hom}(A, \mathrm{Q}(B))$ such that $\varphi \oplus \tau_1 \approx \psi \oplus \tau_2$. In particular $\varphi \sim (\varphi \oplus 0)$, because $\varphi \oplus 0 = \varphi \oplus (0 \oplus 0) \approx (\varphi \oplus 0) \oplus 0$ by Proposition 4.3.2(iv). Thus, we find for the $\sim$-classes $[\varphi]_\sim$ always a representing element $\varphi \in \mathrm{Hom}(A, \mathrm{Q}(B))$ such that the inclusion map of the C^*-subalgebra $\pi_B^{-1}(\varphi(A))$ in $\mathcal{M}(B)$ dominates zero (in the sense of Definition 4.3.3).

The *-morphism $\varphi \oplus_{t_1,t_2} 0$ is unitarily equivalent to $\psi \oplus_{t_1,t_2} 0$ in $\mathrm{Q}(B)$ if and only if $\varphi \oplus 0$ and $\psi \oplus 0$ are conjugate by a unitary in the connected component $\mathcal{U}_0(\mathrm{Q}(B))$ of 1 in the unitaries $\mathcal{U}(\mathrm{Q}(B))$ of $\mathrm{Q}(B)$ (cf. Proposition 4.3.6(iv,c)).

Since $\pi_B\big(\mathcal{U}_0(\mathcal{M}(B))\big) = \mathcal{U}_0(\mathrm{Q}(B))$, it follows that $\varphi \sim \psi$ if and only if, there are “trivial” Busby invariants $\tau_1, \tau_2 \in \mathrm{Hom}(A, \mathrm{Q}(B))$ such that $\varphi \oplus \tau_1 \oplus 0$ and

$\varphi \oplus \tau_2 \oplus 0$ are unitarily equivalent in $\mathrm{Q}(B)$. Hence, *the relation* $\sim$ *is compatible with Cuntz addition.*

Recall that $\mathrm{Ext}(A, B)$ (or better notated as $\mathrm{SExt}(A, B)$) is the semigroup $\mathrm{Hom}(A, \mathrm{Q}(B))/\sim$, where the zero element is the class of "trivial elements". Let $\mathrm{Ext}^{-1}(A, B)$ denote the group of invertible elements in $\mathrm{Ext}(A, B)$, i.e., of $\sim$-classes of elements $\varphi \in \mathrm{Hom}(A, \mathrm{Q}(B))$ such that there are $\psi, \tau_1, \tau_2 \in \mathrm{Hom}(A, \mathrm{Q}(B))$ such that $(\varphi \oplus \psi) \oplus \tau_1 = \tau_2$ and τ_1, τ_2 are trivial. Notice that $V := ((s_1)^2)^* \widehat{\tau_2}(\cdot)(s_1)^2$ is a completely positive lift of of φ if φ is in $\mathrm{Ext}^{-1}(A, B)$.

In the remaining part of this section we suppose in addition, that B *is stable and* σ*-unital and that* A *is separable and is unital or stable* ([18]).

Then, conversely, *every completely positive liftable* $\varphi \in \mathrm{Hom}(A, \mathrm{Q}(B))$ *is "invertible" in* $\mathrm{Ext}(A, B)$, because for a suitable Kasparov-Stinespring dilation $\widehat{\tau} \colon A \to M_2(\mathcal{M}(B)) \cong \mathcal{M}(B)$ of a contractive c.p. lift V of φ there is $\psi \in \mathrm{Hom}(A, \mathrm{Q}(B))$ with $\varphi \oplus \psi \oplus 0 \approx \tau \oplus 0$. Thus, for stable σ-unital B, $\mathrm{Ext}^{-1}(A, B)$ consists of the the $\sim$-classes of completely positive liftable elements of $\mathrm{Hom}(A, \mathrm{Q}(B))$ (with Cuntz addition).

Moreover, for trivial Busby invariants $\tau_1, \tau_2 \in \mathrm{Hom}(A, \mathrm{Q}(B))$, there exists trivial $\tau_3 \in \mathrm{Hom}(A, \mathrm{Q}(B))$ with

$$\tau_1 \oplus \tau_3 \approx \tau_3 \approx \tau_2 \oplus \tau_3\,,$$

(Indeed, $\tau_3 := \pi_B \circ \delta_\infty \circ (\widehat{\tau_1} \oplus \widehat{\tau_2})$ does the job, because, with $\widehat{\tau_3} := \delta_\infty \circ (\widehat{\tau_1} \oplus \widehat{\tau_2})$, $\widehat{\tau_1} \oplus \widehat{\tau_3}$ and $\widehat{\tau_2} \oplus \widehat{\tau_3}$ are both unitarily equivalent to $\widehat{\tau_3}$ in $\mathcal{M}(B)$ by Lemma 5.1.2(i,ii).)

It follows that $h_1 \sim h_2$ for $h_1, h_2 \in \mathrm{Hom}(A, \mathrm{Q}(B))$ if and only if there is trivial $\tau \in \mathrm{Hom}(A, \mathrm{Q}(B))$ with $[h_1] + [\tau] = [h_2] + [\tau]$ (and $[\tau] + [\tau] = [\tau]$) in the semigroup of unitary equivalence classes $([\mathrm{Hom}(A, \mathrm{Q}(B))], +)$.
(Indeed: $h_1 \sim h_2 \Leftrightarrow$ there exists liftable τ with $h_1 \oplus \tau \approx h_2 \oplus \tau \Rightarrow [h_1] + [\tau] = [h_2] + [\tau]$ $\Rightarrow [h_1 \oplus \tau \oplus 0] = [h_2 \oplus \tau \oplus 0] \Rightarrow h_1 \oplus (\tau \oplus 0) \approx h_2 \oplus (\tau \oplus 0)$. The last implication comes from the K_1-injectivity of $\mathrm{Q}(B)$.)

Recall that $\mathrm{Gr}(\mathcal{S})$ denotes the Grothendieck group of an Abelian semigroup $\mathcal{S}$. The above observations imply – for σ-unital stable B – that $\mathrm{Ext}^{-1}(A, B)$ has the following equivalent description as Grothendieck group of a certain semigroup:

Let $\mathrm{Hom}_{\text{l-cp}}(A, \mathrm{Q}(B))$ denote the set of Busby invariants $\varphi \colon A \to \mathrm{Q}(B)$ that have a completely positive lift $V \colon A \to \mathcal{M}(B)$ ([19]). The set of *unitary equivalence classes* $[\mathrm{Hom}_{\text{l-cp}}(A, \mathrm{Q}(B))]$ of elements in $\mathrm{Hom}_{\text{l-cp}}(A, \mathrm{Q}(B))$ by unitaries in $\mathrm{Q}(B)$ are invariant under Cuntz addition $[\varphi] + [\psi] := [\varphi \oplus \psi]$ (where we now have to allow all generators t_1, t_2 of a unital copy of $\mathcal{O}_2$ in $\mathrm{Q}(B)$ for the definition of $\oplus$).

---

[18] Then $\varphi \approx \psi$ if and only if there is $v \in \mathcal{U}_0(\mathrm{Q}(B))$ with $v^* \varphi(\cdot) v = \psi$, because $\mathcal{U}_0(\mathrm{Q}(B)) = \pi_B(\mathcal{U}_0(\mathcal{M}(B)))$ and the unitary group of $\mathcal{M}(B \otimes \mathbb{K}) \cong \mathcal{M}(B)$ is connected by [**180**]. Moreover, one needs only that $[v] = 0$ in $\mathrm{K}_1(\mathrm{Q}(B))$, because $\mathrm{Q}(B)$ is K_1-injective if B is stable and σ-unital, cf. Lemma 5.5.9(ii), or Proposition 4.2.15.

[19] i.e., $\pi_B \circ V = \varphi$, one can always replace V by a completely positive contraction with this property

$\mathrm{Ext}^{-1}(A,B)$ is naturally isomorphic to the Grothendieck group $\mathrm{Gr}([\mathrm{Hom}_{\text{l-cp}}(A,\mathrm{Q}(B))])$ of the commutative semigroup $([\mathrm{Hom}_{\text{l-cp}}(A,\mathrm{Q}(B))],+)$. (Indeed: the isomorphism is induced by the semigroup morphisms

$$[\varphi]_{\approx} \mapsto [\varphi] \mapsto [\varphi]_{\mathrm{Gr}}$$

for $\varphi \in \mathrm{Hom}_{\text{l-cp}}(A,\mathrm{Q}(B))$, because, if $[\varphi]+[\lambda]=[\psi]+[\lambda]$ for $\lambda \in \mathrm{Hom}_{\text{l-cp}}(A,\mathrm{Q}(B))$ then there exist $\kappa \in \mathrm{Hom}_{\text{l-cp}}(A,\mathrm{Q}(B)$ and a *liftable* $\tau \in \mathrm{Hom}_{\text{l-cp}}(A,\mathrm{Q}(B))$ such that $[\tau]=[\lambda\oplus\kappa]$, and, therefore $\varphi\oplus\tau\oplus 0 \approx \psi\oplus\tau\oplus 0$. I.e., $\varphi\sim\psi$ if $[\varphi]_{\mathrm{Gr}}=[\psi]_{\mathrm{Gr}}$ for $\varphi,\psi \in \mathrm{Hom}_{\text{l-cp}}(A,\mathrm{Q}(B))$.
Conversely, $\varphi\sim\psi$ implies the existence of a liftable $\tau \in \mathrm{Hom}_{\text{l-cp}}(A,\mathrm{Q}(B))$ with $\varphi\oplus\tau \approx \psi\oplus\tau$, which implies that $[\varphi]+[\tau]=[\psi]+[\tau]$, i.e., that $[\varphi]_{\mathrm{Gr}}=[\psi]_{\mathrm{Gr}}$.)

We introduce the semigroup $\mathrm{SExt}_{\mathrm{nuc}}(A,B)$ and the group $\mathrm{Ext}_{\mathrm{nuc}}(A,B)$ in a similar way:
Let $\mathrm{Hom}_{\text{l-nuc}}(A,\mathrm{Q}(B))$ denote the elements $\varphi \in \mathrm{Hom}(A,\mathrm{Q}(B))$ which have weakly nuclear lifts $V\colon A\to\mathcal{M}(B)$. Note that $h_1\approx h_2$ if and only if $u^*h_1(\cdot)u=h_2$ by a unitary $u\in\mathcal{U}_0(\mathrm{Q}(B))$, that $h_1\approx h_2$ implies (by definition) that $u^*h_1(\cdot)u=h_2$ for a unitary $u\in\mathrm{Q}(B)$, and that $u^*h_1(\cdot)u\in\mathrm{Hom}_{\text{l-nuc}}(A,\mathrm{Q}(B))$ if $h_1\in\mathrm{Hom}_{\text{l-nuc}}(A,\mathrm{Q}(B))$ and $u\in\mathrm{Q}(B)$ is unitary: Indeed, $V'(a):=d^*V(a)d$ is a weakly nuclear completely positive lift of $u^*h_1(\cdot)u$ if $\pi_B(d)=u$ and $V\colon A\to\mathcal{M}(B)$ is a weakly nuclear lift of h_1. Thus, the subset $\mathrm{Hom}_{\text{l-nuc}}(A,\mathrm{Q}(B))\subset\mathrm{Hom}(A,\mathrm{Q}(B))$ is closed under $\approx$, unitary equivalence and under $\oplus$: if $\varphi,\psi\in\mathrm{Hom}(A,\mathrm{Q}(B)$ have weakly nuclear lifts and $\chi\approx\varphi$, then χ and $\varphi\oplus\psi$ have weakly nuclear lifts. It follows that Cuntz addition $\oplus_{t_1,t_2}$ is defined on the set of classes $[\varphi]_{\approx}$ with $\varphi\in\mathrm{Hom}_{\text{l-nuc}}(A,\mathrm{Q}(B))$ for $t_1=\pi_B(T_1)$, $t_2=\pi_B(T_2)$, where the isometries $T_1,T_2\in\mathcal{M}(B)$ are canonical generators of a copy of $\mathcal{O}_2$ in $\mathcal{M}(B)$. We write $\varphi\sim_{nuc}\psi$ if there exist *weakly nuclear* C^*-morphisms $H_1,H_2\colon A\to\mathcal{M}(B)$ such that $\varphi\oplus(\pi_B\circ H_1)\approx\psi\oplus(\pi_B\circ H_2)$. Note that $h_1\sim_{nuc}h_2$ implies $h_1\sim h_2$, and it happens that $h_1\sim h_2$ for $h_1\in\mathrm{Hom}_{\text{l-nuc}}(A,\mathrm{Q}(B))$ but $h_2\notin\mathrm{Hom}_{\text{l-nuc}}(A,\mathrm{Q}(B))$ if B is simple and is not nuclear (We do not know if $h_1\sim h_2$ implies $h_1\sim_{nuc}h_2$ for $h_1,h_2\in\mathrm{Hom}_{\text{l-nuc}}(A,\mathrm{Q}(B))$.) The relation $\sim_{nuc}$ is compatible with the Cuntz addition on $[\mathrm{Hom}_{\text{l-nuc}}(A,\mathrm{Q}(B))]_{\approx}$ and $h_1\sim h_2$ if and only if there is a weakly nuclear C^*-morphism $H\colon A\to\mathcal{M}(B)$ such that $h_1\oplus\pi\circ H\oplus 0$ is unitarily equivalent to $h_1\oplus\pi\circ H\oplus 0$ by a unitary in $\mathrm{Q}(B)$. Since for every $\varphi\in\mathrm{Hom}_{\text{l-nuc}}(A,\mathrm{Q}(B))$ there exists a contractive weakly nuclear c.p. map $V\colon A\to\mathcal{M}(B)$ and since there is a weakly nuclear C^*-morphism $H\colon A\to\mathcal{M}(B)$ and an isometry $S\in\mathcal{M}(B)$ with $V=S^*H(\cdot)S$, we can see that there is $\psi\in\mathrm{Hom}_{\text{l-nuc}}(A,\mathrm{Q}(B))$ such that $\psi\oplus\varphi\oplus 0$ is unitarily equivalent to $\pi_B\circ H\oplus 0$. We get that the quotient $([\mathrm{Hom}_{\text{l-nuc}}(A,\mathrm{Q}(B)]_{\sim_{nuc}},+)$ of the semigroup $[\mathrm{Hom}_{\text{l-nuc}}(A,\mathrm{Q}(B))]_{\approx}$ with respect to the relation $\sim_{nuc}$ is a group. One can see that this group is isomorphic to the below defined group $\mathrm{Ext}_{\mathrm{nuc}}(A,B)$ (the nuclear Ext-group in the below given Definition 5.8.2). The proof of the isomorphism

$$\mathrm{Hom}_{\text{l-nuc}}(A,\mathrm{Q}(B))/\sim_{nuc}\;\cong\;\mathrm{Ext}_{\mathrm{nuc}}(A,B)$$

is almost verbatim the above outlined proof of the natural isomorphism $\mathrm{Ext}^{-1}(A,B) \cong \mathrm{Gr}([\mathrm{Hom}_{\text{l-cp}}(A, \mathrm{Q}(B))], +)$.

If A is separable and *unital*, then we can consider the set $\mathrm{Hom}_{\text{ul-nuc}}(A, \mathrm{Q}(B))$ of *unital* morphisms $\varphi\colon A \to \mathrm{Q}(B)$ in $\mathrm{Hom}_{\text{l-nuc}}(A, \mathrm{Q}(B))$.

The subset $\mathrm{Hom}_{\text{ul-nuc}}(A, \mathrm{Q}(B)) \subset \mathrm{Hom}_{\text{l-nuc}}(A, \mathrm{Q}(B))$ is closed under unitary equivalence (hence under $\approx$-equivalence) and under Cuntz addition $\oplus$. The Grothendieck group

$$\mathrm{Ext}^{\text{u,strong}}_{\text{nuc}}(A,B) := \mathrm{Gr}([\mathrm{Hom}_{\text{ul-nuc}}(A, \mathrm{Q}(B))]_{\approx}\,, +)$$

can be described equivalently by defining relations $\sim_{u-nuc}$:
We write $\varphi \sim_{u-nuc} \psi$ if there are *unital* weakly nuclear C^*-morphisms $H_1, H_2\colon A \to \mathcal{M}(B)$ such that $\varphi \oplus \pi_B \circ H_1 \approx \psi \oplus \pi_B \circ H_2$.

Then $H_3 := \delta_\infty \circ (H_1 \oplus H_2)$ is unital, weakly nuclear and is unitarily equivalent to $H_3 \oplus H_1$ and to $H_3 \oplus H_2$, and we get: $\varphi \sim_{u-nuc} \psi$, *if and only if, there is a unital weakly nuclear *-morphism* $H\colon A \to \mathcal{M}(B)$ *with* $\varphi \oplus \pi_B \circ H \approx \psi \oplus \pi_B \circ H$. It follows that $\varphi \sim_{u-nuc} \psi$ implies that $[\varphi]_{\mathrm{Gr}} = [\psi]_{\mathrm{Gr}}$ in $\mathrm{Ext}^{\text{u,strong}}_{\text{nuc}}(A,B)$. Conversely, if $[\varphi]_{\mathrm{Gr}} = [\psi]_{\mathrm{Gr}}$ then there exists $\chi \in \mathrm{Hom}_{\text{ul-nuc}}(A, \mathrm{Q}(B))$ with $\varphi \oplus \chi \approx \psi \oplus \chi$. By definition of $\mathrm{Hom}_{\text{ul-nuc}}(A, \mathrm{Q}(B))$, there is a weakly nuclear c.p. lift $W\colon A \to \mathcal{M}(B)$ with $\pi_B \circ W = \chi$. By a standard argument there are $b \in B_+$ with $\|b\| \le 1$ and a unital weakly nuclear c.p. map $U\colon A \to \mathcal{M}(B)$ such that $W'(a) := (1-b^2)^{1/2} W(a) (1-b^2)^{1/2} + bU(a)b$ satisfies $\|W'(1) - 1\| < 1/2$. Thus, $V(a) := W'(1)^{-1/2} W'(a) W'(1)^{-1/2}$ defines a unital weakly nuclear c.p. map with $\pi_B \circ V = \chi$. Let $\mathcal{C} := \mathrm{CP}_{\text{nuc}}(A,B))$ in the (more general) Corollary 5.4.6. It shows that there is a unital weakly nuclear C^*-morphism $H\colon A \to \mathcal{M}(B)$ and isometries $S, T \in \mathcal{M}(B)$ with $SS^* + TT^* = 1$ and $V(a) - S^* H(a) S \in B$ for all $a \in A$. By Lemma 4.3.4(i) (applied to $g := \pi_B(SS^*)$ and $h_1 := \pi_B \circ H$) we get that $SS^* H(a) - H(a) SS^* \in B$ and $SV(a)S^* + TT^* H(a) TT^* - H(a) \in B$ for all $a \in A$, i.e., $\chi \oplus_{s,t} \vartheta = \pi_B \circ H$ for $\vartheta(a) := \pi_B(T^* H(a) T)$ and $s := \pi_B(S)$ and $t := \pi_B(T)$. Hence, $\varphi \oplus \pi_B \circ H \approx \psi \oplus \pi_B \circ H$, i.e., $\varphi \sim_{u-nuc} \psi$.

REMARK 5.8.1. Let E denote a unital C^*-algebra and let $\mathcal{O}_2 \cong C^*(s_1, s_2)$ be unitally contained in E. (Here we use only the unital embedding $\iota\colon \mathcal{O}_2 \hookrightarrow E$ up to unitary equivalence by unitaries in the *connected* component $\mathcal{U}_0(E)$ of 1_E in the unitaries $\mathcal{U}(E)$ of E.)

We say that a C^*-morphism $\varphi\colon A \to E$ **strongly absorbs** $\psi\colon A \to E$ if there is a unitary $u \in \mathcal{U}_0(E)$ with $u^* \varphi(\cdot) u = \varphi \oplus_{s_1,s_2} \psi$, I.e., $\varphi \approx \varphi \oplus \psi$, if $E = \mathrm{Q}(B)$ for stable and σ-unital B.

It allows to formulate a useful lifting criterium (that follows straight from the definitions):
Suppose that a unital C^*-morphism $\varphi\colon A \to \mathrm{Q}(B)$ strongly absorbs every unital C^*-morphism $\pi_B \circ H$, where $H\colon A \to \mathcal{M}(B)$ is unital and weakly nuclear:
There is a unital *weakly nuclear C^*-morphism $\widehat{\varphi}\colon A \to \mathcal{M}(B)$ with $\pi_B \circ \widehat{\varphi} = \varphi$, if and only if, φ is in* $\mathrm{Hom}_{\text{l-nuc}}(A, \mathrm{Q}(B))$ *and* $[\varphi]_{\approx} = 0$ *in* $\mathrm{Ext}^{\text{u,strong}}_{\text{nuc}}(A,B)$.

By the formulas in the proof of part (i) of Proposition 4.3.5, one can see that *φ strongly absorbs $\pi_B \circ \delta_\infty \circ H$ if and only if, there is an isometry S in $\mathcal{M}(B)$ such that $\pi_B \circ \delta_\infty \circ H = \pi_B(S)^*\varphi(\cdot)\pi_B(S)$.*

This links unital lifting problems to Weyl–von-Neumann type results and to KK-theory.

DEFINITION 5.8.2. Suppose that A is separable and B is σ-unital and stable. Let

$$\mathrm{SExt}_{\mathrm{nuc}}(A,B) := [\mathrm{Hom}_{\text{l-nuc}}(A, \mathrm{Q}(B))] \subset [\mathrm{Hom}(A, \mathrm{Q}(B))]$$

denote the unitary equivalence classes $[\varphi]$ (by all unitaries in $\mathrm{Q}(B)$!) of the *weakly nuclear* liftable C^*-morphisms $\varphi\colon A \to \mathrm{Q}(B)$ equipped with Cuntz addition $[\varphi] + [\psi] := [\varphi \oplus \psi]$.

We define the nuclear Ext-group $\mathrm{Ext}_{\mathrm{nuc}}(A,B)$ as the Grothendieck group of $\mathrm{SExt}_{\mathrm{nuc}}(A,B)$:

$$\mathrm{Ext}_{\mathrm{nuc}}(A,B) := \mathrm{Gr}(\mathrm{SExt}_{\mathrm{nuc}}(A,B)) .$$

If C is σ-unital (but not necessarily stable) then we let

$$\mathrm{Ext}_{\mathrm{nuc}}(A,C) := \mathrm{Ext}_{\mathrm{nuc}}(A, C \otimes \mathbb{K})$$

It is naturally isomorphic to the formerly defined group $\mathrm{Ext}_{\mathrm{nuc}}(A,C)$ if C is stable (cf. Lemma 5.8.5 below).

If A is unital, we let $\mathrm{SExt}^{\mathrm{u}}_{\mathrm{nuc}}(A,B)$ denote the sub-semigroup of $\mathrm{SExt}_{\mathrm{nuc}}(A,B)$ of classes $[\varphi] \in \mathrm{SExt}_{\mathrm{nuc}}(A,B)$ with $\varphi(1_A) = 1_{\mathrm{Q}(B)}$, i.e., , thus

$$\mathrm{SExt}^{\mathrm{u}}_{\mathrm{nuc}}(A,B) := [\mathrm{Hom}_{\text{ul-nuc}}(A, \mathrm{Q}(B))] .$$

Then define the "unital" extension group $\mathrm{Ext}^{\mathrm{u}}_{\mathrm{nuc}}(A,B)$ of unital extensions with weakly nuclear c.p. unital lifts $V\colon A \to \mathcal{M}(B)$ by:

$$\mathrm{Ext}^{\mathrm{u}}_{\mathrm{nuc}}(A,B) := \mathrm{Gr}(\mathrm{SExt}^{\mathrm{u}}_{\mathrm{nuc}}(A,B)) .$$

REMARK 5.8.3. The natural semigroup morphisms

$$[\mathrm{Hom}_{\text{ul-nuc}}(A, \mathrm{Q}(B))]_{\approx} \to \mathrm{Ext}^{\mathrm{u}}_{\mathrm{nuc}}(A,B)$$

induces an isomorphism

$$[h_1]_{\approx} + [\mathrm{Hom}_{\text{ul-nuc}}(A, \mathrm{Q}(B))]_{\approx} \cong \mathrm{Ext}^{\mathrm{u}}_{\mathrm{nuc}}(A,B)$$

for $h_1 := \pi_B \circ \rho$ for any unital faithful *-representation $\rho\colon A \to \mathcal{M}(\mathbb{K}) \cong \mathcal{L}(\mathcal{H}) \subset \mathcal{M}(B)$ with $\rho(A) \cap \mathbb{K} = \{0\}$.

If A is unital, then there are natural exact sequences:

$$0 \to \mathrm{Ext}^{\mathrm{u}}_{\mathrm{nuc}}(A,B) \to \mathrm{Ext}_{\mathrm{nuc}}(A,B) \to \mathrm{K}_0(\mathrm{Q}(B)) \cong \mathrm{K}_1(B)$$

and

$$\mathrm{K}_1(h_0(A)' \cap \mathrm{Q}(B)) \to \mathrm{K}_1(\mathrm{Q}(B)) \to \mathrm{Ext}^{\mathrm{u,strong}}_{\mathrm{nuc}}(A,B) \to \mathrm{Ext}^{\mathrm{u}}_{\mathrm{nuc}}(A,B) \to 0 .$$

The problem is now if every element of $\mathrm{CP}_{\mathrm{nuc}}(A,B)$ can be approximated via compressions of $H_0\colon A \to \mathcal{M}(B)$. It respects no ideals!

REMARK 5.8.4. Suppose that A is separable and that B is σ-unital and stable.

Let $H_0 \colon A \to \mathcal{L}(\ell_2) \cong \mathcal{M}(\mathbb{K}) \subset \mathcal{M}(B)$ a *non-degenerate* *-monomorphism with $H_0(A) \cap \mathbb{K} = \{0\}$.

Then H_0 satisfies the assumptions of Corollary 5.4.10 with $D := \mathbb{K}$, thus, H_0 satisfies the assumptions of Corollary 5.4.9 for the cone $\mathcal{S} = \mathrm{CP}_{\mathrm{nuc}}(A, B)$. Thus, $h_0 := \pi_B \circ H_0 \colon A \to \mathrm{Q}(B)$ satisfies $[h_0 \oplus h_0] = [h_0]$, $S(h_0; A, \mathrm{Q}(A)) \subset S(h_0 \oplus 0; A, \mathrm{Q}(B)) \subset [\mathrm{Hom}_{\text{l-nuc}}(A, \mathrm{Q}(B))]$, and $[h] \in S(h_0 \oplus 0;\, A, \mathrm{Q}(B))$ for every $h \in \mathrm{Hom}_{\text{l-nuc}}(A, \mathrm{Q}(B))$, by Corollary 5.4.9. Thus:

$$\mathrm{SExt}_{\mathrm{nuc}}(A, B) = [\mathrm{Hom}_{\text{l-nuc}}(A, \mathrm{Q}(B))] = S(h_0 \oplus 0; A, \mathrm{Q}(B))\,.$$

If A is *unital*, then H_0 is unital the above considerations show that (**??**)

$$\mathrm{SExt}^{\mathrm{u}}_{\mathrm{nuc}}(A, B) = S(h_0; A, \mathrm{Q}(B))$$

and

$$\mathrm{Ext}^{\mathrm{u}}_{\mathrm{nuc}}(A, B) = G(h_0; A, \mathrm{Q}(B)),$$

and finally,

$$\mathrm{Ext}^{\mathrm{u,strong}}_{\mathrm{nuc}}(A, B) = G_{\approx}(h_0; A, \mathrm{Q}(B))\,.$$

If A is *stable* then

$$\mathrm{Gr}([\mathrm{Hom}_{\text{l-nuc}}(A, \mathrm{Q}(B))], +) = [h_0] + S(h_0; A, \mathrm{Q}(B)) = G(h_0; A, \mathrm{Q}(B))$$

because then $[h_0 \oplus 0] = [h_0]$ in $\mathrm{Q}(B)$ by Corollary 5.5.14.

But in general $[\mathrm{Hom}_{\text{l-nuc}}(A, \mathrm{Q}(B))] \ncong S(h_0; A, \mathrm{Q}(B))$, cf. Remark 5.5.8.

Since $\mathrm{Ext}_{\mathrm{nuc}}(A, B) := \mathrm{Gr}([\mathrm{Hom}_{\text{l-nuc}}(A, \mathrm{Q}(B))], +)$, it follows (for separable stable σ-unital A):

$$\mathrm{Ext}_{\mathrm{nuc}}(A, B) \cong [h_0] + S(h_0\,;\, A, \mathrm{Q}(B)) = G(h_0 \oplus 0\,;\, A, \mathrm{Q}(B))$$

and

$$\mathrm{Ext}_{\mathrm{nuc}}(A, B) \cong \mathrm{kernel}(\mathrm{K}_0(h_0(A)' \cap \mathrm{Q}(B)) \to \mathrm{K}_0(B))$$

by Propositions 4.4.2 and 4.4.3.

In particular, the Corollary 5.7.1 implies the following:
Suppose that B is simple, purely infinite, σ-unital and stable, and that A is separable, stable and exact. Then

$$[\mathrm{Mon}_{\mathrm{nuc}}(A, \mathrm{Q}(B))] = \mathrm{Ext}_{\mathrm{nuc}}(A, B)\,.$$

And this formula is equivalent to the following observations (i)-(iv):

(i) Every nuclear *-monomorphism $h \colon A \hookrightarrow \mathrm{Q}(B)$ dominates $h_0 := \pi_B \circ \rho$ for a non-degenerate *-monomorphism $\rho \colon A \hookrightarrow \mathcal{L}(\mathcal{H}) \subset \mathcal{M}(B)$ with $\rho(A) \cap B = \{0\}$ (i.e., $[\mathrm{Mon}_{\mathrm{nuc}}(A, \mathrm{Q}(B))] = [h_0] + [\mathrm{Hom}_{\mathrm{nuc}}(A, \mathrm{Q}(B))]$).
(Indeed: Theorem 5.6.2 with $D = B$, $C := \pi_B^{-1}(h(A))$ and $T := \rho \circ h^{-1}$ yields the existence of an isometry $S_1 \in \mathcal{M}(B)$ with $S_1^* c S_1 - T(c) \in B$ for $c \in C$. Thus $t_1^* h(\cdot) t_1 = h_0$ for $t_1 := S_1 + B \in \mathrm{Q}(B)$.)

(ii) If a C^*-morphism $h\colon A \to \mathrm{Q}(B)$ has a weakly nuclear lift $V\colon A \to \mathcal{M}(B)$ then h_0 dominates h, and h is nuclear (i.e., $[\mathrm{Hom}_{\text{l-nuc}}(A, \mathrm{Q}(B))] \subset S([h_0], A, \mathrm{Q}(B)) \subset \mathrm{Mon}_{\mathrm{nuc}}(A, \mathrm{Q}(B)))$.
(Indeed: it can be managed that the weakly nuclear lift V of h is a contraction, cf. Lemma 5.4.8, then Theorem 5.6.2, with $D = B$, $C := \pi_B^{-1}(h_0(A)) = B + \rho(A)$ and $T := V \circ h_0^{-1}$, yields the existence of an isometry $S_2 \in \mathcal{M}(B)$ with $S_2^*\rho(a)S_2 - V(a) \in B$ for $a \in A$, and $t_2 := S_2 + B \in \mathrm{Q}(B)$ satisfies $t_2^* h_0(\cdot)t_2 = h$.)

(iii) $\mathrm{Hom}_{\mathrm{nuc}}(A, \mathrm{Q}(B)) \subseteq \mathrm{Hom}_{\text{l-nuc}}(A, \mathrm{Q}(B))$, because every nuclear c.p. contraction $V\colon A \to \mathrm{Q}(B)$ has a nuclear lift $T\colon A \to \mathcal{M}(B)$ (by a Theorem of Effros and Choi, cf. [**43**]).

(iv) If $h_1, h_2 \in \mathrm{Hom}(A, \mathrm{Q}(B))$ are unitarily equivalent, then they are unitarily equivalent by a unitary $u = \pi_B(U)$ with $U \in \mathcal{M}(B)$.
(Indeed: h_1 dominates zero by Corollary 5.5.16 and Proposition 5.5.12(ii). The unital C^*-algebra $\mathrm{Q}(B)$ is K_1-injective by Lemmas 5.5.10(iv) and 4.2.6(viii).

`The` K_1`-bijectivity of` $\mathrm{Q}^s(B)$ `for` σ`-unital // has been shown until here 3-times!! // Clear the places !!!`

Thus, Proposition 4.3.6(iv,d). implies that h_1 and h_2 are unitarily equivalent by a unitary $u \in \mathcal{U}_0(\mathrm{Q}(B))$.)

Any two nuclear *-monomorphisms $h, k\colon A \hookrightarrow \mathrm{Q}(B)$ dominate each other (by (i) and (ii)). Therefore, the unitary equivalence classes $[h] \in [\mathrm{Mon}_{\mathrm{nuc}}(A, \mathrm{Q}(B))] = [h_0] + S(h_0\,;\, A, \mathrm{Q}(B))$ of nuclear *-monomorphisms $h\colon A \hookrightarrow \mathrm{Q}(B)$ is the Grothendieck group of $[\mathrm{Hom}_{\mathrm{nuc}}(A, \mathrm{Q}(B))]$ by Proposition 4.4.2(ii).

Recall for applications of the following lemma that $\mathrm{Ext}_{\mathrm{nuc}}(A, B \otimes \mathbb{K})$ onto $\mathrm{Ext}_{\mathrm{nuc}}(A, B) := \mathrm{Ext}(\mathcal{C};\, A, B)$ for the m.o.c. cone $\mathcal{C} := \mathrm{CP}_{\mathrm{nuc}}(A, B)$ and $\mathrm{Ext}_{\mathrm{nuc}}(A, B \otimes \mathbb{K}) := \mathrm{Ext}(\mathcal{C}';\, A, B \otimes \mathbb{K})$ for $\mathcal{C}' := \mathrm{CP}_{\mathrm{nuc}}(A, B)_{\mathbb{K}} := \mathrm{CP}_{\mathrm{nuc}}(A, B \otimes \mathbb{K}) = \mathrm{CP}_{\mathrm{nuc}}(A, B) \otimes \mathrm{CP}(\mathbb{C}, \mathbb{K})$.

Here $\mathcal{C}_{\mathbb{K}} := \mathcal{C} \otimes \mathrm{CP}(\mathbb{C}, \mathbb{K})$ denotes the (non-algebraic) tensor product of matrix operator-convex cones in sense of Definition **??**, i.e., is the smallest point-norm closed m.o.c. cone in $\mathrm{CP}(A, B \otimes \mathbb{K})$ that contains all tensor products $T \otimes S$ with $T \in \mathcal{C}$ and $S \in \mathrm{CP}(\mathbb{C}, \mathbb{K}) \cong \mathbb{K}_+$.

Lemma 5.8.5. *Suppose that B is stable and σ-unital, that A is separable and $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ a countably generated non-degenerate full m.o.c. cone. Let $\lambda\colon B \otimes \mathbb{K} \to B$ be an isomorphism from $B \otimes \mathbb{K}$ onto B such that $b \to \lambda(b \otimes p_{11})$ is unitarily homotopic to id_B (cf. Corollary 5.5.6 and Lemma 5.5.11 for the existence of λ). Denote by $\mathrm{Q}(\lambda)$ the induced isomorphism from $\mathrm{Q}(B \otimes \mathbb{K})$ onto $\mathrm{Q}(B)$.*

Then

$$\varphi \in \mathrm{Hom}(A, \mathrm{Q}(B \otimes \mathbb{K})) \mapsto \mathrm{Q}(\lambda) \circ \varphi \in \mathrm{Hom}(A, \mathrm{Q}(B))$$

defines a isomorphism from $\mathrm{Ext}(\mathcal{C}_{\mathbb{K}};\, A, B \otimes \mathbb{K})$ onto the 0-dominating $\mathrm{Ext}(\mathcal{C};\, A, B)$ or unital version $\mathrm{Ext}(\mathcal{C};\, A, B)$ that is a functor with respect to A.

Check here:
It needs that we consider only zero-dominating
Busby invariants.
Discussion e.g. with $B = M_{2^\infty}$, $B = \mathcal{O}_\infty$, $A = \mathcal{O}_2$.

The inverse is given by

$$\mathrm{Ext}(\mathcal{C};\, A, B) \to \mathrm{Ext}(\,_{\mathbb{K}}\mathcal{C}_{\mathbb{K}}\,;\; A \otimes \mathbb{K}, B \otimes \mathbb{K}) \to \mathrm{Ext}(\mathcal{C}_{\mathbb{K}};\, A, B \otimes \mathbb{K})\,,$$

i.e., is given by forming first the tensor product $E_\varphi \otimes \mathbb{K}$ of the extension E_φ with $\mathbb{K}$ and then by application of the map $a \in A \mapsto a \otimes p_{11} \in A \otimes \mathbb{K}$ (cf. Lemma 5.5.11, Proposition 5.5.12(v)).

In particular, there is a natural isomorphism

$$\mathrm{Ext}_{\mathrm{nuc}}(A \otimes \mathbb{K}, B) \to \mathrm{Ext}_{\mathrm{nuc}}(A, B)$$

from $\mathrm{Ext}_{\mathrm{nuc}}(A \otimes \mathbb{K}, B)$ onto $\mathrm{Ext}_{\mathrm{nuc}}(A, B)$ that is induced by $\varphi \mapsto \varphi((\cdot) \otimes p_{11})$.

Proof. to be filled in ??
Do we need additional properties on the extensions,
e.g. zero absorption or more relaxed equivalence classes? □

Remark 5.8.6. The natural semigroup homomorphism

$$[\mathrm{Hom}_{\text{ul-nuc}}(A, \mathrm{Q}(B))]_{\approx} \to \mathrm{SExt}^{\mathrm{u}}_{\mathrm{nuc}}(A, B)$$

and the induced group homomorphism

$$\mathrm{Ext}^{\mathrm{u,strong}}_{\mathrm{nuc}}(A, B) = \mathrm{Gr}([\mathrm{Hom}_{\text{ul-nuc}}(A, B)]_{\approx}) \to \mathrm{Ext}^{\mathrm{u}}_{\mathrm{nuc}}(A, B)$$

are in general *not* isomorphisms.

The definitions show that there are natural group and semigroup homomorphisms, e.g.

$$\mathrm{SExt}_{\mathrm{nuc}}(A, B) \to [\mathrm{Hom}_{\text{l-cp}}(A, \mathrm{Q}(B))] \to \mathrm{Ext}^{-1}(A, B)\,,$$

$$\mathrm{Ext}_{\mathrm{nuc}}(A, B) \to \mathrm{Ext}^{-1}(A, B)\,.$$

If A is unital, then there are group homomorphisms

$$\mathrm{Ext}^{\mathrm{u,strong}}_{\mathrm{nuc}}(A, B) \to \mathrm{Ext}^{\mathrm{u}}_{\mathrm{nuc}}(A, B) \to \mathrm{Ext}_{\mathrm{nuc}}(A, B) \to \mathrm{K}_0(\mathrm{Q}(B)) \cong \mathrm{K}_1(B)\,,$$

induced by $\varphi \in \mathrm{Hom}(A, \mathrm{Q}(B)) \to [\varphi(1)] \in \mathrm{K}_0(\mathrm{Q}(B))$.

Further, there is the group morphism $\mathrm{Ext}^{\mathrm{u}}_{\mathrm{nuc}}(A, B) \to \mathrm{Ext}_{\mathrm{nuc}}(A \otimes \mathbb{K}, B \otimes \mathbb{K})$, given by forming tensor products $[E_\varphi \otimes \mathbb{K}]$ of the corresponding extensions $[E_\varphi] \in \mathrm{Ext}^{\mathrm{u}}_{\mathrm{nuc}}(A, B)$.

more ?? ?? ?? ??

Remark 5.8.7. Let $\rho\colon A \to \mathcal{L}(\mathcal{H}) \cong \mathcal{M}(\mathbb{K})$ a faithful non-degenerate *-representation of A on a Hilbert space $\mathcal{H} \cong \ell_2(\mathbb{N})$ such that $\rho(A) \cap \mathbb{K} = \{0\}$. Fix a unital strictly continuous *-monomorphism $I\colon \mathcal{M}(\mathbb{K}) \to \mathcal{M}(B)$, and define $H\colon A \to \mathcal{M}(B)$ by $H := I \circ \rho$. We let $h_0 := \pi_B \circ H\colon A \to \mathrm{Q}(B)$, i.e., consider $H(a)$ modulo B.

Then $\mathrm{SExt}_{\mathrm{nuc}}(A,B) = S(h_0;\, A, \mathrm{Q}(B))$ if A is stable, and $\mathrm{SExt}^{\mathrm{u}}_{\mathrm{nuc}}(A,B) = S(h_0;\, A, \mathrm{Q}(B))$ if A is unital, cf. Corollary 5.6.4(iii).

This implies the natural isomorphisms $\mathrm{Ext}_{\mathrm{nuc}}(A,B) \cong G(h_0, A, \mathrm{Q}(B))$, respectively, in case of unital A, $\mathrm{Ext}^{\mathrm{u}}_{\mathrm{nuc}}(A,B) \cong G(h_0, A, \mathrm{Q}(B))$ and $\mathrm{Ext}_{\mathrm{nuc}}(A,B) \cong G(\pi_B \circ (h_0 \oplus 0), A, \mathrm{Q}(B))$.

There are natural homomorphisms

$$\mathrm{K}_1(\pi_B(h_0(A))' \cap \mathrm{Q}(B)) \to \mathrm{K}_1(\mathrm{Q}(B)) \cong \mathrm{K}_0(B)$$

and

$$\mathrm{K}_0(B) \cong \mathrm{K}_1(\mathrm{Q}(B)) \to \mathrm{Ext}^{\mathrm{u,strong}}_{\mathrm{nuc}}(A,B)\,.$$

induced by $u \in \mathcal{U}(\mathrm{Q}(B)) \to [u^* h_0(\cdot) u]_{\approx} \in [\mathrm{Hom}_{\text{ul-nuc}}(A, \mathrm{Q}(B))]_{\approx}$.

The following Corollary 5.8.8 is a consequence of two of Kasparov's theorems: Corollary 5.6.1 and [**73**, prop. 17.6.5].

Corollary 5.8.8. *Suppose that B is σ-unital and stable and that A is separable.*

If A or B is nuclear then

$$G(h_0, A \otimes \mathbb{K}, \mathrm{Q}(B)) \;\cong\; \mathrm{Ext}_{\mathrm{nuc}}(A,B) = \mathrm{Ext}^{-1}(A,B)\,.$$

Note that $\mathrm{Ext}^{-1}(A,B) \cong \mathrm{KK}(A, \mathrm{C}_0(\mathbb{R}, B)) \cong \mathrm{KK}(\mathrm{C}_0(\mathbb{R}, A), B)$ by theorems of Kasparov (cf. [**73**, prop. 17.6.5, thm. 17.10.7, cor. 19.2.2.]).

Proof. By Lemma 5.8.5 and Remark 5.8.7, there is a natural isomorphism from $\mathrm{Ext}_{\mathrm{nuc}}(A,B)$ onto

$$\mathrm{Ext}_{\mathrm{nuc}}(A \otimes \mathbb{K}, B) = [h_0] + [\mathrm{Hom}_{\text{l-nuc}}(A \otimes \mathbb{K}, B)] = G(h_0, A \otimes \mathbb{K}, \mathrm{Q}(B))\,.$$

We have $\mathrm{Hom}_{\text{l-cp}}(A \otimes \mathbb{K}, \mathrm{Q}(B)) = \mathrm{Hom}_{\text{l-nuc}}(A \otimes \mathbb{K}, \mathrm{Q}(B))$ and $\sim_{nuc} = \sim$ for nuclear B. If A is nuclear, then (trivially) $\mathrm{Hom}(A \otimes \mathbb{K}, \mathrm{Q}(B)) = \mathrm{Hom}_{\mathrm{nuc}}(A \otimes \mathbb{K}, \mathrm{Q}(B))$ and $\mathrm{Hom}_{\mathrm{nuc}}(A \otimes \mathbb{K}, \mathrm{Q}(B)) \subset \mathrm{Hom}_{\text{l-nuc}}(A \otimes \mathbb{K}, \mathrm{Q}(B))$ (by the Choi-Effros lifting theorem, cf. [**43**]). In both cases $\mathrm{Ext}^{-1}(A,B) = \mathrm{Gr}([\mathrm{Hom}_{\text{l-cp}}(A, \mathrm{Q}(B))]) = \mathrm{Gr}([\mathrm{Hom}_{\text{l-nuc}}(A, \mathrm{Q}(B))]) = \mathrm{Ext}_{\mathrm{nuc}}(A,B)$. □

Corollary 5.8.9. *Suppose that A is separable and unital, B purely infinite, stable and σ-unital, $h_0 \colon A \to \mathcal{L}(H) \cong \mathcal{M}(\mathbb{K}) \subset \mathcal{M}(B)$ a faithful and unital *-representation with $h_0(A) \cap \mathbb{K} = 0$. Then*

(i) $\mathrm{Ext}^{\mathrm{u}}_{\mathrm{nuc}}(A,B) = G(h_0, A, \mathrm{Q}(B))$*;* **??**
(ii) $0 \to \mathrm{Ext}^{\mathrm{u}}_{\mathrm{nuc}}(A,B) \to \mathrm{Ext}_{\mathrm{nuc}}(A,B) \to K_1(B)$ *is an exact sequence.*
(iii) *There is a natural exact sequence*

$$\mathrm{K}_1(\pi_B(h_0(A))' \cap \mathrm{Q}^{\mathrm{s}}(B)) \to \mathrm{K}_0(B) \to \mathrm{Ext}^{\mathrm{u,strong}}_{\mathrm{nuc}}(A,B) \to \mathrm{Ext}^{\mathrm{u}}_{\mathrm{nuc}}(A,B) \to 0.$$

In particular, $\mathrm{Ext}^{\mathrm{u,strong}}_{\mathrm{nuc}}(A,B) = \mathrm{Ext}^{\mathrm{u}}_{\mathrm{nuc}}(A,B)$ *if* $\mathrm{K}_0(B) = 0$.

Proof. `to be filled in` **??** □

COROLLARY 5.8.10. *If A is a separable unital C^*-algebra, then*

$$\mathrm{Ext}^{\mathrm{u,strong}}_{\mathrm{nuc}}(A, \mathcal{O}_2 \otimes \mathbb{K}) = \mathrm{Ext}^{\mathrm{u}}_{\mathrm{nuc}}(A, \mathcal{O}_2 \otimes \mathbb{K}) = \mathrm{Ext}^{-1}(A, \mathcal{O}_2) \cong 0\,.$$

*In particular, if $h\colon A \to \mathrm{Q}^{\mathrm{s}}(\mathcal{O}_2)$ is a unital *-monomorphism which has a completely positive lift $V\colon A \to \mathcal{M}(\mathcal{O}_2 \otimes \mathbb{K})$, then there is a unital C^*-morphism $\varphi\colon A \to \mathcal{M}(\mathcal{O}_2 \otimes \mathbb{K})$ with $\pi_{\mathcal{O}_2\otimes\mathbb{K}}\varphi = h$.*

PROOF.

$$\mathrm{Ext}^{\mathrm{u,strong}}_{\mathrm{nuc}}(A, \mathcal{O}_2) = \mathrm{Ext}^{\mathrm{u}}_{\mathrm{nuc}}(A, \mathcal{O}_2) \subset \mathrm{Ext}_{\mathrm{nuc}}(A, \mathcal{O}_2) = \mathrm{Ext}^{-1}(A, \mathcal{O}_2)$$

by Corollary 5.8.9(iii), because $\mathrm{K}_0(\mathcal{O}_2) = 0$ and $\mathcal{O}_2$ is simple, purely infinite and nuclear, cf. [**172**], [**169**].

$$\mathrm{Ext}^{-1}(A, \mathcal{O}_2) \cong \mathrm{KK}^1(A, (\mathcal{O}_2)_{(1)}) \cong \mathrm{KK}(SA, \mathcal{O}_2)$$

by Kasparov's isomorphisms and Bott periodicity, cf. [**73**, prop. 17.6.5, cor. 19.2.2] (see also Chapter 8).

By [**172**], $\mathrm{id}_{\mathcal{O}_2}$ is homotopic to $\mathrm{id}_{\mathcal{O}_2} \oplus_{s,t} \mathrm{id}_{\mathcal{O}_2}$ in the unital endomorphisms of $\mathcal{O}_2$. Thus $\mathrm{KK}(SA, \mathcal{O}_2) = 0$, because $\mathrm{KK}(SA, \,\cdot\,)$ is a homotopy invariant functor such that the Cuntz addition $\oplus$ induces the addition in $\mathrm{KK}(SA, \mathcal{O}_2)$, cf. Chapter 8.

Now let $h\colon A \hookrightarrow \mathrm{Q}^{\mathrm{s}}(\mathcal{O}_2)$ a unital *-monomorphism that has a c.p. lift $V\colon A \to \mathcal{M}(\mathcal{O}_2 \otimes \mathbb{K})$. Then $\mathrm{Ext}^{\mathrm{u,strong}}_{\mathrm{nuc}}(A, \mathcal{O}_2) = 0$ implies the existence of unital *-monomorphisms $h_1, h_2\colon A \to \mathcal{M}(\mathcal{O}_2 \otimes \mathbb{K})$ and of a unitary $U_1 \in \mathcal{M}(\mathcal{O}_2 \otimes \mathbb{K})$ such that $(V(a) \oplus h_1(a)) - U_1^* h_2(a) U_1 \in \mathcal{O}_2 \otimes \mathbb{K}$ for $a \in A$, where $V\colon A \to \mathcal{M}(\mathcal{O}_2 \otimes \mathbb{K})$ is a unital completely positive lift of $h\colon A \to \mathrm{Q}^{\mathrm{s}}(\mathcal{O}_2)$. We get a unitary $U_2 \in \mathcal{M}(\mathcal{O}_2 \otimes \mathbb{K})$ with $U_2^*(V(a) \oplus h_1(a))U_2 - V(a) \in \mathcal{O}_2 \otimes \mathbb{K}$ for every $a \in A$ from Theorem 5.6.2, which has to be applied to $C := V(A) + \mathcal{O}_2 \otimes \mathbb{K}$ and the completely positive unital map

$$T \;:=\; h_1 \circ h^{-1} \pi_{\mathcal{O}_2\otimes\mathbb{K}}\colon C \to \mathcal{M}(\mathcal{O}_2 \otimes \mathbb{K})\,.$$

Thus, $\varphi\colon A \ni a \mapsto U_3^* h_2(a) U_3$ with unitary $U_3 := U_1 U_2$ is a unital C^*-morphism that is a lift of h. □

COROLLARY 5.8.11. *Suppose that A is separable and unital.*

(i) $\mathrm{SExt}^{\mathrm{u}}_{\mathrm{nuc}}(A, \mathcal{O}_2 \otimes \mathbb{K}) \cap [\mathrm{Mon}(A, \mathrm{Q}^{\mathrm{s}}(\mathcal{O}_2))] = \mathrm{Ext}^{\mathrm{u}}_{\mathrm{nuc}}(A, \mathcal{O}_2 \otimes \mathbb{K}) = 0$.
(ii) *If a C^*-morphism $h\colon A \to \mathrm{Q}^{\mathrm{s}}(\mathcal{O}_2)$ has a unital completely positive lift $T\colon A \to \mathcal{M}(\mathcal{O}_2 \otimes \mathbb{K})$ then h has a lift as a unital C^*-morphism $\varphi\colon A \to \mathcal{M}(\mathcal{O}_2 \otimes \mathbb{K})$, i.e., $\pi_{\mathcal{O}_2\otimes\mathbb{K}}\varphi = h$.*

PROOF. (i) follows from Corollary 5.6.4(iv), because $\mathcal{O}_2 \otimes \mathbb{K}$ is purely infinite and simple.

???? **??**

(ii): Let $T\colon A \to \mathcal{M}(\mathcal{O}_2 \otimes \mathbb{K})$ a unital completely positive map with $\pi T = h$. Since $\mathcal{O}_2$ is nuclear, T is weakly nuclear, and thus $h \in \mathrm{Hom}_{\text{ul-nuc}}(A, \mathrm{Q}(\mathcal{O}_2 \otimes \mathbb{K}))$, i.e., $[h] \in \mathrm{SExt}^{\mathrm{u}}_{\mathrm{nuc}}(A, \mathcal{O}_2 \otimes \mathbb{K})$ by Definition 5.8.2.

Let $d\colon A \to \mathcal{L}(H) \subset \mathcal{M}(\mathcal{O}_2 \otimes \mathbb{K})$ a faithful unital *-representation of A such that $d(A) \cap \mathbb{K} = 0$. Let $k := \pi d$. By Kasparov's generalized Weyl–von Neumann theorem ([**?**], see Corollary 5.6.4), we have $\mathrm{Ext}_u(A, \mathcal{O}_2) := \mathrm{Gr}([Ext_u^{-1}(A, \mathcal{O}_2)]) = G(k, A, \mathrm{Q}^{\mathrm{s}}(\mathcal{O}_2))$, where we have used that $\mathcal{O}_2$ is nuclear (cf. [**169**]).

By Corollary 5.8.10, $\mathrm{Ext}_u(A, \mathcal{O}_2) = 0$.

Thus there exists a unitary v in $\mathrm{Q}^{\mathrm{s}}(\mathcal{O}_2)$ such that $h \oplus k = v^* k(\cdot) v$.

From now on we use that $\mathcal{O}_2$ is purely infinite and simple, [**169**], [**172**].

h absorbs k by Corollary 5.6.4(iv), i.e., there exists a unitary $w \in \mathcal{U}_0(\mathrm{Q}^{\mathrm{s}}(\mathcal{O}_2))$ such that $w^* h(\cdot) w = h \oplus k$.

It is easy to see, e.g. with help of Lemma 5.1.2(ii), that multiplier algebras of stable algebras have trivial K-theory. Therefore we get $\mathrm{K}_1(\mathrm{Q}^{\mathrm{s}}(\mathcal{O}_2)) \cong \mathrm{K}_0(\mathcal{O}_2) = 0$ from the 6-term exact sequence of K-theory, [**73**].

By Corollary 5.7.2, $\mathrm{Q}^{\mathrm{s}}(\mathcal{O}_2)$ is simple and purely infinite. By a theorem of Cuntz [**172**], the quotient of the unitary group of $\mathrm{Q}^{\mathrm{s}}(\mathcal{O}_2)$ by its connected component is naturally isomorphic to $\mathrm{K}_1(\mathrm{Q}^{\mathrm{s}}(\mathcal{O}_2)) = 0$. (More generally stable coronas of σ-unital C^*-algebras are K_1-bijectivity by Proposition 4.2.15.)

Thus vw^* is in the connected component of 1 in the unitary group of $\mathrm{Q}^{\mathrm{s}}(\mathcal{O}_2)$ and therefore there exists a unitary $U \in \mathcal{M}(\mathcal{O}_2 \otimes \mathbb{K})$ with $\pi(U) = vw^*$.

$U^* d(\cdot) U$ is a unital lift of h, i.e., $\pi(U^* d(a) U) = k(a)$. □

Corollary 5.8.12. *Suppose that E is a unital separable C^*-algebra, $\lambda\colon E \to A$ is an epimorphism such that the kernel D of λ is essential in E, $D \cong \mathcal{O}_2 \otimes \mathbb{K}$, and that there exists a unital completely positive map $V\colon A \to E$ such that $\lambda V = \mathrm{id}_A$. Then there exists a unital *-monomorphism $\psi\colon A \to E$ with $\lambda\psi = \mathrm{id}_A$.*

Proof. Expressed in algebraic terminology, we show that a semi-split essential exact sequence $0 \to D \to E \to A \to 0$ splits unitally if $D \cong \mathcal{O}_2 \otimes \mathbb{K}$.

Let $\pi\colon \mathcal{M}(\mathcal{O}_2 \otimes \mathbb{K}) \to \mathrm{Q}^{\mathrm{s}}(\mathcal{O}_2)$ be the natural epimorphism with kernel $\mathcal{O}_2 \otimes \mathbb{K}$ and let θ be the *-monomorphism from E into $\mathcal{M}(\mathcal{O}_2 \otimes \mathbb{K})$ which is defined by the isomorphism from D onto $\mathcal{O}_2 \otimes \mathbb{K}$. It is a monomorphism, because D is an essential ideal of E (by our assumptions). In particular, $\theta(D) = \mathcal{O}_2 \otimes \mathbb{K}$.

Then there is a unique unital *-monomorphism $\tau\colon A \to \mathrm{Q}^{\mathrm{s}}(\mathcal{O}_2)$ with $\pi\theta(E) = \tau(A)$ and $\pi\theta = \tau\lambda$.

$W := \theta V$ is a unital completely positive lift of τ, i.e., $\pi W = \tau$.

By Corollary 5.8.10 there exists a unital lift h of τ, i.e., $\pi(h(a)) = \tau(a)$. But then $h(A) \subset \pi^{-1}(\tau(A)) = \theta(E)$, and $\psi(\cdot) := \theta^{-1}(h(\cdot))$ is a unital *-monomorphism from A into E such that $\lambda\psi = \mathrm{id}_A$, because $\tau\lambda\psi = \pi\theta\psi = \pi h = \tau$ and τ is faithful. Thus ψ is as desired. □

9. The Ψ-residually nuclear case and $\mathrm{Ext}(\mathcal{C};\, A, B)$

Start of collection for Chapter 5:

Needed for Theorem 6.3.1.

But is the here used notation ok?

DEFINITION 5.9.1. Let X be a Dini-space, i.e., a sober second countable locally quasi-compact T_0 space.

Suppose that A and B are stable and σ-unital C^*-algebras, and that $\Psi_A \colon \mathcal{O}_X \to \mathcal{I}(A)$ is a *lower* semi-continuous action of X on A and $\Psi_B \colon \mathcal{O}_X \to \mathcal{I}(B)$ an *upper* semi-continuous action of X on B (cf. Definition 1.2.6). A completely positive map $V \colon A \to \mathcal{M}(B)$ is called **weakly Ψ_A-Ψ_B-residually nuclear**, (or shortly Ψ-residual nuclear) if, for every $b \in B$ the completely positive map $a \in A \mapsto b^* V(a) b \in B$ is Ψ_A-Ψ_B-residually nuclear in the sense of Definition 1.2.8. We denote by $\mathrm{Hom}_{\text{l-nuc}}(X;\, A, \mathrm{Q}(B)) \subset \mathrm{Hom}(A, \mathrm{Q}(B))$ the set of C^*-morphisms h from A into the (stable) corona $\mathrm{Q}(B) = \mathcal{M}(B)/B$ of B which have a weakly Ψ_A-Ψ_B-residually nuclear completely positive lift $V \colon A \to \mathcal{M}(B)$. Then $\mathrm{Hom}_{\text{l-nuc}}(X;\, A, \mathrm{Q}^{\mathrm{s}}(B))$ is invariant under passage to unitary equivalent C^*-morphisms and under Cuntz addition. Let $\mathrm{SExt}_{\mathrm{nuc}}(X;\, A, B)$ denote the semigroup of unitary equivalence classes of morphisms in $\mathrm{Hom}_{\text{l-nuc}}(X;\, A, \mathrm{Q}^{\mathrm{s}}(B))$ with Cuntz addition.

We define:

$$\mathrm{Ext}_{\mathrm{nuc}}(X;\, A, B) := \mathrm{Gr}(\mathrm{SExt}_{\mathrm{nuc}}(X;\, A, B)).$$

We generalize the above definitions in the following manner, because all constructions of ideal-system equivariant versions of Kasparov's Ext-theory factorize anyway though the variants of Ext-theory for the corresponding m.o.c. cones:
Let A separable, B σ-unital and stable, and let $\mathcal{C} \subset \mathrm{CP}(A, B)$ a matricial operator-convex cone. We denote by $\mathrm{Hom}_l(\mathcal{C};\, A, \mathrm{Q}(B)) \subset \mathrm{Hom}(A, \mathrm{Q}(B))$ the set of the C^*-morphisms $h \colon A \to \mathrm{Q}(B) \cong \mathrm{Q}^{\mathrm{s}}(B)$ that have a c.p. lift $V \colon A \to \mathcal{M}(B)$ with the property that $b^* V(\cdot) b \in \mathcal{C}$ for all $b \in B$. Again, $\mathrm{Hom}_l(\mathcal{C};\, A, \mathrm{Q}(B))$ is invariant under unitary equivalence and Cuntz addition, and we can define the semigroups and its Grothendieck groups by

$$\mathrm{SExt}(\mathcal{C};\, A, B) := [\mathrm{Hom}_l(\mathcal{C};\, A, \mathrm{Q}(B))] \subset [\mathrm{Hom}(A, \mathrm{Q}(B))]$$

Here $[\cdot]$ means the unitary equivalence classes of morphisms in $\mathrm{Hom}_l(\mathcal{C};\, A, \mathrm{Q}(B))$ with Cuntz addition.)

$$\mathrm{Ext}(\mathcal{C};\, A, B) := \mathrm{Gr}(\mathrm{SExt}(\mathcal{C};\, A, B))\,.$$

Note that $\mathrm{Ext}_{\mathrm{nuc}}(X;\, A, B) = \mathrm{Ext}_{\mathrm{nuc}}(\mathcal{C};\, A, B)$ for the m.o.c. cone $\mathcal{C} \subset \mathrm{CP}(A, B)$ of Ψ_A–Ψ_B-residually nuclear c.p. maps from A into B. If A is exact and B is separable, then there is a unique action Ψ_A of $X := \mathrm{Prim}(B)$ such that a given point-norm closed m.o.c. cone $\mathcal{C}$ is the same as $\mathrm{CP}_{\mathrm{rn}}(X;\, A, B)$ with Ψ_B defined as the identity action of X on X.

REMARK 5.9.2. Special cases of the groups $\mathrm{Ext}(\mathcal{C};\, A,B)$ are $\mathrm{Ext}(A,B) = \mathrm{Ext}(\mathrm{CP}(A,B);\, A,B)$, $\mathrm{Ext}_{\mathrm{nuc}}(A,B) = \mathrm{Ext}(\mathrm{CP}_{\mathrm{nuc}}(A,B);\, A,B)$, $\mathrm{Ext}_{\mathrm{nuc}}(X;\, A,B) = \mathrm{Ext}(\mathrm{CP}_{\mathrm{rn}}(X;\, A,B);\, A,B)$, where $\mathrm{CP}_{\mathrm{rn}}(X;\, A,B) \subset \mathrm{CP}(A,B)$ denotes the Ψ_A-Ψ_B-residually nuclear c.p. maps, depending on fixed actions $\Psi_A \colon \mathbb{O}(X) \to \mathcal{I}(A)$ and $\Psi_B \colon \mathbb{O}(X) \to \mathcal{I}(B)$ of X on A and B.

We can also define

$$\mathrm{Ext}(X;\, A,B) := \mathrm{Ext}(\mathrm{CP}(X;\, A,B);\, A,B)\,,$$

the group of Ψ_A-Ψ_B-equivariant extensions, where $\mathrm{CP}(X;\, A,B) \subset \mathrm{CP}(A,B)$ is the Ψ-equivariant c.p. maps.

Next Def's could be in Chp.3

The cone $\mathcal{C} \subset \mathrm{CP}(A,B)$ is **faithful** (respectively **non-degenerate**) if there is no non-zero ideal J of A with $T(J) = \{0\}$ for all $T \in \mathcal{C}$ (respectively there is no ideal $I \neq B$ of B with $T(A) \subset I$ for all $T \in \mathcal{C}$).

There is also an explanation of $\mathrm{Ext}(\mathcal{C};\, A,B)$ with help of extensions with Busby invariant that have lifts that are limits of maps in $\mathcal{C}$ with respect to the strict topology on $\mathcal{M}(B)$. It can be done in a similar manner as in the explanation given in Section 8 for the case X =point (Note that $\mathrm{Ext}_{\mathrm{nuc}}(X;\, A,B) = \mathrm{Ext}_{\mathrm{nuc}}(A,B)$ if $X = \{p\}$ is a point).

Corollaries 5.4.4 and 5.4.9 tell us:
If $\mathcal{C}$ is countably generated, then there is a "universal" element $H_0 \in \mathrm{Hom}(A, M(B))$ that defines the point-norm closure of $\mathcal{C}$, with $\delta_\infty \circ H_0$ unitarily equivalent to H_0, and $H_0(A)BH_0(A)$ a split corner of B. It can be chosen non-degenerate if $\mathcal{C}$ is *non-degenerate* , i.e., if $\mathcal{C}$ is not contained in $CB(A,J)$ for some closed ideal J of B. Let $h_0 := \pi_B \circ H_0$. Then $\mathrm{Ext}(\mathcal{C};\, A,B) = [h_0] + \mathrm{SExt}(\mathcal{C};\, A,B) = G(h_0;\, A,B)$. The split extension $B + H_0(A) = \pi_B$ is stable if $\mathcal{C}$ is non-degenerate. By Proposition 5.5.12(i+ii), this implies that every extension with Busby invariant in $\mathrm{Ext}(\mathcal{C};\, A,B)$ is a stable C^*-algebra. (Here we can see that the questions about the non-degeneracy of $\mathrm{CP}_{\mathrm{rn}}(X;\, A,B)$ is of importance for actions of X on A and B.)

Recall that a **corner** of a C^*-algebra E is a hereditary C^*-subalgebra F of E such that there is a projection $p \in \mathcal{M}(E)$ with $F = pEp$, and that a subalgebra $G \subset E$ **generates a corner** of E, if $C^*(G)EC^*(G)$ is a corner of E ([20]). The following Ψ-equivariant generalization of Theorem 5.6.2 seems to be the maximal possible, only special cases are used in our applications.

THEOREM 5.9.3. *Suppose that B is a σ-unital C^*-algebra, $D \subset \mathcal{M}(B)$ is strongly purely infinite, separable and stable C^*-subalgebra such that DB is dense in B (and thus $\mathcal{M}(D) \subset \mathcal{M}(B)$ naturally), and that $C \subset \mathcal{M}(D)$ is a separable C^*-subalgebra. Define $\Psi_C := \Psi^{\mathrm{up}}_{D,C}$ and $\Psi_B := \Psi^{D,B}_{\mathrm{down}}$ as in Chapter* 1.

[20] The *set* (!) of products $C^*(G) \cdot E \cdot C^*(G)$ is always a hereditary C^*-subalgebra of E by the Cohen factorization theorem for Banach modules.

Suppose further that

($\alpha 3$) *for every closed ideal J of D, the subalgebra $\mathcal{M}(\pi_J)(C) \cap \pi_J(D)$ of $\pi_J(D) = D/J$ generates a corner of D/J, and*

($\beta 3$) *Let $V\colon C \to \mathcal{M}(B)$ be a weakly Ψ_C-Ψ_B–residually nuclear completely positive map such that, for every $J \in \mathcal{I}(D)$, $\xi \in \mathbb{C}$ and $c \in C \cap (\xi 1 + D + \mathcal{M}(D, J))$ the element $V(c)$ is in the strict closure of $\xi 1 + \mathrm{span}(BJB)$* ([21]).

Then id_C asymptotically dominates V in the sense of Definition 5.0.1.

If, moreover, V is a C^*-morphism then id_C asymptotically absorbs V, i.e., $\mathrm{id}_C \oplus V\colon C \to \mathcal{M}(B)$ and id_C are unitarily homotopic in the sense of Definition 5.0.1.

Proof. Since B and D are σ-unital, there are natural isomorphisms $\mathcal{M}(B)/\mathcal{M}(B, I) \cong \mathcal{M}(B/I)$ and $\mathcal{M}(D)/\mathcal{M}(D, J) \cong \mathcal{M}(D/J)$ for closed ideals I of B and J of D by the non-commutative version of the Tietze extension theorem ([22]).

They allow us to proceed as in the proof of Theorem 5.6.2:

First, ($\beta 3$) implies $V(C \cap D) = \{0\}$ if we take $\xi = 0$ and $J = \{0\}$. Furthermore $C \cap D$ is a corner of D by ($\alpha 3$). The same properties hold for $\mathcal{M}(\pi_J)(C) = C/\Psi_C(J)$ and $\pi_J(D) = D/J$ and the unit element 1 of $\mathcal{M}(D/J) \cong \mathcal{M}(D)/\mathcal{M}(D, J)$ in place of C, D and $1 \in \mathcal{M}(D)$ by ($\beta 3$) and ($\alpha 3$).

Notice that $\mathcal{M}(D, J) \subset \mathcal{M}(D) \cap \mathcal{M}(B, \Psi_B(J))$ and $\Psi_C(J) = C \cap \mathcal{M}(D, J)$. The latter identity is the definition of $\Psi_C = \Psi^{\mathrm{up}}_{D,C}$, and the first inclusion follows from $JB \subset \Psi_B(J)$, i.e., from $J \subset \mathcal{M}(B, \Psi_B(J))$, because $\mathcal{M}(B, \Psi_B(J))$ is strictly closed in $\mathcal{M}(B)$, the inclusion $\mathcal{M}(D) \to \mathcal{M}(B)$ is strictly continuous and $\mathcal{M}(D, J)$ is the strict closure of J in $\mathcal{M}(D)$ (Recall that $\Psi_B(J)$ is the closure of $\mathrm{span}(BJB)$).

It follows that $\mathcal{M}(D) \cap \mathcal{M}(B, \Psi_B(J))$ is a strictly closed ideal of $\mathcal{M}(D)$. Thus $\mathcal{M}(D) \cap \mathcal{M}(B, \Psi_B(J)) = \mathcal{M}(D, J_1)$ for the ideal $J_1 := D \cap \mathcal{M}(B, \Psi_B(J))$ of D. Then $J \subset J_1$ and $\Psi_B(J_1) = \Psi_B(J)$. The arguments show that our J_1 is the biggest ideal of D with $\Psi_B(J_1) = \Psi_B(J)$, and that, for every closed ideal I of B, the ideal $\Psi_D(I) := D \cap \mathcal{M}(B, I)$ of D satisfies $\mathcal{M}(D, \Psi_D(I)) = \mathcal{M}(D) \cap \mathcal{M}(B, I)$, $\Psi_C(\Psi_D(I)) = C \cap \mathcal{M}(B, I)$ and $\Psi_B(\Psi_D(I)) \subset I$. In particular, $V(C \cap \mathcal{M}(B, I)) = V(\Psi_C(\Psi_D(I))) \subset \mathcal{M}(B, I)$ for all ideals I of B.

We let $C_1 := D + C + \mathbb{C}1$ and define $V_e\colon C_1 \to \mathcal{M}(B)$ by $V^e(d + c + \xi 1) := V(c) + \xi 1$ for $d \in D$, $c \in C$, $\xi \in \mathbb{C}$. It is well-defined, because $d' + c' + \xi' 1 = d + c + \xi 1$ implies that $c' - c \in (\xi - \xi')1 + D$, thus, $V(c' - c) = (\xi - \xi')1$ by ($\beta 3$) with $J = \{0\}$, which yields $V(c') + \xi' 1 = V(c) + \xi 1$. By definition $V^e(D) = 0$ and $[V^e]_D\colon C_1/D \to \mathcal{M}(B)$ is the extension of $[V]_{D \cap C}\colon C/(D \cap C) \to \mathcal{M}(B)$ to a

[21] I.e., $V(C \cap (\xi 1 + D + \mathcal{M}(D, J))) \subset \xi 1 + \mathcal{M}(B, \Psi_B(J))$ for $J \in \mathcal{I}(D)$ and $\xi \in \{0, 1\}$.

[22] Cf. [**616**, Prop.3.12.10.] for the case of separable B. It extends to σ-unital C^*-algebras B, because then $\mathcal{M}(B/J)$ is the algebraic inductive limit of its C^*-subalgebras $\mathcal{M}(A/(A \cap J))$ where the C^*-algebras $A \subset B$ are separable and $e \in A$ for some $e \in B_+$ that is strictly positive in B.

unital map of $C_1/D \cong C/(D\cap C) + \mathbb{C}1$ into $\mathcal{M}(B)$. Since V is a c.p. contraction with $V(D\cap C)=0$, it follows that $V^e\colon C_1 \to \mathcal{M}(B)$ is a u.c.p. map with $V^e(D)=0$.

Thus, condition (α) of Proposition 5.4.1 is satisfied for C_1, V^e and a strictly positive contraction $h \in D \subset C_1$.

Let $\Phi(J) := C_1 \cap \mathcal{M}(D,J)$ for ideals J of D. We have that $V^e(\Phi(J)) \subset \mathcal{M}(B, \Psi_B(J))$ by (β3): Indeed, if $d+c+\xi 1 \in \mathcal{M}(D,J)$, then $c \in C\cap((-\xi)1 + D + \mathcal{M}(D,J))$, and, by condition ($\beta$3), $V(c) \in (-\xi)1 + \mathcal{M}(B,\Psi_B(J))$, i.e., $V^e(d+c+\xi 1) = V(c) + \xi 1 \in \mathcal{M}(B,\Psi_B(J))$.

Lemma B.7.7(ii) shows that assumption (β3) implies that V^e is even Φ-Ψ_B–residually nuclear: The (induced class-)map

$$[V^e]_J\colon C_1/\Phi(J) \to \mathcal{M}(B/\Psi_B(J))$$

is weakly nuclear by Lemma B.7.7(ii) for every closed ideal J of D, because $C_1/\Phi(J) = \mathcal{M}(\pi_J)(C) + \pi_J(D) + \mathbb{C}1 \subset \mathcal{M}(D/J)$, $[V^e]_J(d+c+\xi 1) = [V]_J(c) + \xi 1 \in \mathcal{M}(B/\Psi_B(J))$, $\mathcal{M}(\pi_J) \cap \pi_J(D)$ generates a corner F_J of $D/J = \pi_J(D)$ and $[V]_J\colon \mathcal{M}(\pi_J)(C) \to \mathcal{M}(B/\Psi_B(J))$ is weakly nuclear.

It follows that $T := \delta_\infty \circ V^e$ is also a unital Φ-Ψ_B–residual weakly nuclear u.c.p. map from $C_1 \subset \mathcal{M}(D)$ into $\mathcal{M}(B)$. The strictly positive contraction $h \in D_+$ again satisfies condition (α) of Proposition 5.4.1 for $T\colon C_1 \to \mathcal{M}(B)$.

Proposition 3.6.1 applies to T, and shows that the Φ-Ψ_B–residual nuclear maps $b^*T(\cdot)b$ ($b \in B$) are approximately 1-step inner in $\mathcal{M}(B)$. Thus, also condition (β) of 5.4.1 is satisfied, and the conclusions follow from parts (iii) and (iv) of Proposition 5.4.1. □

Remark 5.9.4. The tricky points of the reduction to Proposition 5.4.1 in the proof of Theorem 5.9.3 are contained in the proof of Lemma B.7.7 and in the proof of the local approximation result in Proposition 3.6.1. The latter proof essentially reduces to the case, where there is a weakly residually nuclear *-monomorphism $H_1\colon C \to \mathcal{M}(D)$ such that $H_1(C)\cap \mathcal{M}(D,J) = H_1(C\cap \mathcal{M}(D,J))$ for every closed ideal J of D, as it is the case for the ultrapower D_ω in place of D.

The following Corollary 5.9.5 is an immediate consequence of our above given Weyl–von-Neumann–Voiculescu type Theorem 5.9.3 for weakly residually nuclear maps. We define for $D \subseteq B$ and $X := \operatorname{Prim}(D)$, an action

$$\Psi_E\colon \mathbb{O}(X) \cong \mathcal{I}(D) \to \mathcal{I}(\mathrm{Q}(B))$$

of X on $E := \mathrm{Q}(B)$ by

$$\Psi_E(J) := \pi_B(\mathcal{M}(B, \operatorname{span}(BJB))) \quad \text{for } J \in \mathcal{I}(D)\,.$$

If $\Psi_A\colon \mathbb{O}(X) \to \mathcal{I}(A)$ is an action of X on A, we denote by $\operatorname{Mon}(X;\, A, E)$ the set of *-monomorphisms $\varphi\colon A \to E$ with $\varphi(\Psi_A(U)) = \varphi(A) \cap \Psi_E(U)$ for $U \in \mathbb{O}(X)$. (It might happen that $\operatorname{Mon}(X;\, A, E)$ is empty.)

Corollary 5.9.5. *Suppose that A, and $D \subseteq B$ are stable C^*-algebras, such that A and D are separable, D is strongly purely infinite and DB is dense in B.*

*Let $X := \mathrm{Prim}(D)$. Further let $H_1\colon A \to \mathcal{M}(D)$ be a weakly residually nuclear *-monomorphism such that H_1 is unitarily equivalent to $\delta_\infty \circ H_1$ and that $H_1(A)D$ is dense in D. Denote by $H_0\colon A \to \mathrm{Q}(B) = \mathcal{M}(B)/B \cong \mathrm{Q}^{\mathrm{s}}(B)$ the corresponding monomorphism from A into the stable corona $\mathrm{Q}^{\mathrm{s}}(B)$ of B, i.e., $H_0 := \pi_B H_1$.*

Consider the actions $\Psi_B := \Psi^{D,B}_{\mathrm{down}}$ of X on B and the action $\Psi_A := H_1^{-1}\Psi^{\mathrm{up}}_{D,H_1(A)}$ of X on A.

Then there are natural isomorphisms

$$\mathrm{SExt}_{\mathrm{nuc}}(X;\, A, B) \cong S(H_0,\, A, \mathrm{Q}(B))$$

and

$$\mathrm{Ext}_{\mathrm{nuc}}(X;\, A, B) \cong G(H_0,\, A, \mathrm{Q}(B))\,.$$

If, in addition, $B = D$ then

$$\mathrm{SExt}_{\mathrm{nuc}}(X;\, A, B) \cap [\mathrm{Mon}(X;\, A, \mathrm{Q}(B))] = G(H_0, A, \mathrm{Q}(B))\,.$$

Recall that $G(H_0, A, \mathrm{Q}(B))$ is naturally isomorphic to the kernel of $\mathrm{K}_0(H_0(A)' \cap \mathrm{Q}(B)) \to \mathrm{K}_0(\mathrm{Q}(B))$ by Proposition 4.4.3(ii).

PROOF. `to be filled in` ?? □

LEMMA 5.9.6. *Suppose that B is σ-unital, A is a separable C^*-subalgebra of $\mathcal{M}(B)/B$, and that $V\colon A \to \mathcal{M}(B)/B$ is a completely positive contraction.*

If there exist a sequence $d_1, d_2, \ldots$ of contractions in $\mathcal{M}(B)/B$, such that, for $a \in A$,

(i) $\lim_{n\to\infty} \|d_n^* a d_{n+1}\| = 0\,,\ \ \lim_{n\to\infty} \|d_n^* d_{n+1}\| = 0\,,$ *and*
(ii) $\lim_{n\to\infty} \|d_n^* a d_n - V(a)\| = 0,$

then there exists a contraction $d \in \mathcal{M}(B)$, such that $V(a) = \pi_B(d)^* a \pi_B(d)$ for $a \in A$.

PROOF. Since A is separable, there is a strictly positive contraction $c \in A_+$ with $\|c\| = 1$.

The proof is similar to that of Proposition 5.4.1. Let Ω be a compact subset of the contractions in A_+ that linearly generates a dense linear subspace of A, and let $\gamma\colon \Omega \to \mathcal{M}(B)_+$ (respectively $\tau\colon V(\Omega) \to \mathcal{M}(B)_+$) a topological lift of $\Omega \subseteq \mathrm{Q}(B)$ (respectively of $V(\Omega) \subseteq \mathrm{Q}(B)$) into the positive contractions in $\mathcal{M}(B)$. Further let $e \in B_+$ a strictly positive contraction with $\|e\| = 1$, and let $f_1, f_2, \ldots \in \mathcal{M}(B)$ contractive lifts of $d_1, d_2, \ldots$. The unital C^*-subalgebra $D := C^*(1, e, \gamma(\Omega), \tau(V(\Omega)), \{f_n\}_n) \subseteq \mathcal{M}(B)$ generated by $\{e, 1, f_1, f_2, \ldots\} \cup \gamma(\Omega) \cup \tau(V(\Omega))$ is separable.

By Remark 5.1.1(3), we find elements $g_n \in C^*(e)_+$, namely, square roots of suitable differences of elements in a suitable approximate unit of B that is approximately central for D, with the following properties

(1) $\sum_n g_n^2$ converges strictly to $1_{\mathcal{M}(B)}$, $g_n g_m = 0$ for $|m-n| > 1$, $\|e g_n\| < 2^{-n}$

(2) $\|f_k g_n - g_n f_k\| < 2^{-n}$ for $k \leq n$,
(3) $\|g_n\gamma(a) - \gamma(a)g_n\| < 2^{-n}$ and $\|g_n\tau(V(a)) - \tau(V(a))g_n\| < 2^{-n}$ for $a \in \Omega$,
(4) $\|g_n f_n^* b f_{n+1} g_{n+1}\| \leq 2^{-n} + \mathrm{dist}(f_n^* b f_{n+1}, B)$ for $b \in \gamma(\Omega) \cup \{1\}$, and
(5) $\|g_n(f_n^*\gamma(a)f_n - \tau(V(a)))g_n\| \leq 2^{-n} + \mathrm{dist}(f_n^*\gamma(a)f_n - \tau(V(a)), B)$ for $a \in \Omega$.

Let $\Gamma(b_1, b_2, \ldots) := \sum g_n b_n g_n$ for $(b_1, b_2, \ldots) \in \ell_\infty(\mathcal{M}(B))$. By Remarks 5.1.1(2,4) check numbers 2 and 4!, Γ is a unital c.p. map from $\ell_\infty(\mathcal{M}(B))$ into $\mathcal{M}(B)$. It holds $\Gamma(b_1, b_2, \ldots) \in B$ if $\lim \|g_n b_n g_n\| = 0$, because then $\Gamma(b_1, b_2, \ldots)$ is the sum of the two series $\sum g_{2n-1}b_{2n-1}g_{2n-1}$ and $\sum g_{2n}b_{2n}g_{2n}$ which have mutually orthogonal summands by (1). Thus, by (5) and (ii),

$$\Gamma(f_1^*\gamma(a)f_1 - \tau(V(a)), f_2^*\gamma(a)f_2 - \tau(V(a)), \ldots) \in B\,.$$

Moreover, by Remarks 5.1.1(4,5,6), $\tau(V(a)) - \Gamma(\tau(V(a)), \tau(V(a)), \ldots) \in B$ (by (3)), $\sum f_n g_n$ converges strictly to an element $f \in \mathcal{M}(B)$, and, by (2)–(4)

$$f^*bf - \Gamma(f_1^*bf_1, f_2^*bf_2, \ldots) \in B$$

for $b \in \gamma(\Omega) \cup \{1\}$, because $\lim_n \|g_n f_n^* b f_{n+1} g_{n+1}\| = 0$ by (4) and (i).

Thus, $\pi_B(f)$ is a contraction and $\pi_B(f)^* a \pi_B(f) = V(a)$ for $a \in \Omega$. Let $d := h\lambda(h^*h)$, where $\lambda(t) := \min(1, t^{-1/2})$ for $t \in [0, \infty)$. Then d is a contraction in $\mathcal{M}(B)$ with $\pi_B(d)^* a \pi_B(d) = V(a)$ for $a \in \Omega$, and thus for all $a \in A$. □

Remark 5.9.7. If (in addition to the assumptions of Lemma 5.9.6) B is stable and A is contained in a σ-unital stable C^*-subalgebra D of $\mathcal{M}(B)/B$ such that $\pi_B^{-1}(D)$ is stable, then d can be replaced by an isometry $s = \pi_B(S)$ for some isometry $S \in \mathcal{M}(B)$, i.e., $d^*ad = s^*as$ for all $a \in A$.
(Indeed: there are isometries $T_1, T_2 \in \mathcal{M}(B)$ such that $T_1T_1^* + T_2T_2^* = 1$, $ct_2 = 0$ and $t_1c = c = ct_1$ for all $c \in D \supseteq A$ and $t_k = \pi_B(T_k)$,$k = 1, 2$, by Corollary 5.5.14. Let $S := T_1 d + t_2(1 - d^*d)^{1/2} \in \mathcal{M}(B)$.)

Proposition 5.9.8. *Suppose that A is separable, B is stable and σ-unital and* (1-)*purely infinite, $h\colon A \to \mathrm{Q}(B)$ is a C^*-morphism, and that $(V_k\colon \mathrm{Q}(B) \to \mathrm{Q}(B))$ is a sequence of approximately inner completely positive maps.*

If h dominates $h \oplus h$ and $V_n \circ h$ converges point-wise on A to a c.p. contraction $T\colon A \to \mathrm{Q}(B)$, then h dominates T.

Proof. The multiplier algebra $\mathcal{M}(B)$ and the corona $\mathrm{Q}(B)$ contain copies of $\mathcal{O}_2$ unitally, because B is stable. Since h dominates $h \oplus h$, there is a copy of $\mathcal{O}_\infty$ unitally contained in $h(A)' \cap \mathrm{Q}(B)$ (cf. Proposition 4.3.5(iv)). The sequence of c.p. maps $(V_k \circ h)$ (with point-norm limit T) allows to construct a sequence d_n of contractions in $\mathrm{Q}(B)$ such that $d_{n+k}^* b d_n = 0$ for $b \in h(A) + \mathbb{C}1$, $k > 0$, and $\lim_{n\to\infty} \|d_n^* h(a) d_n - T(a)\| = 0$ (cf. Lemma 3.10.5). Thus, Lemma 5.9.6 applies and there is a contraction $d \in \mathrm{Q}(B)$ with $d^*h(\cdot)d = T$. Since A is stable and B is purely infinite, $\pi_B^{-1}(h(A))$ is stable by Corollary 5.5.16. Thus d can be replaced by an isometry (by Remark 5.9.7). □

REMARK 5.9.9.

`Where 5.9.9 is used? ??`

If $B \cong B \otimes \mathcal{D}_\infty$ (with $\mathcal{D}_\infty = \mathcal{O}_\infty \otimes \mathcal{O}_\infty \otimes \ldots$), then the latter approximate domination should be the case if and only if (for suitable topological lifts) $\widetilde{h}\colon \Omega \to \mathcal{M}(B \otimes \mathcal{D}_\infty)$ approximately dominates $\widetilde{T}$ modulo a suitable commutative approximate unit $e_1 \leq e_2 \leq \ldots$ of B. More precisely: Let $\widetilde{h}$ and $\widetilde{T}$ denote topological lifts of h and T on a linearly generating compact subset Ω of A. Then, for every $\varepsilon > 0$ there should exist $k_\varepsilon \in \mathbb{N}$, such that, for every $m > n > k_\varepsilon$, there is a contraction $d_{n,m} \in B \otimes \mathcal{D}_\infty$ with

$$\|d_{n,m}^* \widetilde{h}(a) d_{n,m} - e_m(1-e_n)\widetilde{T}(a)(1-e_n)e_m\| < \varepsilon.$$

for $a \in \Omega$. (Also some orthogonality relations of the $d_{n,m}$ are required, coming here from a central sequence of copies of $\mathcal{O}_\infty$ in $\mathcal{M}(B \otimes \mathcal{D}_\infty)$ for $B \otimes \mathcal{D}_\infty$.)

LEMMA 5.9.10. *Let B a stable and σ-unital C^*-algebra and $b \in \mathcal{M}(B)_+$. Denote by $J(b) := \overline{\operatorname{span} BbB}$ the closed ideal of B, and by $I(b) := \overline{\operatorname{span} \mathcal{M}(B)b\mathcal{M}(B)}$ the norm-closed ideal of $\mathcal{M}(B)$ generated by b. Then, for every $b \in \mathcal{M}(B)_+$,*

$$\mathcal{M}\big(B, J((b-\varepsilon)_+)\big) \subseteq I\big(\delta_\infty(b)\big) \subseteq \mathcal{M}\big(B, J(b)\big)\,,$$

and $b \in I\big(\delta_\infty(b)\big) \in \mathcal{I}(\mathcal{M}(B))$.

PROOF. Let e denote a strictly positive element of B_+, $s_1, s_2, \ldots \in \mathcal{M}(B)$ a sequence of isometries with $\sum s_n s_n^* = 1$ strictly, and $b \in \mathcal{M}(B)_+$. Then

$$bB \subseteq J(b) := \overline{\operatorname{span} BbB}\,,$$

because $\lim_{n\to\infty} e^{1/n}bc = bc$ for $c \in B$. Thus, $Bb \cup bB \subseteq J(b)$, i.e., $b \in \mathcal{M}(B, J(b))$ for every $b \in \mathcal{M}(B)_+$.

It follows that $\delta_\infty(b) \in \mathcal{M}(B, J(b))$ for each $b \in \mathcal{M}(B)_+$, because $\overline{\operatorname{span} BbB} = \overline{\operatorname{span}(B\delta_\infty(b)B)}$ by strict convergence of $\sum_n s_n b s_n^* =: \delta_\infty(b)$, i.e., by norm-convergence in B of $\sum_{n=1}^m s_n b s_n^* a$ to $\delta_\infty(b)a$ for all $a \in B$.

Clearly, $b = s_1^* \delta_\infty(b) s_1 \in I\big(\delta_\infty(b)\big)$.

Let $J := J((b-\varepsilon)_+) = \overline{\operatorname{span}(B(b-\varepsilon)_+B)}$, and let $t \in \mathcal{M}(B,J)_+$. If we use functional calculus and convex combination, then we find $e_n \in C^*(e)$ with $0 \leq e_n \leq 1$, $e_n e_{n+1} = e_n$, $\|e_n e - e\| < 2^{-n}$, $\|e_n t - t e_n\| < 2^{-n}$, and $\|g_n t - t g_n\| < 2^{-n}$ for $g_n := (e_n - e_{n-1})^{1/2}$ with $e_0 := 0$, cf. Remark 5.1.1(3).

`Next still to be checked:`

The sum $V(t) := \sum_{0\leq n\leq\infty} g_n t g_n$ converges strictly and the elements tg_n and $V(t) - t$ are in J, cf. Remark 5.1.1(4). Since $g_n t g_n \in J_+$ for $t \in \mathcal{M}(B,J)$ and since J_+ is the closed linear span of $\{b^*(a-\varepsilon)_+ b\,;\ b \in B\,\}$, we get $(a-\varepsilon)_+^\delta \cdot B \subseteq J$ for each $\delta \in (0,1)$.

By definition of J and $\mathcal{M}(B,J)$, there exist $k_n \in \mathbb{N}$ and $b_{n,k} \in B$ where $k \in \{1,\ldots,k_n\}$, with

$$\| g_n t g_n - \sum_{k=1}^{k_n} (b_{n,k})^*(a-\varepsilon)_+ b_{n,k} \| < 2^{-n}.$$

Let $s_1, s_2, \ldots$ a sequence of isometries in $\mathcal{M}(B)$, such that $\sum s_n s_n^*$ strictly converges to 1. We define a bounded continuous function $\varphi\colon [0,\infty)$ by $\varphi(0) := 0$ and $\varphi(\tau) := ((\tau-\varepsilon)_+/\tau)^{1/2}$ for $\tau \in (0,\infty)$. Then $\varphi(\tau)^2 \le \varepsilon^{-1}(\tau-\varepsilon)_+$ because $\tau\varphi(\tau)^2 = (\tau-\varepsilon)_+$. It follows that $\varphi(a)b_{n,k} \in J$ for each $n \in \mathbb{N}$ and $k = 1,\ldots,k_n$.

The elements $f_n := (e_{n+2} - e_{n-1})^{1/2}$ are positive contractions with $g_n f_n = g_n$ if we let $e_0 := 0$.

We define inductively $m_n \in \mathbb{N}$, $d_n \in B$ and $q_n \in \mathcal{M}(B)$, by $m_1 = 0$, $m_{n+1} := m_n + k_n$,

$$d_n := \sum_{k=1}^{k_n} s_{k+m_n}\varphi(a)b_{n,k}f_n \quad \text{and} \quad q_n := \sum_{k=1}^{k_n} s_{k+m_n}s_{k+m_n}^* .$$

The sum $\sum q_n$ of the projections $q_n \in \mathcal{M}(B)$ converges strictly to $1_{\mathcal{M}(B)}$. The d_n satisfy

$$\|g_n t g_n - d_n^*\delta_\infty(a)d_n\| = \|f_n\big(g_n t g_n - \sum_{k=1}^{k_n}(b_{n,k})^*(a-\varepsilon)_+ b_{n,k}\big)f_n\| < 2^{-n}$$

and $d_n = q_n x_n f_n$, where $x_n \in B$ is defined by $x_n := \sum_{k=1}^{k_n} s_{k+m_n}\varphi(a)b_{n,k}$. Notice that x_n and d_n are in J, because $b_{n,k}^*\varphi(a)^2 b_{n,k} \le \varepsilon^{-1}(b_{n,k})^*(a-\varepsilon)_+ b_{n,k} \in J$. The sequence $x_1, x_2, \ldots$ is bounded, because $b_{n,k}^*\varphi(a)^2 b_{n,k} \le \varepsilon^{-1}(b_{n,k})^*(a-\varepsilon)_+ b_{n,k}$ implies that

$$x_n^* x_n = \sum_{k=1}^{k_n} b_{n,k}^*\varphi(a)^2 b_{n,k} \le \varepsilon^{-1}(2^{-n}1 + g_n t g_n) \le \varepsilon^{-1}(1 + \|t\|) .$$

Since also $\sum f_n^2 \le 3\sum g_n^2 = 3 \cdot 1_{M(B)}$ converges strictly to some element $F \in \mathcal{M}(B)_+$ with $\|F\| \le 3$, we get that $\sum_{n=1}^\infty d_n$ is strictly convergent in $\mathcal{M}(B)$, cf. Remark 5.1.1(2). Let $d := \sum_{n=1}^\infty d_n \in \mathcal{M}(B)$. Using that $d_m^*\delta_\infty(a)d_n = \delta_{m,n}d_n^*\delta_\infty(a)d_n$ we get

$$d^*\delta_\infty(a)d = \sum_n d_n^*\delta_\infty(a)d_n .$$

The estimates $\|d_n^*\delta_\infty(a)d_n - g_n t g_n\| < 2^{-n}$ and that $d_n^*\delta_\infty(a)d_n, g_n t g_n \in J$ show that $d^*\delta_\infty(a)d - V(t)$ is in J, because $d_n^*\delta_\infty(a)d_n$, $g_n t g_n \in J$. It implies $V(t) \in J + I(\delta_\infty(a))$. Since $J = J((a-\varepsilon)_+) \subseteq J(a) \subseteq I(\delta_\infty(a))$, the element $t = V(t) + (t - V(t)) \in \mathcal{M}(B,J)_+$ is contained in $I(\delta_\infty(a)) + J(a)$. Clearly $I(\delta_\infty(a)) + J(a) = I(\delta_\infty(a))$. □

The following Proposition 5.9.11 characterizes the *invertible elements* of

$$\mathrm{SExt}_{\mathrm{nuc}}(\mathrm{Prim}(B);\, A, B) \subseteq [\mathrm{Hom}(A, \mathrm{Q}^{\mathrm{s}}(B))]$$

for exact $A \subseteq \mathcal{M}(B)$ with the property that the imbedding map $a \in A \to a \in \mathcal{M}(B)$ is (weakly) nuclear, where B is σ-unital, stable and has the WvN-property. It generalizes the characterization of invertible elements in $\mathrm{SExt}_{\mathrm{nuc}}(A,B)$ given in Remark 5.8.4 (using Theorem 5.6.2). This characterization will be *used for the proof of Theorem K.*

PROPOSITION 5.9.11 (Absorbing elements). *Suppose that B is σ-unital and stable, satisfies the WvN-property, and that $A \subseteq \mathcal{M}(B)$ is a separable stable exact C^*-subalgebra, such that $\mathrm{id}_{\mathcal{M}(B)}|A$ is weakly nuclear and non-degenerate. Let $\varphi\colon A \to \mathrm{Q^s}(B) = \mathcal{M}(B)/B$ a *-monomorphism, and let h_0 the restriction of $\pi_B \circ \delta_\infty$ to A.*

Define the "natural" lower semi-continuous action of $\mathrm{Prim}(B)$ on A by $\Psi_A(J) := A \cap \mathcal{M}(B,J)$ for $J \in \mathcal{I}(B)$.

Then φ defines an element in $G(h_0;\, A, \mathrm{Q}(B)) \cong \mathrm{Ext}_{\mathrm{nuc}}(\mathrm{Prim}(B);\, A, B)$ (i.e., φ and h_0 dominate in $\mathrm{Q}(B)$ each other), if and only if,

(i) *φ is nuclear, and*
(ii) *$\varphi(\Psi_A(J)) = \pi_B(\mathcal{M}(B,J)) \cap \varphi(A)$ for $J \in \mathcal{I}(B)$.*

PROOF. The weak nuclearity of $\mathrm{id}|A$ and the exactness of A imply, that $H_0 := \delta_\infty|A$ is nuclear, cf. `Chp.3: if` A `is exact then ''weakly nuclear''` H_0 `(norm-)''nuclear'' ??`. Since $\delta_\infty(\mathcal{M}(B)) \cap \mathcal{M}(B,J) = \delta_\infty(\mathcal{M}(B,J))$, we have $H_0(\Psi_A(J)) = H_0(A) \cap \mathcal{M}(B,J)$ for $J \in \mathcal{I}(B)$. Since A is exact, this, together with the nuclearity of H_0, implies that H_0 is Ψ_A-Ψ^{up}-residually nuclear.

Let e denote a strictly positive element of B. Since $E_\varphi := \{b \in \mathcal{M}(B)\colon \pi_B(b) \in \varphi(A)\}$ is stable by Corollary 5.5.16 and Remark 3.10.9(iii), we find a stable separable C^*-subalgebra C of $\mathcal{M}(B)$, such that $e \in C$ and $\pi_B(C) = \varphi(A)$.

Let $h := \varphi^{-1}\pi_B\colon C \to A$, then h is residually equivariant, because $h(C \cap \mathcal{M}(B,J)) \subseteq \Psi_A(J)$, by (ii), because $\pi_B\,(C \cap \mathcal{M}(B,J)) \subset \varphi(A) \cap \pi_B(\mathcal{M}(B,J)) = \varphi(\Psi_A(J))$.

Thus, $T := H_0 \circ h$ is a non-degenerate weakly residually nuclear C^*-morphism from C into $\mathcal{M}(B)$.

By Theorem 5.9.3, there exists an isometry S in $\mathcal{M}(B)$, such that $S^*cS - T(c) \in B$ for $c \in C$. This means that φ dominates $h_0 := \pi_B \circ H_0$.

Let $a \in A_+$ and $\varepsilon > 0$. By Lemma 5.9.10, $(a-\varepsilon)_+$ is in $\Psi_A(J) = A \cap \mathcal{M}(B,J)$ for $J := \overline{\mathrm{span}(B(a-\varepsilon)_+B)}$. By condition (ii), $\varphi((a-\varepsilon)_+) \subseteq \pi_B(\mathcal{M}(B,J))$.

On the other hand, again by Lemma 5.9.10, $\mathcal{M}(B,J)$ is contained in the norm-closed ideal of $\mathcal{M}(B)$ that is generated by $H_0(a) = \delta_\infty(a)$. Thus, $\varphi((a-\varepsilon)_+)$ is contained in the closed ideal of $\mathrm{Q^s}(B)$, that is generated by $h_0(a)$.

If follows that, for every closed ideal I of A, $\varphi(I)$ is contained in the ideal of $\mathrm{Q^s}(B)$ that is generated by $h_0(I)$. Since $h_0 \oplus\ h_0$ is unitarily equivalent to h_0, and since φ is nuclear, it follows that h_0 approximately dominates φ by Corollary 3.10.8(ii). The C^*-algebra $\pi_B^{-1}(h_0(A)) = \delta_\infty(A) + B$ is stable, because $\delta_\infty(A)$ is stable and is a *non-degenerate* C^*-subalgebra. The commutant $h_0(A)' \cap \mathrm{Q^s}(B)$

contains a copy of $\mathcal{O}_\infty = C^*(s_1, s_2, \dots)$ unitally, because $\delta_\infty(A)' \cap \mathcal{M}(B)$ contains a copy of $\mathcal{O}_\infty = C^*(s_1, s_2, \ldots)$ unitally by Lemma 5.1.2(i). If $c_1, c_2, \ldots$ is a sequence of contractions in $\mathrm{Q}^{\mathrm{s}}(B)$ such that $\| c_n^* h_0(a) c_n - \varphi(a) \| \to 0$, then $d_n := s_n c_n$ satisfy the assumptions (i) and (ii) of Lemma 5.9.6 (for $h_0(A)$ and φ in place of A and V there). By Lemma 5.9.6 there exists an isometry $T \in \mathcal{M}(B)$ such that $\pi_B(T)^* h_0(\cdot) \pi_B(T) = \varphi$. Thus $a \mapsto T^* \delta_\infty(a) T$ is a Ψ_A residually nuclear lift of φ. Thus $[\varphi] \in G\big(h_0;\, A, Q^s(B)\big)$. I.e. $[\varphi]$ is the Busby invariant of an element in $\mathrm{Ext}_{\mathrm{nuc}}(\mathrm{Prim}(B);\, A, B)$. □

REMARK 5.9.12. Let $\mathcal{D}_\infty := \mathcal{O}_\infty \otimes \mathcal{O}_\infty \otimes \ldots$. (It is isomorphic to $\mathcal{O}_\infty$ by Corollary H, or by a result of Lin and Phillips [**531**].)

We consider $\psi_1 \colon a \in \mathcal{D}_\infty \to 1 \otimes a \in \mathcal{D}_\infty \otimes \mathcal{D}_\infty$ and an isomorphism ψ_2 from $\mathcal{D}_\infty$ onto $\mathcal{D}_\infty \otimes \mathcal{D}_\infty$. ($\psi_1$ and ψ_2 are unitarily homotopic by Corollary H.)

It holds $C \cong C \otimes \mathcal{D}_\infty$ for separable hereditary C^*-subalgebras C of $B \otimes \mathcal{D}_\infty$, cf. [**443**].

Suppose that A and B are separable, and that

$$0 \to B \otimes \mathcal{D}_\infty \to E \to A \otimes \mathcal{D}_\infty \to 0$$

is an extension. Then there exists an isomorphism λ from E onto $E \otimes \mathcal{D}_\infty$, cf. [**443**, chp. 8].

If A and B are stable then E is stable by Corollary 5.5.16, because $B \otimes \mathcal{D}_\infty$ is purely infinite.

QUESTION 5.9.13. Suppose that A and B are separable stable C^*-algebras and that

$$\varphi_1, \varphi_2 \in \mathrm{Hom}(A \otimes \mathcal{O}_\infty, \mathrm{Q}(B \otimes \mathcal{O}_\infty))$$

are (*not necessarily c.p. liftable*) Busby invariants, and suppose that φ_1 and φ_2 are unitarily homotopic (by unitaries in $\mathrm{Q}(B \otimes \mathcal{O}_\infty)$). Does it imply $\varphi_1 \approx \varphi_2$?

(Recall that $\varphi_1 \approx \varphi_2$ means the rather strong property that there is a unitary $u \in \mathcal{M}(B \otimes \mathcal{O}_\infty)$ with $\varphi_1(a) = \pi(u) \varphi_2(a) \pi(u^*)$ for all $a \in A \otimes \mathcal{O}_\infty$.

NEXT TRUE?:

The question has a positive answer, if - in addition - φ_1 has a completely positive lift. The latter is e.g. the case, if A is nuclear, cf. [**443**].)

`Collection/ to be sorted/ to be integrated: ??`

`next used in Chapter 8:`

The next lemma shows that the relation introduced by J. Cuntz for an alternative definition of Kasparov's $\mathrm{Ext}(A, B)$ also hold for our $\mathrm{Ext}(\mathcal{C};\, A, B)$ with obvious modifications.

LEMMA 5.9.14. *Suppose that A is separable and that B is σ-unital and stable, and that $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ is a point-norm closed matrix operator-convex cone.*

Let $\mathcal{S}$ denote the set of pairs (φ, p), where $\varphi\colon A \to \mathcal{M}(B)$ is a C^*-morphism with $b^*\varphi(\cdot)b \in \mathcal{C}$ for all $b \in B$ and $p \in \mathcal{M}(B)$ is a projection that satisfies $\varphi(a)p - p\varphi(a) \in B$ for all $a \in A$.

We denote by $[\mathcal{S}]$ the set of unitary equivalence classes $[(\varphi, p)]$ using unitaries in $\mathcal{M}(B)$. An element $(\varphi, p) \in \mathcal{S}$ is ***degenerate*** *if $p\varphi(a) = \varphi(a)p$ for all $a \in A$.*

(i) *$[\mathcal{S}]$ is a commutative semigroup (with Cuntz-Addition on maps and projections).*
(ii) *The map $[\varphi, p] \mapsto \pi_B(\varphi(\cdot)p) \in \mathrm{Hom}(A, \mathrm{Q}(B))$ defines an additive semigroup morphism ϑ from $[\mathcal{S}]$ onto $\mathrm{SExt}(\mathcal{C};\, A, B)$. The image of ϑ contains $[0] + \mathrm{SExt}(\mathcal{C}\,;\; A, B)$.*
(iii) *The map $\mathcal{S} \to \mathrm{Ext}(\mathcal{C};\, A, B)$ induces an equivalence relation $\sim$ on $\mathcal{S}$ that is compatible with Cuntz addition and is generated by the following operations and relations:*
   (a) *unitary equivalence by unitaries in $\mathcal{M}(B)$, i.e., $(\varphi, p) \sim (\psi, q)$ if there is a unitary $u \in \mathcal{M}(B)$ with $\psi = u^*\varphi(\cdot)u$ and $q = u^*pu$,*
   (b) *addition $(\varphi \oplus \psi, p \oplus q)$ of* degenerate *elements $(\psi, q) \in \mathcal{S}$ to elements $(\varphi, p) \in \mathcal{S}$, i.e., $(\varphi \oplus \psi, p \oplus q) \sim (\varphi, p)$, and*
   (c) *unitary perturbation: $(\varphi, p) \sim (\varphi, q)$ if there is $b^* = b \in \mathcal{M}(B)$ such that $\varphi(a)b - b\varphi(a) \in B$ and $(p - e^{-ib}qe^{ib})\varphi(a) \in B$ for all $a \in A$.*
(iv) *The natural semigroup morphism from $\mathrm{SExt}(\mathcal{C};\, A, B)$ into $\mathrm{Ext}(\mathcal{C};\, A, B)$ is an epimorphism.*
(v) *If $\mathcal{C}$ is countably generated and non-degenerate, and if $H\colon A \otimes \mathbb{K} \to \mathcal{M}(B)$ is as in Corollary 5.4.4, then the unitary equivalence classes $[(H, p)] \in [\mathcal{S}]$ build a sub-semigroup $[\mathcal{P}]$ of $[\mathcal{S}]$ such that ϑ maps $[\mathcal{P}]$ onto $\mathrm{Ext}(\mathcal{C}; A, B)$.*

Proof. Let $S, T \in \mathcal{M}(B)$ isometries with $SS^* + TT^* = 1$, and let $s := \pi_B(S) = S + B$ and $t := \pi_B(T) = T + B$ in $\mathrm{Q}(B) := \mathcal{M}(B)/B$.

(i): Unitary equivalence $(\varphi, p) \approx (\psi, q)$ for $(\varphi, p), (\psi, q) \in \mathcal{S}$ means that there is a unitary $U \in \mathcal{M}(B)$ with $\psi = U^*\varphi(\cdot)U$ and $q = U^*pU$. Now straight calculation shows that the Cuntz addition

$$(\varphi, p) \oplus (\psi, q) := (\varphi \oplus_{S,T} \psi, p \oplus_{S,T} q)$$

defines an operation on $\mathcal{S}$. It is associative and commutative on the set $[\mathcal{S}]$ of unitary equivalence classes $[\varphi, p]_\approx$ of elements $(\varphi, p) \in \mathcal{S}$, by Proposition 4.3.2.

(ii): The map

$$\gamma(\varphi, p)\colon a \in A \mapsto \pi_B(\varphi(a)p) \in \mathrm{Q}(B)$$

is a *-morphism from A into $\mathrm{Q}(B)$ if $(\varphi, p) \in \mathcal{S}$, and the c.p. map $V = p\varphi(\cdot)p \in \mathrm{CP}(A, \mathcal{M}(B))$ satisfies $b^*V(\cdot)b = (pb)^*\varphi(\cdot)pb \in \mathcal{C}$ for each $b \in B$, because $\psi(\cdot)$ is in the closure of $\mathcal{C}$ with respect to the strict topology (by definition of $\mathcal{S}$). Thus, $\gamma(\varphi, p)$ is in $\mathrm{Hom}_l(\mathcal{C};\, A, \mathrm{Q}(B))$ and defines an Element $[\gamma(\varphi, p)]$ of

$$\mathrm{SExt}(\mathcal{C}; A, B) := [\,\mathrm{Hom}_l(\mathcal{C};\, A, \mathrm{Q}(B))\,]\,.$$

Clearly, $\gamma(U^*\varphi(\cdot)U, U^*pU^*) = \pi_B(U)^*\gamma(\varphi, p)\pi_B(U)$ for unitary $U \in \mathcal{M}(B)$. One gets $[\gamma(\varphi\oplus\psi, p\oplus q)] = [\gamma(\varphi, p)] + [\gamma(\psi, q)]$ in $\mathrm{SExt}(\mathcal{C};\, A, B)$ by straight calculation. We define $\vartheta\colon [\mathcal{S}] \to \mathrm{SExt}(\mathcal{C}; A, B)$ by

$$\vartheta([(\varphi, p)]_{\approx}) := [\gamma(\varphi, p)]\,.$$

If $\rho \in \mathrm{Hom}_l(\mathcal{C};\, A, \mathrm{Q}(B))$, then there is a c.p. contraction $V\colon A \to \mathcal{M}(B)$ with $b^*V(\cdot)b \in \mathcal{C}$ for all $b \in B$ (by definition of $\mathrm{Hom}_l(\mathcal{C};\, A, \mathrm{Q}(B))$). By Lemma 3.6.24, there is a *-morphism $\psi\colon A \to \mathcal{M}(B)$ with $b^*\psi(\cdot)b \in \mathcal{C}$ and isometries $s_1, t_1 \in \mathcal{M}(B)$ such that $t_1^*\psi(\cdot)t_1 = V$ and $s_1s_1^* + t_1t_1^* = 1$. Let $U := s_1S^* + t_1T^*$, $\varphi(\cdot) := U^*\psi(\cdot)U$ and $p := SS^*$. Then $(\varphi, p) \in \mathcal{S}$ and $0 \oplus_{s,t} \rho = \gamma(\varphi, p)$. Thus $[0] + \mathrm{SExt}(\mathcal{C};\, A, B) \subseteq \vartheta([\mathcal{S}])$.

(iii) +(iv): Recall that $\mathrm{Ext}(\mathcal{C};\, A, B) := \mathrm{Gr}(\mathrm{SExt}(\mathcal{C}; A, B))$ is the Grothendieck group of the semigroup of unitary equivalence classes of morphisms $\rho \in \mathrm{Hom}_l(\mathcal{C};\, A, \mathrm{Q}(B))$ *by unitaries* $u = \pi_B(U)$ *for unitaries* U *in* $M(B)$.

Let $(\varphi, p) \in \mathcal{S}$, $q \in \mathcal{M}(B)$ a projection and $U \in \mathcal{M}(B)$ a unitary with $(p - q)\varphi(A) \subseteq B$, respectively with $U\varphi(a) - \varphi(a)U \in B$ for all $a \in A$. Then (φ, q) and (φ, U^*pU) are in $\mathcal{S}$, i.e., $q\varphi(a) - \varphi(a)q \in B$ and $U^*pU\varphi(a) - \varphi(a)U^*pU \in B$ for all $a \in A$. Moreover, $\gamma(\varphi, p) = \gamma(\varphi, q)$ and $\pi_B(U)^*\gamma(\varphi, p)\pi_B(U) = \gamma(\varphi, U^*pU)$ in $\mathrm{Hom}_l(\mathcal{C}; A, \mathrm{Q}(B))$. Thus, the relations (a) and (c) on $\mathcal{S}$ are stronger (or equal) to the relation on $\mathcal{S}$ induced by $\vartheta\colon [\mathcal{S}] \to \mathrm{SExt}(\mathcal{C}; A, B)$.

If $(\varphi, p) \in \mathcal{S}$ is degenerate, then $\psi := \delta_\infty \circ \varphi$ and $q := \delta_\infty(p)$ ([23]) satisfy $b^*\psi(\cdot)b \in \mathcal{C}$ for all $b \in B$ and $q\psi(a) = \psi(a)q$ for all $a \in A$. Thus $(\psi, q) \in \mathcal{S}$. Since $\mathrm{K}_*(\mathcal{M}(B)) = 0$ and $s_1^*s_2 = 0$, it follows from Lemma 4.2.6(ii) that there is an isometry $R \in \mathcal{M}(B)$ with $RR^* = 1 - s_1s_1^*$. More explicitly the series $\sum s_{n+1}s_n^*$ converges strictly in $\mathcal{M}(B)$ to an element $R := \sum s_{n+1}s_n^*$ of $\mathcal{M}(B)$ by Remark 5.1.1(2). The element R is an isometry in $\mathcal{M}(B)$ with $RR^* = 1 - s_1s_1^*$ and $Rs_n = s_{n+1}$ for $n = 1, 2, \ldots$.

Then $U := Ss_n^* + TR^*$ is unitary, $U^*(\varphi \oplus_{S,T} \psi)U = \psi$ and $U^*(p \oplus_{S,T} q)U = q$, i.e., $\vartheta([\varphi, p]) + \vartheta([\psi, q]) = \vartheta([\psi, q])$ in $\mathrm{SExt}(\mathcal{C}; A, B)$. Thus, $[\vartheta([\varphi, p])] = 0$ in $\mathrm{Ext}(\mathcal{C}; A, B)$ if (φ, p) is a degenerate element in $\mathcal{S}$. It implies that $(\varphi_1, p_1) \oplus_{S,T} (\varphi, p)$ and (φ_1, p_1) define the same class in $\mathrm{Ext}(\mathcal{C}; A, B)$ for all $(\varphi_1, p_1) \in \mathcal{S}$ if (φ, p) is degenerate.

It follows that the equivalence relation $(\varphi, p) \sim (\psi, q)$ on $\mathcal{S}$ defined by the operations (a), (b) and (c) is stronger or equal to the equivalence relation $(\varphi, p) \sim (\psi, q)$ defined by $[\vartheta([\varphi, p])] = [\vartheta([\psi, q])]$ in $\mathrm{Ext}(\mathcal{C}; A, B)$. If we consider the semigroup $[\mathcal{S}]$ then (a) becomes equality and (b) describes there addition by elements in the sub-semigroup $\mathcal{D}$ of $[\mathcal{S}]$ of unitary equivalence classes of degenerate elements. Thus, relation (b) is compatible with Cuntz addition on $[\mathcal{S}]$. Straight calculations show that also relation (c) is compatible with Cuntz addition on $[\mathcal{S}]$. It follows that the

[23] Here $\delta_\infty\colon \mathcal{M}(B) \to \mathcal{M}(B)$ is defined by a sequence of isometries $s_1, s_2, \ldots \in \mathcal{M}(B)$ with strictly converging sum $\sum s_ns_n^* = 1$, as considered in Remark 5.1.1(8) and Lemma 5.1.2.

relation $\sim$ – coming from (a), (b), (c) – defines on $[\mathcal{S}]$ an equivalence relation that is compatible with addition and that $[(\varphi, p)] \sim [(\psi, q)]$ implies $[(\varphi, p)] \sim_c [(\psi, q)]$.

To see that $\sim_c$ is equal to $\sim$, it suffices now to show that $[\mathcal{S}]/\sim$ is a group and that $\vartheta([\varphi, p]) = \vartheta([\psi, q])$ implies $(\varphi, p) \sim (\psi, q)$.

We show first that $\vartheta([\varphi, p]) = \vartheta([\psi, q])$ implies $(\varphi, p) \sim (\psi, q)$, which is the crucial and most involved part of the whole proof:

By definition of ϑ and of the equivalence classes $[\mathrm{Hom}_l(\mathcal{C}; A, \mathrm{Q}(B))]$, there is a unitary $U \in \mathcal{M}(B)$ such that $\gamma(\varphi, p) = \gamma(U^*\psi(\cdot)U, U^*qU)$. Since $(U^*\psi(\cdot)U, U^*qU) \sim (\psi, q)$ by relation (a). We may rename $U^*\psi(\cdot)U$ and U^*qU by ψ respectively by q.

Thus we have to study the implication of the property

$$\varphi(a)p - \psi(a)q \in B \quad \forall\, a \in A\,.$$

Let $\rho := (\varphi \oplus \psi) \oplus 0$, $p' := (p \oplus 0) \oplus 0$, $q' := (0 \oplus q) \oplus 0$, $V := S(ST^* + TS^*)S^* \oplus TT^*$. Then $\rho(\cdot)T = 0$, i.e., ρ dominates zero, $(\rho, p') \sim (\varphi, p)$ and $(\rho, q') \sim (\psi, q)$ by relation (b), and $\rho(a)p' - V^*\rho(a)q'V \in B$ for all $a \in A$. Let $s_1, s_2, \ldots \in \mathcal{M}(B)$ a sequence of isometries with $\sum s_n s_n^* = 1$, and let $\lambda := \delta_\infty \circ \rho$, $p'' := s_1 p' s_1^*$, $q'' = s_1 q' s_1^*$ and $W := \delta_\infty(V)$. It holds $(\lambda, p'') \sim (\rho, p')$, $(\lambda, q'') \sim (\rho, q')$, and $\lambda(a)p'' - W^*\lambda(a)q''W \in B$ for $a \in A$. Moreover, $\lambda(\cdot)$ dominates zero, the algebra $C^*(\lambda(A), W)$ is contained in $\delta_\infty(\mathcal{M}(B))$ and there is a copy $C^*(S_1, T_1) \cong \mathcal{O}_2$ unitally contained in $\delta_\infty(\mathcal{M}(B))' \cap \mathcal{M}(B)$, cf. Remark 5.1.1(8).

It follows that Lemma 4.6.11 applies to $D := A$, $E := \mathrm{Q}(B)$, $h := \pi_B \circ \lambda$, the unitary $\pi_B(W)$, and the projections $p_1 := \pi_B(p'')$, $q_1 := \pi_B(q'')$, because $\mathrm{K}_*(\mathcal{M}(B)) = 0$ by Lemma 5.5.9(i):
We get the existence of $u \in \mathcal{U}_0(h(A)' \cap \mathrm{Q}(B))$ with $u^*(p_1 \oplus 1 \oplus 0)u = (q_1 \oplus 1 \oplus 0)$ with Cuntz addition $\oplus$ taken with respect to the generators $s_1 := \pi_B(S_1)$ and $t_1 := \pi_B(T_1)$ of a unital copy of $\mathcal{O}_2$ in $\pi_B(\lambda(A)' \cap \mathcal{M}(B)) \subseteq h(A)' \cap \mathrm{Q}(B)$. It follows that there are self-adjoint $h_1, h_2, \ldots, h_m \in \mathcal{M}(B)$ with $h_k\lambda(a) - \lambda(a)h_k \in B$ for $k = 1, \ldots, m$ such that $u = \pi_B(U)$ for $U := e^{ih_1} \cdot \ldots \cdot e^{ih_m}$.

Note that $\lambda \oplus_{S_1,T_1} \lambda = \lambda$. Thus $(\lambda, p'') \sim (\lambda, p'' \oplus 1 \oplus 0) = (\lambda, p'') \oplus (\lambda, 1 \oplus 0)$ and $(\lambda, q'') \sim (\lambda, q'' \oplus 1 \oplus 0)$. Let $p_2 := p'' \oplus 1 \oplus 0$ and $q_2 := q'' \oplus 1 \oplus 0$, then $U^*p_2U - q_2 \in B$.

The equivalence relation $\approx_{(c)}$ generated by (c) is stronger than $\sim$ and yields that $(\lambda, p_2) \approx_{(c)} (\lambda, q_2)$ if there are selfadjoint $h_1, \ldots, h_m \in \mathcal{M}(B)$ with $h_k\lambda(a) - \lambda(a)h_k \in B$ for $k = 1, \ldots, m$ and $U^*p_2U - q_2 \in B$ for $U := e^{h_1} \cdot \ldots \cdot e^{h_m}$.
All together shows that $(\varphi, p) \sim (\psi, q)$.

We check that $[\mathcal{S}]/\sim$ is a group:
For $(\varphi, p) \in \mathcal{S}$, the element $(\varphi, 1 - p)$ is in $\mathcal{S}$ and

$$(\varphi, 1 - p) \oplus (\varphi, p) \sim (\varphi, 1) \oplus (\varphi, 0) \sim (0, 0)\,.$$

This is because $[u, \varphi(a) \oplus_{s,t} \varphi(a)] \in B$ for all $a \in A$ and $u^*(1 \oplus 0)u = (1-p) \oplus p$, where $u := \exp(iH) = s(1-p)s^* + t(1-p)t^* + spt^* - tps^*$ for $H := i(\pi/2)(tps^* - spt^*)$ (respectively with $z = s(1-p)s^* + spt^*$) in (iii,b) ([24]). It follows that the natural image of the semi-group $\mathrm{SExt}(\mathcal{C};\, A, B)$ in $\mathrm{Ext}(\mathcal{C};\, A, B)$ is a group, because the image of $\vartheta\colon [\mathcal{S}] \to \mathrm{SExt}(\mathcal{C};\, A, B)$ contains $[0] + \mathrm{SExt}(\mathcal{C};\, A, B)$ by part (ii) and because $[0] + [0] = [0]$.

If we combine this with the observation that the image of $\mathrm{SExt}(\mathcal{C};\, A, B)$ generates $\mathrm{Ext}(\mathcal{C};\, A, B)$, then we get that the natural semigroup morphism from $\mathrm{SExt}(\mathcal{C};\, A, B)$ into $\mathrm{Ext}(\mathcal{C};\, A, B)$ is a semigroup epimorphism.

(v): Suppose that $\mathcal{C}$ is countably generated and that $h_0\colon A \to \mathrm{Q}(B)$ is defined as in Corollary 5.4.9. If $(\varphi, p) \in \mathcal{S}$, then there is a unitary $u \in \mathcal{M}(B)$ and a projection $q \in \mathcal{M}(B)$ such that $u^*(H(a) \oplus 0)qu - \varphi(a)p \in B$ for all $a \in A$, cf. Corollary 5.4.9(ii). Since there is a suitable copy of $\mathcal{O}_2 = C^*(S_1, T_1)$ unitally contained in $(H \oplus 0)(A)' \cap \cap \mathcal{M}(B)$, it follows that the elements $(H \oplus 0, q)$ build a sub-semigroup of $\mathcal{S}$ under Cuntz-addition. □

next.ref: cor:5.X1.chp12 ??

Corollary 5.9.15. *Let A and B stable and separable C^*-algebras and let $\Psi\colon \mathcal{I}(B) \to \mathcal{I}(A)$ a lower semi-continuous action of* Prim(B) *on A, such that $\Psi(0) = 0$ and $\Psi^{-1}(A) = \{B\}$.*

*Suppose that there exists a non-degenerate weakly Ψ-residually nuclear *-monomorphism $H_0\colon A \to \mathcal{M}(B)$, such that $\delta_\infty \circ H_0$ is unitarily equivalent to H_0, and, for each $J \in \mathcal{I}(B)$,*

$$\Psi(J) = H_0^{-1}(H_0(A) \cap \mathcal{M}(B, J)) \,.$$

Then the H_0 with this properties is uniquely determined up to unitary homotopy.

Proof. Let $\mathcal{C}(H_0) \subseteq \mathrm{CP}(A, B)$ the point-norm closed m.o.c. cone generated by the maps $a \in A \mapsto b^* H_0(a) b$.

Then $\mathcal{C}(H_0)$ is contained in the m.o.c. cone $\mathcal{C}_{\mathrm{nuc}}(\Psi)$ of all Ψ-residually nuclear c.p. maps $V\colon A \to B$ with $V(\Psi(J)) \subseteq J$ for all $J \in \mathcal{I}(B)$ and $[V]\colon A/\Psi(J) \to B/J$ is nuclear.

But, by assumptions, for each $J \in \mathcal{I}(B)$,

$$\Psi(J) = H_0^{-1}(H_0(A) \cap \mathcal{M}(B, J)) \,,$$

i.e., that $\mathcal{C}(H_0)$ is separating for the action Ψ.

By Corollary 3.9.1 this implies that the m.o.c. cone $\mathcal{C}(H_0)$ is identical with the m.o.c. cone of the – with respect to the l.s.c. action Ψ – residually nuclear c.p. maps.

[24] Use that $C^*(s(1-p)s^*, sps^*, tps^*)$ is naturally isomorphic to $\mathbb{C} \oplus M_2$.

If $H_1 \colon A \to \mathcal{M}(B)$ has the same properties as H_0, – i.e., $\delta_\infty \circ H_1$ is unitary equivalent to H_1 and, for each $J \in \mathcal{I}(B)$,

$$\Psi(J) = H_1^{-1}(H_1(A) \cap \mathcal{M}(B, J)),$$

and $[H_1] \colon A/\Psi(J) \to \mathcal{M}(B/J)$ is nuclear for every closed ideal J of B –, then this implies by Corollary 3.9.1 that the m.o.c. cone $\mathcal{C}(H_1)$ is again the m.o.c. cone of all Ψ-residually nuclear c.p. maps. Thus, $\mathcal{C}(H_0) = \mathcal{C}(H_1)$.

It implies that H_0 and H_1 are unitarily homotopic by Corollary 3.9.2. □

`Ref. to 5.9.16 still exists in Chp. 12!!`

Corollary 5.9.16. *Suppose that A is separable and B is σ-unital and stable.*

If $h_1, h_2 \colon A \to \mathcal{M}(B)$ are non-degenerate nuclear monomorphisms and define the same action of $\mathcal{I}(B)$ on A, then $\delta_\infty \circ h_1$ and $\delta_\infty \circ h_2$ are unitarily homotopic.

Chapter 12 asks also for a Corollary

`cor:5.?.same.lsc.action.gives.unitary.homotop`

that says that for stable σ-unital B the same l.s.c. action of $\mathrm{Prim}(B)$ on $C^*(b) \subset \mathcal{M}(B)$ and (– by pull-back also on $C^*(b)$ –) on $C^*(\lambda(b)) \subset \mathcal{M}(B)$ – for some C^*-morphism $\lambda \colon C^*(b) \to \mathcal{M}(B)$ implies that $\delta_\infty(b)$ and $\delta_\infty(\lambda(b))$ are unitary homotopic in $\mathcal{M}(B)$.

`Have the` h_k `same kernel` J?
`Seems to need/check still that the` $[h_k] \colon A/J \to \mathcal{M}(B)$
`is again nuclear!! Then it reduces to the residually nuclear case with exact` A/J.

The following elementary corollary allows to (in proofs of Chapter 6) the use of results on the generalized KK–theory $\mathrm{KK}_{\mathrm{nuc}}(X;\, A, B)$ (cf. Chapters 1 and 8). `next.ref: cor:5.lifting-criterium ?? Is needed that the action is monotonous upper s.c.?`

Corollary 5.9.17. *Suppose that A and B are separable and stable, that A is exact and that B has the WvN–property of Definition 1.2.3. Further suppose that $\psi \colon A \to \mathrm{Q}(B)$ is a nuclear C^*-morphism and $H \colon A \to \mathcal{M}(B)$ is a non-degenerate nuclear *-monomorphism. Furthermore suppose that, for $J \in \mathcal{I}(B)$,*

$$\psi\left(H^{-1}(H(A) \cap \mathcal{M}(B, J))\right) \in \pi_B(\mathcal{M}(B, J)).$$

Then $H_0 := \pi_B \circ \delta_\infty \circ H$ dominates ψ in $\mathrm{Hom}(A, \mathrm{Q}(B))$, i.e.,

$$[\psi] \in \mathrm{SExt}_{\mathrm{nuc}}(X\,;\; A, B) = S(H_0\,,\, A, \mathrm{Q}(B))$$

for the action of $X := Prim(B)$ on A given by

$$\Psi \colon J \in \mathcal{I}(B) \cong \mathbb{O}(X) \mapsto \Psi(J) := H^{-1}\left(H(A) \cap \mathcal{M}(B, J)\right),$$

and the semi-group $S(H_0; A, \mathrm{Q}(B)$ as defined in Chapter 4, Section 4.

If moreover

$$\psi^{-1}\left(\psi(A)\cap\pi_B(\mathcal{M}(B,J))\right) = H^{-1}\left(H(A)\cap\mathcal{M}(B,J)\right)$$

for $J\in\mathcal{I}(B)$, and if there exists a C^*-morphism $\varphi\colon A\otimes\mathcal{O}_2\to \mathrm{Q}(B)$ with $\psi(a)=\varphi(a\otimes 1)$ for $a\in A$, then there exists a unitary $U\in\mathcal{M}(B)$ such that $\pi_B(U^*\delta_\infty\circ H(a)U)=\psi(a)$ for $a\in A$.

next.ref: prop:5.char-Extnuc. needed? ??

Proposition 5.9.18. *Suppose that A and B are separable and stable, that A is exact and that B has the WvN–property (cf. Definition 1.2.3). Further let $\psi\colon A\to \mathrm{Q}(B)$ and $H\colon A\to\mathcal{M}(B)$ a weakly nuclear *-monomorphisms such that $BH(A)B$ generates B.*

Let $\Psi(J):=H^{-1}(H(A)\cap\mathcal{M}(B,J))$ for $J\in\mathcal{I}(B)$, and $h_0:=\pi_B\circ\delta_\infty\circ H\colon A\to \mathrm{Q}(B)$.

Then:

Ψ is a lower semicontinuous action of $\mathrm{Prim}(B)$ on A (corresponding to H).

$$\mathrm{Ext}_{\mathrm{nuc}}(\mathrm{Prim}(B),A,B) = [h_0]+S(h_0;A,\mathrm{Q}(B))$$

$[\psi]\in[h_0]+S(h_0;A,\mathrm{Q}(B))$, if and only if, $\psi(A)\cap\pi_B(\mathcal{M}(B,I))=\psi(\Psi(I))$ for all $I\in\mathcal{I}(B)$.

The following Lemma allows to apply above to the asymptotic case.

next.ref:lem:asympt-absorbtion ??
Chp.7ref:lem:asympt-absorbtion.to.chp.7?
next: check if (1) and (2) are used in chp.7 !!

Lemma 5.9.19. (1) *If B is a C^*-algebra, then*

$$\pi_{SB}(\mathcal{M}(SB,SI))\cap\mathrm{Q}(\mathbb{R},B)=\mathrm{Q}(\mathbb{R},I)$$

for all $I\in\mathcal{I}(B)$, where $SB:=\mathrm{C}_0(\mathbb{R},B)$ and $SI:=\mathrm{C}_0(\mathbb{R},I)$.

(2) *Suppose that A is separable, B is σ-unital and stable, and $h_0\colon A\to B$ satisfies $[h_0]+[h_0]=[h_0\oplus h_0]=[h_0]$. Let $s_1,s_2,\ldots\in\mathcal{M}(B)$ a sequence of isometries such that $\sum s_ns_n^*$ converges strictly to 1 in $\mathcal{M}(B)$, and let $H:=\delta_\infty\circ h_0$ – e.g. realized by $s_1,s_2,\ldots$. Denote by $H_{\mathbb{R}}(a):=\eta(H(a))$, where $\eta\colon\mathcal{M}(B)\to\mathcal{M}(SB)$ denotes the natural embedding that extends the inclusion map $B\subset\mathrm{C_b}(\mathbb{R},B)\subset\mathcal{M}(SB)$.*

If $H_{\mathbb{R}}$ dominates $k\colon A\to\mathrm{Q}(\mathbb{R},I)$ then h_0 dominates k.

Proof. (1): Let $b\in\mathcal{M}(SB,SI))$ and $c\in\mathrm{C_b}(\mathbb{R},B)\supset SB:=\mathrm{C}_0(\mathbb{R},B)$ with $b+SB=c+SB$. There is $a\in SB$ with $b=c+a\in\mathrm{C_b}(\mathbb{R},B)$. Thus $b(t)\in B\cap\mathcal{M}(B,I)=I$ for $t\in\mathbb{R}$, i.e., $b\in\mathrm{C_b}(\mathbb{R},I)$. Since $\mathrm{C_b}(\mathbb{R},I)\cap SB=SI$ it follows $b+SB\in\mathrm{Q}(\mathbb{R},I)\cong\pi_{SB}(\mathrm{C_b}(\mathbb{R},I))$.

(2): Let $d \in \mathcal{M}(SB)$ a contraction with $\pi_{SB}(d^* H^{\mathbb{R}} d) = k$. By assumption, there is a unitary $u \in \mathcal{M}(B)$ with $u^* s_1 h_0(\cdot) s_1^* u + u^* s_2 h_0(\cdot) s_2^* u = h_0$, and $H = \sum_n s_n h_0(\cdot) s_n^*$. Let $t_n = (u^* s_1)^n u^* s_2$. Then $t_n^* t_m = \delta_{n,m} 1$ and $t_n h_0(\cdot) = h_0(\cdot) t_n$.

There exists a positive contraction $e \in \mathrm{C_b}(\mathbb{R}, B)$ and a strictly increasing continuous function $\mu\colon \mathbb{R}_+ \to (0, \infty)$ with $e(t) \leq \sum_{n=1}^{k} s_n s_n^*$ for $k \geq \mu(t)$, $ed - de \in SB$, $H_{\mathbb{R}}(a) e - e H_{\mathbb{R}}(a) \in SB$ for all $a \in A$ and $\pi_{SB}(e) k(a) = k(a) = k(a) \pi_{SB}(e)$ for all $a \in A$. This can be seen with help of a convex commutative approximate unit of B, that approximately commutes with the elements of $H(A)$, $s_1, s_2, \ldots$, $\widetilde{k}(A)_t$ $(t \in [-n, n])$ $d|[-n, n]$. Here $\widetilde{k}\colon A \to \mathrm{C_b}(\mathbb{R}, B)$ is some continuous topological (not necessarily linear) lift of the C^*-morphism $k\colon A \to \mathrm{C_b}(\mathbb{R}, B)/SB$. Then $t \mapsto g(t) := \sum_{1 \leq n \leq [\mu(t)]+1} t_n s_n^* e(t) d(t) e(t)$ is a norm-continuous map from $\mathbb{R}$ into the contractions of B. It satisfies $g^* h_0(a) g - d^* H_{\mathbb{R}}(a) d \in SB$ for all $a \in A$, because $e^2 d^* H_{\mathbb{R}}(a) d e^2 - d^* H^{\mathbb{R}} d \in SB$.

ref {cor:5.Y?1.chp9} (??) needed in this generality??

COROLLARY 5.9.22. *Suppose that A and B are stable, A is separable and B is σ-unital. Let $\mathcal{C} \subseteq \mathrm{CP}(A,B)$ a countably generated non-degenerate operator convex cone, and $H_0\colon A \to \mathcal{M}(B)$ the non-degenerate C*-morphism described in Corollary 5.4.4. If Y is a locally compact space, let $H_Y := \pi_{\mathrm{C}_0(Y,B)} \circ \epsilon_X \circ H_0$ and $E_Y := \mathcal{M}(\mathrm{C}_0(Y,B))/\,\mathrm{C}_0(Y,B)$, where $\epsilon_X\colon \mathcal{M}(B) \to \mathcal{M}(\mathrm{C}_0(Y,B))$ is the natural strictly continuous embedding of $\mathcal{M}(B)$ into $\mathcal{M}(\mathrm{C}_0(Y,B)) \cong \mathrm{C}_{\mathrm{b,st}}(Y,\mathcal{M}(B))$.*

Then:

(i)

$$\mathrm{Ext}(\mathcal{C} \otimes \mathrm{CP}(\mathbb{C},\mathrm{C}_0(Y));\, A, \mathrm{C}_0(Y,B)) = G(H_Y\,,\, A, E_Y) =: F(\mathcal{C},Y)\,.$$

In particular,

$$\mathrm{Ext}(\mathcal{C} \otimes \mathrm{CP}(\mathbb{C},\mathrm{C}_0(\mathbb{R})); A, SB) = G(H_{\mathbb{R}}\,,\, A, E_{\mathbb{R}}) =: F(\mathcal{C},\mathbb{R})$$

for the above defined $H_{\mathbb{R}}\colon A \to E_{\mathbb{R}}$.

(ii) *In particular, if X is a T_0 space that acts on A and B by Ψ_A respectively Ψ_B, and if H_0 (and then $H_{\mathbb{R}}$) is formed with respect to the cone of Ψ_A-Ψ_B–residually nuclear maps from A into B, then*

$$\mathrm{Ext}_{\mathrm{nuc}}(X;\, A, SB) = G(H_{\mathbb{R}}, A, E_{\mathbb{R}})\,.$$

(iii) *If $H_0\colon A \to \mathcal{M}(B)$ is the infinite repeat of a non-degenerate $h_0\colon A \to B$ with $h_0 \oplus h_0 \cong h_0$, then $H_{\mathbb{R}}$ dominates $h_0\colon A \to \mathrm{Q}(\mathbb{R}_+, B) \subset E_{\mathbb{R}} := \mathrm{Q}(SB)$. Every element $h \in S(h_0; A, E_{\mathbb{R}})$ is also in $S(H_{\mathbb{R}}; A, E_{\mathbb{R}})$ and $[h \oplus H_0] \in G(H_{\mathbb{R}}, A, E_{\mathbb{R}})$.*

(iv) *In particular, if A is exact and h_0 is nuclear, then for $h\colon A \to \mathrm{Q}(\mathbb{R}_+, B)$ holds $[h \oplus H_0] \in \mathrm{Ext}_{\mathrm{nuc}}(X;\, A, SB)$ if and only if $[h] \in S(h_0, A, E_{\mathbb{R}})$. (Here the action of $X := \mathrm{Prim}(B)$ on A is defined by h_0.)*

We have e.g. $E_{\mathbb{R}} := \mathcal{M}(SB)/SB$ if B is stable $SB := \mathrm{C}_0(\mathbb{R}, B)$.

`next: ref: cor:5.Y5.chp9`

COROLLARY 5.9.23. *Suppose that D is separable and stable, B is σ-unital and stable, and that $k_0\colon D \to B$ is a non-degenerate *-monomorphism such that $k_0 \oplus k_0$ is unitarily homotopic to k_0.*

Let $\mathcal{C} \subseteq \mathrm{CP}(D,B)$ denote the point-norm closed m.o.c. cone of c.p. maps generated by k_0. Let $\mathcal{C}(\mathbb{R}) := \mathcal{C} \otimes \mathrm{CP}(\mathbb{C}, C_0(\mathbb{R}))$.

*We define a *-monomorphism*

$$H_0 := \delta_\infty \circ k_0\colon D \to \mathcal{M}(B).$$

Let $H_{\mathbb{R}} := IH_0\colon D \to E_{\mathbb{R}} := \mathrm{Q}(SB)$, where $I\colon \mathcal{M}(B) \to \mathrm{Q}(SB)$ is the natural embedding.

Then

$$\mathrm{Ext}(\mathcal{C}(\mathbb{R})\,; D, SB) \cong G(H_{\mathbb{R}}; D, E_{\mathbb{R}}).$$

If D is exact, we have moreover,

$$\mathrm{Ext}_{\mathrm{nuc}}(X; D, SB) = G(H_{\mathbb{R}}, D, E_{\mathbb{R}}) = [H_{\mathbb{R}}] + [\mathrm{Hom}_{\mathrm{nuc}}(X; D, E_{\mathbb{R}})]$$

for $X := \mathrm{Prim}(B)$ *and action* $\Psi_D(J) := k_0^{-1}(k_0(D) \cap J)$ *for* $J \in \mathcal{I}(B) \cong \mathbb{O}(\mathrm{Prim}(B))$.

Let A and B stable C^*-algebras, where A is separable and B is σ-unital. Suppose that the operator convex cone $\mathcal{C}_{\mathrm{rn}}(\Psi_A)$ of all Ψ-residually nuclear maps from A to B for a given lower semi-continuous action $\Psi_A \colon \mathbb{O}(\mathrm{Prim}(B)) \cong \mathcal{I}(B) \to \mathcal{I}(A)$ of $\mathrm{Prim}(B)$ on A is countably generated (as e.g. in the case of separable B).

The universal C^*-morphism $H_{\mathrm{rn}} \colon A \to \mathcal{M}(B)$, that is determined (and defined) by m.o.c. cone $\mathcal{C}_{\mathrm{rn}}(\Psi_A) := \mathcal{C}_{\mathrm{rn}}(\Psi_A, \mathrm{id}; A, B)$ in the sense of Corollary 5.4.4, will be called the **universal weakly residually nuclear map** from A into $\mathcal{M}(B)$.

Recall that H_{rn} is uniquely determined up to unitary homotopy by Corollary 5.4.4. It is now known that $\mathcal{C}_{\mathrm{rn}}(\Psi_A)$ – and therefore also H_{rn} – defines the action Ψ, because B has “weak Abelian separation” which is (formally ?) stronger than residually separation for B. But the proof of “weak Abelian separation” for B (which is a weaker property than the existence of an ideal-separating regular abelian C^*-subalgebra of B) deserves several steps, e.g. that every coherent Dini space X is the primitive ideal space of a separable nuclear C^*-algebra that has Abelian separation, and study some “almost minimal” embedding of of Dini spaces into coherent Dini spaces. It uses some results of this book, but can not summarized here.

PROPOSITION 5.9.24. *If B is stable and separable, then the universal residually nuclear map $H_{\mathrm{rn}} \colon B \to \mathcal{M}(B)$ exists for $\Psi_B = \mathrm{id}_{\mathcal{I}(B)}$.*

*Separable B has residually nuclear separation (cf. Definition 1.2.3), if and only if, H_{rn} is a non-degenerate *-monomorphism and $H_{\mathrm{rn}}(J) = H_{\mathrm{rn}}(B) \cap \mathcal{M}(B, J)$ for all $J \in \mathcal{I}(B)$.*

*If $B \neq \{0\}$ is simple separable and stable, then $H_{\mathrm{rn}} \colon B \to \mathcal{M}(B)$ is unitarily homotopic to $\mathcal{M}(\iota) \circ \rho$ for any non-degenerate *-morphism $\iota \colon \mathbb{K} \mapsto \mathcal{M}(B)$ and any non-degenerate *-representation $\rho \colon B \to \mathcal{L}(\ell_2) = \mathcal{M}(\mathbb{K})$.*

In particular, every *simple separable C^*-algebra has residually nuclear separation.*

PROOF. `to be filled in` ?? □

`Used in Chp.8, ref: prop:5.stabilty.of.Ext.Co :`

`Stability, (partial) Functoriality of` Ext?

PROPOSITION 5.9.25. *Suppose that A and B are σ-unital and that $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ is a point-norm closed m.o.c. cone.*

Then the inclusions $\iota_A \colon A \cong A \otimes p_{11} \subseteq A \otimes \mathbb{K}$ *and* $\iota_B \colon B \cong B \otimes p_{11} \subseteq B \otimes \mathbb{K}$ *induce* natural isomorphisms

$$i(A,B) \;:=\; (\iota_A)^* \colon \operatorname{Ext}(\mathcal{C};\, A \otimes \mathbb{K}, B) \to \operatorname{Ext}(\mathcal{C};\, A, B) \qquad (9.1)$$

$$j(A,B) \;:=\; (\iota_B)_* \colon \operatorname{Ext}(\mathcal{C};\, A, B) \to \operatorname{Ext}(\mathcal{C};\, A, B \otimes \mathbb{K})\,, \qquad (9.2)$$

such that $(\iota_B)_* \circ ((\iota_A)^*)^{-1} = ((\iota_A)^*)^{-1} \circ (\iota_B)_*$ *in the sense*

$$j(A \otimes \mathbb{K}, B) \circ i(A,B) = i(A, B \otimes \mathbb{K}) \circ j(A,B)\,.$$

If, moreover, $\mathcal{C} \subseteq \operatorname{CP}(A,B)$ *is countably generated,* A, A' *are separable,* B, C *are* σ*-unital, then* $\psi \in \operatorname{Hom}(B,C)$*, then there is group morphism*

$$\psi_* \colon \operatorname{Ext}(\mathcal{C};\, A, B) \to \operatorname{Ext}(\mathcal{C}(\psi) \circ \mathcal{C};\, A, C)\,.$$

*A *-morphism* $\varphi \in \operatorname{Hom}(A', A)$ *defines a group morphism*

$$\varphi_* \colon \operatorname{Ext}(\mathcal{C};\, A, B) \to \operatorname{Ext}(\mathcal{C} \circ \varphi; A', B)\,.$$

Proof. **??**

This was outlined in a proof of the corresponding (non-nuclear) Proposition [**73**, 17.6.5]. Note here that the stabilization of any relation that contain at least the (unitary) isomorphisms, automatically allows in the class of each representative also the Cuntz addition of so-called "degenerate" pairs, which can be defined as those with the property that their infinite Hilbert B-module sum defines again a $\mathcal{C}$-compatible Kasparov module. Therefore they have no significance for us, because we pass anyway to the stabilized relations, i.e., to the Grothendieck group. □

`Split both Remarks into one ‘‘common Remark’’ and a Proposition`
`Change then all references to them!!!`

Remark 5.9.26. The reader should notice that in general the closed ideal $I(\delta_\infty(B))$ of $\mathcal{M}(B)$ generated by $\delta_\infty(B)$ for a separable *stable* C^*-algebra B is not identical with $\mathcal{M}(B)$ e.g. even for $B = \mathrm{C}_0(0,1] \otimes \mathbb{K}$, because $\mathcal{M}(B) \cong \mathrm{C}_{\mathrm{b,st}}(\mathbb{R}_+, \mathcal{M}(\mathbb{K}))$ is unital and 1 is not in the ideal J of $\mathrm{C}_{\mathrm{b,st}}(\mathbb{R}_+, \mathcal{M}(\mathbb{K}))$ that is generated by $\delta_\infty(\mathrm{C}_0((0,1], \mathbb{K}))$, because it is contained in the ideal generated by $\mathrm{C}_0([0,\infty)) \otimes 1$.

Following properties of σ-unital stable B are equivalent:

(i) $I(\delta_\infty(B)) = \mathcal{M}(B)$.
(ii) $\operatorname{Prim}(B)$ is quasi-compact.

`Equivalent to` $/(B)$ `quasi-compact?`

(iii) $B \otimes \mathcal{O}_2$ contains a full projection.

We can replace in (iii) $B \otimes \mathcal{O}_2$ by $B \otimes \mathcal{O}_\infty$, because $\mathcal{O}_\infty \subseteq \mathcal{O}_2$ (unital) and $\mathcal{O}_2 \subseteq \mathcal{O}_\infty$ (non-unital).

PROOF. Since $\mathcal{L}(\ell_2) \cong \mathcal{M}(\mathbb{K}) \subseteq \delta_\infty(B))' \cap \mathcal{M}(B)$ (by a strictly continuous unital monomorphism), $\delta_\infty(B)$ commutes with a unital copy of $\mathcal{O}_2 \cong C^*(t_1, t_2) \subseteq \mathcal{M}(\mathbb{K})$ and a sequence of isometries $s_1, s_2, \ldots \in \mathcal{M}(\mathbb{K})$ with $\sum_n s_n s_n^*$ strictly convergent to 1 and $t_i s_j = s_j t_i$, $t_i^* s_j = s_j t_i^*$. Let $e \in B_+$ a strictly positive contraction.
(i)⇒(ii): The element $\delta_\infty(e)$ is a strictly positive contraction for $B + \delta_\infty(B)$. And $\delta_\infty(e)$ is properly infinite because $\delta_\infty \circ \delta_\infty$ is unitarily equivalent to δ_∞. Thus, there are $\varepsilon > 0$, $X \in \mathcal{M}(B)$ with $X^* \delta_\infty((e-\varepsilon)_+)X = 1$. It follows that e is in the closed ideal $I((e-\varepsilon)_+)$ of B generated by $(e-\varepsilon)_+$, i.e., $B = I((e-\varepsilon)_+)$. Thus $\|\pi_J((e-\varepsilon)_+)\| = 0$ implies $J = B$ for closed ideals J of B, and $\|J + a\| \geq \varepsilon$ for all $J \neq B$. Since the set $Y_\varepsilon \subseteq \mathrm{Prim}(B)$ of primitive ideals J of B with $\|\pi_J(e)\| = \|J + e\| \geq \varepsilon$ is a quasi-compact G_δ-subset, of $\mathrm{Prim}(B)$, it follows that $\mathrm{Prim}(B) = Y_\varepsilon$ is quasi-compact.
(ii)⇒(iii): The algebra $B \otimes \mathcal{O}_2$ is (strongly) purely infinite by Corollary **??**. If $\mathrm{Prim}(B)$ is quasi-compact, then the purely infinite algebra $B \otimes \mathcal{O}_2$ has quasi-compact primitive ideal space $\mathrm{Prim}(B \otimes \mathcal{O}_2) \cong \mathrm{Prim}(B)$.

By Proposition 2.10.4 $B \otimes \mathcal{O}_2$ contains a full projection.
(iii)⇒(i): If $B \otimes \mathcal{O}_2$ contains a full projection p, then there is a non-degenerate C^*-morphism $h\colon \mathbb{K} \to B \otimes \mathcal{O}_2$.

Above we have seen that we can define by $\mu(b \otimes t_j) = \delta_\infty(b)t_j$ a *-monomorphism $\mu\colon B \otimes \mathcal{O}_2 \to \mathcal{M}(B)$ with $\mu(b \otimes 1) = \delta_\infty(b)$ and with $\delta_\infty \circ \mu = \mu$ (if we take new isometries $s_1, s_2, \ldots$ for the definition of the new infinite repeat δ_∞). It follows, $I(\delta_\infty(B)) = I(\mu(B \otimes \mathcal{O}_2)) = I(\mu \circ h(\mathbb{K}))$ in $\mathcal{M}(B)$. The morphism $\mu \circ h(\mathbb{K}) \subseteq \mathcal{M}(B)$ is non-degenerate, i.e., $\mathcal{M}(\mu \circ h)\colon \mathcal{M}(\mathbb{K}) \to \mathcal{M}(B)$ exists and is unital.

If we use the sequence $s_1, s_2, \ldots$, then $\delta_\infty(\mu \circ h(x)) = \mu \circ h(x)$ for each $x \in \mathbb{K}$. We find a sequence of isometries $r_1, r_2, \ldots$ in $\mathcal{M}(\mathbb{K})$ with $\sum_n r_n r_n^* = 1$ for the definition of $\delta_\infty\colon \mathbb{K} \to \mathcal{M}(\mathbb{K})$, then $\mathcal{M}(\mu \circ h) \circ \delta_\infty$ is unitarily equivalent to $\delta_\infty \circ \mu \circ h = \mu \circ h$ by Lemma 5.1.2(i), because there is a unitary $U \in \mathcal{M}(B)$ with $U^* \mathcal{M}(\mu \circ h)(r_n) = s_n$ and $U^* \mathcal{M}(\mu \circ h)(\cdot)U$ is strictly continuous. Thus, $I(\mu \circ h(\mathbb{K})) \supset \mathcal{M}(\mu \circ h)(I(\delta_\infty(\mathbb{K})))$. But there is an isometry $S \in \mathcal{M}(\mathbb{K}) \cong \mathcal{L}(\ell_2)$ with $SS^* = \delta_\infty(e_{1,1})$. It follows $1 \in I(\mu \circ h(\mathbb{K})) = I(\delta_\infty(B))$. □

`Compare next with Remark 5.9.26`

REMARK 5.9.27. We consider sometimes elements that are in the ideal generated by $\delta_\infty(B)$ in $\mathcal{M}(B)$, e.g. in some proofs of Chapters 2, 5, 6, 8 and 12. Therefore the following rather strong equivalent properties of the ideal of $\mathcal{M}(B)$ generated by $\delta_\infty(B)$ should be noticed. They show that some care is needed if one establish results with help of elements in the ideal generated by $\delta_\infty(B)$.

Suppose that B is stable, then the following are equivalent:

(a) The ideal $\mathcal{J}$ of $\mathcal{M}(B)$ generated by $\delta_\infty(B)$ is equal to $\mathcal{M}(B)$.
(b) B is σ-unital and prime(B) is quasi-compact.
(c) prime(B) quasi-compact.

(d) There exists a positive contraction $e \in B_+$ such that e is strictly positive and $f := (2e-1)_+$ is "full" in B – in the sense that f generates B as closed ideal –, and that there exists $a_1, \ldots, a_n \in B$ such that

$$g := 2e - (2e-1)_+ = \sum_{k=1}^{n} a_k^* f a_k \,.$$

If B contains a projection $p \in B$ that generates B as a closed ideal, then $\delta_\infty(p)$ is the range of an isometry in $\mathcal{M}(B)$. In particular, then B satisfies the property (a) and $B \cong pBp \otimes \mathbb{K}$.

If B is weakly purely infinite – in addition –, then property (a) implies that B contains a properly infinite projection that generates B as a closed ideal.

Compare proof that stable stable B
with simple $\mathcal{M}(B)/B$ is σ-unital.
Is this proof here applicable?

Proof. For the proof of the existence of a countable approximate unit consisting of contractions $0 \leq b_1 \leq b_2 \leq \cdots$ in B_+ from the existence of $e \in B_+$ and $d_1, \ldots, d_n \in \mathcal{M}(B)$ with $1 - \sum_{k=1}^{n} d_k^* \delta_\infty(e) d_k \in B$, see Chapter 2[Cor.2.1.7(i)?] or proof of Corollary 2.2.11 in case of simple B?

We remind the *definition* of **Dini functions** f on topological T_0 spaces X (by requiring that the generalized classical Lemma of Dini is valid for f):

The function f is lower semi-continuous, and satisfies the Lemma of Dini: *If g_τ is an upward directed net of non-negative lower semi-continuous functions on X that converges point-wise to f on X, then the net converges uniformly on X to f.*

An equivalent definition of bounded Dini functions is: The function f is non-negative, lower semi-continuous and, for every decreasing sequence $F_1 \supseteq F_2 \supseteq \cdots$ of closed subsets $F_n \in X$, holds $\sup f(\bigcap_n F_n) = \inf_n \sup f(F_n)$.

On sober topological T_0 spaces this is equivalent to saying that for each $t > 0$ the set $f^{-1}[t, \infty)$ is a quasi-compact subset of X. (Notice that it is always a G_δ subset of X).

The latter characterization implies that each Dini functions f on $\mathrm{prime}(B)$ is a generalized Gelfand transformations $N(b)\colon \mathrm{prime}(B) \to [0, \infty)$ where $N(b)(J) := \|b + J\| = \|\pi_J(b)\|$ of some $b \in B$, cf. [**447**] ([25]). This is fairly easy to see directly for stable weakly purely infinite C^*-algebras B.

Notice that $\mathrm{prime}(B) \supseteq \mathrm{Prim}(B)$ is the "point-wise completion" of $\mathrm{Prim}(B)$ because both have the same lattice of open subsets. The restriction of a Dini function on $\mathrm{prime}(B)$ to $\mathrm{Prim}(B)$ is again a Dini function, and each bounded Dini function f on $\mathrm{Prim}(B)$ is a generalized Gelfand transformation $N(b)$ by [**447**].

[25] Typo: Replace b by c in the last line of the proof of [**447**, lem.3.3]

(a)⇒(b): Since the (non-zero) elements of $\delta_\infty(B)$ are properly infinite inside the hereditary C^*-subalgebra D of $\mathcal{M}(B)$ generated by $\delta_\infty(B)$, – because $\mathcal{O}_2 \subset \mathcal{M}(\mathbb{K}) \subseteq \delta_\infty(B)' \cap \mathcal{M}(B)$ – there exists a contraction $b \in B_+$ and an operator $T \in \mathcal{M}(B)$ with $T^*\delta_\infty(b)T = 1$.

It follows that there exists $\gamma > 0$ and $S \in \mathcal{M}(B)$ such that $S^*T^*\delta_\infty((b - \gamma)_+)TS = 1$. That implies that $c := (b-\gamma)_+$ generates B as a closed ideal. Thus $\|\pi_J(c)\| > 0$ for all closed ideals of B.

Let $e := \gamma^{-1}(b - (b-\gamma)_+)$. Then $\|e\| \leq 1$ and $ec = c$. It follows $\|\pi_J(e)\| \cdot \|\pi_J(c)\| = \|\pi_J(e)\| > 0$ for every closed ideal $J \neq B$. Thus the function $1 = N(e)$ is a Dini function on prime(B). It implies that prime(B) is quasi-compact (by definition of the Dini functions).

(c)⇒(b): prime(B) is quasi-compact, because $\|\pi_J(g)\| = 1$ for all $J \lhd B$ with $J \neq B$ follows from $gf = f$ and $\|\pi_J(f)\| > 0$ for all $J \lhd B$, $J \neq B$.

(b)⇒(c): The definition of Dini functions implies: prime(B) is quasi-compact, if and only if 1 is a Dini function on prime(B).

Since 1 is the point-wise supremum of the norm functions $N(b)(J) := \|b+J\| = \|\pi_J(b)\|$ (for $J \in$ prime(B)) on prime(B), where $b \in B_+$ with $\|b\| < 1$ and since the positive elements in the open unit ball of B build an upward directed family, the net of this functions $N(b)$ converges point-wise to 1. Since 1 is Dini, it follows that the net converges uniformly to 1. In particular, there exists a contraction $b \in B_+$ with $\|\pi_J(b)\| > 2/3$ for all closed ideals $J \neq B$ of B. Let $a := \min(2b, 1) = 2b - (2b-1)_+$. Then $\|\pi_J(a)\| = 1$ for all closed ideals $J \neq B$ of B.

Indeed: Clearly $0 \leq a$ and $\|a\| \leq 1$. Take a character χ on $C^*(\pi_J(b))$ with $\chi(\pi_J(b)) = \|\pi_J(b)\| > 2/3$. Then $\chi((2\pi_J(b) - 1)_+) = 2\chi(\pi_J(b)) - 1 > 0$ and $\chi(\pi_J(a)) = 2\chi(\pi_J(b)) - (2\chi(\pi_J(b)) - 1)_+ = 1$. Thus, $\|\pi_J(a)\| = 1$.

It follows that ???? and $\|\pi_J(4(a - 1/4)_+)\| = 1$ for all $J \lhd B$ with $J \neq B$.

This implies that $(a - 1/4)_+$ is again full in B and that there exists $n \in \mathbb{N}$ and $d_1, \ldots, d_n \in B$ such that $\|2b - \sum d_k^*(a-1/4)_+ d_k\| < \delta$.

It follows from Lemma 2.1.9

??????

that there is a contraction $e \in B$ with $(2b - \delta)_+ = \sum e^* d_k^*(a - 1/4)_+ d_k e$.

more ???????

(c)⇒(a): We construct a projection $Q \in \delta_\infty(B)\mathcal{M}(B)\delta_\infty(B)$ that majorizes $\delta_\infty(f)$. It follows that $P := \delta_\infty(Q)$ is in the closed ideal generated by $\delta_\infty(B)$ (because δ_∞^2 is unitary equivalent to δ_∞ in $\mathcal{M}(B)$) and PBP is stable full split-corner of B. It follows from the stable isomorphism theorem of L.G. Brown [**107**], respectively from Kasparov absorption theorem [**404**] that P is equivalent to 1 in $\mathcal{M}(B)$.

$\delta_\infty(B)$ commutes with a copy of $C^*(t_1, t_2, \ldots) = \mathcal{O}_\infty \subseteq \mathcal{M}(B)$.

If B contains a projection $p \in B$ that generates B as a closed ideal, then $\delta_\infty(p)$ is the range of an isometry in $\mathcal{M}(B)$. In particular, then B satisfies the property (a) and $B \cong pBp \otimes \mathbb{K}$.

If B is weakly purely infinite –in addition–, then property (a) implies that B contains a properly infinite projection that generates B as a closed ideal.

If B is weakly purely infinite then there exists $n \in \mathbb{N}$ such that $F := s_1 f s_1^* + \cdots + s_n f s_n^*$ is properly infinite in B. Let $E := s_1 e s_1^* + \cdots + s_n e s_n^*$ and $G := s_1 g s_1^* + \cdots + s_n g s_n^*$. Then $G = \min(2E, 1)$, $F = (2E-1)_+$ and $GF = F$. Since $G = \sum_{k=1}^n A_k^* F A_k$ for $A_k := s_1 a_k s_1^* + \cdots + s_n a_k s_n^*$, and F is properly infinite, there exist $T_1, T_2 \in B$ such that $\|T_k^* F T_k - G\| < 1/4$ $(k = 1, 2)$. We can manage that $T_1^* F T_2 = 0$ in addition, because for every $\varepsilon > 0$ there are $D_1, D_2 \in B$ with $D_j^* F D_k = \delta_{jk}(F - \varepsilon)_+$

(by a suitable 2×2-matrix arguments using Lemma 2.1.9 ??). It follows that there exists S_1, S_2 with $(T_j S_j)^* F (T_k S_k) = \delta_{jk} \cdot 2(G - 1/2)_+$. Since $GF = F$ it follows that $2(G - 1/2)_+ F = F$. We get contractions $V_k := F^{1/2} T_k S_k$ with $V_1^* V_2 = 0$ and $V_1^* V_1 = V_2^* V_2$ and $V_j^* V_j V_k = V_k$ The isometry $Z :=$????? satisfies ????. □

`Refer to inventer of this example!`

Remark 5.9.28. An algebra B with properties (a)–(c) of Remark 5.9.27 can be stably projection-less, e.g. there exist simple stable separable nuclear C^*-algebras B that are stably projection-less.

An easy example of a stably projection-less simple nuclear C^*-algebra B is the inductive limit of the C^*-algebras $A_n := \mathrm{C}_0((0,1], M_{3^n})$, with *-monomorphisms $\phi_n \colon A_n \to A_{n+1}$ given for $f \in A_n$ and $t \in (0,1]$ by

$$\phi_n(f)(t) := f(t/2) \oplus f(t^2) \oplus f(t^{1/2}) \in M_{3^{n+1}} .$$

The closed ideals J of A_n are given by $J = \mathrm{C}_0(U) \otimes M_{3^n}$, where U is a countable union of pair-wise disjoint intervals (α_n, β_n) $0 \le \alpha < \beta \le 1$ possibly further united with $(\gamma, 1]$ where $\sup_n \beta_n \le \gamma < 1$.

If the ideal $J(f)$ generated by $f \in A_n^+$ contains $\mathrm{C}_0(\alpha, \beta) \otimes M_{3^n}$ for some $0 < \alpha < \beta < 1$, then for each given $\delta > 0$ there exists (sufficiently big) $k \in \mathbb{N}$ such that the element

$$(\phi_{n+k} \circ \cdots \circ \phi_{n+1} \phi_n)(f)$$

generates an ideal of A_{n+k+1} that contains $\mathrm{C}_0((\delta, 1], M_{3^{n+k+1}})$.

Thus, $\mathrm{indlim}_{n\to\infty}(A_n \to A_{n+1})$ is a simple C^*-algebra. It is stably projection-less, because $A_n \otimes \mathbb{K} \cong \mathrm{C}_0((0,1], \mathbb{K})$ does not contain a non-zero projection.

Remark 5.9.29. Suppose that B is stable and σ-unital, and that A is a pi-sun algebra. Let $\psi \colon A \otimes \mathbb{K} \to \mathrm{Q}(B)$ a C^*-morphism with $0 = [\psi] \in \mathrm{Ext}(A, B)$.

This implies that ψ has a *non-degenerate* lift $h \colon A \otimes \mathbb{K} \to \mathcal{M}(B)$ where h is a homomorphism with $\psi = \pi_B \circ h$ and $h(A \otimes \mathbb{K})B = B$.

It follows that $\mathcal{M}(h) \colon \mathcal{M}(A \otimes \mathbb{K}) \to \mathcal{M}(B)$ is unital and injective ?????

It follows that ψ has a *non-degenerate* lift $h\colon A \otimes \mathbb{K} \to \mathcal{M}(B)$, if an only if, the closed ideal $I(\psi(A \otimes \mathbb{K}))$ generated by $\psi(A \otimes \mathbb{K})$ is equal to $\mathrm{Q}(B)$

????????? why this ???????

and ψ dominates zero

(i.e., there exists an isometry $S \in \mathcal{M}(B)$ with $S^* h(A \otimes \mathbb{K}) S \subseteq B$).

The latter condition holds by Proposition 5.5.12, because $B + h(A \otimes \mathbb{K})$ is (obviously) stable if h is non-degenerate.

`Or is s.p.i. needed?` If B is purely infinite, then ψ always dominates zero.

Thus, the question about existence of non-degenerate split morphisms for ψ reduces to the verification of the necessary and sufficient condition $I(\mathrm{Im}(\psi)) = \mathrm{Q}(B)$.

It is always the case if B is, in addition, simple and $\psi \neq 0$.

There is no useful condition for the existence of possible *degenerate* lifts. But the existence of a properly infinite projection $p \in \mathcal{M}(B)$ with $\pi_B(p)\psi(\cdot)\pi_B(p) = \psi$ and $\pi_B(p) \in I(\mathrm{Im}(\psi))$ seems to be sufficient in the case of purely infinite B.

10. The case of purely large extensions

Definition, from [264] :

Let B be a C^*-algebra, and let C be a C^*-algebra containing B as a closed two-sided ideal.

Let us say that C is *purely large* with respect to B if for every element $c \in C \setminus B$, the C^*-algebra cBc^* (the intersection with B of the hereditary C^*-subalgebra of C generated by cc^*) contains a C^*-subalgebra which is stable (i.e., isomorphic to its tensor product with the C^*-algebra $\mathbb{K}$ of compact operators on an infinite-dimensional separable Hilbert space) and is full in B (i.e., not contained in any proper closed two-sided ideal of B).

`EK comment: It implies that` $\mathrm{Ann}(B, C) = \{0\}$ `(annihilator of` B `in` C`)`,i.e., B `is essential in` C.

Criterium:

Let A and B be C^*-algebras, and let

$$0 \to B \to C \to A \to 0$$

be an extension of B by A (i.e., a short exact sequence of C^*-algebras). Let us say that the extension is **purely large** if the C^*-algebra of the extension, C, is purely large with respect to the image of B in it, in the sense described above.

Note that, if B is non-zero, a purely large extension of B by A is essential (that is, the image of B in the C^*-algebra of the extension C is an essential closed two-sided ideal every non-zero closed two-sided ideal has non-zero intersection with it).

`My comment:` B `is ''essential'' in` C `because` $B \subseteq C$ `is ''purely large'' in` C`.`

Lemma (in Section 7 of [264] ?):

Let C be a C^*-algebra that is purely large with respect to a closed two-sided ideal B (of C ?), in the sense of "Section 1".

Then, for any positive element c of C which is not in B, any $\varepsilon > 0$, and any positive element b of B, there exists $b_0 \in B$ with

$$\|b - b_0 c b_0^*\| < \varepsilon .$$

If b is of norm one, and if the image of c in C/B is of norm one, then b_0 may be chosen to have norm one.

Theorem (in Section 6 of [**264**]).
Let A and B be separable C^*algebras, with B stable and A unital.

A unital extension $B \to C \to A$?? Notation ?? is absorbing, "in the nuclear sense", if, and only if, it is "purely large".

Let us say, correspondingly, that an extension *is absorbing in the nuclear sense* if it absorbs every extension which is *trivial in the nuclear sense.*

Again, "let us say" that a unital extension *is absorbing in the nuclear sense* to mean that " this holds within the semigroup of (equivalence classes of) unital extensions". (With triviality in the nuclear sense the existence of a unital weakly nuclear splitting.)

`EK remark:`
`Precise math. definition is not given!?`
`In the case of non-unital` A`, one has to require in addition`
`that` $\phi\colon A \to \mathcal{M}(B)/B$ `''dominates zero'' in sense of Chapter 4,`
`because only then the map` $a + \alpha \cdot 1 \to \phi(a) + \alpha \cdot 1$
`defines again ???? a purely large extension`
`???? for the unitization (in general).`

EK comments (to Lemma in Section 7 of [**264**]):

One can take (if B is σ-unital) $c_n = (1 - e_n^2)^{1/2} c (1 - e_n^2)^{1/2}$, for a suitable quasi-central unit of B and gets elements $b_n \in B$ with $c - \sum_n b_n^* c b_n \in B + 1$.

When the algebra C/B is simple?

When elements of C/B are properly infinite in $\mathrm{Q}(B)$?

My (or of others ???????????) conjecture:

This criterium is satisfied *for all* nuclear separable unital C^*-subalgebras of the stable corona $\mathrm{Q}^{\mathrm{s}}(B)$ of a σ-unital C^*-algebra B, if and only if, $B = \mathbb{C}$ or B is simple and purely infinite.

One could consider $A := \mathrm{C}[0,1]$ and $A := \mathbb{C}$.

If $B = C \otimes \mathbb{K}$ with pi-sun C, the the result holds for all unital separable $A \subset \mathrm{Q}^{\mathrm{s}}(B)$...?

Questions:

Is it always satisfied for all non-zero stable σ-unital B for given separable simply purely infinite A, $A \subset \mathrm{Q}^{\mathrm{s}}(B)$, that is not contained in an ideal of $\mathrm{Q}^{\mathrm{s}}(B)$?

Has $A \subseteq \mathrm{Q}^{\mathrm{s}}(B)$ the property that for each non-zero $a \in A_+$ there exist $d \in \mathrm{Q}^s(B)$ with $d^*ad = 1$?

What really implies the property that $A \hookrightarrow \mathrm{Q}^s(B)$ absorbs all "hyper-nuclear" and (at the same time) "hyper-inner" c.p. contraction maps $V \colon A \to \mathrm{Q}^s(B)$, in the sense that there exists $T \in \mathrm{Q}^s(B)$ with $T^*(\cdot)T = V$.

Let B σ-unital and stable. It seems that the it would be enough to require that every $a \in A_+ \subset \mathrm{Q}(B)$ is properly infinite in $\mathrm{Q}(B)$. (And full??)

Take the stronger assumption that there exists $x \in \mathcal{M}(B)$ with $\pi_B(x)^* a \pi_B(x) = \|a\| \cdots 1$ (for $a \in A_+$?). It is then equivalent to the property that each $a \in A_+$ is infinite properly infinite in B and ???????????????

Let B σ-unital and stable $c \in \mathcal{M}(B)_+$ with $\pi_B(c^2) = a \in A_+$, $x \in \mathcal{M}(B)$ with $x^*cx \in 1 + B$. $e \in B_+$ strictly positive contraction, $e_1, e_2, \ldots$ suitable quasi-central approximate unit in $C^*(e)$ for $C^*(c)$.

Find $d_{n,1}, d_{n,2}$ with $d_{n,k}d_{n,k}^* \in (c-\delta)_+ B (c-\delta)_+$, $d_{n,1}^* d_{n,2} = 0$, $d_{n,k}^* d_{n,k} = e_n$.

Good? For what?

...

Lemma 5.10.1. *("Kirchberg" cited in [**264**]). Let C be a unital separable C^*-algebra and let B be an essential closed two-sided ideal of C, so that we may view C as a unital subalgebra of $\mathcal{M}(B)$:*

$$B \subseteq C \subseteq \mathcal{M}(B); \quad 1 \in C\,.$$

Let $\phi \colon C \to \mathcal{M}(B)$ be a completely positive map which is zero on B, and suppose that, for every $b_0 \in B$, the map

$$b_0^* \phi(\cdot) b_0 \colon C \to B,$$

given by $c \mapsto b_0^* \phi(c) b_0$, can be approximated (on finite sets) by the maps

$$c \mapsto b^* c b, \quad b \in B\,.$$

It follows that there exists $v \in \mathcal{M}(B)$ such that

$$\phi(c) - v^* c v \in B, \; \; c \in C\,.$$

The element v may be chosen so that the map $c \mapsto v^* c v$ also approximates ϕ on a given finite subset of C (up to $\varepsilon > 0$).

Question 5.10.2. Let $C \subset \mathrm{Q}^{\mathrm{s}}(B)$ a separable unital C^*-subalgebra of $\mathrm{Q}^{\mathrm{s}}(B)$ with σ-unital B.

Suppose that C satisfies the following criteria that is equivalent to the absorption criteria of G. Elliott and D. Kucerovsky in [**264**] (compare J. Gabe [**310**] for the non-unital case):

The hereditary C^*-subalgebra $\overline{d^*(B \otimes \mathbb{K})d}$ contains a stable and full hereditary C^*-subalgebra of $B \otimes \mathbb{K}$ for each $d \in \mathcal{M}(B \otimes \mathbb{K})$ with $\pi_{B\otimes\mathbb{K}}(d) \in C \setminus \{0\}$.

I.e., the ideal $B \otimes \mathbb{K}$ is "purely large" in $\pi^{-1}_{B\otimes\mathbb{K}}(C)$.

Does there exist a non-degenerate stable separable purely infinite simple C^*-subalgebra D of $\mathcal{M}(B \otimes \mathbb{K})$ such that C is contained in $\pi_{B\otimes\mathbb{K}}(\mathcal{M}(D))$?

Is this even an equivalent criteria for absorption?

`An answer is not obvious.`

```
In case that C is non-unital then
one has to require here that the inclusion map
map C ↪ Q^s(A) ''dominates zero''
in sense of Definition ??
see [310].
```

The closing question in [**264**]:
As pointed out above, any extension which is trivial in the nuclear sense has a weakly nuclear splitting – i.e., is weakly nuclear. Is every weakly nuclear trivial extension trivial in the nuclear sense?

REMARK 5.10.3. Suppose that $P \in \mathcal{M}(B\otimes\mathbb{K})$ is a projection with the property that $\pi_{B\otimes\mathbb{K}}(P)$ is properly infinite and full in $\mathrm{Q}^s(B)$. Then there exists an isometry $T \in \mathcal{M}(B \otimes \mathbb{K})$ with $TT^* = P$.

Indeed: It says equivalently that there exists a contraction $d \in \mathcal{M}(B\otimes\mathbb{K})$ with $X := 1 - d^*Pd \in (B\otimes\mathbb{K})_+$. On the other hand, exists an isometry $R \in \mathcal{M}(B\otimes\mathbb{K})$ with $\|R^*XR\| < 1/2$ for given $X \in B \otimes \mathbb{K}$. Then R^*D^*PDR is a positive operator with $1 \leq 2R^*D^*PDR \leq 2$. Thus, there exists $Q := (R^*D^*PDR)^{-1/2} \in \mathcal{M}(B \otimes \mathbb{K})_+$ that satisfies $\|Q\| \leq \sqrt{2}$ and $1 = S^*S = S^*PS$ for $S := PDRQ$. This shows that P majorizes a range of an isometry and is – therefore – itself properly infinite in $\mathcal{M}(B \otimes \mathbb{K})$. The existence of an infinite repeat endomorphism δ_∞ on $\mathcal{M}(B \otimes \mathbb{K})$ with $t\delta_\infty(q)t^* + s^*qs$ unitarily equivalent to $\delta_\infty(q)$ for all projections $q \in \mathcal{M}(B \otimes \mathbb{K})$ implies that $0 = [P] \in \mathrm{K}_0(\mathcal{M}(B \otimes \mathbb{K})) \cong \{0\}$. Thus there exists an isometry $T \in \mathcal{M}(B \otimes \mathbb{K})$ with $TT^* = P$.

CHAPTER 6

Exact subalgebras of Purely infinite algebras

We give a proof of Theorem A in this chapter and study a special case of Theorem K. The proof of Theorem A is simple and short, but it looks lengthy, because we carry out every detail.

Let us give a short guide to a proof of Theorem A for the impatient readers: We take Glimm's theorem [**324**] (see [**616**, thm. 6.7.3]) to obtain that $\mathcal{O}_2$ contains M_{2^∞} as a quotient of a C^*-subalgebra of $\mathcal{O}_2$ ([1]). Then we combine it with the result of [**438**] that every separable exact C^*-algebra is a quotient of a C^*-subalgebra of the CAR-algebra M_{2^∞}, in order to realise every separable exact C^*-algebra as a quotient of a C^*-subalgebra of $\mathcal{O}_2$. The embedding into $\mathcal{O}_2$ is then obtained from the KK-triviality of $\mathcal{O}_2$ and from Corollary 5.8.12 of our generalized Weyl–von-Neumann Theorem 5.6.2.

Certainly, for the first part of Theorem A, one could use also the natural embedding of M_{2^∞} into $\mathcal{O}_2$ instead of Glimm's theorem. But then one gets not the additional result in Remark 6.2.2, and one has to manage with additional tools that the below considered extension $0 \to \mathcal{O}_2 \otimes \mathbb{K} \to E \to A \to 0$ (with $E \subset \mathcal{O}_2$) becomes essential. But one could here also first menage to find a sub-quotient C^*-algebra of $s_1(s_1)*\mathcal{O}_2 s_1(s_1)* \cong \mathcal{O}_2$ that is isomorphic to the given separable exact C^*-algebra A (... that can be considered as unital (!) ...) ... If the generated hereditary kernel C^*-subalgebra of the constructed extension is not stable, then the construction is ready, because all non-zero hereditary C^*-subalgebras of $\mathcal{O}_2$ are isomorphic to $\mathcal{O}_2$ or are isomorphic to $\mathcal{O}_2 \otimes \mathbb{K}$ by Lemma 6.1.1(ii). Since the extension algebra is contained in the nuclear C^*-algebra $\mathcal{O}_2$, it is an exact C^*-algebra and as an extension it is locally semi-split. This allows to derive that we have only two cases: A is automatically C^*-subalgebra of $\mathcal{O}_2$, or we get an extension B of A by $\mathcal{O}_2 \otimes \mathbb{K}$ that is contained up to isomorphisms in $\mathcal{O}_2$. The KK-triviality and Ext-triviality of $\mathcal{O}_2 \otimes \mathbb{K}$ implies that the extension is split, as shown below ???ref???

Our proof of Theorem K follows a similar route, but the technical ingredients of the proof of Theorem A have to be improved considerably. Therefore we prove in Section 3 the intermediate result Corollary 6.3.2 (of Theorem 6.3.1), where we assume, in addition to the assumptions on B in Theorem K, that

[1] Alternatively to the general theorem of Glimm we could alternatively use for the first part of the proof the very different natural copy of M_{2^∞} inside $\mathcal{O}_2$ that is just the closed linear span of all elements $TS*$ where T and S are all products of the generating isometries s_1, s_2 of the C^*-algebra $\mathcal{O}_2 := C*(s_1, s_2)$ with relations $(s_1)*s_1 = 1$, $(s_2)*s_2 = 1$, $(s_2)*s_1 = 0$ and $s_1(s_1)* + s_2(s_2)* = 1$.

????

B is separable and that $B \otimes \mathcal{O}_2$ contains a regular Abelian C^*-subalgebra (cf. Definition 1.2.9).

```
Decide:
Below transfer from old Chp.  5 more useful?
```

The generalized Weyl–von Neumann Theorem 5.6.2 will be an ingredient of the proofs of Theorems A and of an important special case of *Theorem M ????* in Chapter 6, under the additional assumption that the algebra B in Theorem M has *residual nuclear separation* (cf. Definition 1.2.3), i.e., that the m.o.c. cone $\mathcal{C}_{rn} \subseteq \mathrm{CP}_{\mathrm{nuc}}(B, B)$ is separating for B and its ideals. This extra assumption will be removed finally in Chapter 12 that uses results from Chapters 7-11.

We assume in Chapter 6, – in addition to the assumptions of Theorem M –, that the universal weakly residually nuclear C^*-morphism $H_{rn} \colon B \to \mathcal{M}(B)$ from B into its multiplier algebra $\mathcal{M}(B)$ is non-degenerate for the in Theorem **??** considered stable separable B and that there exists a C^*-morphism $h \colon A \to \mathcal{M}(B)$ that defines the action of $\mathrm{Prim}(B)$ on A. This additional assumptions will be completely removed in Chapter 12 by using results of Chapters 3 and 7 -11 .

Its generalization to weakly residually nuclear maps – and, more generally, to maps in a given m.o.c. cone $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ – will be used in Chapters 6 and 12 for the proof of Theorem K.

This additional assumptions will be removed both in Chapter 12.

The here given proof of Theorem 6.3.1 gives also an alternative proof of Theorem A that does *not* use [**438**], but requires to generalise some results of [**437**], see Section 19 of Appendix A.

1. Normalizers of hereditary subalgebras (Part 1)

Recall that a *-subalgebra B of a C^*-algebra A is an **essential subalgebra** of A if it has no non-zero left annihilators in A, i.e., if $aB = \{0\}$ implies $a = 0$ for all a in A. E.g., always a dense *-subalgebra B of a C^*-algebra C is an essential subalgebra of the multiplier $A := \mathcal{M}(C)$ of C.

```
Next red:  Is here a good place?
```

Our Proposition 6.2.1 implies that the classification of (the positions in $\mathcal{O}_2$ of) the essential hereditary C^*-subalgebras D of $\mathcal{O}_2$ – together with a certain semi-splitting property – would in particular create invariants for the classification of all nuclear separable unital C^*-algebras. Unfortunately, up to now there is no method to link the points of this "classifying space" with known invariants of K-theoretic nature.

LEMMA 6.1.1. *Suppose that $D \subseteq J \subseteq E \subseteq B$ are C^*-subalgebras of a C^*-algebra B, and that J is an ideal of E.*

(i) *If D is essential in B and $J \neq E$, then J is an essential ideal of E and is an essential hereditary C^*-subalgebra of B.*

In particular, the C^*-algebra J can not have a unit element.

(ii) *If $D \subset \mathcal{O}_2$ is an essential hereditary C^*-subalgebra of $\mathcal{O}_2$ and $D \neq \mathcal{O}_2$, then D is isomorphic to $\mathcal{O}_2 \otimes \mathbb{K}$.*

PROOF. (i): Every annihilator of J in $B \supset E$ is in an annihilator of D in B. But the annihilators of D in B are zero.

Suppose J has a unit element $e \in J$, i.e., $e = e^*e$ and $ex = xe = x$ for all $x \in J$. The elements of $(1-e)B(1-e)$ are two-sided annihilators of J. Thus $\|(1-e)b^*b(1-e)\| = \|b - be\|^2 = 0$ for every $b \in B$, and e is the unit of B. Since J is an ideal of E, this contradicts our assumption $J \neq E$.

(ii): All this is given by the equivalence of its Parts (ix) and (i) of Proposition 2.2.1, if we use that $\mathcal{O}_2$ is simple and purely infinite in the sense of J. Cuntz.

An alternative proof is the following: Let $E := D + \mathbb{C} \cdot 1 \subset \mathcal{O}_2$. If D is an essential hereditary C^*-subalgebra of $\mathcal{O}_2$ and $D \neq \mathcal{O}_2$, then $D \neq E$ and D has not a unit element.

The non-zero hereditary C^*-subalgebra D of $\mathcal{O}_2$, is simple, purely infinite and separable. It follows that D is either unital or stable by Corollary 5.5.4 (Zhang dichotomy). Thus, $D \cong D \otimes \mathbb{K} \cong \mathcal{O}_2 \otimes \mathbb{K}$ by Corollary 5.5.6 (Brown stable isomorphism theorem, [**107**]). □

Some of the, in Remarks 6.1.2 mentioned, properties are also at other places discussed. Check this!!!

REMARKS 6.1.2. The study of quotients of C^*-subalgebras of a given C^*-algebra C leads to the study of hereditary C^*-subalgebras D of C and of its **normalizer algebra** $\mathcal{N}(D) \subset C$, which is defined as $\mathcal{N}(D) := \{b \in C : bD + Db \subset D\}$ (and is usually very different from the multiplier algebra $\mathcal{M}(D)$ of D).

(1) The set of products CD is a *closed* left ideal of C and the sum $CD + DC$ is a closed linear subspace of C ([2]). We define $C//D := C/(CD + DC)$ (considered as an operator subspace of the W*-algebra C^{**}, see below).

We consider $\mathcal{N}(D)/D$, its natural maps into $C//D$ and into $\mathcal{M}(D)/D$, and the behavior of this maps on the system of closed ideals of C. They lead to the guiding principles for all proofs in this chapter (except some additional arguments on approximation and inductive limits in the Ψ-residually nuclear case).

(2) A hereditary C^*-subalgebra D of C is a closed ideal of $\mathcal{N}(D)$ by definition of $\mathcal{N}(D)$, and, therefore, there is a natural C^*-morphism $\rho\colon \mathcal{N}(D) \to \mathcal{M}(D)$ from

[2] The closed left ideal $L := \overline{\text{span}(CD)}$ is identical with the set of products CD by Cohen factorization theorem, – or simply observe that every element a of a closed left ideal L can be expressed as $a = cd$ for $c \in C$ suitable and $d := (a^*a)^{1/4}$ in $D = L^* \cap L$ –. The set $CD + DC$ is a closed linear subspace of C, because it is the sum of a closed left ideal L and a closed right ideal R, and because $C^{**}p + pC^{**}$ is $\sigma(C^{**}, C^*)$-closed in C^{**}.

$\mathcal{N}(D)$ into the multiplier algebra $\mathcal{M}(D)$ of D. Clearly, the kernel of $\rho\colon \mathcal{N}(D) \to \mathcal{M}(D)$ is the (two-sided) **annihilator** $\mathrm{Ann}(D) := \{c \in C\colon cD + Dc = 0\} \subset \mathcal{N}(D)$ of D in C. From the definition, one sees that $\mathrm{Ann}(D)$ is a closed ideal of $\mathcal{N}(D)$, and that the *-epimorphism $\mathcal{N}(D) \to \mathcal{N}(D)/D$ is faithful on $\mathrm{Ann}(D)$.

(3) A hereditary C^*-subalgebra $D \subset C$ is *essential* in C, if and only if, $\mathrm{Ann}(D) = \{0\}$. Thus, the natural *-morphism $\mathcal{N}(D) \to \mathcal{M}(D)$ is *faithful*, if and only if, D is *essential* in C. The natural morphism $\mathcal{N}(D) \to \mathcal{M}(D)$ is *not necessarily an epimorphism.* Different essential hereditary C^*-subalgebras D and D' have in general non-isomorphic $\mathcal{N}(D)/D$ and $\mathcal{N}(D')/D'$, even if D and D' are isomorphic.

The corona construction $\mathrm{Q}(D) := \mathcal{M}(D)/D$ defines an isomorphism invariant for all algebras D.

(4) Let $F \subset C$ a C^*-subalgebra and J a closed ideal of F, then the set $D := JCJ$ is a hereditary C^*-subalgebra of C such that $F \subset \mathcal{N}(D)$ and $F \cap D = J$, because an approximate unit of J is also an approximate unit of D. Therefore, there is a natural *-monomorphism from F/J into $\mathcal{N}(D)/D$ and the unit of the weak closure of J in the second conjugate C^{**} of C is also the unit of the weak closure of D. Moreover, $F + D$ is closed, because $FD + DF \subset D$, cf. [**767**, Vol. I, chap. I,sec. 8, exercise 2].

(5) Let D be a hereditary C^*-subalgebra of C. Then the unit element p_D of the weak closure of D in C^{**} is called the **support projection** of D. It is a so-called **open** projection, and $q_D := 1 - p_D$ is a **closed** projection.

(6) There are well-known one-to-one relationships between hereditary C^*-subalgebras, open projections, closed left ideals, weakly closed faces of the state space of C, weakly closed right invariant subspaces of C^*, and the (with respect to C) closed projections in C^{**}.
Indeed, let $S(C)$ denotes the state space of C, and let $X \mapsto X^o \mapsto X^{oo}$ the passage to the polar and bipolar of a set, then the one-to-one relations are given by the maps $D \mapsto L := CD$, $L \mapsto D = L^* \cap L$, $D \mapsto K_D = D^o \cap S(C)$, $L \mapsto L^o \mapsto X := L^o \cap S(C) = D^o$, $D \mapsto p_D$, $p \mapsto L_p := C \cap (C^{**}p)$, $K \mapsto L_K := \{a \in C\colon f(a^*a) = 0 \quad \forall f \in K\}$, $p \mapsto q = 1 - p$, $q \mapsto C^*q$, $X \mapsto K_X = S(C) \cap X$, $q \mapsto D_q := \{a \in C\colon q(a^*a + aa^*)q = 0\}$.

We refer the reader to [**767**, Vol. I, chap. III, def. 6.19, cor. 6.20], and to [**616**, prop. 3.11.9, thms. 3.10.7, 3.11.10]. (For our particular needs, the reader can simplify the there given proofs if he uses instead 2×2-matrix arguments.)

(7) It is useful to consider also the quotient $X_D := C//D := C/(CD+DC)$ of C by $CD+DC$ (which is a closed linear subspace of C), and let $\pi_{CD+DC}\colon C \to C//D$ denote the natural epimorphism. The space X_D with its natural matrix order structure and matrix norms ([3]) becomes a (special kind of) ***C*-system*** (defined

[3]It is given on the vector space $M_n(C/(CD + DC))$ by the natural isomorphism with the quotient Banach space norms $M_n(C) \to M_n(C)/M_n(CD + DC)$.

more generally in [**437**]). If C is unital, then the C^*-system X_D is unital with matrix order unit $\pi_{CD+DC}(1)$. The bi-dual operator system of X_D is nothing else $q_D C^{**} q_D$ (under natural identification given by the restriction of π^{**}_{CD+DC} to $q_D C^{**} q_D$), cf. [**437**]. The unital C^*-systems are non-commutative generalizations of the spaces of continuous affine functions on a Choquet simplex, cf. [**437**], [**472**].

The natural isomorphism $q_D C^{**} q_D \to X_D^{**}$ defines a completely isometric isomorphism $\lambda \colon q_D c q_D \to c + (CD + DC)$ from the subspace $q_D C q_D$ of C^{**} onto X_D, Therefore, the kernel of the completely positive map $a \in C \mapsto q_D a q_D$ is just $CD + DC$.

It is easy to see that $\mathcal{N}(D) = \{q_D\}' \cap C$, and therefore, that there is a natural unital C^*-morphism $\mathcal{N}(D) \to \mathcal{N}(D) q_D \subset q_D C q_D$. By definition of $p_D = 1 - q_D$, the kernel of this *-epimorphism onto $q_D \mathcal{N}(D)$ is just D. We get a natural *-isomorphism $\tau(b + D) := b q_D$ from $\mathcal{N}(D)/D$ onto $q_D \mathcal{N}(D) \subset q_D C q_D$, and we have for $a \in \mathcal{N}(D)$:

$$\operatorname{dist}(a, C^{**} p_D + p_D C^{**}) = \operatorname{dist}(a, CD + DC) = \|a + D\| = \|q_D a q_D\| .$$

(8) We use for the proof of Proposition 6.2.1 results from the paper [**438**] which rely on the following (non-trivial) fact [**437**, thm. 1.4(iii)] on normalizer algebras: *If C is unital, then the natural unital C^*-morphism*

$$\pi'_D \colon \mathcal{N}(D) \ni a \mapsto a q_D = q_D a q_D \in q_D C^{**} q_D$$

defines a completely isometric and completely positive isomorphism from $\mathcal{N}(D)/D$ onto *the (two-sided) multiplier algebra $\mathcal{M}(X_D) \subset X_D$ of X_D in $X_D^{**} \cong q_D C^{**} q_D$* (the latter naturally identified by the map λ from (7)).

(9) An obvious consequence of (8) is the following:
Suppose that F is a C^*-subalgebra of $\mathcal{N}(D) \subset \{p_D\}' \cap C = \{q_D\}' \cap C$ and that the image $F q_D$ of the map $c \to q_D c q_D$ is $\sigma(C^{**}, C^*)$-dense in the image $q_D C q_D$ of C (which happens e.g. if $q_D C q_D = q_D F$). Then, $\pi_{CD+DC}(F) = C/(CD + DC)$, because it is a C^*-subalgebra of $\mathcal{M}(C/(CD+DC))$). In particular $F + D = \mathcal{N}(D)$ and $C = \mathcal{N}(D) + DC + CD$.
Notice that, conversely, $q_D C q_D = q_D \mathcal{N}(D)$ if $C = \mathcal{N}(D) + CD + DC$.
From the above collected results, we get that the following properties (i)-(v) of hereditary C^*-subalgebras D of a unital C^*-algebra C are equivalent:

(i) The C^*-system $C//D$ is unitally and isometrically isomorphic to a C^*-algebra.
(ii) $\mathcal{M}(C//D) = C//D$ (i.e., $C//D$ is a C^*-subalgebra of $q_D C^{**} q_D$).
(iii) $C = \mathcal{N}(D) + CD + DC$.
(iv) There is a C^*-algebra A and a completely positive contraction $T \colon C \to A$ such that $T(D) = \{0\}$, $T|\mathcal{N}(D)$ is a *-epimorphism from $\mathcal{N}(D)$ onto A with kernel D, and that there is a projection $q \in C^{**}$ and an W*-isomorphism S from $q C^{**} q$ onto A^{**} with $T^{**}(c) = S(qcq)$ for all $c \in C$.

(v) There is a completely positive map $T\colon C \to \mathcal{N}(D)/D$ with $T|\mathcal{N}(D) = \pi_D$ and $\ker(T) = CD + DC$.

(10) Let $T\colon C \to G$ be a unital completely positive map. We define the **multiplicative domain** $M_T \subset C$ of T as the set of $d \in C$ with $T(db) = T(d)T(b)$ and $T(bd) = T(b)T(d)$ for $b \in C$. M.D. Choi's generalized Kadison inequality $T(a)^*T(a) \le T(a^*a)$ shows that $d \in M_T$, if and only if, $T(d^*d) = T(d)^*T(d)$ and $T(dd^*) = T(d)T(d)^*$. Unfortunately, the multiplicative domain (resp. the kernel) of the unital completely positive map $T^{**}\colon C^{**} \to G^{**}$ is not necessarily contained in the weak closure of the multiplicative domain (resp. the kernel) of T, cf. Part (11).

The multiplicative domain of the unital completely positive map

$$T_D\colon a \in C \mapsto q_D a q_D \in q_D C^{**} q_D$$

is just $\mathcal{N}(D) = \{q_D\}' \cap C$ and $\mathcal{N}(D)^{**} \neq \{q_D\}' \cap C^{**}$.

(11) The above remarks on the quotient spaces $X_D = C//D$ show that the second conjugate $(\pi_{CD+DC})^{**}$ of $\pi_{CD+DC}\colon x \in C \mapsto x + (CD + DC) \in C//D$ is just the normalization $a \in C^{**} \mapsto q_D a q_D$ of T_D in Part (10). The multiplicative domain $p_D C^{**} p_D + q_D C^{**} q_D$ of $(\pi_{CD+DC})^{**}$ is in general much bigger than the weak closure of $\mathcal{N}(D)$ in C^{**}. But the *kernel* of $(\pi_{CD+DC})^{**}$ is just $p_D C^{**} + C^{**} p_D$, which is the weak closure of the kernel $DC + CD$ of T_D and of π_D.

(12) Let $X := X_D := C//D \subset q_D C^{**} q_D$, and let $\eta_1\colon X \to X^{**} \cong q_D C^{**} q_D$, $\eta_2\colon X^* \to X^{***}$ and $\eta_3\colon X^{**} \to X^{****}$ the natural inclusions. Then $(\eta_1)^{**}\colon X^{**} \to X^{****}$ is a normal unital completely isometric map, $(\eta_2)^*\colon X^{****} \to X^{**}$ is a normal *-epimorphism, and η_3 is a (non-normal) *-monomorphism. The map $E := (\eta_1)^{**} \circ (\eta_2)^*$ is a normal u.c.p. map on the fourth conjugate W*-algebra of X with $E^2 = E$.

We say that $y \in X^{**} \cong q_D C^{**} q_D$ is a (two-sided) *multiplier* of X if $yx, xy \in X$ for all $x \in X$, where the multiplication is given by the W*-algebra structure on X^{**}. Let $\mathcal{M}(X) \subset X^{**}$ denote the set of all multipliers of X. Then, clearly, $\mathcal{M}(X)$ is a unital C^*-subalgebra of X^{**}, and is contained in X, because $q_D = 1_{X^{**}} \in X$.

One can see by a separation argument, that $y \in \mathcal{M}(X)$, if and only if, $\eta_3(y)$ is in the multiplicative domain of E (see [**437**] for details). It follows from Remark (10) that $y \in \mathcal{M}(X)$, if and only if, y, y^*y and yy^* are all in X.

(13) By [**437**, cor. 1.5], $a \in \mathcal{N}(D) \mapsto aq_D \in q_D C q_D \cong C//D$ is a *-epimorphism from $\mathcal{N}(D)$ onto $\mathcal{M}(C//D)$ with kernel equal to D. It implies together with Remark (12) the following observation:

Let $x \in q_D C^{**} q_D$. There is $a \in \mathcal{N}(D)$ with $aq_D = x$ if and only if, $x, x^*x, xx^* \in C//D$, if and only if, $x \in \mathcal{M}(C//D)$.

(14) If C is *not unital*, then we can pass to the unitization $\widetilde{C}$ of C, and get immediately the following reformulation of (13):

Let $x \in q_D C^{**} q_D$. There is $a \in \mathcal{N}(D)$ with $aq_D = x$ if and only if, $x, x^*x, xx^* \in C//D$, if and only if, $x \in C//D \cap \mathcal{M}(C//D)$.

In particular, $\mathcal{N}(D)/D \cong (C//D) \cap \mathcal{M}(C//D)$ via identifications of $a + D$, ap_D and $a + (DC + CD)$ for $a \in \mathcal{N}(D)$.

Lemma 6.1.3. *Suppose that $E \subset B$ is a C^*-subalgebra of a* nuclear *C^*-algebra B, D is a σ-unital hereditary C^*-subalgebra of B, $D \subset E$, and that D is an ideal of E.*

Then every completely positive contraction φ from a separable *unital C^*-algebra A into E/D has a completely positive and contractive lifting $V: A \to E$, i.e., $\pi_D \circ V = \varphi$.*

If, in addition, B and A are unital, $1_B \in E$, and $\varphi: A \to E/D$ is unital, then a unital *nuclear c.p. map $V: A \to E$ with $\pi_D \circ V = \varphi$ exists.*

Notice, that a lift $V: A \to E$ of an isomorphism $\varphi: A \to E/D$ from A onto E/D can't be nuclear if A is not a nuclear C^*-algebra. But $V: A \to B \supset E$ is a nuclear c.p. map from A into B, because B is nuclear.

Proof. If A is separable and unital, B is unital with $1_B \in E$ and $\varphi: A \to E/D$ is unital, then we can replace A by the separable unital C^*-subalgebra F of E/D generated by $\varphi(A)$, φ by the identity map of this new algebra F, and finally E by $G := \pi_D^{-1}(F)$. The extension given by the exact sequence

$$0 \to D \to G \to F \to 0$$

has a splitting unital c.p. map $T: F \to E \subseteq B$ for π_D by [**238**, thm. B, prop. 4.3]. It uses that D is nuclear as a hereditary C^*-subalgebra of the nuclear algebra B, i.e., D fulfills assumption (1) of [**238**, thm.B]. The C^*-subalgebra $G \subseteq B$ inherits property (C) from the nuclear B by [**238**, prop. 5.3] (citing [**35**, thms. 3.2, 3.3]).

Property (C″) – which is equivalent to local reflexivity in the operator space sense –, follows from property (C) and allows to verify the assumption (2) of [**238**, thm.B], with help of [**238**, prop. 5.3(3)] and [**238**, prop. 5.5].

(Notice that the properties (C) and (C′) both are equivalent to exactness by [**438**], because every separable exact C^*-algebras is a quotient of some C^*-subalgebras of the CAR algebra M_{2^∞}.)

Check next again: Unit OK?

If one of B, E, A or φ are not unital, or if $1_B \notin E$, then we can adjoin to all algebras (except D) an *outer* unit 1, and extend φ to a unital c.p. map

$$\widetilde{\varphi}: \widetilde{A} \to \widetilde{E}/D \cong \widetilde{E/D},$$

by $\widetilde{\varphi}(a+t1) := \varphi(a)+t1$. There is a unital u.c.p. map $W: \widetilde{A} \to \widetilde{E}$ with $\pi_D \circ W = \widetilde{\varphi}$. Then $W(A) \subset E$ and the map $V := W|A$ is a completely positive contraction from A into E with $\pi_D \circ V = \varphi$. □

Remark 6.1.4. Other methods in Section 3 that are different from those of [**238**] and are more near to the study of the convex cone of c.p. maps $V: A \to E$

like methods of Arveson in the proof of [**43**, thm. 6]. The results are more general lifting results than that stated in Lemma 6.1.3, e.g.

Suppose that B is separable and that $B//D$ is a *nuclear C^*-space* (i.e., that $q_D B^{**} q_D$ is an injective von-Neumann algebra), that D is an *essential* hereditary C^*-subalgebra of B and that $D \subseteq E \subseteq \mathcal{N}(D) \subseteq B$.

Then for every separable C^*-algebra A and every c.p. contraction $\varphi\colon A \to E/D$ there exist a c.p. contraction $V\colon A \to E$ with $\pi_D \circ V = \varphi$ such that $V\colon A \to B$ is nuclear (but is not necessarily nuclear as a map from A to E).

If A and B are unital, $1_B \in E$ and φ is unital, then one can manage that V is unital.

(In fact, the reduction to [**43**, thm. 6] is done be showing that there exists a (not necessarily unique) c.p. contraction $T\colon B//D := B/(BD + DB) \to \mathcal{M}(D)/D$ such that $T|\mathcal{N}(D)/D$ is the natural C^*-morphism from $\mathcal{N}(D)/D$ into $B//D$.)

LEMMA 6.1.5. *Suppose that F is a C^*-subalgebra of a C^*-algebra C, and that $q \in F' \cap C^{**}$ is a projection that is closed in C^{**} and satisfies $Fq = qCq$.*

Let D denote the hereditary C^*-subalgebra of C with open support projection $1 - q$. Then:

(i) *$\mathcal{N}(D) = D + F$.*
(ii) *$T_q\colon c \in C \mapsto qcq \in C^{**}$ is a c.p. contraction and has kernel equal to $DC + CD$.*
(iii) *The multiplicative domain of T_q is given by $\{c \in C\,;\; cq = qc\}$, which is the same as $\mathcal{N}(D)$.*
(iv) *There are natural isomorphisms*

$$Fq \cong F/(F \cap D) \cong \mathcal{N}(D)/D \cong C/(DC + CD)$$

that are given by

$$[T_q]\colon \pi_{DC+CD}(c) \mapsto qcq \in Fq = \mathcal{N}(D)q \cong \mathcal{N}(D)/D\,.$$

(v) *$C = \mathcal{N}(D) + DC + CD$.*

PROOF. `to be filled in` ?? □

LEMMA 6.1.6. *Suppose that $D_1 \subset C$ is a hereditary C^*-subalgebra of a C^*-algebra C such that $C = \mathcal{N}(D_1) + D_1 C + C D_1$. Let $\rho\colon \mathcal{N}(D_1) \to B$ a *-epimorphism from $\mathcal{N}(D_1)$ onto a C^*-algebra B with kernel equal to D_1, and let $D_2 \subset B$ a hereditary C^*-subalgebra of B.*

Denote by J the hereditary C^*-subalgebra $J := \rho^{-1}(D_2)$ of $\mathcal{N}(D_1)$, and define the hereditary C^*-subalgebra $D \subset C$ by $D := JCJ$.

(i) *$D_1 \subset D$, and $\mathcal{N}(D) = \rho^{-1}(\mathcal{N}(D_2)) + D$.*
(ii) *There is a unique positive contraction $T\colon C \to B$ that extends ρ. T is completely positive, has kernel $\ker(T) = D_1 C + C D_1$ and multiplicative domain $\mathcal{N}(D_1)$.*

(iii) $T(D) = D_2$, $T(DC + CD) = D_2B + BD_2$ *and* $T(\mathcal{N}(D)) = \mathcal{N}(D_2)$.

(iv) *The c.p. map* $T|\mathcal{N}(D)$ *defines an isomorphism of* C^**-algebras*

$$\eta\colon \mathcal{N}(D)/D \mapsto \mathcal{N}(D_2)/D_2\,,$$

with $\eta(\pi_D(c)) = \pi_{D_1}(T_1(c))$ *for* $c \in \mathcal{N}(D)$.
In particular, $\eta(c + D) = \rho(c) + D_1$ *for* $c \in \rho^{-1}(\mathcal{N}(D_2))$.

(v) *The class-map* $[T]_{(DC+CD)}$ *is a completely positive and completely isometric isomorphism from the* C^**-system* $C//D$ *onto* $B//D_2$.

PROOF. to be filled in ??

Let $F \subset \mathcal{N}(D_1) \subset C$ denote the inverse image $\rho^{-1}(\mathcal{N}(D_2)) =: F$ of $\mathcal{N}(D_2)$ under the epimorphism ρ from $\mathcal{N}(D_1)$ onto B.

The inverse image $J := \rho^{-1}(D_2)$ of D_2 is the kernel of the epimorphism $\pi_{D_2} \circ \rho\colon F \to \mathcal{N}(D_2)/D_2$. In particular, J is an ideal of F, J contains the kernel D_1 of ρ, $\rho(J) = D_2$. Thus, there is an isomorphism $\mu\colon F/J \to \mathcal{N}(D_2)/D_2$ with $\mu \circ \pi_J = \pi_{D_2} \circ \rho$.

Now we consider the hereditary C^*-subalgebra $D := JCJ = \overline{JCJ}$ of C. Then D is a hereditary C^*-subalgebra of C, and $D_1 \subset D$. Since the ideal J of F contains an approximate unit of D, we get that the hereditary C^*-subalgebra $F \cap D$ of F must be equal to the ideal J of F, and that $F \subset \mathcal{N}(D)$. In particular, F/J is naturally isomorphic to a C^*-subalgebra of $\mathcal{N}(D)/D$. The above defined natural unital monomorphism $F/J \to \mathcal{N}(D)/D$ and the isomorphism $\mu^{-1}\colon \mathcal{N}(D_2)/D_2 \xrightarrow{\sim} F/J$ define together a unital *-monomorphism

$$\xi\colon \mathcal{N}(D_2)/D_2 \hookrightarrow \mathcal{N}(D)/D\,,$$

such that $\xi(\pi_{D_2}(\rho(a)) = \pi_D(a)$ for $a \in F$. □

2. The Proof of Theorem A

PROPOSITION 6.2.1. *Suppose that* A *is a unital separable exact* C^**-algebra. Then there exist a unital* C^**-subalgebra* E *of* $\mathcal{O}_2$*, a closed ideal* D *of* E*, and a* **-isomorphism* φ *from* A *onto* E/D*, such that*

(i) D *is an* essential *hereditary* C^**-subalgebra of* $\mathcal{O}_2$*;*

(ii) φ *has a unital completely positive lifting* $V\colon A \to E$*, i.e.,* $\varphi = \pi_D \circ V$*,*

(iii) $D \cong \mathcal{O}_2 \otimes \mathbb{K}$.

If A *is nuclear, then the subalgebras* $D \subset E \subset \mathcal{O}_2$*, and the isomorphism* $\varphi\colon A \xrightarrow{\sim} E/D$ *can be chosen such that the epimorphism* $\varphi^{-1} \circ \pi_D\colon E \to A$ *extends to a unital completely positive map* $T\colon \mathcal{O}_2 \to A$ *with kernel* $D \cdot \mathcal{O}_2 + \mathcal{O}_2 \cdot D$.

PROOF. Let B denote the CAR-algebra M_{2^∞} and let $C := \mathcal{O}_2$. We define $D \subset E \subset C$ and $\varphi\colon A \xrightarrow{\sim} E/D$ and show later that they satisfy (i)–(iii).

First we consider the case of an *exact* separable A that is not necessarily nuclear:

Since C is not a C^*-algebra of type I, we can apply the improved variant [**616**, thm. 6.7.3] of Glimm's theorem: There exist a unital subalgebra F_1 of C and a *closed* projection q_1 in C^{**} such that q_1 commutes with F_1, $q_1 C q_1 = q_1 F_1$ and that the C^*-subalgebra $q_1 C q_1$ of $q_1 C^{**} q_1$ is isomorphic to the CAR-algebra $B := M_{2^\infty}$.

Let $p_1 := 1 - q_1$ the open complement of q_1, and let D_1 denote the hereditary C^*-subalgebra of B with open support projection $p_1 = p_{D_1}$, cf. Remark 6.1.2(5), i.e., $(D_1)_+ = \{c \in C_+ ;\, q_1 c q_1 = 0\}$. Furthermore, let $h_1 \colon q_1 C q_1 \xrightarrow{\sim} B$ a *-isomorphism from $q_1 C q_1 \cong q_1 F_1$ onto B, and define $T_1 \colon C \to B$ by $T_1(a) := h_1(q_1 a q_1)$.

By Lemma 6.1.5, T_1 is a unital completely positive map, and the kernel of T_1 is $CD_1 + D_1 C$. Moreover, $\mathcal{N}(D_1) = F_1 + D_1$, and $\mathcal{N}(D_1)$ is just the multiplicative domain of T_1. It implies that $C = \mathcal{N}(D_1) + CD_1 + D_1 C$.

Let $\rho := T_1 | \mathcal{N}(D_1)$. Then $\rho \colon \mathcal{N}(D_1) \to B$ is a *-epimorphism from $\mathcal{N}(D_1)$ onto B with kernel $D_1 = \mathcal{N}(D_1) \cap (D_1 C + CD_1)$.

By [**438**, cor. 1.3, 1.4, thm. 4.1], for every separable *unital* exact C^*-algebra A, there exists a hereditary C^*-subalgebra $D_2 \subset B$ and a unital *-monomorphism $\psi \colon A \to \mathcal{N}(D_2)/D_2$.

Since D_2 is an ideal of $\mathcal{N}(D_2)$, the inverse image $J := \rho^{-1}(D_2)$ is an ideal of the C^*-subalgebra $\rho^{-1}(\mathcal{N}(D_2))$ of $\mathcal{N}(D_1)$. We let $D := JCJ$.

The equation $C = \mathcal{N}(D_1) + CD_1 + D_1 C$ and the Lemma 6.1.6 on iterated normalizers show that that $T_1 \colon C \to B$ is the unique completely positive extension of the epimorphism $\rho \colon \mathcal{N}(D_1) \to B$, that $T_1(D) = D_2$, that $T_1(\mathcal{N}(D)) = \mathcal{N}(D_2)$ and that $T_1 | \mathcal{N}(D)$ defines a C^*-isomorphism η from $\mathcal{N}(D)/D$ onto $\mathcal{N}(D_2)/D_2$ with $\eta(\pi_D(c)) = \pi_{D_1}(T_1(c))$ for $c \in \mathcal{N}(D)$.

We define a unital *-monomorphism $\varphi \colon A \to \mathcal{N}(D)/D$ by $\varphi := \eta^{-1} \circ \psi$ and let

$$E := \pi_D^{-1}(\varphi(A)) \subset \mathcal{N}(D) \subset \mathcal{O}_2$$

be the inverse image of $\varphi(A)$ under the quotient map $\pi_D \colon \mathcal{N}(D) \to \mathcal{N}(D)/D$.

Thus, we get *a hereditary C^*-subalgebra D of $C := \mathcal{O}_2$, a C^*-subalgebra $E \subset \mathcal{N}(D) \subset \mathcal{O}_2$ with $D_1 \subset D \subset E \subset \mathcal{N}(D)$, and a unital *-isomorphism $\varphi \colon A \xrightarrow{\sim} E/D$.*

(i,iii): We use Lemma 6.1.1: Since $D_1 \subset D$ and $D \neq \mathcal{O}_2$, it suffices to show that D_1 is essential in $\mathcal{O}_2$, i.e., that $\mathrm{Ann}(D_1) = \{0\}$. Recall, that $\mathrm{Ann}(D_1)$ is a closed ideal of $\mathcal{N}(D_1)$ and is a hereditary C^*-subalgebra of $C := \mathcal{O}_2$. The epimorphism $\rho \colon \mathcal{N}(D_1) \to B := M_{2^\infty}$ has kernel D_1. Thus, $\rho | \mathrm{Ann}(D_1)$ is faithful, and $\rho(\mathrm{Ann}(D_1))$ is a closed ideal of M_{2^∞}. Since every non-zero hereditary C^*-subalgebra of $\mathcal{O}_2$ is stably infinite and since M_{2^∞} is stably finite, we get $\rho(\mathrm{Ann}(D_1)) = \{0\}$ and $\mathrm{Ann}(D_1) = \{0\}$.

(ii): By Lemma 6.1.3, there is a u.c.p. map $V \colon A \to E$ with $\pi_D \circ V = \varphi$.

This completes the proof for general exact A.

We consider now the special *case of nuclear* A:
If A is *nuclear*, then [**438**, cor. 1.5] says that the hereditary C^*-subalgebra $D_2 \subset B := M_{2^\infty}$ and $\psi\colon A \to \mathcal{N}(D_2)/D_2$ can be chosen such that ψ is an isomorphism from A onto $\mathcal{N}(D_2)/D_2$ and, moreover, that $B = \mathcal{N}(D_2) + D_2B + BD_2$, i.e., $\psi(A) = \mathcal{N}(D_2)/D_2 \cong B//D_2$.

As in the case of (not-necessarily nuclear) exact A we define $D \subset E \subset C$, and $\varphi\colon A \to E/D$:
Let $D := JCJ$ for $J := \rho^{-1}(D_2) \supset D_1$ with $\rho := T_1|\mathcal{N}(D_1)$ (defined as in the case of exact A), and use the isomorphism $\eta\colon \mathcal{N}(D)/D \to \mathcal{N}(D_2)/D_2$ to define $\varphi := \eta^{-1} \circ \psi$. Then $\varphi\colon A \to \mathcal{N}(D)/D$ is an isomorphism of A onto $\mathcal{N}(D)/D$. Thus $E := \pi_D^{-1}(\varphi(A)) = \mathcal{N}(D)$.

We apply Lemma 6.1.6 to $(B,\ D_2,\ \psi^{-1} \circ \pi_{D_2},\ A,\ 0)$, in place of the there considered general system $(C,\ D_1,\ \rho,\ B,\ D_2)$, and get the unique u.c.p. extension $T_2\colon B \to A$ of the *-epimorphism

$$\rho_1 := \psi^{-1} \circ \pi_{D_2}\colon \mathcal{N}(D_2) \to A\,,$$

and T_2 has kernel $D_2B + BD_2$ and multiplicative domain $\mathcal{N}(D_2)$.

Since $C = \mathcal{N}(D_1) + CD_1 + D_1C$, we get from Lemma 6.1.6, that

$$T_1(DC + CD) = D_2B + BD_2\,.$$

It implies that the u.c.p. map $T := T_2 \circ T_1\colon C \to A$ has kernel $DC + CD$.

Let $c \in \mathcal{N}(D) \subset C$. Then $V_1(c) \in \mathcal{N}(D_2)$ and $\pi_{D_2}(V_1(c)) = \eta(\pi_D(c))$ by Lemma 6.1.6. Thus,

$$V(c) = \rho_1(V_1(c)) = \varphi^{-1}(\pi_D(c)) \qquad \text{for} \quad c \in \mathcal{N}(D)\,.$$

Thus, the u.c.p. map $V\colon C \to A$ extends the *-epimorphism from $E = \mathcal{N}(D)$ onto A, and is given by $\varphi^{-1} \circ \pi_D$. □

We have seen so far, that there exists, for every separable unital exact C^*-algebra A, an essential semi-split exact sequence

$$0 \to D \to E \to A \to 0$$

where E is a unital C^*-subalgebra of $\mathcal{O}_2$, and where $D \cong \mathcal{O}_2 \otimes \mathbb{K}$ is essential in $\mathcal{O}_2$. This extension splits unital by Corollary 5.8.12. The unital splitting C^*-morphism is a monomorphism from A onto a unital subalgebra of $E \subset \mathcal{O}_2$.

The desired conditional expectation onto the image of A in $\mathcal{O}_2$ is then just the composition of $T\colon \mathcal{O}_2 \to A$ with the splitting C^*-morphism. More details are given below in Remark 6.2.2.

Proof of Theorem A.. Ad(i): Let A be a separable exact C^*-algebra. If A is not unital then the unitization of A is again exact, as our $A \otimes (\cdot)$ -exactness definition of exactness of A in Chapter 3 immediately implies (e.g. use the 3×3-lemma of category theory). Thus we can restrict our considerations to the case of *unital* exact C^*-algebras A.

The unital semi-split essential extension

$$0 \longrightarrow D \longrightarrow E \xrightarrow{\lambda} A \longrightarrow 0$$

with $\lambda := \varphi^{-1} \circ \pi_D$ from Proposition 6.2.1 has a unital split morphism by Corollary 5.8.12, because $D \cong \mathcal{O}_2 \otimes \mathbb{K}$ and E is exact.

The unital split C^*-morphism $\psi \colon A \to E \subseteq \mathcal{O}_2$ with $\lambda \circ \psi = \mathrm{id}_A$ is the desired unital *-monomorphism A into $\mathcal{O}_2$.

Conversely, $\mathcal{O}_2$ is nuclear ([**169**]), nuclear C^*-algebras are exact and C^*-subalgebras of exact C^*-algebras are again exact ([**432**, prop. 7.1(i)] or [**810**, 2.5.1, 2.5.2], or see Remark 3.1.2(ii) and (iii)).

Ad(ii): If A is nuclear and $T \colon \mathcal{O}_2 \to A$ is the completely positive map from Proposition 6.2.1, then $P := \psi \circ T$ is a conditional expectation from $\mathcal{O}_2$ onto $\psi(A) \subset E$.

Indeed: P is a completely positive contraction that maps $\mathcal{O}_2$ into $\psi(A)$. The maps T, ψ and λ satisfy $T(\mathcal{O}_2) = A$, $\psi(A) \subset E$, $T|E = \lambda$, and $\lambda \circ \psi = \mathrm{id}_A$. Therefore, $T \circ \psi = \mathrm{id}_A$, $P^2 = P$ and

$$P(\psi(a)) = \psi(T(\psi(a))) = \psi(\lambda(\psi(a)) = \psi(a) \qquad \forall\ a \in A\,.$$

Conversely, let P be a conditional expectation from a nuclear C^*-algebra B onto a C^*-subalgebra $A \subset B$ and $\eta_A \colon A \hookrightarrow B$ the inclusion map. Then $\mathrm{id}_A = P \circ \mathrm{id}_B \circ \eta_A$ is nuclear because id_B is nuclear and nuclearity is preserved under composition with other completely positive maps. □

Remark 6.2.2. The conditional expectation $P := \psi \circ T \colon \mathcal{O}_2 \to \psi(A)$ that has been defined in the proof of Part (ii) of Theorem A(ii) is an extreme point of the convex set of all linear contractions from $\mathcal{O}_2$ into $\mathcal{O}_2$.

Proof. Let M be a von Neumann algebra, $q \in M$ a projection, and $\mu \colon M \to M$ a *unital* contraction such that $\mu(1-q) = 0$ (i.e., $\mu(q) = 1$), $q\mu(qaq)q = qaq$ for $a \in M$ and $\mu|qMq$ is a C^*-morphism.

Then μ is an extreme point of the convex set of linear contractions from M into M. Indeed:

We use that each unitary $U \in M$ is an extreme point of the closed unit-ball of M, (cf. [**704**, thm. 1.6.4]). If $T, S \colon M \to M$ are contractions and $\theta \in (0,1)$ with $\theta T + (1-\theta)S = \mu$, then $\theta T(1) + (1-\theta)S(1) = 1$. It implies that $T(1) = 1 = S(1)$. Hence T and S are positive unital maps. It follows $T(1-q) \geq 0$, $S(1-q) \geq 0$ and $0 = \mu(1-q) = \theta T(1-q) + (1-\theta)S(1-q)$, thus $T(1-q) = 0 = S(1-q)$ and $T(a) = T(qaq)$, $S(a) = S(qaq)$ for $a \in M$. For unitaries u of qMq we get that $U := \mu(u)$ is unitary and $U = \theta T(u) + (1-\theta)S(u)$. Thus $\mu(u) = T(u) = S(u)$ for all unitaries of qMq. Together it implies $\mu = T = S$.

The $P \colon \mathcal{O}_2 \to \psi(A)$ annihilates D and, therefore, $M := {\mathcal{O}_2}^{**}$, $\mu := P^{**}$ and $q = 1 - p_D$ satisfy the above assumptions on M, μ and q, where p_D denotes the support projection of D. Since P^{**} is an extreme point of the contractions on M, P must be an extreme point of the contractions on $\mathcal{O}_2$. □

next Rem's have overlapping statements

REMARKS 6.2.3. Let $\varphi_j \colon A \to \mathcal{O}_2$ $(j = 1, 2)$ unital *-monomorphisms, then they are unitarily homotopic by Theorem B. In particular, they are approximately unitarily equivalent.

By Remark 6.2.2, one finds always for separable unital *nuclear* A at least one unital embedding $\iota \colon A \hookrightarrow \mathcal{O}_2$ such that there is an extremal conditional expectation P from $\mathcal{O}_2$ onto $\iota(A)$.

For any other embedding $\kappa \colon A \hookrightarrow \mathcal{O}_2$ there is a norm-continuous path $t \in [0, \infty) \mapsto U(t)$ into the unitary group of $\mathcal{O}_2$, such that $U(0) = 1$ and $\lim_{t\to\infty} \|U(t)^*\iota(a)U(t) - \kappa(a)\|$ for all $a \in A$. One can use this to show that for any (more general type of) unital *-monomorphism $\kappa \colon A \hookrightarrow \mathcal{O}_2$ there exists a norm-continuous path $t \in [0, \infty) \mapsto V(t)$ into the *isometries* in $\mathcal{O}_2$ such that $\lim_{t\to\infty} \|V(t)^*\kappa(a)V(t) - \kappa(a)\|$ for all $a \in A$ and $\lim_{t\to\infty} \operatorname{dist}(V(t)^*bV(t), \kappa(A))$ *for all* $b \in \mathcal{O}_2$. (This could replace the existence of conditional expectations in an approximate sense.)

There can not be stronger results, even under very reasonable additional conditions, because *there exist a unital nuclear C^*-algebra A unital *-monomorphisms φ_1 and φ_2 from a unital nuclear C^*-algebra A into $\mathcal{O}_2$, such that there does* not *exist an automorphism γ of $\mathcal{O}_2 \otimes \mathcal{O}_2$ with $\gamma(\varphi(a) \otimes 1) = \psi(a) \otimes 1$ for $a \in A$.*

Let us consider two nuclear unital C^*-algebras $A \subset B$ such that there is no conditional expectation from B onto A:

If $h \colon B \to \mathcal{O}_2$ is any unital *-monomorphism, and if $\psi \colon A \to \mathcal{O}_2$ and $P \colon \mathcal{O}_2 \to \psi(A)$ are as in Remark 6.2.2, then there can not exist an automorphism γ of $\mathcal{O}_2 \otimes \mathcal{O}_2$ with the property $\gamma \circ (h \otimes \mathrm{id})|A \otimes 1 = (\psi \otimes \mathrm{id})A \otimes 1$.

This is, because, on one side, there is a conditional expectation $Q := P \otimes (\lambda(\cdot)1)$ from $\mathcal{O}_2 \otimes \mathcal{O}_2$ onto $\psi(A) \otimes 1$, (where λ is a pure state on $\mathcal{O}_2$), but there can not be a conditional expectation Q' from $\mathcal{O}_2 \otimes \mathcal{O}_2$ onto $h(A) \otimes 1$, because otherwise $((h|A)^{-1} \otimes 1)((Q'|(h(B) \otimes 1))$ defines an conditional expectation from B onto A.

Suppose that A is a nuclear C^*-subalgebra of a separable unital exact C^*-algebra B such that $1_B \in A$ and such that there does not exist a conditional expectation from B onto A. If $k \colon B \hookrightarrow \mathcal{O}_2$ is a unital embedding and if we define $i := k|A$ as the restriction of k to A, then there does not exist any conditional expectation E from $\mathcal{O}_2$ onto $i(A) = k(A)$, because otherwise $k^{-1} \circ E \circ k$ would be a conditional expectation from B onto A.

Examples:

(o) Suppose that D is a hereditary C^*-subalgebra of a unital C^*-algebra B such that the normalizer algebra $\mathcal{N}(D) := \{b \in B\,;\, bD + Db \subset D\}$ is different from $A := D + \mathbb{C}1$ and that $bD \neq \{0\}$ for all $b \in B_+ \setminus \{0\}$. Then there does not exist a conditional expectation E from B onto A. (Here $\mathbb{C}$ denotes the complex numbers.) Indeed: $(E(b)-b)^*(E(b)-b)d=0$ for all $b\in\mathcal{N}(D)$, $d\in D$, i.e. $E|\mathcal{N}(D)=\mathrm{id}$. It yields e.g. the following two examples (i) and (ii):

(i) Consider $\mathcal{O}_2$ as a unital C*-subalgebra of $\mathcal{L}(\ell_2)$ (by some *-representation). Let $\mathbb{K}$ denote the compact operators, and let $A:=\mathbb{K}+\mathbb{C}1$, $B:=\mathbb{K}+\mathcal{O}_2$.

(ii) Let $B:=\mathcal{T}$, $A:=\mathbb{K}+\mathbb{C}1$, where $\mathcal{T}$ denotes the Toeplitz algebra, generated as C*-algebra by the Toeplitz operator T (i.e. the unilateral shift of ℓ_2).

(iii) Consider the natural continuous epimorphism σ from the Cantor Space $\Omega:=\{0,1\}^\infty$ onto $[0,1]$ given by

$$\sigma\colon (a_1,a_2,...)\mapsto \sum_{n=1}^{\infty} a_n 2^{-n}$$

Then $\gamma\colon f\in \mathrm{C}[0,1]\mapsto \gamma(f):=f\circ\sigma\in \mathrm{C}(\Omega)$ gives a unital embedding of $\mathrm{C}[0,1]$ into $\mathrm{C}(\Omega)=\bigotimes_{n=1}^{\infty}(\mathbb{C}\oplus\mathbb{C})\subset M_{2^\infty}$.

Let $A:=\mathrm{C}[0,1]\subset \mathrm{C}(\Omega)=:B$, where Ω is the Cantor set $\Omega:=\{0,1\}^\infty$, and the monomorphism $A\hookrightarrow B$ is given by $f\mapsto f\circ\rho$ for the continuous map

$$\rho\colon (\alpha_1,\alpha_2,\ldots)\to\sum_{n=1}\alpha_n 2^{-n}$$

from Ω onto $[0,1]$.

The pairs $A:=\gamma(\mathrm{C}[0,1])$ and $B:=\mathrm{C}(\Omega)$ – or $B:=M_{2^\infty}$ – have the property that there does not exist a conditional expectation from B onto A, because the continuous map σ is not open.

Still Question ?: Suppose that $i,j\colon A\hookrightarrow\mathcal{O}_2$ are unital embeddings such that there are extremal conditional expectations from $\mathcal{O}_2$ onto $i(A)$, respectively onto $j(A)$.

Is there an automorphism γ of $\mathcal{O}_2\otimes\mathcal{O}_2$ with $\gamma(i(a)\otimes 1)=j(a)\otimes 1$ for all $a\in A$?

There are nuclear A and unital embeddings $i,j\colon A\hookrightarrow\mathcal{O}_2$ such that there is a conditional expectation P from $\mathcal{O}_2$ onto $i(A)$, but that there does not exist a conditional expectation from $\mathcal{O}_2$ onto $j(A)$.

It follows that there is no automorphism γ of $\mathcal{O}_2\otimes\mathcal{O}_2$ such that $\gamma(i(A)\otimes 1)=j(A)\otimes 1$, because — otherwise — there is an automorphism $\beta\in\mathrm{Aut}(A)$ with $\gamma(i(a)\otimes 1)=j(\beta(a))\otimes 1)$ for $a\in A$ and the the conditional expectation $P\colon\mathcal{O}_2\to i(A)$ (with $P(\mathcal{O}_2)=i(A)$) defines a conditional expectation $Q\colon\mathcal{O}_2\to j(A)$ (with $Q(\mathcal{O}_2)=j(A)=(j\circ\beta)(A))$ by $Q(b):=\mathrm{id}\otimes\lambda\big(\gamma(P\otimes\lambda(\gamma^{-1}(b\otimes 1)))\big)$, where $\lambda(b):=\rho(b)1\in\mathcal{O}_2$ for $b\in\mathcal{O}_2$.

`What the hell is that ?:`

One can show that there exist unital endomorphisms $h_1,h_2\colon\mathcal{O}_2\to\mathcal{O}_2$, such that there is no automorphism γ of $\mathcal{O}_2\otimes\mathcal{O}_2$ such that $\gamma\circ(h_1\otimes\mathrm{id})=h_2\otimes\mathrm{id}$. An example is given by h_1,h_2 as $h_k(a)=1\otimes\iota_k(a)$ defined by isomorphisms ι_1 from

$M_{2^\infty} \otimes \mathcal{O}_2$ onto $\mathcal{O}_2$ and ι_2 from $\mathcal{O}_2 \otimes \mathcal{O}_2 \cong \mathcal{O}_2$ onto $\mathcal{O}_2$: Here such an automorphism γ would also define an isomorphism from M_{2^∞} onto $\mathcal{O}_2$.

???????????

Notice that, moreover, the latter endomorphisms h_k have the property that there is an extremal conditional expectation P from $\mathcal{O}_2 \otimes \mathcal{O}_2$ onto $h_k(\mathcal{O}_2) \otimes \mathcal{O}_2$.

The above examples suggest, that a separable unital exact C^*-algebra A is finite-dimensional if all unital *-monomorphisms $h\colon A \hookrightarrow \mathcal{O}_2$ are conjugate by an automorphism γ of $\mathcal{O}_2$. (The K_0-triviality of $\mathcal{O}_2$ implies immediately that all unital *-monomorphisms $h\colon A \to \mathcal{O}_2$ are unitarily equivalent by a unitary in $\mathcal{O}_2$.)

Does there exist simple separable nuclear unital C^*-subalgebras $A \subset B$ such that $1_B \in A$ and such that there does not exist conditional expectation from B onto A?

Does there exist a unital endomorphism $\iota\colon M_{2^\infty} \hookrightarrow M_{2^\infty}$ such that there is no conditional expectation from M_{2^∞} onto $\iota(M_{2^\infty})$?

Then it would follow that there are unital endomorphisms $i\colon \mathcal{O}_2 \hookrightarrow \mathcal{O}_2$ such that there does not exist a conditional expectation from $\mathcal{O}_2$ onto $i(\mathcal{O}_2)$, because $\mathcal{O}_2 \cong A \otimes \mathcal{O}_2 \subset B \otimes \mathcal{O}_2 \cong \mathcal{O}_2$.

3. The residually nuclear case

The proof of a Ψ-residually equivariant version of Proposition 6.2.1 requires some generalizations of the above used ideas. In particular, we must generalize some definitions and results of [**437**] and [**438**]. The following Theorem 6.3.1 is half on the way to the proof of Theorem K. The proof of Theorem K will be completed in Chapter 12. Compare Definitions 1.2.6, 1.2.8 and 1.2.3 and Chapters 3 and 5 for the used notation.

THEOREM 6.3.1. *Suppose that A and B are separable stable C^*-algebras, and $\Psi\colon \mathcal{I}(B) \to \mathcal{I}(A)$ is an action of* Prim(B) *on A, that has the following properties (i)–(v):*

(i) *B has the WvN-property* ([4]), *and*
(ii) *B has residually nuclear separation* ([5]),
(iii) *A is exact* ([6]).
(iv) *Ψ is non-degenerate, lower semi-continuous, and monotone upper semi-continuous* ([7]).

[4] Def. WvN-property ????

[5] Residually nuclear separation is defined in Definition 1.2.3. Equivalently, the universal weakly residually nuclear *-morphism $H_{\mathrm{rn}}\colon B \to \mathcal{M}(B)$ of Definition **??** is a non-degenerate *-monomorphism and separates the ideals of B by Proposition 5.9.24.

[6] give Def. exact ??

[7] Defs. non-degenerate, lsc, monotone usc.

(v) *The m.o.c. cone* $\mathcal{C} \subset \mathrm{CP}(A,B)$ *of* Ψ*-equivariant completely positive maps* ([8]) *from* A *into* B *is separating for* Ψ*, i.e.,* $\Psi_{\mathcal{C}} = \Psi$ *by Proposition* **??** *I.e. there exists a *-monomorphism* $H\colon A \to \mathcal{M}(B)$*, with the property* $\Psi(J) = H^{-1}(H(A) \cap \mathcal{M}(B,J))$ *for all* $J \in \mathcal{I}(B)$ ([9])*.*

*The above properties lead to a non-degenerate nuclear *-monomorphism* $k\colon A \otimes \mathcal{O}_2 \hookrightarrow B$ *such that* $h(\Psi(J)) = h(A) \cap J$ *for all* $J \in \mathcal{I}(B)$*, where* $h(a) := k(a \otimes 1)$*.*

The infinite repeats $\delta_\infty h$ *and* $\delta_\infty \circ H$ *are unitarily homotopic.*

If, in addition, A *is nuclear,* A *contains a regular Abelian* C^**-subalgebra, and the action* Ψ *is continuous (i.e.,* $\Psi(I) \cup \Psi(J) = \Psi(I \cup J)$ *– in addition), then* h *is unitarily homotopic to a non-degenerate *-morphism* $h_1\colon A \to B$ *such that there exists an approximately inner conditional expectation* P *from* B *onto* $h_1(A)$*.*

([10]).

It follows from [**464**] that $A \otimes \mathcal{O}_2$ contains a regular abelian C^*-subalgebra for every nuclear separable C^*-algebra A.

If B is any separable C^*-algebra, and $B \otimes \mathcal{O}_2$ contains a *regular Abelian* C^**-subalgebra* $C \subset B \otimes \mathcal{O}_2$, then every lower semi-continuous action $\Psi\colon \mathcal{I}(B) \to \mathcal{I}(A)$ is realized by $\mathrm{CP}_{\mathrm{rn}}(\Psi; A, B) = \mathrm{CP}_{\mathrm{rn}}(\mathrm{Prim}(B); \Psi, \mathrm{id}; A, B)$, cf. Proposition **??**. In particular, then B has residually nuclear separation (in the sense of Definition 1.2.3, i.e., $\mathrm{CP}_{\mathrm{rn}}(B,B)$ defines the identity action of $\mathrm{Prim}(B)$ on B), cf. Corollary **??**. A separable C^*-algebra B with residually nuclear separation has the WvN-property, if and only if, B is strongly purely infinite (cf. Proposition **??**). Hence, Theorem 6.3.1 implies:

Corollary 6.3.2. *Theorem K is valid under the* additional *assumptions that* B *is* separable *and that* $B \otimes \mathcal{O}_2$ *contains a* regular Abelian C^**-subalgebra* $C \subset B \otimes \mathcal{O}_2$*.*

Remark 6.3.3. We derive from Corollary 6.3.2 a complete proof of Theorem K in Chapter 12, using the study of scale-invariant morphisms in Chapter 9. The proof relies on the construction of a suitable strongly purely infinite separable C^*-subalgebra B_1 of $\mathrm{Q}(\mathbb{R}_+, B) := \mathrm{C_b}(\mathbb{R}_+, B)/\,\mathrm{C_0}(\mathbb{R}_+, B)$ that contains a regular Abelian C^*-subalgebra and a sufficiently large separable C^*-subalgebra of B as a non-degenerate subalgebra (of B_1).

[8] Give Ref to Def.Psi.equivariant.maps

[9] I.e., $\Psi_{\mathcal{C}} = \Psi$ for the action Ψ of $\mathrm{Prim}(B)$ on A and the m.o.c. cone $\mathcal{C} \subset \mathrm{CP}(A,B)$ of the Ψ-equivariant nuclear maps. Then there is a C^*-morphism $h_1\colon A \to \mathcal{M}(B)$ such that $h_2 := \mathcal{M}(H_{\mathrm{rn}}) \circ h_1$ induces the action Ψ_A of $\mathrm{Prim}(B)$ on A by $\Psi_A(J) = h^{-1}(h(A) \cap \mathcal{M}(B,J))$ for $J \in \mathcal{I}(B)$, cf. Proposition 5.9.24.

[10] We assume, in addition to the assumptions of Theorem K, that B has residually nuclear separation in sense of Definition 1.2.3, i.e., that the universal weakly residually nuclear *-morphism $H_{\mathrm{rn}}\colon B \to \mathcal{M}(B)$ of Proposition 5.9.24

is non-degenerate and is separating for the ideals of B, and that $\Psi_{\mathcal{C}} = \Psi$ for the action Ψ of $\mathrm{Prim}(B)$ on A and the m.o.c. cone $\mathcal{C} \subset \mathrm{CP}(A,B)$ of the Ψ-residually nuclear maps, i.e., that there is a C^*-morphism $h_1\colon A \to \mathcal{M}(B)$ such that $h_2 := \mathcal{M}(H_{\mathrm{rn}}) \circ h_1$ induces the action Ψ_A of $\mathrm{Prim}(B)$ on A by $\Psi_A(J) = h^{-1}(h(A) \cap \mathcal{M}(B,J))$ for $J \in \mathcal{I}(B)$, cf. Proposition 5.9.24. This additional assumptions will be removed both in Chapter 12.

Corollary 6.3.2 gives a nuclear *-monomorphism $k\colon A\otimes\mathcal{O}_2\to B_1\subset \mathrm{Q}(\mathbb{R}_+,B)$ with image in the ideal generated by $B\subset \mathrm{Q}(\mathbb{R}_+,B)$ and with the property that $k(A\otimes 1)\cap J=k(\Psi_A(B\cap J)\otimes 1)$ for any closed ideal J of $\mathrm{Q}(\mathbb{R}_+,B)$.

The latter property induces the existence of a unitary $U\in \mathrm{C_b}(\mathbb{R}_+,\mathcal{M}(B))$ and of a non-degenerate nuclear *-monomorphism $h\colon A\otimes\mathcal{O}_2\to B$ with $k(a\otimes 1)=U^*h(a\otimes 1)U+\mathrm{C}_0(\mathbb{R}_+,B)$ for $a\in A$ (see Chapter 9). The *-morphism h is as stipulated in Theorem K.

Remark 6.3.4. *Since every simple algebra has residually nuclear separation, Theorem 6.3.1 contains Theorem A(i), if we consider $\mathcal{O}_2\otimes A\otimes\mathbb{K}\subset\mathcal{L}(\ell_2)\cong\mathcal{M}(\mathbb{K})\subset\mathcal{M}(B)$ for $B=\mathcal{O}_2\otimes\mathbb{K}$.* Our proof of Theorem 6.3.1 is independent from almost all results on p.i.s.u.n. algebras, because for the existence of the lift $k\colon A\otimes\mathcal{O}_2\to B$ we have only used that $A\otimes\mathcal{O}_2\otimes\mathcal{O}_2$ is exact, and our elementary characterization of absorbing liftable elements in $\mathrm{SExt}_{\mathrm{nuc}}(\mathrm{Prim}(B);A,B)$.

We describe now the steps of the proof of Theorem 6.3.1.

Recall that $H\colon A\to\mathcal{M}(B)$ is weakly nuclear, iff, or every $b\in B$, the map $A\ni a\to b^*H(a)b\in B$ is nuclear.

Since Ψ is non-degenerate, we get that $H\colon A\to\mathcal{M}(B)$ is faithful and $BH(A)B$ is dense in B. We have see in Chapter 3 `where exactly?` that there exists a non-degenerate weakly nuclear *-monomorphism $H_0\colon A\to\mathcal{M}(B)$ with $\delta_\infty\circ H_0$ unitarily equivalent to H_0, such that H_0 is unitarily homotopic to $\delta_\infty\circ H$.

It follows that $H_0(A)\subset\delta_\infty(\mathcal{M}(B))$. The commutant of $\delta_\infty(\mathcal{M}(B))$ in $\mathcal{M}(B)$ contains a copy of $\mathcal{O}_2$ unitally.

We rename $\delta_\infty\big(\overline{\mathrm{span}(H_0(A)\cdot\mathcal{O}_2)}\big)\cong A\otimes\mathcal{O}_2$ by A. Then, from now on, $A\cong A\otimes\mathcal{O}_2$. Then (i)–(v) imply:

(1) A is non-degenerate,i.e., AB is dense in B, and

(2) for every $b\in B$, the map $A\ni a\to b^*H(a)b\in B$ is nuclear.

(3) The action $\Psi\colon\mathcal{I}(B)\to\mathcal{I}(A)$ is given by $\Psi(J):=A\cap\mathcal{M}(B,J)$ and is monotone upper semicontinuous,i.e., $\bigcup_n\Psi(J_n)$ is dense in $\Psi(J)$ for $J:=\overline{\bigcup_n J_n}$, $J_1\subset J_2\subset\cdots\subset B$.

The proof of Theorem 6.3.1 will be given at the end of this Section. But here we describe the steps of the proof:
First step:
With A satisfies also $\delta_\infty(A)$ and $C^*(\delta_\infty(A),\mathcal{O}_2)\cong A\otimes\mathcal{O}_2$ the properties (1)-(3).
Second step:

Next had disappeared and is restored from beamers

Steps of the embedding realization. Step 1:
We start with $\lambda\colon B\to\mathcal{M}(B)$, a weakly continuous non-degenerate C^*-morphism $\lambda\colon B\to\mathcal{M}(B)$ that defines the identity action $J=\lambda^{-1}\big(\lambda(B)\cap\mathcal{M}(B,J)\big)$ on $\mathcal{I}(B)$

and is in "general position" (i.e., $\delta_\infty \circ \lambda = u^*\lambda(\cdot)u$). It exists because our B has in particular "Abelian" factorization (and is separable, stable and s.p.i.).

Then obtain for $A \cong A \otimes \mathcal{D}_2$ our non-degenerate Ψ-realization $H_1 \colon A \to \mathcal{M}(B)$ – coming also from the "Abelian" factorization property of B that reduces it to a classical selection problem. Get non-degenerate

$$H_0 := \mathcal{M}(\lambda) \circ H_1 \colon A \subset \mathcal{M}(\lambda)(\mathcal{M}(B)) \subset \mathcal{M}(B)\,.$$

Here we list the former results that are needed for the "remaining" parts of the proof:

(1) $H_0(A)$ is non-degenerate, i.e., $H_0(A)B$ is dense in B, and is in "general position" (i.e., there exists a unitary $U \in \mathcal{M}(B)$ $U^*H_0(\cdot)U = \delta_\infty \circ H_0$).

(2) The given lower s.c. action $\Psi \colon \mathcal{I}(B) \to \mathcal{I}(A)$ is realized by $\Psi(J) := H_0^{-1}(H_0(A) \cap \mathcal{M}(B,J))$ and Ψ is monotone upper semi-continuous, i.e., $\bigcup_n \Psi(J_n)$ is dense in $\Psi(J)$ for $J := \overline{\bigcup_n J_n}$, if the sequence $J_n \in \mathcal{I}(B)$ is increasing: $J_1 \subset J_2 \subset \cdots$.

(3) For every $b \in B$, the Ψ_A-compatible map $A \ni a \mapsto b^*H_0(a)b \in B$ is nuclear, and can be approximated by compositions $V_2 \circ V_1$ of the residually nuclear maps $V_1 \colon a \in A \mapsto b_1^*H_1(a)b_1 \in B$ and $V_2 \colon b \in B \mapsto b_2^*\lambda(b)b_2$. I.e. V_2 satisfies $V_2(J) \subset J$ for all $J \in \mathcal{I}(B)$ and that $[V_2]_J \colon B/J \to B/J$ is nuclear for all $J \in \mathcal{I}(B)$.

Step 2:
If A satisfies (1)–(3), then, – with $a \in A$ identified with $H_0(a) \in H_0(A) \subset \mathcal{M}(B)$ – for every $a_1, \ldots, a_n \in A$ and $\varepsilon > 0$, there exist completely positive contractions $V \colon \mathcal{M}(B) \to B$ and $W \colon B \to \mathcal{M}(B)$ that satisfy the following conditions (a), (b) and (c):

(a) $\|W \circ V(a_j) - a_j\| < \varepsilon$, for $j = 1, \ldots, n$.
(b) V is strictly continuous and is residually equivariant, i.e., $\lim_n \|V(b_n) - V(b)\| = 0$ if $b_n \to b$ in $\mathcal{M}(B)$ strictly and $V(J) \subset J \cap B$ for $J \in \mathcal{I}(\mathcal{M}(B))$.
(c) $W \colon B \to \mathcal{M}(B)$ is weakly residually nuclear, i.e., $W(J)B \subset J$ for $J \in \mathcal{I}(B)$, and the maps $[W]_J \colon B/J \to \mathcal{M}(B/J) \cong \mathcal{M}(B)/\mathcal{M}(B,J)$ satisfy that $([W]_J)_d \colon b \in B/J \mapsto d^*[W]_J(b)d \in B/J$ is a nuclear map for all $d \in B/J$. Here $[W]_J(a+J) := W(a) + \mathcal{M}(B,J)$, i.e., $d^*[W]_J(b)d = \pi_J(f^*W(a)f)$ for $b = a+J$ and $d = f+J$.

More on Step 2:

Consider the set of maps $V := V_c \colon \mathcal{M}(B) \to B$ given by $V_c \colon b \in \mathcal{M}(B) \mapsto c^*\mathcal{M}(\lambda)(b)c$. The point-norm closure is an m.o.c. cone $\mathcal{C}_1$.

Do the same with the maps $W := W_T \colon B \to \mathcal{M}(B)$ given by $W_T(b) := T^*\lambda(b)T$, for $T \in \mathcal{M}(B)$, and we denote this m.o.c. cone by $\mathcal{C}_2$.

Both cones are singly generated (as m.o.c.c.), e.g. $\mathcal{C}_1$ by $e\mathcal{M}(\lambda)(\cdot)e$ where $e \in B_+$ is strictly positive, and $\mathcal{C}_2$ by λ (as u.c.p. map).

The properties (b) and (c) follows from the properties of λ and the fact that $\mathcal{M}(\lambda)$ is the unique strictly continuous extensions of λ.

Continuation 1: More on Step 2:

Notice that $\lambda(b)$ and $\delta_\infty(b)$ for each self-adjoint $b \in B$ must be unitarily homotopic in $\mathcal{M}(B)$ by the generalized W-vN theorem, because both define *-mono-morphisms from $C^*(b)$ into $\mathcal{M}(B)$ that are in "general position" and define the same action of $\mathrm{Prim}(B)$ on $C^*(b)$ by definition of λ, namely the action $J \in \mathcal{I}(B) \mapsto \mathcal{M}(B, J) \cap C^*(b)$.

It follows that each $W \in \mathcal{C}_2$ maps B into the closure I_0 of $\mathcal{M}(B)\delta_\infty(B)\mathcal{M}(B)$, the closed ideal of $\mathcal{M}(B)$ generated by $\delta_\infty(B)$.

Moreover, $b \in \mathcal{M}(B)_+$ will be mapped by all $P \in \mathcal{C}_2 \circ \mathcal{C}_1$ into the ideal of $\mathcal{M}(B)$ that is the norm-closure of the union of the ideals $\mathcal{M}(B, J((ebe - 1/n)_+))$, with $J(b) \in \mathcal{I}(B)$ as defined above, $e \in B_+$ strictly positive contractions.

`A clear statement is now in Chapter 12:`
The point-norm closed m.o.c. cone $\mathcal{C}_1 \subset \mathrm{CP}(A, \mathcal{M}(B))$ generated by $a \in A \to W(V(a))) \in \mathcal{M}(B)$ is contained in $\mathrm{CP}_{\mathrm{nuc}}(A, \mathcal{M}(B))$ and is element-wise approximating. Thus, is point-norm approximating for $H_0 \colon A \to \mathcal{M}(B)$.

Continuation 3: More on Step 2:

The condition (a) is equivalent to $H_0 \in \mathcal{C}_3 := \mathcal{C}_2 \circ \mathcal{C}_1 \circ \mathcal{C}_{H_0}$. The m.o.c. cone $\mathcal{C}_3$ is contained in the cone of (norm-) nuclear c.p. maps from A into $\mathcal{M}(B)$, and the elements of $\mathcal{C}_3$ map A into the norm-closed ideal $I(\delta_\infty(B))$ of $\mathcal{M}(B)$ that is generated by $\delta_\infty(B)$.

More precisely, the elements of $\mathcal{C}_3$ map $a \in A_+$ into the closed ideal of $I(\delta_\infty(B)) \subset \mathcal{M}(B)$ generated by the element $\delta_\infty(e)\delta_\infty^2(e)\delta_\infty^3(a)\delta_\infty^2(e)\delta_\infty(e)$.

If there is $b \in B_+$ such that $\delta_\infty(b)$ and a generate the same closed ideal of $\mathcal{M}(B)$, then there are $T_n \in \mathcal{C}_2 \circ \mathcal{C}_1$ such that $\|T_n(a) - a\| \to 0$.

Step 3:
We use that $A \cong A \otimes \mathcal{O}_2 \otimes \mathcal{O}_2 \otimes \cdots$, ([11]). and select suitable $V_n \colon \mathcal{M}(B) \to B$, $W_n \colon B \to \mathcal{M}(B)$ from Step 2, such that $W_n \circ V_n|A$ converges sufficiently fast in point-norm to the inclusion $A \hookrightarrow \mathcal{M}(B)$ (where $H_0(A)$ and A are naturally identified). Then A is in the multiplier sub-algebra of the separable (non-unital) C^*-system

$$Y := \mathrm{indlim}_n(W_n \circ V_n \colon \mathcal{M}(B) \to \mathcal{M}(B)) \subset \mathcal{M}(B)_\infty\,.$$

By a standard Banach space theory argument, (cf. Section 14 of Appendix B), Y is completely positive and completely isometric isomorphic to the (nuclear) C^*-system

$$X := \mathrm{indlim}_n(V_{n+1} \circ W_n \colon B \to B) \subset B_\infty = \ell_\infty(B)/c_0(B)\,.$$

---

[11]Notice that we do not use that $\mathcal{O}_2 \cong \mathcal{O}_2 \otimes \mathcal{O}_2 \otimes \cdot$, because we want to give a proof that is independent from the former results on p.i.s.u.n./ algebras, and gives also a new proof of Theorem A.

Step 4:
An inspection of the natural completely positive and completely isometric isomorphism I from Y onto X shows that

(α) The isomorphism I maps $A \subset Y$ into the intersection $X \cap \mathcal{M}(X)$ of the (two-sided) multiplier algebra $\mathcal{M}(X) \subset X^{**}$ of X with $X \subset X^{**}$.

(β) This happens in an ideal-system equivariant way, i.e.,

$$I(\mathcal{M}(B,J)_\infty \cap Y) = J_\infty \cap X \quad \text{for all } J \in \mathcal{I}(B)\,.$$

(γ) The operator system X is *nuclear* because the maps $T_n\colon V_{n+1} \circ W_n$ are nuclear, i.e., T_n can be approximated point-wise by "decomposable" contractions that factorize approximately through suitable matrix-algebras M_{k_n}.

Use here and above that inductive limits of – not necessarily unital – *C^*-systems* by using c.p. contractions always are *C^*-systems*, and that the second conjugate with the natural matrix-order and matrix-norm is a W*-algebra.

Step 5:
We construct a hereditary C^*-subalgebra $D \subset B$ and a completely positive and completely isometric isomorphism φ from X onto $B//D$, that have the properties

(P1) D is residually essential – in particular D is stable,

(P2) $\varphi(J_\infty \cap X) = \pi_{DB+BD}(J)$,

(P3) $\varphi(X \cap \mathcal{M}(X)) = \pi_D(\mathcal{N}(D))$,

(P4) the natural map $\mathcal{N}(D)/D \to \mathcal{M}(D)/D \cong \mathrm{Q}(B)$ extends to completely positive map γ from $B//D$ into $\mathcal{M}(D)/D$ with the property that $\gamma(J//D) = \gamma(B//D) \cap \mathcal{M}(D, D \cap J)$ for all $J \triangleleft B$.

Idea for finding D in Step 5 is the following
Lemma on replacements of inductive limits:

(See somewhere below)

End of Lemma.

Since B is stable, separable and s.p.i., we get that the ($\mathcal{I}(B)$-) residually nuclear contractions $P\colon B \to B$ can be approximated point-wise by maps $T\colon B \to B$ given by $T_S(b) := S^*bS$ for isometries $S \in \mathcal{M}(B)$ with $1 - SS^*$ properly infinite. Thus we can take a fixed copy of $C^*(s,t) \cong \mathcal{O}_2$ in $\mathcal{M}(B)$ and find the approximating T_S as $S = U^*sU$ for suitable unitary $U \in \mathcal{M}(B)$.

Thus X becomes by the Lemma simply *the same* as $\operatorname{indlim} T_n\colon B \to B$ with $T_n(b) = U_n^* s^* U_n b U_n^* s U_n$ for a suitable sequence of unitaries $U_n \in \mathcal{M}(B)$. It turns then out that X is c.i. and c.p. isomorphic to $B//D$ where D is found in a certain inductive limit of copies of B by inner automorphisms of B.

Step 6:
We apply the Proposition on Ψ-compatible Busby invariants to the Busby invariant $\gamma \circ \varphi \circ I\colon A \to \mathcal{M}(D)/D$. It has image in $\mathcal{N}(D)/D$ and admits a Ψ-equivariant lift $h\colon A \to \mathcal{N}(D) \subset B$, that is nuclear as map from A into B.

(But h is not necessarily nuclear as a map from A into $\mathcal{N}(D)$.)

It turns out that h is unitarily homotopic to a *non-degenerate* nuclear monomorphism $h_0 \colon A \to B$ that is Ψ-equivariant.

Step 7:

????????????????????????

The case of (bi-) continuous action Ψ of $\mathrm{Prim}(B)$ on A.

Target: If A is nuclear and $h_0(A)$ regular in B, then there exists an Ψ-equivariant conditional expectation from B to $h_0(A)$ or at least a sequence of Ψ-equivariant c.p. contractions $V_n \colon B \to h_0(A)$ with $V_n(h_0(a)) \to h_0(a)$ for $n \to \infty$.

If $\Psi \colon \mathcal{I}(B) \to \mathcal{I}(A)$ is "continuous", then $h_0(A)$ must be a regular C^*-subalgebra of B. It follows, that there is a lower semi-continuous action $\Phi \colon \mathcal{I}(A) \to \mathcal{I}(B)$ with $\Phi(h(J)) :=$ biggest $K \triangleleft B$ with $K \cap h(A) \subset h(J)$.

REF ??????????

Since A contains a regular abelian C^*-subalgebra, the cone $\mathrm{CP}_{\mathrm{rn}}(\Phi; B, A)$ of Φ-residually nuclear maps $W \colon B \to A$ is separating for Φ, i.e., for each $b \in B_+$ and each pure state λ on A with $\lambda(J) \neq \{0\}$, there is $W \in \mathrm{CP}_{\mathrm{rn}}(\Phi; B, A)$ with $\lambda(W(\Phi(J))) \neq \{0\}$.

Since $\Phi(K \cap h(A)) \supset K$ for all ideals $K \triangleleft B$, it follows that $\Phi \circ \Psi$ majorizes Id of $\mathcal{I}(B)$.

??????? ??????????????????? If A is nuclear, ??????????????

??

`Overview on proof Thm. 6.3.1 finished?`

We need some simple general results on residually essential hereditary C^*-subalgebras D of a C^*-algebra B, non-unital C^*-systems and on inductive limits. First we explain some properties of certain subspaces of C^*–algebras.

REMARK 6.3.5. Suppose that B is separable and that $A \subset \mathcal{M}(B)$ is a separable *stable* exact C^*-subalgebra, such that AB is dense in B and that the maps $a \in A \mapsto b^*ab \in B$ are nuclear for all $b \in B$.

Then B is stable, and maps $V \colon \mathcal{M}(B) \to B$ and $W \colon B \to \mathcal{M}(B)$ with properties (a), (b) and (c) for (given) $a_1, \ldots, a_n \in A$ and $\varepsilon > 0$ exist, if and only if,

(i) The m.o.c. cone $\mathrm{CP}_{\mathrm{rn}}(\mathrm{Prim}(B), B, B)$ of residually nuclear maps from B to B is non-degenerate, i.e., the universal weakly residually nuclear $H_{rn} \colon B \to \mathcal{M}(B)$ C^*-morphism (given by Corollary **??** for $\mathcal{C} := \mathrm{CP}_{\mathrm{rn}}(\mathrm{Prim}(B); B, B)$) is non-degenerate.
  And separating for $\mathrm{Prim}(B)$??

(ii) The representations $a \in A \mapsto \mathcal{M}(H_{rn})(a) \in \mathcal{M}(B)$ and $a \in A \mapsto a \in \mathcal{M}(B)$ define the same action of of $\mathrm{Prim}(B)$ on A.

(iii) The (lower semi-continuous) action of $\mathrm{Prim}(B)$ on A is monoton upper semi-continuous.

(See the arguments in Chapter 12 for a proof.)

????????????

`Move the needed arguments of Chapter 12 to here. ??`

The conditions (i)–(iii) are satisfied if the action of $\mathrm{Prim}(B)$ on B defined by H_{rn} is the identity map of $\mathcal{I}(B) \cong \mathbb{O}(\mathrm{Prim}(B))$.

Definition 6.3.6. A hereditary C^*-subalgebra $D \subset B$ is *residually essential* in B, if for every closed ideal $J \in \mathcal{I}(B)$ holds that $\pi_J(D)$ is essential in B/J, i.e., $b \in B_+$ and $bD \subset J$ imply $b \in J$ (equivalently: $\mathrm{Ann}(\pi_J(D)) = 0$ in B/J).

Lemma 6.3.7. *Let $T\colon X \to C$ a positive and isometric linear map from a (not necessarily unital) C^*-system X into a C^*-algebra C.*

Then $T^{-1}(C_+ \cap T(X)) = X_+$.

Proof. We can pass to the second adjoint $T^{**}\colon X^{**} \to C^{**}$. The map T^{**} is still positive and isometric, $T^{**}|X = T$, $X_+ = (X^{**})_+ \cap X$, and X^{**} is unitally order isomorphic to a unital C^*-algebra. Thus, we may suppose that X is a C^*-algebra.

Let $a = h + ik \in X$ with self-adjoint $h, k \in X$ with polar decompositions $h = h_+ - h_-$, $k = k_+ - k_-$, and suppose $T(a) \in C_+$. Then $T(h_+)$, $T(h_-)$, $T(k_+)$ and $T(k_-)$ are all in C_+. Thus $T(k) = 0$, $a = h_+ - h_-$ and $0 \leq T(h_-) \leq T(h_+)$.

Suppose that $h_- \neq 0$. Then $T(h_+) \neq 0$ and $h_+ \neq 0$. Let $x := \|h_-\|^{-1}h_-$ and $y := \|h_+\|^{-1}h_+$. It follows $x, y \in X_+$, $xy = 0$, $T(x), T(y) \in C_+$, $\|T(x)\| = \|x\| = 1$, $\|T(y)\| = \|y\| = 1$ and $\|T(x + y)\| = \|x + y\| = \max(\|x\|, \|y\|) = 1$. Thus, there exists a state ρ on C with $\rho(T(x)) = 1$ (by extending a suitable character of $C^*(T(x))$ to C). Then $1 \leq \rho(T(x)) + \rho(T(y)) = \rho(T(x + y)) \leq 1$. It implies $\rho(T(y)) = 0$, which contradicts $\|h_-\|T(x) \leq \|h_+\|T(y)$ if $\|h_-\| > 0$. Thus $h_- = 0$ and $a = h_+$. □

Lemma 6.3.8. *Suppose that B and C are C^*-algebras, that A is a C^*-subalgebra of C, that $\Psi_C\colon \mathcal{I}(B) \to \mathcal{I}(C)$ is a monotone map, that $D \subset B$ is a hereditary C^*-subalgebra of B.*

If $T\colon B//D \to C$ is a completely positive and completely isometric linear map, such that $A \subset T(B//D)$ and, for $J \in \mathcal{I}(B)$,

$$T(\pi_D(J)) = \Psi_C(J) \cap T(B//D)\,,$$

*then the *-monomorphism $\lambda := T^{-1}|A\colon A \to \mathcal{N}(D)/D$ satisfies, for $J \in \mathcal{I}(B)$,*

$$\lambda(A \cap \Psi_C(J)) = \lambda(A) \cap \pi_D(J)\,.$$

Proof. The map $\lambda\colon A \to (B//D)^{**} \cong q_D B^{**} q_D$ is an isometric completely positive map by Lemma 6.3.7, because

$$T^{**} \otimes \mathrm{id}_n = (T \otimes \mathrm{id}_n)^{**}\colon q_D B^{**} q_D \otimes M_n \to C^{**} \otimes M_n$$

is isometric and positive for each $n \in \mathbb{N}$. Since $\|\lambda\| \leq 1$, we get from the generalized Kadison inequality of Choi that $\lambda(a^*a) \geq \lambda(a)^*\lambda(a)$ for $a \in A$. If we apply T^{**} to this inequality and use the Choi-Kadison inequality for T^{**}, we get

$$a^*a = T^{**}(\lambda(a^*a)) \geq T^{**}(\lambda(a)^*\lambda(a)) \geq T^{**}(\lambda(a))^*T^{**}(\lambda(a)) = a^*a\,.$$

Thus, $T^{**}(\lambda(a^*a) - \lambda(a)^*\lambda(a)) = 0$. Using that T^{**} is faithful on $C^*(\lambda(A))$ we get $\lambda(a^*a) = \lambda(a)^*\lambda(a)$ for all $a \in A$.

Thus $\lambda \colon A \to q_D B^{**} q_D$ is a *-monomorphism with $\lambda(A) \subset q_D B q_D = B/\!/D$. By Remark 6.1.2(14), $\lambda(A) \subseteq \mathcal{M}(B/\!/D) \cap (B/\!/D) = \mathcal{N}(D)/D$.

The equation follows from $A \cap \Psi_C(J) = A \cap T(\pi_D(J))$, because T is isometric. □

LEMMA 6.3.9. *Suppose that D is a σ-unital hereditary C^*-subalgebra of a C^*-algebra B, and that A is a separable C^*-subalgebra of the normalizer algebra $\mathcal{N}(D) \subset B$.*

Let $\pi_0 \colon B \to B/\!/D$ and $\pi_2 \colon \mathcal{M}(D) \to \mathcal{M}(D)/D$ denote the quotient maps, and let ρ denote the natural C^*-morphism from $\mathcal{N}(D)$ into $\mathcal{M}(D)$ with kernel $\mathrm{Ann}(D)$ *(the two-sided annihilator of D in B).*

For a closed ideal J of B let

$$\mathrm{Ann}(D, J) := \{a \in B\,;\, aD + Da \subset J\} \supset J\,.$$

Then there exists a completely positive contraction T from the C^*-system $B/\!/D$ into the C^*-algebra $\mathcal{M}(D)/D$, such that T has the following properties (i)-(ii)*:*

(i) *$T(\pi_0(\mathrm{Ann}(D, J))) \subset \pi_2(\mathcal{M}(D, D \cap J))$ for every $J \in \mathcal{I}(B)$.*
(ii) *$(T \circ \pi_0)|A$ is the C^*-morphism $(\pi_2 \circ \rho)|A$ from A into $\mathcal{M}(D)/D$, and has kernel $A \cap (D + \mathrm{Ann}(D))$.*
(iii) *$T \circ \pi_0(A \cap \mathrm{Ann}(D, J)) = T(\pi_0(A) \cap \pi_0(\mathrm{Ann}(D, J))) = T(\pi_0(A)) \cap \pi_2(\mathcal{M}(D, D \cap J))$ for $J \in \mathcal{I}(B)$.*

*In particular, – if $B/\!/D$ is nuclear –, then $\pi_2 \circ \rho$ defines a nuclear *-monomorphism from $A/(A \cap (D + \mathrm{Ann}(D)))$ into $\mathcal{M}(D)/D$.*

PROOF. It holds $\mathcal{N}(D) \supseteq \mathrm{Ann}(D) = \mathrm{Ann}(D, \{0\}) \cong (\mathrm{Ann}(D) + D)/D$ because $D + \mathrm{Ann}(D) \cong D \oplus \mathrm{Ann}(D)$ naturally, thus $D + \mathrm{Ann}(D)$ is the kernel of $\pi_2 \circ \rho\colon \mathcal{N}(D) \to \mathrm{Q}(D) = \mathcal{M}(D)/D$.

Since D is σ-unital, it contains a strictly positive contraction $e \in D_+$. We can suppose that $e \in A$ (consider otherwise $A_1 := C^*(A, e)$). Let $a_1, a_2, \ldots \in A$ a dense sequence in the unit ball of A. There is an approximate unit $e_1 \leq e_2 \leq \ldots \in C^*(e) \subset D$ with $e_n e_{n+1} = e_n \leq 1$, $\|e_n e - e_n\| < 2^{-n}$ and $\|[a_k, e_n^{1/2}]\| < 2^{-n-2}$ for $k \leq n$. Let $g_1 := e_1^{1/2}$, $g_{n+1} := (e_{n+1} - e_n)^{1/2}$

$b \mapsto W(b) := \sum_n g_n b g_n$ is a completely positive contraction from B into $\mathcal{M}(D)$ with $W(e) = e$, $W(\mathrm{Ann}(D)) = 0$ and $W(D) \subset D$, because $\sum_n g_n b g_n$ strictly converges in $\mathcal{M}(D)$, cf. Remark 5.1.1(4). Moreover,

$$\|(\rho(a)-W(a))(1-e_m)\| \leq \sup_{n\geq m} \|a(e_n-e_m) - \sum_{m-1\leq k\leq n+1} g_k a g_k (e_n-e_m)\| \leq 2^{-m}\,.$$

Thus $\rho(a) - W(a) \in D$ for $a \in A$.

$\pi_2 \circ W \colon B \to \mathcal{M}(D)/D$ is completely positive and contains D in its kernel. It follows $W(BD+DB) \subset D$ and that there is a unique completely positive map $T\colon B/\!/D = B/(BD+DB) \to \mathrm{Q}(D) = \mathcal{M}(D)/D$ with $T\circ\pi_0 = \pi_2\circ W$.

(i): Let $J \in \mathcal{I}(B)$. Then $W(\mathrm{Ann}(D,J)) \subset \mathcal{M}(D, D\cap J)$, because $eW(b)e = \sum eg_n b g_n e \in D\cap J$ for $b \in \mathrm{Ann}(D,J)$. Thus $T(\pi_0(\mathrm{Ann}(D,J))) \subset \pi_2(\mathcal{M}(D,D\cap J))$.

(ii): $T\circ \pi_0|A = \pi_2\circ\rho|A$ because $\pi_2(W(a)) = \pi_2(\rho(a))$ for $a\in A$. The kernel of $\pi_2\circ\rho\colon \mathcal{N}(D) \to \mathcal{M}(D)/D$ is $\rho^{-1}(D) = D + \mathrm{Ann}(D)$.

(iii): $\pi_2 \circ \rho(A\cap \mathrm{Ann}(D,J)) = T\circ\pi_0(A\cap\mathrm{Ann}(D,J)) \subset T(\pi_0(A)\cap \pi_0(\mathrm{Ann}(D,J))) \subset T(\pi_0(A))\cap\pi_2(\mathcal{M}(D,D\cap J)) = \pi_2(\rho(A))\cap\pi_2(\mathcal{M}(D,D\cap J)$, because $W(\mathrm{Ann}(D,J)) \subset \mathcal{M}(D,D\cap J)$, $T\circ\pi_0 = \pi_2\circ W$ and $T\circ\pi_0|A = \pi_2\circ\rho$.

Conversely, if $b\in\mathcal{N}(D)$ and $\rho(b) = c+d$ with $d\in D$ and $c\in\mathcal{M}(D,D\cap J)$ then $c = \rho(b)-d = \rho(b-d) \in \rho(\mathcal{N}(D))$ and $\rho(b-d)\in\mathcal{M}(D,D\cap J)$, i.e., $b-d\in\mathrm{Ann}(D,J)$. Thus $b\in\mathcal{N}(D)\cap\mathrm{Ann}(D,J)+D$ and $\pi_0(b)\in\pi_0(\mathrm{Ann}(D,J))$.

Since $D\subset\mathcal{N}(D)$, $(\mathcal{N}(D)\cap\mathrm{Ann}(D,J))+D = \mathcal{N}(D)\cap(\mathrm{Ann}(D,J)+D) = (\pi_2\circ\rho)^{-1}(\mathcal{N}(D)\cap\mathcal{M}(D,D\cap J))$. □

`Related/re-formulated text (new` φ `good?) for Lemma 6.3.9: Next version better? ??`

Recall that for C^*-subalgebra D of a C^*-algebra B, $\mathcal{N}(D)$ ($=\mathcal{N}(B,D)$) is defined as the set of two-sided normalizers $b\in B$ of D: $bD\cup Db\subseteq D$.

This definition of $\mathcal{N}(B,D)$ gives also a natural C^*-morphism $\varphi_D\colon\mathcal{N}(D)\to\mathcal{M}(D)$ given by $\varphi_D(b)d := bd$ for $b\in\mathcal{N}(D)$ and $d\in D$. The kernel of φ_D is the two-sided annihilator $\mathrm{Ann}(D)$ ($=\mathrm{Ann}(D,0)$) of D in B defined as the set of $b\in B$ with $bD = \{0\} = Db$.

Some of the following are discussed in Chapter 2 ? Ref's??

LEMMA 6.3.10. *Suppose that $D\subset B$ is a σ-unital residually essential* hereditary *C^*-subalgebra of B.*

(i) *If B has no unital quotient, then D has no unital quotient.*
(ii) *The map $J\in\mathcal{I}(B)\mapsto D\cap J\in\mathcal{I}(D)$ is a bijection onto $\mathcal{I}(D)$.*
(iii) *The natural map $\varphi_D\colon\mathcal{N}(D)\to\mathcal{M}(D)$ given is injective, and $\varphi_D(a)\in\mathcal{M}(D,D\cap J)$, if and only if, $a\in\mathcal{N}(D)\cap J$.*
(iv) *For $a\in\mathcal{N}(D)$ and $J\in\mathcal{I}(B)$ holds:*

$$a\in D+(\mathcal{N}(D)\cap J) \;\Leftrightarrow\; \pi_{B/\!/D}(a)\in\pi_{B/\!/D}(J) \;\Leftrightarrow\; \varphi_D(a)\in D+\mathcal{M}(D,D\cap J)\,.$$

(v) *For each separable C^*-subalgebra $A \subset B$ there is a completely positive contraction $T_A \colon A \to \mathcal{M}(D)/D$ such that $T_A|(A \cap \mathcal{N}(D)) = \pi_D \circ \varphi_D$ and $T_A(A \cap J) \subset \pi_D(\mathcal{M}(D, D \cap J))$ for each closed ideal J of B.*

`Sort out: Where `` hereditary in` $B$`'' is needed for` $D$`??`

PROOF. Recall that the definition of "residual essential" (in B) for a (not necessarily hereditary) C^*-subalgebra $D \subseteq B$ is:

For each closed ideal $K \subseteq B$, there is no non-zero element of $(B/K)_+$ that is orthogonal to $\pi_K(D)$.

Give ref. to Definition?

This implies obviously that $D \subseteq K := \overline{\text{span}(BDB)} = B$. Moreover, the hereditary C^*-subalgebra $E := \overline{\text{span}(DBD)}$ of B is again residually essential C^*-subalgebra of B.

(ii): If D is a hereditary C^*-subalgebra of a C^*-algebra B that is not contained in any closed ideal K of B with $K \neq B$, then the map

$$K \in \mathcal{I}(B) \mapsto J_K := K \cap D \in \mathcal{I}(D)$$

is a bijective lattice isomorphism.

`cite TEXT books for this`

(i): Suppose that B has no unital quotient, and suppose that there exists a closed ideal J of D such that D/J is unital.

The closed ideal $K := \overline{BJB}$ of B is the smallest closed ideal of B that contains J.

Since D is hereditary, each ideal J of D is the intersection of D with an ideal L of B, i.e., $J = D \cap L$. Thus $J \subseteq D \cap K \subseteq D \cap L = J$, i.e., $J = D \cap K$.

It implies that $D/J \cong \pi_K(D) = p(B/K)p$ for some projection in $p \in B/K$, because $\pi_K(D)$ is a unital hereditary C^*subalgebra of B by $\pi_K(D)\pi_K(B)\pi_K(D) = \pi_K(DBD) = \pi_K(D)$.

Since $\pi_K(D)$ is "essential" in B/K it follows that $(1-p)(B/K)(1-p) = \{0\}$, i.e., that B/K is unital, a contradiction to the assumption that all non-zero quotients B/K of B are not unital.

(iii): The map $\varphi_D \colon \mathcal{N}(D) \to \mathcal{M}(D)$ is injective because the kernel is $\text{Ann}(D)$ and $\text{Ann}(D) = \{0\}$ for essential C^*-subalgebras D of B (by definition of "essential").

For $a \in \mathcal{N}(D) \subseteq B$ holds that $\varphi_D(a) \in \mathcal{M}(D, D \cap J)$, if and only if, $a \in \mathcal{N}(D) \cap J$:

If $a \in \mathcal{N}(D) \cap J$, then $aD \cup Da \subseteq D \cap J$. Thus, $\varphi_D(a) \in \mathcal{M}(D, D \cap J)$. If $a \in \mathcal{N}(D)$ and $\varphi_D(a) \in \mathcal{M}(D, D \cap J)$, then $aD \cup Da \subseteq D \cap J$. It follows that $\pi_J(a)\pi_J(D) = \{0\}$ and $\pi_J(D)\pi_J(a) = \{0\}$. It says that $\pi_J(a^*a + aa^*)$ is orthogonal to $\pi_J(D)$.

The algebra D is "residually essential", which means that $\pi_J(D)$ is essential in $\pi_J(B)$ for each $J \in \mathcal{I}(B)$.

It follows that $\pi_J(a^*a + aa^*) = 0$ or that $\pi_J(D) = \{0\}$ must happen, i.e., $a \in J$ or $D \subseteq J$. Thus $a \in \mathcal{N}(D) \cap J$ or $D \subseteq J$.

But essential C^*-subalgebras in B generate B as ideal, i.e., if $D \subseteq J$ and D is essential in B imply that $J = B$ and $a \in \mathcal{N}(D) \subseteq J = B$.

(iv): For $a \in \mathcal{N}(D)$ are equivalent

$$a \in D + (\mathcal{N}(D) \cap J) \;\Leftrightarrow\; \pi_{B//D}(a) \in \pi_{B//D}(J) \;\Leftrightarrow\; \varphi_D(a) \in D + \mathcal{M}(D, D \cap J)\,.$$

Let $a \in D + (\mathcal{N}(D) \cap J)$ then $a = d + c$ with $d \in D$ and $c \in \mathcal{N}(D) \cap J$. Then trivially $\pi_{B//D}(a) = \pi_{B//D}(c)$ because the kernel of $\pi_{B//D}$ is $BD + DB \supseteq D$. Thus $\pi_{B//D}(a) \in \pi_{B//D}(J)$.

Notice that $\mathcal{N}(D)/D \cong \mathcal{M}(B//D) \cap (B//D)$ by a natural isomorphism. $\pi_{B//D}$ coincides on $\mathcal{N}(D)$ with the C^*-morphism $a \mapsto a + D$. If $\pi_{B//D}(a) \in \pi_{B//D}(J)$ and $a \in \mathcal{N}(D)$, then $a \in (J + BD + DB) \cap \mathcal{N}(D) = D + (\mathcal{N}(D) \cap J)$.

(To see more look to the second conjugate of B: $\mathcal{N}(D) = \{P_D\}' \cap B \subset \{P_D\}' \cap B^{**}$.)

(v): `To be filled in` ??

For each separable C^*-subalgebra $A \subset B$ there is a completely positive contraction $T_A \colon A \to \mathcal{M}(D)/D$ such that $T_A|(A \cap \mathcal{N}(D)) = \pi_D \circ \varphi_D$ and $T_A(A \cap J) \subset \pi_D(\mathcal{M}(D, D \cap J))$ for each closed ideal J of B:

□

Proposition 6.3.11. *Suppose that D is a residually essential hereditary C^*-subalgebra of a separable stable C^*-algebra B with WvN-property, and that the operator space $B//D := B/(DB + BD)$ is nuclear.*

Let $\pi_1 \colon \mathcal{N}(D) \to \mathcal{N}(D)/D$ and $\pi_2 \colon \mathcal{M}(D) \to \mathcal{M}(D)/D$ denote the natural epimorphisms, and let A is a stable separable C^*-subalgebra of $\mathcal{M}(B)$, such that $A \hookrightarrow \mathcal{M}(B)$ is weakly residually nuclear and AB is dense in B. Then:

(i) *D is stable and there is an isomorphism φ from B onto D, which is unitarily homotopic to id_B, and, therefore, satisfies $\varphi(J) = D \cap J$ for $J \in \mathcal{I}(B)$.*
(ii) *The natural C^*-morphism ρ from $\mathcal{N}(D)/D$ into $\mathcal{M}(D)/D$ is a nuclear *-monomorphism, and satisfies, for closed ideals J of B,*

$$\rho(\pi_1(\mathcal{N}(D) \cap J)) = \rho(\mathcal{N}(D)/D) \cap \pi_2(\mathcal{M}(D, D \cap J)).$$

(iii) *If $\lambda \colon A \to \mathcal{N}(D)/D \subset B//D$ is a *-monomorphism with*

$$\lambda(A \cap \mathcal{M}(B, J)) = \lambda(A) \cap \pi_1(\mathcal{N}(D) \cap J) \qquad \textit{for} \quad J \in \mathcal{I}(B)\,,$$

then an element

$$H \;:=\; \mathrm{Q}(\varphi)^{-1} \circ \rho \circ \lambda \colon\; A \to \mathrm{Q}(B)$$

is nuclear and defines an element $[H]$ *of the semi-group*

$$\mathrm{SExt}_{\mathrm{nuc}}(\mathrm{Prim}(B); A, B) := S(H_0; A, \mathrm{Q}(B))$$

where $H_0 := \pi_B \circ \delta_\infty | A$ *with* $2[H_0] = [H_0]$.
The element $[H]$ *is contained in the subgroup*

$$\mathrm{Ext}_{\mathrm{nuc}}(\mathrm{Prim}(B); A, B) = [H_0] + \mathrm{SExt}_{\mathrm{nuc}}(\mathrm{Prim}(B), A, B)\,.$$

(iv) *If, in addition to* (iii), $[H] = 0$ *in* $\mathrm{Ext}_{\mathrm{nuc}}(\mathrm{Prim}(B), A, B)$, *then there is a non-degenerate nuclear *-monomorphism* h *from* A *to* B, *such that*

$$h(A \cap \mathcal{M}(B, J)) = h(A) \cap J \qquad \textit{for} \quad J \in \mathcal{I}(B)\,.$$

The infinite repeats $\delta_\infty \circ h$ *and* $\delta_\infty | A$ *are unitarily homotopic.*

PROOF. Since D is residually essential, we have in particular that B is the closed span of BDB.

(i): Since B has the WvN-property, B and its hereditary C^*-subalgebra D must be purely infinite in particular. D is separable and can not have a unital quotient, because for every closed ideal I of D there is a closed ideal J of B with $I = D \cap J$, and $D/I \cong \pi_J(D)$ is an essential subalgebra of the stable C^*-algebra $\pi_J(B)$ (cf. assumptions). By Corollary 5.5.4, D is stable. Now use Corollary 5.5.6 to get φ with property(i).

(ii): The C^*-algebras $\mathcal{N}(D)$ and $\mathcal{N}(D)/D$ are separable. The natural C^*-morphism $\rho\colon \mathcal{N}(D)/D \to \mathcal{M}(D)/D$ is faithful because $\mathrm{Ann}(D) = \{0\}$. Let $T\colon B//D \to \mathcal{M}(D)/D$ be as in Lemma 6.3.9 with

$$T\pi_{BD+DB}|\mathcal{N}(D) = \pi_2 \circ \eta|\mathcal{N}(D) = \rho \circ \pi_1\,,$$

where $\pi_2\colon \mathcal{M}(D) \to \mathrm{Q}(D) = \mathcal{M}(D)/D$ is the quotient map and $\eta\colon \mathcal{N}(D) \to \mathcal{M}(D)$ denotes the natural *-morphism with $\eta(d) = d$ for $d \in D$. Then $T = T \circ \mathrm{id}_{B//D}$ is nuclear, because $B//D$ is nuclear. We obtain $\rho = T \circ \gamma$, where γ denotes the natural isomorphism from $\mathcal{N}(D)/D$ onto $\mathcal{M}(B//D) \cap (B//D)$ with $\gamma \circ \pi_1 = \pi_{BD+DB}|\mathcal{N}(D)$ that is given by Lemma A.19.8(i). Thus ρ is a *nuclear* *-monomorphism.

By Lemma 6.3.9, $\mathrm{Ann}(D, J) \subset \pi_J^{-1}(\mathrm{Ann}(\pi_J(D)) = J$ for residually essential D and for $J \in \mathcal{I}(B)$. It follows:

$$\rho\pi_1(\mathcal{N}(D) \cap J) = \rho\pi_1(\mathcal{N}(D)) \cap \pi_2(\mathcal{M}(D, D \cap J)).$$

(iii): The C^*-algebra A is a stable C^*-subalgebra of $\mathcal{M}(B)$, such that $\mathrm{id}\,|A$ is weakly residually nuclear, and AB is dense in B. If there is a *-monomorphism λ from A into $\mathcal{N}(D)/D$ with

$$\lambda(A \cap \mathcal{M}(B, J)) = \lambda(A) \cap \pi_1(\mathcal{N}(D) \cap J)$$

for $J \in \mathcal{I}(B)$, then

$$H := (\mathrm{Q}(\varphi))^{-1} \circ \rho \circ \lambda\colon A \hookrightarrow \mathrm{Q}(B) := \mathcal{M}(B)/B$$

is a monomorphism from A into $\mathrm{Q}(B)$. Here $\mathrm{Q}(\varphi)$ is the isomorphism from $\mathrm{Q}(D) := \mathcal{M}(D)/D$ onto $\mathrm{Q}(B)$ induced by φ, i.e., $\mathrm{Q}(\varphi)(d + D) = \mathcal{M}(\varphi)(d) + B \in \mathrm{Q}(B)$ for

$d \in \mathcal{M}(D)$. Note $\mathrm{Q}(\varphi)^{-1} = \mathrm{Q}(\varphi^{-1})$. Then $H\colon A \to \mathrm{Q}(B)$ is nuclear, because ρ is a nuclear monomorphism. In particular, A is an *exact* C^*-algebra. By Corollary ??, the inclusion map $\mathrm{id}\colon A \hookrightarrow \mathcal{M}(B)$ is *nuclear*, because $\mathcal{M}(B)$ is weakly nuclear and A is exact.

The map H satisfies, by asumptions in (ii),

$$H(A \cap \mathcal{M}(B,J)) = \mathrm{Q}(\varphi)^{-1}\rho(\lambda(A) \cap \pi_1(\mathcal{N}(D) \cap J)) \tag{3.1}$$

$$= H(A) \cap \mathrm{Q}(\varphi)^{-1}(\pi_2(\mathcal{M}(D, D \cap J))). \tag{3.2}$$

But $Q(\varphi)^{-1}(\pi_2(\mathcal{M}(D, D \cap J))) = \pi_B(\mathcal{M}(B,J))$, because $\varphi(B) = D$ and $\mathcal{M}(\varphi)(\mathcal{M}(B,J)) = \mathcal{M}(D, \varphi(J)) = \mathcal{M}(D, D \cap J)$.

The exactness of A gives that H is moreover residually nuclear with respect to the natural actions of $\mathrm{Prim}(B)$ on $A \subset \mathcal{M}(B)$ and $\mathrm{Q}(B)$ (cf. **??**).

Thus $H\colon A \hookrightarrow \mathrm{Q}(B)$, B and $A \subset \mathcal{M}(B)$ satisfy the assumptions of Proposition **??**. **??** Therefore, $[H]$ is in $G(H_0; A, \mathrm{Q}(B)) = \mathrm{Ext}_{\mathrm{nuc}}(\mathrm{Prim}(B), A, B)$, where $H_0 := \pi_B \circ \delta_\infty | A\colon A \to \mathrm{Q}(B)$.

`to be filled in: show` $[H] \in G(H_0; A, \mathrm{Q}(B))$ **??**

(iv): Since $[H] = 0 = [H_0]$ in $\mathrm{Ext}_{\mathrm{nuc}}(\mathrm{Prim}(B); A, B)$, it follows by Remark **??** **??**). that $H = w^* H_0(\cdot) w$ where $w \in \mathcal{U}_0(\mathrm{Q}(B))$ and $H_0 = \pi_B \circ \delta_\infty | A$, because the extensions given by elements of $\mathrm{Ext}_{\mathrm{nuc}}(\mathrm{Prim}(B), A, B)$ are stable C^*-algebras ([12]).

We find a unitary $u \in \mathcal{M}(B)$, such that

$$H_1 \colon a \in A \mapsto u^* \delta_\infty(a) u \in \mathcal{M}(B)$$

is a residually nuclear lift of $H\colon A \to \mathrm{Q}(B)$ with $H_1(A) \cap \mathcal{M}(B,J) = H_1(A \cap \mathcal{M}(B,J))$ for $J \in \mathcal{I}(B)$. Then

$$H_2 := \mathcal{M}(\varphi) \circ H_1 \colon A \to \mathcal{M}(D)$$

is a residually nuclear lift of $\rho \circ \lambda\colon A \hookrightarrow \mathcal{M}(D)/D$. Necessarily, $H_2(A) \subset \eta(\mathcal{N}(D)) = \pi_2^{-1}\rho(D)$. Thus, the *-monomorphism $H_3 := \eta^{-1} \circ H_2$ maps A into $\mathcal{N}(D) \subset B$. We have $H_3(A) \cap J = \eta^{-1}(H_2(A) \cap \eta(\mathcal{N}(D) \cap J))$, $\mathrm{Ann}(D,J) := \pi_J^{-1}(\mathrm{Ann}(\pi_J(D))) = \pi_J^{-1}(0) = J$, $\mathrm{Ann}(D,J) = \{b \in B\,;\ bD + Db \subset J\}$ **??**

and that $b \in \mathcal{N}(D) \cap \mathrm{Ann}(D,J)$, if and only if $bD + Db \subset D \cap J$. It implies

$$\begin{aligned} \eta(\mathcal{N}(D) \cap J) &= \eta(\mathcal{N}(D) \cap \mathrm{Ann}(D,J)) \\ &= \eta(\mathcal{N}(D)) \cap \mathcal{M}(D, D \cap J). \end{aligned}$$

Thus

$$\begin{aligned} H_3(A) \cap J &= \eta^{-1}(H_2(A) \cap \mathcal{M}(D, D \cap J)) \\ &= \eta^{-1}\mathcal{M}(\varphi)(H_1(A) \cap \mathcal{M}(B,J)) \\ &= \eta^{-1}\mathcal{M}(\varphi) H_1(A \cap \mathcal{M}(B,J)) \\ &= H_3(A \cap \mathcal{M}(B,J)) \end{aligned}$$

---

[12] Use here that A is stable, and that B is σ-unital, stable and purely infinite, cf. Corollary 5.5.16 .

for $J \in \mathcal{I}(B)$.

Further, $H_3^{-1}(0) = \{0\}$, and $H_3(A)$ must generate B as a two-sided closed ideal, because $J_1 := \overline{\operatorname{span} BH_3(A)B}$ satisfies $H_3(A) \cap J_1 = H_3(A)$ and,thus, $A \subset \mathcal{M}(B, J_1)$, $AB \subset J_1 \subset B$ and $J_1 = B\,\overline{AB} = B$.

Since A and B are stable and separable, it follows, by Proposition **?? ??**, that H_3 is unitarily homotopic to a nuclear *non-degenerate* *-monomorphism $h \colon A \hookrightarrow B$. We get $h(A) \cap J = h(A \cap \mathcal{M}(B, J))$ for $J \in B$.

Thus $k_1 := \delta_\infty \circ h$ and $k_2 := \delta_\infty | A$ are both nuclear, non-degenerate *-monomorphisms and satisfy $k_i(A) \cap \mathcal{M}(B, J) = k_i(A \cap \mathcal{M}(B, J))$ for $J \in \mathcal{I}(B)$ and $i = 1, 2$. By Corollary **??**, k_1 and k_2 are unitarily homotopic. □

LEMMA 6.3.12. *Suppose that $E \subset F \subset B$ are hereditary C^*–subalgebras of B.*

(i) *If for every $a \in \mathcal{M}(B//E)_+ \cap (B//E)$ with $a \neq 0$ there is $b \in \pi_{BE+EB}(F)$ with $ab \neq 0$, then F is essential in B.*
(ii) *If $D \subset C$ is hereditary, $B = C \otimes M_{2^\infty}$, $E = D \otimes M_{2^\infty}$ and ρ is a pure state on M_{2^∞}, then $B//E \cong (C//D) \otimes M_{2^\infty}$ by a natural completely positive and completely isometric map V from $B//E$ onto $(C//D) \otimes M_{2^\infty}$.*
The hereditary C^*-subalgebra $F \subset B$ that ist generated by $\{b \in B_+ \,;\, (\mathrm{id}_{C//D} \otimes \rho)(V(\pi_{BE+EB}(b))) = 0\}$ satisfies the assumption of (i). *In particular, F is essential in B.*

PROOF. Recall that the product ab in (i) has to be calculated in the von Neumann algebra $(B//E)^{**}$, that is naturally isomorphic to $(1 - p_E)B^{**}(1 - p_E)$.

(i): Let $c \in B_+$ with $cF = \{0\}$. Then $cE = \{0\}$ and, therefore, $c \in \operatorname{Ann}(E)_+ \subset \mathcal{N}(E)_+$. It follows that $a := \pi_{BE+EB}(c) \in \mathcal{M}(B//E)_+ \cap (B//E)$ and that $a\pi_{BE+EB}(F) = \{0\}$. Thus $a = 0$ by assumption (i), i.e., $(1-p_E)c(1-p_E) = 0$, $c^{1/2}(1 - p_E) = 0$, $c = cp_E$ and $c = p_E c$, where $p_E \in B^{**}$ denotes the open support projection of E. Thus $c \in E$. Since $cE = \{0\}$ and $c \in E_+$, we get $c^2 = 0$ and $c = 0$.

(ii): Let $L := CD$ and $R := DC$ the closed left respectively right ideals of C generated by D. Then $EB + BE = (L + R) \otimes M_{2^\infty}$. Therefore, there is a natural completely positive and completely isometric isomorphism V from $B//E := (C \otimes M_\infty)//(D \otimes M_\infty)$ onto $(C//D) \otimes M_\infty$ that satisfies $V((c \otimes d) + EB + BE) = (c + (CD + DC)) \otimes d$ for $c \in C$ and $d \in M_{2^\infty}$, i.e., $V \circ \pi_{BE+EB} = \pi_{CD+DC} \otimes \mathrm{id}$. Let $A := \mathcal{M}(C//D) \cap (C//D)$. Using slice maps, one can see that $V|\mathcal{M}(B//E) \cap (B//E)$ is a *-isomorphism from $\mathcal{M}(B//E) \cap (B//E)$ onto $A \otimes M_{2^\infty}$, and $\mathcal{N}(E) = \mathcal{N}(D) \otimes M_{2^\infty}$.

Let $G := \{g \in M_{2^\infty} \,;\, \rho(g^*g + gg^*) = 0\}$. The G is the hereditary C^*-subalgebra of M_{2^∞} generated by $\{0 \leq g \in M_{2^\infty} \,;\, \rho(g) = 0\}$, and G is essential in M_{2^∞} because $0 \leq a \in M_{2^\infty}$ and $aG = 0$ implies that $a = 0$ or that the pure state ρ is faithful on the hereditary C^*-subalgebra of M_{2^∞} generated by a is faithful, but the latter can not happen because M_{2^∞} is anti-liminal.

Thus, $\mathcal{N}(D)\otimes G\subset F$. If $a\in(A\otimes M_{2^\infty})_+$ and $aV(F)=\{0\}$, then $a(A\otimes G)=\{0\}$. But this implies that $(f\otimes\mathrm{id})(a)G=\{0\}$ for every positive linear functional f on A, thus $f\otimes\mathrm{id}(a)=0$ for all $f\in A^*$, hence $a=0$.

It follows that $c\in\mathcal{M}(B//E)_+\cap(B//E)$ and $c\pi_{BE+EB}(F)=\{0\}$ together implies $c=0$. □

LEMMA 6.3.13. *Suppose that D_1,D_2 are hereditary C^*–subalgebras of B, that $T\colon B//D_2\to(B//D_1)\otimes M_{2^\infty}$ is a completely positive and completely isometric map from $B//D_2$ onto $(B//D_1)\otimes M_{2^\infty}$ with $T(\pi_2(J))=\pi_1(J)\otimes M_{2^\infty}$ for every closed ideal J of B, where $\pi_k\colon B\to B//D_k:=B/(BD_k+D_kB)$ are the quotient maps for $k=1,2$. Let $\rho\colon M_{2^\infty}\to\mathbb{C}$ a pure state, and let D_3 denote the hereditary C^*-algebra of B that is generated by the elements $f\in B_+$ with $(id\otimes\rho)(T(\pi_2(f)))=0$.*

Then

(i) *$D_3\supset D_2$, D_3 is residually essential in B, and*
(ii) *there is a completely positive and completely isometric isomorphism I from $B//D_3$ onto $B//D_1$ with*

$$I(\pi_3(J))=\pi_1(J)$$

for every $J\in\mathcal{I}(B)$, where $\pi_3\colon B\to B//D_3$ is the quotient map $\pi_3(b):=b+BD_3+D_3B$.

PROOF. Clearly, $V\colon b\in B\mapsto(\mathrm{id}\otimes\rho)(T(\pi_2(b)))\in B//D_1$. is a completely positive contraction from B onto $B//D_1$ with $V(D_3)=0$ and $V(J)=\pi_1(J)$.

Let $A:=M_{2^\infty}$ and $G\subset A$ the hereditary C^*-subalgebra $G:=\{a\in A\,;\ \rho(a^*a+aa^*)=0\}$. It turns out that $I:=[V]\colon B//D_3\to B//D_1$ is a complete isometry: One has $T(\pi_2(D_3))=(B//D_1)\otimes G$ and $T(\pi_2(BD_3+D_3B))=(B//D_1)\otimes(AG+GA)$. The same happens with $T\otimes\mathrm{id}_n$.

to be filled in: new proof coming from Lemma 6.3.12 or 3.1.8

??

Let $G:=\{a\in M_{2^\infty}\,;\ \rho(a^*a)=0=\rho(aa^*)\}$. G is essential in M_{2^∞}. There is no non-zero element $x\in((B//D_1)\otimes M_{2^\infty})_+$ that is orthogonal to the support projections of $(B//D_1)\otimes G$ in $((B//D_1)\otimes M_{2^\infty})^{**}$, because there is no non-zero $x\in(B//D_1)^{**}\otimes M_{2^\infty}$ which is orthogonal to $(B//D_1)^{**}_+\otimes e$ for a strictly positive element e of G.

γ has the property that $\pi_1(J)\otimes M_{2^\infty}$ corresponds to the natural image of $J\otimes M_{2^\infty}$ in $(B\otimes M_{2^\infty})//(D_1\otimes M_{2^\infty})$. Thus, one has natural isomorphisms

$$((B/J)//\pi_J(D_1))\otimes M_{2^\infty}\cong((B//D_1)\otimes M_{2^\infty})/(\pi_1(J)\otimes M_{2^\infty})\,.$$

?? Clearly, $D_2\subset D_3$ and $\pi_2(D_3)$ contains $T((B//D_1)\otimes G)$. Recall that T^{**} is a W*-algebra isomorphism from $((B//D_1)\otimes M_{2^\infty})^{**}$ onto $(B//D_2)^{**}$. If $b\in B_+$ with $bD_3+D_3b=\{0\}$ then $\pi_2(b)$ is orthogonal to $T((B//D_1)\otimes G)$ in $(B//D_2)^{**}$. The element $x:=T^{-1}(\pi_2(b))$ is orthogonal to $(B//D_1)\otimes G$ in $((B//D_1)\otimes M_{2^\infty})^{**}$, which implies (step by step) $x=0$, $\pi_2(b)=0$, $b\in D_1\subset D_3$ and $b^2=0$, $b=0$.

Hence, D_3 is essential in B.

If J is a closed ideal of B, then $\pi_k(J)$ is an M-ideal of $B//D_k$ (i.e., there is a projection z_J in the center of $(B//D_k)^{**}$ with $\pi_k(J)^{**} = z_J(B//D_k)^{**}$) and there are natural completely positive and completely isometric isomorphisms $(B/J)//\pi_J(D_k) \cong (B//D_k)/\pi_k(J)$. Thus T defines a completely isometric and completely positive isomorphism $[T]_J$ from $(B/J)//\pi_J(D_2) \cong (B//D_2)/\pi_2(J)$ onto

$$((B/J)//\pi_J(D_1)) \otimes M_{2^\infty} \cong ((B//D_1) \otimes M_{2^\infty})/(\pi_1(J) \otimes M_{2^\infty}) .$$

Let $[\pi_2]_J$ denote the quotient map $B/J \to (B/J)/\pi_J(D_2)$. $\pi_J(D_3)$ is essential in B/J, because $\pi_J(D_3)$ is the hereditary C^*–subalgebra of B/J which is generated by the elements $g \in (B/J)_+ = \pi_J(B_+)$ with $\mathrm{id} \otimes \rho)([T]_J^{-1}([\pi_2]_J(g))) = 0$, and because we can replace in the above arguments B, $B//D_2$, $(B//D_1)$, D_2, T and π_2 by B/J, $(B/J)//\pi_J(D_2)$, $((B/J)//\pi_J(D_1))$, $\pi_J(D_3)$, $[T]_J$ and $[\pi_2]_J$. □

LEMMA 6.3.14. *Suppose that B is stable and that $T_n\colon B \to B$ is a sequence of completely positive contractions. Then there is a sequence of isomorphisms $\gamma_n\colon B \to B\otimes M_{2^n}$, such that γ_n is unitarily homotopic to the map $b \in B \mapsto b\otimes p_{11} \in B\otimes M_{2^n}$. The sequence (γ_n) defines a *-isomorphism γ_∞ from $B_\infty := \ell_\infty(B)/c_0(B)$ onto*

$$E := \left(\prod_n B \otimes M_{2^n}\right) / \bigoplus_n (B \otimes M_{2^n}) \subset (B \otimes M_{2^\infty})_\infty$$

by

$$\gamma_\infty((b_1, b_2, \ldots) + c_0(B)) := (\gamma_1(b_1), \gamma_2(b_2), \ldots) + c_0(B \otimes M_{2^\infty}) .$$

Let $S_n := \gamma_{n+1}^{-1}(T_n \otimes \iota_n) \circ \gamma_n$, where $\iota_n\colon a \in M_{2^n} \mapsto a \otimes 1_2 \in M_{2^{n+1}}$. Consider $X := \mathrm{indlim}(T_n\colon B \to B)$ and $Y := \mathrm{indlim}(S_n\colon B \to B)$ as subspaces of $B_\infty := \ell_\infty(B)/c_0(B)$, and let

$$Z := \mathrm{indlim}(T_n \otimes \iota_n\colon B \otimes M_{2^n} \to B \otimes M_{2^{n+1}}) \subset E .$$

Then

(i) *Z coincides with the image of $X \otimes M_{2^\infty}$ by the natural *-monomorphism η from $B_\infty \otimes M_{2^\infty}$ into E.*

(ii) *The isomorphism γ_∞ from B_∞ onto E maps Y onto $Z = \eta(X \otimes M_{2^\infty})$ and satisfies*

$$\gamma_\infty(Y \cap J_\infty) = \eta((X \cap J_\infty) \otimes M_{2^\infty})$$

for all closed ideals J of B.

(iii) *If T_n is residually nuclear, then S_n is residually nuclear and X is a nuclear (non-unital) operator system.*

PROOF. Let κ_n an isomorphism from the algebra of compact operators $\mathbb{K}$ onto $\mathbb{K} \otimes M_{2^n}$. Since every endomorphism of $\mathbb{K}$ onto a hereditary C^*–subalgebra D of $\mathbb{K}$ is unitarily homotopic to the identity map on $\mathbb{K}$ (cf. e.g. Corollary 5.5.6), we get that $a \in \mathbb{K} \mapsto a \otimes p_{11} \in \mathbb{K} \otimes M_{2^\infty}$ is unitarily homotopic to κ_n. There is an isomorphism λ from B onto $B \otimes \mathbb{K}$, because B is stable and $\mathbb{K} \otimes \mathbb{K} \cong \mathbb{K}$. Then $\gamma_n := (\lambda \otimes \mathrm{id}_n)^{-1} \circ (\mathrm{id}_B \otimes \kappa_n) \otimes \lambda$ is an isomorphism from B onto $B \otimes M_{2^n}$ that is unitarily homotopic to $b \in B \mapsto b \otimes p_{11} \in B \otimes M_{2^n}$. In particular, $\gamma_n(J) = J \otimes M_{2^n}$ for $J \in \mathcal{I}(B)$, which implies

$$\gamma_\infty(J_\infty) = \prod_n (J \otimes M_{2^n}) / \bigoplus_n (J \otimes M_{2^n}) .$$

(i): Let $I := \bigoplus_n B \otimes M_{2^n} \subset c_0(B \otimes M_{2^\infty})$ and let $V_n \colon M_{2^\infty} \to M_{2^n}$ the natural conditional expectation from M_{2^∞} onto $M_{2^n} \cong M_{2^n} \otimes 1 \otimes 1 \otimes \ldots \subset M_{2^\infty}$ with $V_n(a \otimes b) = \mathrm{tr}(b)a$ for $a \in M_{2^n}$, $b \in M_{2^\infty}$. Then $\eta \colon B_\infty \otimes M_{2^\infty} \to E$ is the C^*-morphism that is defined by

$$\eta\left(((b_1, b_2, \ldots) + c_0(B)) \otimes c\right) := (b_1 \otimes V_1(c), b_2 \otimes V_2(c), \ldots) + I$$

for $(b_1, b_2, \ldots) \in \ell_\infty(B)$ and $c \in M_{2^\infty}$. This defines η, because $B_\infty \otimes M_{2^\infty} = B_\infty \otimes^{\max} M_{2^\infty}$ by nuclearity of M_{2^∞}.

Let $U_{k,\infty} \colon B \otimes M_{2^k} \to Z \subset E$ the canonical maps for the inductive limit Z defined by the maps $T_n \otimes \iota_n$, i.e., starting with $k-1$ zeros one has

$$U_{k,\infty}(d) = (0, \ldots, 0, d, T_k \otimes \iota_k(d), (T_{k+1}T_k) \otimes (\iota_{k+1}\iota_k)(d), \ldots) + I ,$$

where $d \in B \otimes M_{2^k}$.

Then Z is the closed linear span of $U_{k,\infty}(b \otimes c)$ for $b \in B$ and $c \in M_{2^k}$, $k \in \mathbb{N}$. A straight calculation shows that this set coincides with $\eta(X \otimes M_{2^\infty})$.

(ii): We have $(T_n \otimes \iota_n) \circ \gamma_n = \gamma_{n+1} \circ S_n$. Thus,

$$\gamma_\infty \circ S_{m,\infty}(b) = U_{m,\infty}(\gamma_m(b)) ,$$

for $b \in B$, which implies that the *-isomorphism γ_∞ from B_∞ onto E maps the closed subspace Y onto Z.

Clearly, $\eta(J_\infty \otimes M_{2^\infty}) \subset \gamma_\infty(J_\infty)$. Since $\gamma_\infty(J_\infty)$ is an ideal, and since M_{2^∞} is simple and nuclear, there is a unique closed ideal K of B_∞ such that $\eta(K \otimes M_{2^\infty}) = \eta(B_\infty \otimes M_\infty) \cap \gamma_\infty(J_\infty)$. Let $(b_1, b_2, \ldots) \in \ell_\infty(B)$ with $(b_1, b_2, \ldots) + c_0(B) \in K$. Then

$$\eta\left(((b_1, b_2, \ldots) + c_0(B)) \otimes 1\right) := (b_1 \otimes 1_2, b_2 \otimes 1_4, \ldots) + I \in \gamma_\infty(J_\infty) ,$$

i.e., there exists a sequence $c_n \in J \otimes M_{2^n}$ with $\lim \|(b_n \otimes 1_{2^n}) - c_n\| = 0$. If we apply the slice maps $\mathrm{id}_B \otimes \mathrm{tr}_{2^n} \colon B \otimes M_{2^n} \to B$, we get that there is a sequence $d_1, d_2, \ldots \in J$ with $\lim \|b_n - d_n\| = 0$, i.e., $(b_1, b_2, \ldots) + c_0(B) \in J_\infty$ and $K = J_\infty$.

The equation $(X \otimes M_{2^\infty}) \cap (J_\infty \otimes M_{2^\infty}) = (X \cap J_\infty) \otimes M_{2^\infty}$ holds by nuclearity of M_{2^∞}.

(iii): Let J a closed ideal of B. Then $\gamma_n(J) = J \otimes M_{2^n}$ and $(T_n \otimes \iota_n)(J \otimes M_{2^n}) \subset J \otimes M_{2^{n+1}}$. Thus, $S_n(J) = \gamma_{n+1}^{-1}\big((T_n \otimes \iota_n)(\gamma_n(J))\big) \subset J$, i.e., S_n is residually equivariant if T_n is residually equivariant. Since residually nuclear maps are residually equivariant, S_n is residually equivariant if T_n is residually nuclear. Then the completely positive quotient map $[S_n]_J \colon B/J \to B/J$ is given by $[S_n]_J = [\beta_{n+1}] \circ ([T_n]_J \otimes \iota_n) \circ [\beta_n]$, where $[T_n]_J \colon B/J \to B/J$ is nuclear and β_n is an isomorphism from B/J onto $(B/J) \otimes M_{2^n}$. Thus, $S_n \colon B \to B$ is residually nuclear.

The inductive limit X of the residually nuclear contractions $T_n : B \to B$ is a nuclear C^*-system by Lemma A.19.6, because residually nuclear maps in particular are nuclear. $\square$

LEMMA 6.3.15. *Suppose that B is a stable and σ-unital C^*-algebra. Let $d \in \mathcal{M}(B)$ with $\|d\| \leq 1$. Then there is a norm-continuous path $t \in [0, \infty) \mapsto s(t) \in \mathcal{M}(B)$ into the isometries of $\mathcal{M}(B)$, such that $\lim_{t\to\infty} s(t)^* b s(t) = d^* b d$ for all $b \in B$.*

PROOF. By Lemma 5.1.2(iv), there exist norm-continuous maps $t \in [0, \infty) \mapsto T_0(t), T_1(t) \in \mathcal{M}(B)$ with $T_0(t)^* T_0(t) = T_1(t)^* T_1(t) = T_0(t) T_0(t)^* + T_1(t) T_1(t)^* = 1$, and $\lim_{t\to\infty} T_k(t)^* b = kb$ for $b \in B$, $k = 0, 1$. Let $s(t) := T_0(t)(1 - d^* d)^{1/2} + T_1(t) d$. Then $t \mapsto s(t)$ is norm-continuous and $\lim_{t\to\infty} s(t)^* b = d^* b$. Since $B = BB$, it follows $\lim_{t\to\infty} s(t)^* b s(t) = d^* b d$. $\square$

Next has to be checked again ??

LEMMA 6.3.16. *Suppose that B a C^*-algebra and that $s_1, s_2, \ldots \in \mathcal{M}(B)$ is a sequence of isometries in $\mathcal{M}(B)$. Let $S_n(b) := s_n^* b s_n$ for $b \in B$ and $n \in \mathbb{N}$, $t_n := s_1 s_2 \cdots s_n$, $q_n := 1 - t_n t_n^*$, and denote by E the closure of $\bigcup_n q_n B q_n$.*

Then E is a hereditary C^*-subalgebra of B and there is a natural completely positive and completely isometric map V from $B//E$ onto $\mathrm{indlim}(S_n : B \to B) \subset B_\infty$ *that satisfies*

$$V(\pi_{BE+EB}(J)) = V(B//E) \cap J_\infty \qquad \text{for} \quad J \in \mathcal{I}(B)\,.$$

PROOF. Since $q_n \leq q_{n+1}$, the set E is the hereditary C^*-subalgebra of B generated by $\bigcup_n q_n B q_n$.

Let $p_n := 1 - q_n = t_n t_n^*$, $R_n(b) := p_n b p_n$, $\pi_{BE+EB} : B \to B//E$ the quotient map, $X := \mathrm{indlim}(S_n : B \to B)$, $T_n(b) := t_n^* b t_n$ and $\rho_n(b) := t_n b t_n^*$ for $b \in B$. Notice that $T_n \circ \rho_n = \mathrm{id}_B$ and $T_{k+n} \circ \rho_{k-1} = S_n \circ S_{n-1} \circ \cdots \circ S_k$.

Let $\pi_\infty(b_1, b_2, \ldots) := (b_1, b_2, \ldots) + c_0(B)$. We define completely positive contractions $T_\infty : B_\infty \to B_\infty$ and $\rho_\infty : B_\infty \to B_\infty$ by

$$\begin{aligned} T_\infty(\pi_\infty(b_1, b_2, \ldots)) &:= \pi_\infty(T_1(b_1), T_2(b_2), \ldots) \\ \rho_\infty((b_1, b_2, \ldots)) &:= \pi_\infty(\rho_1(b_1), \rho_2(b_2), \ldots)\,. \end{aligned}$$

Notice $T_\infty \circ \rho_\infty = \mathrm{id}$ on B_∞, and that $T_\infty(\pi_\infty(b_1, b_2, \ldots)) = t_\infty^* \pi_\infty(b_1, b_2, \ldots) t_\infty$ for the isometry

$$t_\infty := \pi_\infty(t_1, t_2, \ldots) \in \mathcal{M}(B)_\infty \subset \mathcal{M}(B_\infty)$$

with range projection

$$p_\infty := t_\infty t_\infty^* = \pi_\infty(p_1, p_2, \ldots) \in \mathcal{M}(B)_\infty\,.$$

We introduce a "diagonal" map $\Delta : B \to B_\infty$ by $\Delta(b) := \pi_\infty(b, b, \ldots)$.

The C^*-space $B//E$ is isomorphic to $Y := \operatorname{indlim}(R_n\colon B \to B)$, because $R_m R_n = R_n R_m = R_{\max(m,n)}$ (coming from $p_{n+1}p_n = p_{n+1}$) implies that a completely positive and isometric isomorphism from $B//E$ onto

$$Y := \operatorname{indlim}_n(R_n\colon B \to B) \subset B_\infty$$

is given by

$$b \in B \mapsto P_\infty(b) := \pi_\infty((p_1 b p_1, p_2 b p_2, \ldots)) = p_\infty \Delta(b) p_\infty \in B_\infty\,,$$

i.e., for $y = [y_{ij}] \in M_k(B//E) \cong M_k(B)//M_k(E)$ and any $b := [b_{ij}] \in M_k(B)$ with $\pi(b_{ij}) = y_{ij}$ holds that $\|[P_\infty(b_{ij})]\| = \|[y_{ij}]\|$ for the norms in $M_k(B_\infty) \cong (M_k(B))_\infty$ respectively in $M_k(B//E)$, and $[P_\infty(b_{ij})]$ is positive if and only if y is positive in $M_k(B//E)$. This is because

$$\|[y_{ij}]\| = \operatorname{dist}\big([b_{ij}], M_n(BE + EB)\big) = \limsup_n \|[p_n b_{ij} p_n]\|\,.$$

The argument for the complete positivity of the class-map $\eta := [P_\infty]\colon B//E \to Y$ is similar. The completely isometric and completely positive isomorphism η from $B//E$ onto Y is determined by $\eta \circ \pi_{BE+EB} = P_\infty$.

It follows that $\eta(\pi_{BE+EB}(J)) = P_\infty(J) \subseteq J_\infty \cap Y$ for $J \in \mathcal{I}(B)$. The inclusion "$\supseteq$" needs a less simple argument: If $\pi_\infty(p_1 a p_1, p_2 a p_2, \ldots) \in J_\infty$, then there is a bounded sequence $b_1, b_2, \ldots \in J$ with $\lim_{n\to\infty} \|p_n a p_n - p_n b_n p_n\| = 0$. It follows that $\pi_{BE+EB}(a) = \lim_n \pi_{BE+EB}(p_n b_n p_n)$ in $B//E$, i.e., $\pi_{BE+EB}(a)$ is in the closure of $\pi_{BE+EB}(J)$. But it turns out that $J \cap (BE + EB) = J(E \cap J) + (E \cap J)J$ and that the natural map from $J//(E \cap J)$ to $B//E$ is (completely) isometric. This can be seen from the second conjugate spaces which are naturally isomorphic to $(1 - q_E)B^{**}(1 - q_E)q_J$ and to $(1 - q_E)B^{**}(1 - q_E)$. Here we denote by q_E and q_J the open support projection of E and J in B^{**}. This implies together that

$$\eta(\pi_{BE+EB}(J)) = P_\infty(J) = J_\infty \cap Y = (p_\infty J_\infty p_\infty) \cap Y\,.$$

Since $t_n^* t_n = p_n$, we get – for the isometry $t_\infty := \pi_\infty(t_1, t_2, \ldots) \in \mathcal{M}(B)_\infty \subseteq \mathcal{M}(B_\infty)$ – that the restriction to Y of the c.p. contraction

$$T_\infty(\pi_\infty(b_1, b_2, \ldots)) := t_\infty^* \pi_\infty(b_1, b_2, \ldots) t_\infty$$

is a completely positive complete isometry from Y onto the image of the map $S_{1,\infty}\colon B \to X \subset B_\infty$.

In fact, $S_{1,\infty}(b) = T_\infty(\Delta(b)) = T_\infty(P_\infty(b))$. The defining maps $S_{k,\infty}\colon B \to X \subset B_\infty$ for the inductive limit $X = \operatorname{indlim}_n(S_n\colon B \to B)$ are given by

$$S_{k,\infty}(b) := \pi_\infty(0, \ldots, 0, S_k(b), S_{k+1}(S_k(b)), \ldots)\,.$$

(It is not important if one takes zero at places 1 to $k-1$ or takes other elements of B.) The inductive limit $X = \operatorname{indlim}_n(S_n\colon B \to B)$ is the closure of $\bigcup_k S_{k,\infty}(B)$ in B_∞. But, since $S_{1,\infty} = S_{k,\infty} \circ S_{k-1} \circ \cdots \circ S_1$, $S_{k,\infty} = S_{1,\infty} \circ \rho_{k-1}$, and $\rho_n(B) = q_n B q_n$, it follows that

$$S_{k,\infty}(B) = S_{0,\infty}(B) = \{T_\infty(\Delta(b))\,;\ b \in B\} = T_\infty(Y)$$

are the same linear subspace of B_∞. The image $T_\infty(Y) = S_{1,\infty}(B)$ of the (not necessarily unital) C^*-system $Y \subseteq p_\infty B_\infty p_\infty$ for the projection $p_\infty := \pi_\infty(p_1, p_2, \ldots) \in \mathcal{M}(B)_\infty \subseteq \mathcal{M}(B_\infty)$ is closed, because the restriction of $\rho_\infty \circ T_\infty$ to $p_\infty B_\infty p_\infty$ is the identity map, i.e., $T_\infty | p_\infty B_\infty p_\infty$ must be isometric on Y.

The map $T_\infty \circ \eta \colon B//E \to X$ is induced from $T_\infty \circ \eta \circ \pi_{BE+EB} = T_\infty \circ P_\infty$. Since $T_\infty(P_\infty(B)) = T_\infty(Y) = X$, it follows that $T_\infty \circ \eta = [T_\infty \circ P_\infty] \colon B//E \to X$ defines a complete isometry from $B//E$ onto X.

Thus, $\rho_\infty | X$ is a completely positive and completely isometric map from $X \cong B//E$ onto Y, and the map $(\rho_\infty | X)^{-1}$ is given by the class-map $V := [S_{1,\infty}] \colon B//E \to X$ with $V \circ \pi_{BE+EB} = S_{1,\infty} = T_\infty \circ \Delta$.

Since $T_n(p_n J p_n) = T_n(J) = t_n^* J t_n = J$ and $\rho_n(J) = p_n J p_n = J \cap p_n B p_n$, we get for all $J \in \mathcal{I}(B)$ that

$$T_\infty(p_\infty J_\infty p_\infty) = T_\infty(J_\infty) = J_\infty$$

and

$$\rho_\infty(J_\infty) = p_\infty J_\infty p_\infty = J_\infty \cap p_\infty B_\infty p_\infty \,.$$

$$\eta(B//E) \cap \pi(J)_\infty = \rho_\infty(X \cap J_\infty) = P_\infty(J) == \eta(\pi_{BE+EB}(J)) \,.$$

It follows that $V := [T_\infty \circ \Delta] = T_\infty \circ \eta \colon B//E \to X = \mathrm{indlim}_n(S_n \colon B \to B)$ is a complete isometry from $B//E$ onto X and satisfies

$$V(\pi_{BE+EB}(J)) = J_\infty \cap X = \mathrm{indlim}_n(S_n \colon J \to J) \,.$$

□

Proposition 6.3.17. *Suppose that B is separable and stable and has the WvN-property, and that $T_n \colon B \to B$ is a sequence of residually nuclear completely positive contractions. Consider $X := \mathrm{indlim}(T_n \colon B \to B)$ naturally as operator subspace of $B_\infty := \ell_\infty(B)/c_0(B)$.*

Then X is a nuclear subspace of B_∞ and there exist a residually essential *hereditary C^*-subalgebra D of B and a completely isometric and completely positive isomorphism I from $B//D$ onto $X = \mathrm{indlim}(T_n \colon B \to B)$, such that*

$$I(\pi_{BD+DB}(J)) = J_\infty \cap X$$

for every closed ideal J of B.

Proof. The inductive limit X is nuclear by Lemma 6.3.14(iii), because the maps T_n are residually nuclear contractions. Since B has the WvN-property, the maps T_n are in the point-norm closure of the set of one-step inner maps $b \mapsto c^*bc$. By Lemma 3.1.8 the T_n are in the point-norm closure of the *contractive* inner c.p. maps $b \mapsto d^*bd$, i.e., with $\|d\| \leq 1$. By Lemma 6.3.15, the maps $b \mapsto d^*bd$ with $\|d\| \leq 1$ can be approximated in point-norm topology by maps $b \mapsto t^*bt$ with an isometry $t \in \mathcal{M}(B)$, because B is stable and σ-unital.

Now we can apply Lemma A.14.2 to the sequence of maps $T_1, T_2, \ldots$ and the set of maps $b \mapsto t^*bt$ with isometries $t \in \mathcal{M}(B)$, because B is separable. We get that are isomeries $t_n \in \mathcal{M}(B)$ such that $X = \text{indlim}(L_n \colon B \to B)$ for the maps $L_n(b) := t_n^* b t_n$.

Then, by Lemma 6.3.16, there is a hereditary C^*-subalgebra F of B and completely isometric and completely positive isomorphism φ from $B//F$ onto X with $\varphi(\pi_{BF+FB}(J)) = J_\infty \cap X \subset B_\infty$ for $J \in \mathcal{I}(B)$. By Lemma 6.3.14 there are residually nuclear contractions $S_n \colon B \to B$ such that there is a completely isometric and completely positive isomorphism ψ from $Y := \text{indlim}(S_n \colon B \to B)$ onto $X \otimes M_{2^\infty}$ with $\psi(J_\infty \cap Y) = (J_\infty \cap X) \otimes M_{2^\infty}$ for $J \in \mathcal{I}(B)$. In particular,

$$Y \cong (B//F) \otimes M_{2^\infty} \cong (B \otimes M_{2^\infty})//(F \otimes M_{2^\infty}),$$

If we repeat the above arguments with S_n (in place of T_n), then we get that there is a hereditary C^*-subalgebra $E \subset B$ and a completely isometric and completely positive isomorphism χ from $B//E$ onto Y such that $\chi(\pi_{BE+EB}(J)) = J_\infty \cap Y$. If $\rho \colon M_{2^\infty} \to \mathbb{C}$ is a pure state and $V \colon X \otimes M_{2^\infty} \to X \subset B_\infty$ is the completely positive contraction with $V(c \otimes d) = \rho(c)d$, then there is a hereditary C^*-subalgebra D of B with $E \subset D \subset B$ such that $BD + DB$ is the kernel of the completely positive map $W := V \circ \psi \circ \chi \circ \pi_{BE+EB} \colon B \to X$ from B into X. Let $I := [W]_{BD+DB} \colon B//D \to X$. By Lemma 6.3.13, D is residually essential in B and I is a completely isometric and completely positive isomorphism from $B//D$ onto X. If J is a closed ideal of B then, for $J \in \mathcal{I}(B)$,

$$\begin{aligned} I\pi_{BD+DB}(J) &= V\big(\psi\big(\chi\,(\pi_{BE+EB}(J))\big)\big) = V\big(\psi(Y \cap J_\infty)\big) \\ &= V\big((X \cap J_\infty) \otimes M_{2^\infty}\big) = X \cap J_\infty\,. \end{aligned}$$

□

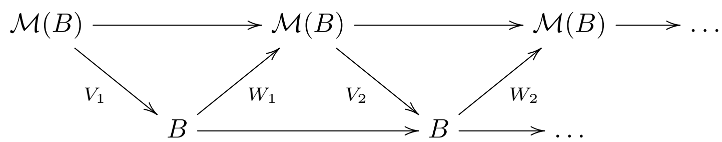
Proof of Theorem 6.3.1: Ad(I): Let a_k be a dense sequence in the unit-ball of A. There are completely positive maps $V_n \colon \mathcal{M}(B) \to B$ and $W_n \colon B \to \mathcal{M}(B)$ that satisfy conditions (b) and (c) of Theorem 6.3.1 and

$$\|W_n V_n(a_j) - a_j\| < 2^{-n} \qquad \text{for } \ 1 \leq j \leq n\,.$$

Then $A \subseteq \mathcal{M}(B) \subset \mathcal{M}(B)_\infty := \ell_\infty(\mathcal{M}(B))/c_0(\mathcal{M}(B))$ is naturally contained in

$$Y := \text{indlim}(S_n \colon \mathcal{M}(B) \to \mathcal{M}(B)) \subset J_\infty$$

with $S_n := W_n V_n$. Indeed, the compositions of the upper rows S_n of the commutative diagram



converge asymptotically to id_A on $A \subset \mathcal{M}(B) \subset \mathcal{M}(B)_\infty$, in the sense, that $S_{n,\infty} \colon \mathcal{M}(B) \to \mathcal{M}(B)_\infty$ converges in point-norm on A to $\text{id}_A \colon A \to \mathcal{M}(B)_\infty$, where

$$S_{n,\infty}(b) := (0, \dots, 0, b, S_n(b), S_{n+1}S_n(b), \dots) + c_0(B).$$

The product maps $\prod_{n\geq 1} V_n$ and $(b_1, b_2, \dots) \mapsto (0, W_1(b_1), W_2(b_2), \dots)$ define complete contractions V_∞ from $\mathcal{M}(B)_\infty$ into B_∞ and $\sigma \circ W_\infty$ from B_∞ into $\mathcal{M}(B)_\infty$. Let $T_n := V_{n+1}W_n \colon B \to B$. Then T_n is a residually nuclear contraction by construction of V_n and W_n, indeed: $U_e \colon B \ni b \mapsto V_{n+1}(eW_n(b)e) \in B$ is a residually nuclear map by conditions (a),(b) and (c) for every $e \in B_+$, and, since V_{n+1} strictly continuous as a map from $\mathcal{M}(B)$ into B (with norm topology), T_n is the point-norm limit of $\{U_{e_\tau}\}$ if $e_\tau \subset B_+$ is an approximate unit of B. V_∞ maps Y into

$$X = \text{indlim}(T_n \colon B \to B) \subset B_\infty$$

and σW_∞ maps X into Y.

We have $W_\infty \circ V_\infty \circ \sigma | Y = (S_\infty \circ \sigma)|Y = \text{id}_Y$ because $S_\infty \circ \sigma \circ S_{m,\infty} = S_{m,\infty}$. Clearly $V_\infty \circ \sigma \circ W_\infty) = T_\infty$. Since $\sigma \circ T_\infty | X = \text{id}_X$, we get $\sigma V_\infty \circ (\sigma W_\infty)|X = \text{id}_X$. If follows that $\sigma W_\infty | X$ is a completely isometric and completely positive map from X *onto* Y.

Let us consider the actions $\Psi_1(J) = J_\infty \subset B_\infty$ and $\Psi_2(J) = \mathcal{M}(B, J)_\infty \subset \mathcal{M}(B)_\infty$ for $J \in \mathcal{I}(B)$ of $\text{Prim}(B)$ on B_∞ and $\mathcal{M}(B, J)_\infty$. Since W_n and V_n are weakly residually equivariant, we get

$$\begin{aligned} V_\infty(\Psi_2(J)) &\subset \Psi_1(J) \quad \text{and} \\ \sigma W_\infty(\Psi_1(J)) &\subset \Psi_2(J). \end{aligned}$$

$$\text{Thus} \quad \begin{aligned} V_\infty(\Psi_2(J) \cap Y) &\subset \Psi_1(J) \cap X \quad \text{and} \\ \sigma W_\infty(\Psi_1(J) \cap X) &\subset \Psi_2(J) \cap Y. \end{aligned}$$

Since $(V_\infty|Y)^{-1} = (\sigma W_\infty | X)$, we get $\sigma W_\infty(\Psi_1(J) \cap X) = \Psi_2(J) \cap Y$. By Proposition 6.3.17 there is a residually essential hereditary C^*-subalgebra D of B and a completely isometric and completely positive map $T \colon B/\!/D \xrightarrow{\sim} X \subset B_\infty$, such that $\overline{BDB} = B$ and

$$T(\pi_D(J)) = \Psi_1(J) \cap X$$

for $J \in \mathcal{I}(B)$. Let $V := (\sigma \circ W_\infty) \circ T$, $C := J_\infty$ and $\Psi_C(J) := \Psi_2(J)$ for J in $\mathcal{I}(B)$.

`to be filled in! ??`

Then Lemma 6.3.8 and Lemma A.19.8 define a *-monomorphism λ from A into $\mathcal{M}(B/\!/D) \cap (B/\!/D) = \pi_1(\mathcal{N}(D))$ such that $\lambda = V^{-1}|A$ and that $\lambda(A \cap \mathcal{M}(B, J)) = \lambda(A) \cap \pi_1(\mathcal{N}(D) \cap J)$, because $V^{-1}(A \cap \mathcal{M}(B, J)) = V^{-1}(A \cap \Psi_C(J)) = V^{-1}(A) \cap \pi_1(J)$.

The operator space X is nuclear, because $T_n \colon B \to B$ is nuclear for every $n \in \mathbb{N}$. Thus $B/\!/D \cong X$ is nuclear, and the assumptions of Proposition 6.3.11 are satisfied for B and $D \subset B$, and $A \subset \mathcal{M}(B)$, $\lambda \colon A \hookrightarrow \pi_1(\mathcal{N}(D)) = \mathcal{M}(B/\!/D) \cap (B/\!/D)$

are as in part (iii) of Proposition 6.3.11. By 6.3.11(iii) we get the class $[H] \in \mathrm{Ext}_{\mathrm{nuc}}(\mathrm{Prim}\, B, A, B)$.

Now suppose that $A \cong E \otimes \mathcal{O}_2$ or $B \cong E \otimes \mathcal{O}_2$ for a stable separable C^*-algebras E. Then we can use the natural isomorphisms

$$\mathrm{Ext}_{\mathrm{nuc}}(\mathrm{Prim}(B); E \otimes \mathcal{O}_2, B) \cong \mathrm{KK}_{\mathrm{nuc}}(\mathrm{Prim}(B); SE \otimes \mathcal{O}_2, B)$$

(for separable stable B with WvN-property [13]) respectively

$$\mathrm{Ext}_{\mathrm{nuc}}(\mathrm{Prim}(B); A, E \otimes \mathcal{O}_2) \cong \mathrm{KK}_{\mathrm{nuc}}(\mathrm{Prim}(E) : SA, E \otimes \mathcal{O}_2)$$

cf. Chapter 8. The left sides of the above isomorphisms are zero because $\mathrm{KK}_{\mathrm{nuc}}(\mathrm{Prim}(B), \cdot, \cdot)$ is homotopy invariant in each variable and id is unitarily homotopic to $\mathrm{id} \oplus \mathrm{id}$ for all C^*-algebras $\cong C \otimes \mathcal{O}_2$.

Hence $[H] = 0$ in this cases, and Proposition 6.3.11(iv) gives the desired non-degenerate nuclear *-monomorphism $h \colon A \hookrightarrow B$ with $h(A \cap \mathcal{M}(B, J)) = h(A) \cap J$. $\delta_\infty \circ h$ is unitarily homotopic to $\delta_\infty | A$ by Corollary **??**.

Ad(II): Suppose, that we can find the W_n such that $W_n(B) \subset A$ (in addition). Then $S_n(A) = W_n V_n(A) \subset A$, $A = \mathrm{indlim}(S_n \colon A \to A) \subset A_\infty \subset B_\infty$, $S_{m,\infty}(B) = S_{m+1,\infty}(S_n(B)) \subset S_{m+1,\infty}(A) \subset A$. It follows that $Y = A$ in B_∞, because Y is the closure of $\bigcap_m S_{m,\infty}(B)$.

Thus, $\lambda = V^{-1} \colon A \hookrightarrow \pi_D(\mathcal{N}(D))$ is an isomorphism from A onto $B//D$ and $\pi_D(\mathcal{N}(D)) = B//D$, i.e., $B = \mathcal{N}(D) + \overline{BD} + \overline{DB}$. In particular, $A \cong B//D$ is nuclear.

If $[H] = 0$ in $\mathrm{Ext}_{\mathrm{nuc}}(\mathrm{Prim}(D), A, D) \cong \mathrm{Ext}_{\mathrm{nuc}}(\mathrm{Prim}(B), A, B)$, then again we find a non-degenerate *-monomorphism $H_3 \colon A \to \mathcal{N}(D) \subset B$ with $\pi_D(H_3(a)) = \lambda(a)$ such that

$$H_3(A \cap \mathcal{M}(B, J)) = H_3(A) \cap J$$

(cf. proof of Proposition 6.3.11(iv)). As in the proof of Proposition 6.3.11(iv), it follows that $H_3(A)$ generates B as a two-sided closed ideal. The hereditary C^*-subalgebra $D_1 := \overline{H_3(A) B H_3(A)}$ of B is stable.

There is a *-isomorphism φ from B onto D_1 that is unitarily homotopic to id_B by 5.5.6. In particular, $\varphi(J) = D_1 \cap J$ for $J \in \mathcal{I}(B)$. Let $\pi_D \colon B \to B//D = \lambda(A) = \pi_D(H_3(A))$ the natural quotient map. Then $P_1 := H_3 \lambda^{-1} \pi_D$ satisfies $P_1 H_3 = H_3$ and $P_1(B) \subset H_3(A)$.

It follows $P_1(D_1) \subset D_1$. Thus, $P := \varphi^{-1} \circ P_1 \circ \varphi$ and $h := \varphi^{-1} \circ H_3$ are as desired.

The extremality of the conditional expectation $P \colon B \to h(A)$ follows as in Remark 6.2.2. □

[13] Recall that our nuclear Ext-groups have rather strong equivalence relations that require e.g. that the extensions are *stable* as C^*-algebras.

CHAPTER 7

Groups of asymptotic morphisms $\mathrm{R}(\mathcal{C};\, A, B)$

We consider here "nuclear" (respectively "residually nuclear" , respectively "$\mathcal{C}$-compatible") asymptotic morphisms. Their unitary equivalence classes modulo $\mathrm{C}_0(\mathbb{R}_+, B)$ form a semigroup $\mathrm{SR}(A, B)$ (respectively $\mathrm{SR}(X;\, A, B)$, $\mathrm{SR}(\mathcal{C};\, A, B)$) if the multiplier algebra of B contains a copy of $\mathcal{O}_2$ unitally. The corresponding Grothendieck group $\mathrm{R}(A, B)$ (respectively $\mathrm{R}(X;\, A, B)$, $\mathrm{R}(\mathcal{C};\, A, B)$) is a continuous analog of **Rørdam's group** of asymptotic morphisms over $\mathbb{N}$, cf. [**677**], [**679**], [**680**] [**681**]. This groups are the mediators between the semi-groups $[\mathrm{Hom}(\mathcal{C}; A, B)]$ of unitary equivalence classes of the under Cuntz-addition invariant morphisms in $\mathrm{Hom}(A, B) \cap \mathcal{C}$ and the $\mathcal{C}$-equivariant KK-groups $\mathrm{KK}(\mathcal{C};\, A, B)$. If this is an isomorphism then $\mathrm{KK}(\mathcal{C};\, \cdot, \cdot)$-equivalence implies Morita equivalence of A and B. It means that we "reduce" some classification problems to questions on the "realization" of KK-theory equivalence by isomorphisms.

The main tools are continuous modifications and generalizations of the Rørdam groups $\mathrm{R}(A, B)$. They play a role in several generalizations, e.g. to the non-simple case as described above, or others, mentioned in the remarks of this Chapter. Some of the known stable invariants for simple separable nuclear C^*-algebras are the same for $\mathrm{R}(.,.)$-equivalent C^*-algebras A and B (e.g. they are KK-equivalent, $F(A)$ and $F(B)$ contain, up to isomorphisms, the same simple separable C^*-subalgebras, the stable rank, the real rank and decomposition rank are the same). A part of further study on classification could be the study of the consequences of $\mathrm{R}(.,.)$-equivalence.

??

1. The semigroups $\mathrm{SR}(\mathcal{C};\, A, B)$

By $\mathrm{CP}(A, B) \subset \mathcal{L}(A, B)$ we denote the matrix operator-convex cone of the completely positive contractions from a C^*-algebra A into a C^*-algebra B.

(We shall later require in addition that A and B are stable, that A is separable and that B is σ-unital.)

Definition 7.1.1. Let $\mathcal{C} \subset CP(A, B)$ denote a point-norm closed matricial operator-convex sub-cone of the cone of completely positive maps from A to B.

Suppose that $V\colon [0, \infty) \ni t \mapsto V(t) \in \mathcal{C} \subset \mathrm{CP}(A, B)$ is a point-norm continuous map (i.e., is continuous with respect to the strong operator topology on $\mathcal{L}(A, B)$). The map V is called an **asymptotic $\mathcal{C}$-morphism** from A to B if V satisfies the following conditions (a), (b) and (c):

(a) For every $t \in \mathbb{R}_+$, $V(t)\colon A \to B$ has norm $\|V(t)\| \leq 1$.
(b) The $V(t)$ are **asymptotically multiplicative** , i.e.,

$$\lim_{t\to\infty} \|V(t)(a^*a) - V(t)(a)^*V(t)(a)\| = 0$$

for every $a \in A$.
(c) for every $a \in A_+$ and $\varepsilon > 0$ there exist $b_1, \ldots, b_n \in B_+$ and $c_1, \ldots, c_n \in \mathrm{C_b}(\mathbb{R}_+, B)$ such that $\limsup_{n\to\infty} \|V(t)(a) - \sum_{i=1}^n c_i(t)^* b_i c_i(t)\| \leq \varepsilon$ ([1]).

Compare next blue with def. of unitary homotopy in Definition 5.0.1 !!

Let V_1, V_2 asymptotic $\mathcal{C}$-morphisms. We call V_1 **unitarily homotopic** to V_2 if there is a map $u\colon t \in \mathbb{R}_+ \mapsto u(t) \in \mathcal{M}(B)$ such that $u(t)$ is unitary, is continuous with respect to the strict topology on $\mathcal{M}(B)$ (Is the footnote really true ?? Likely not. No proof exists so far. [2]), and $\lim \|u(t)^*V_1(t)(a)u(t) - V_2(t)(a)\| = 0$ for every a in A.

Suppose that $\mathcal{M}(B)$ contains a copy of $\mathcal{O}_2$ unitally (i.e., there are isometries $s_1, s_2 \in \mathcal{M}(B)$ with $s_1s_1^* + s_2s_2^* = 1$). It is easy to check that the Cuntz sum

$$(V_1 \oplus V_2)(t) := V_1(t) \oplus_{s_1,s_2} V_2(t) := s_1V_1(t)(\cdot)s_1^* + s_1V_1(t)(\cdot)s_1^*$$

defines again an asymptotic $\mathcal{C}$-morphism $t \mapsto (V_1 \oplus V_2)(t)$ from A to B.

The properties of Cuntz addition (cf. Chapter 4) show that the equivalence classes $[V]$ of unitarily homotopic morphisms V form A to B build a semigroup under Cuntz addition. This semigroup and its Grothendieck group will be denoted by $\mathrm{SR}(\mathcal{C};\, A, B)$, respectively by $\mathrm{R}(\mathcal{C};\, A, B)$.

If $\mathcal{C} = CP_{nuc}(A, B)$ is the cone of all nuclear maps from A to B the we shall write $\mathrm{SR}(A, B)$ for $\mathrm{SR}(CP_{nuc}(A, B); A, B)$ and call $\mathrm{SR}(A, B)$ the **Rørdam semigroup**. Its Grothendieck group $\mathrm{Gr}(\mathrm{SR}(A, B))$ will be denoted by $\mathrm{R}(A, B)$ and call it the **Rørdam group**.

Suppose that X is a T_0 space and that $\Psi_A\colon \mathrm{O}(X) \to \mathcal{I}(A)$ and $\Psi_B\colon \mathrm{O}(X) \to \mathcal{I}(B)$ are actions of X on A respectively B. Let $\mathcal{C}_X \subseteq CP(A, B)$ denote the cone of Ψ_A-Ψ_B-residually nuclear maps from A into B. We call the asymptotic $\mathcal{C}_X$-morphisms **residually nuclear asymptotic morphisms**.

Then we write $\mathrm{SR}(X;\, A, B)$ and $\mathrm{R}(X;\, A, B)$ in place of $\mathrm{SR}(\mathcal{C}_X\,;\, A, B)$ respectively of $\mathrm{R}(\mathcal{C}_X;\, A, B)$. We call $\mathrm{R}(X;\, A, B)$ a **Ψ-equivariant Rørdam group**.

Clearly, all the definition depend from the actions Ψ_A and Ψ_B and not from X alone. The point is that they all come from before chosen non-degenerate point-norm closed matrix operator-convex cone $\mathcal{C} \subseteq \mathrm{CP}(A, B)$.

---

[1] Property (c) means, equivalently, that the morphism $h_V\colon A \to \mathrm{Q}(\mathbb{R}_+, B)$ corresponding to $V\colon \mathbb{R}_+ \to \mathcal{C}$ with properties (a) and (b) maps A into the ideal of $\mathrm{Q}(\mathbb{R}_+, B)$ generated by $B \subset \mathrm{Q}(\mathbb{R}_+, B)$.

[2] The map $t \mapsto u(t)$ can be chosen norm-continuous if B is σ-unital and stable and A is separable.

Remark 7.1.2. If $t \to V(t) \in \mathcal{C} \subseteq \mathrm{CP}(A,B)$ is an asymptotic $\mathcal{C}$-morphism, then $V(a)(t) := V(t)(a)$ defines an element $V(a) \in \mathrm{C_b}(\mathbb{R}_+, B)$ and

$$h_V \colon a \in A \mapsto V(a) + \mathrm{C_0}(\mathbb{R}_+, B)$$

is a C^*-morphism from A into $\mathrm{Q}(\mathbb{R}_+, B) := \mathrm{C_b}(\mathbb{R}_+, B)/\mathrm{C_0}(R_+, B)$.

If h_V is unitarily equivalent to a C^*-morphism $k\colon A \to B \subset \mathrm{Q}(\mathbb{R}_+, B)$ by a unitary in $\mathcal{M}(\mathrm{Q}(\mathbb{R}_+, B))$ then $t \mapsto V(t)$ and h_V satisfies in particular the following additional continuity conditions:

(d) For all lower semi-continuous 2-quasi-traces $\tau_1, \tau_2 \colon \mathrm{Q}(\mathbb{R}_+, B)_+ \to \mathbb{R}_+ \cup \{+\infty\} = [0, \infty]$ holds $\tau_1 \circ h_V = \tau_2 \circ h_V$ if $\tau_1 | B_+ = \tau_2 | B_+$.

(e) Let $\tau_\gamma, \rho \colon \mathrm{Q}(\mathbb{R}_+, B)_+ \to [0, \infty]$ denote lower semi-continuous 2-quasi-traces on $\mathrm{Q}(\mathbb{R}_+, B)_+$, where the family of quasi-traces $\{\tau_\gamma\}$ are indexed by elements γ is an element of a directed net Γ.

If $\{\tau_\gamma \,;\ \gamma \in \Gamma\}$ and ρ satisfy that

$$\sup_{\delta > 0} \lim_{\gamma \in \Gamma} \tau_\gamma((b - \delta)_+) = \rho(b)$$

for all $b \in B_+$ then we require here the condition of the map V that h_V satisfies in addition that

$$\sup_{\delta > 0} \lim_{\gamma \in \Gamma} \tau_\gamma(h_V((a - \delta)_+)) \;=\; \rho(h_V(a))$$

for all $b \in A_+$.

We call the asymptotic $\mathcal{C}$-morphism V **continuous** if it satisfies (in addition) the above conditions (d) and (e). One can see that the continuous asymptotic $\mathcal{C}$-morphism V define a sub-semigroup $\mathrm{SR}_c(\mathcal{C};\, A, B)$ of of $\mathrm{SR}(\mathcal{C};\, A, B)$.

The condition (d) implies in particular that

$$h_V(A) \cap I_1 = h_V(A) \cap I_2 \qquad \text{if} \quad I_1 \cap B = I_2 \cap B$$

for all closed ideals I_1, I_2 of $\mathrm{Q}(\mathbb{R}_+, B)$, if we consider the lower semi-continuous traces $\tau_k \colon \mathrm{Q}(\mathbb{R}_+, B)_+ \to \{0, \infty\}$, $k = 1, 2$, given by $\tau_k(f) := 0$ if $f \in (I_k)_+$ and by $\tau_k(f) := \infty$ if $f \in \mathrm{Q}(\mathbb{R}_+, B) \setminus I_k$. Thus, conditions (a), (b) and (d) imply the following properties (f) and (g). It shows that the conditions (a,b,d,e) together imply moreover the following property (h):

(f) For every $a \in A$ and every closed ideal J of B there exists

$$\lim_{t \to \infty} \| V(t)(a) + J \| \,,$$

and $\Psi(J) := (h_V)^{-1}(h_V(A) \cap \mathrm{Q}(\mathbb{R}_+, J))$ defines a monotone-continuous action of $\mathrm{Prim}(B)$ on A in the sense of Definition 1.2.6.

(g) $\tau_V(a) := \sup_{\delta > 0} \lim_{t \to \infty} \tau((V(t)(a) - \delta)_+) \in [0, \infty]$ exists for every $a \in A_+$ and for every lower semi-continuous 2-quasi-trace $\tau \colon B_+ \to [0, \infty]$.

The map $\tau_V \colon A_+ \to [0, \infty]$ is necessarily a lower semi-continuous 2-quasi-trace.

(h) The map $\tau \mapsto \tau_V$ is continuous from the set of l.s.c. 2-quasi-traces on B_+ to those on A_+ with respect to the topology of point-wise convergence ([3]).

REMARK 7.1.3. Below we will show that the map $t \mapsto u(t) \in \mathcal{M}(B)$ can be chosen norm-continuous if asymptotic $\mathcal{C}$-morphism V_1 and V_2 are unitarily homotopic and if B is σ-unital and stable, cf. ??.

On the other hand, it is easy to check that $V'(t)(a) := u(t)^*V(t)(a)u(t)$ satisfies conditions (a)-(c) for $\mathcal{C} = CP_{nuc}(A, B)$, if $t \mapsto V(t) \in \mathcal{L}(A, B)$ defines a weakly nuclear contraction $V\colon A \to \mathrm{C_b}(\mathbb{R}_+, B) \subseteq \mathcal{M}(\mathrm{C_0}(\mathbb{R}_+, B))$ from A into $\mathcal{M}(\mathrm{C_0}(\mathbb{R}_+, B))$ such that $h_V := \pi_{\mathrm{C_0}(\mathbb{R}_+,B)} \circ V$ is a C^*-morphism from A into $\mathcal{M}(\mathrm{C_0}(\mathbb{R}_+, B))/\,\mathrm{C_0}(\mathbb{R}_+, B)$, and if $t \mapsto u(t)$ is a strictly continuous map from $\mathbb{R}_+$ to $\mathcal{M}(B)$.

It follows, that, equivalently, we can consider $\mathrm{SR}(A, B)$ as a the sub-semigroup of the semigroup of unitary equivalence classes of those C^*-morphisms h from A into

$$\mathrm{Q}(\mathbb{R}_+\,, B) := \mathrm{C_b}(\mathbb{R}_+\,, B)/\,\mathrm{C_0}(\mathbb{R}_+\,, B) \subseteq \mathcal{M}(\mathrm{C_0}(\mathbb{R}_+\,, B))/\,\mathrm{C_0}(\mathbb{R}_+\,, B)$$

that have a completely positive contractive lift $V\colon A \to \mathrm{C_b}(\mathbb{R}_+, B)$ which satisfies the conditions (a)-(c).

By Lemma ??,

the unitaries for the unitary equivalences can be chosen in any of the following unital algebras

$$\mathrm{C_b}(\mathbb{R}_+\,, \mathcal{M}(B))/\,\mathrm{C_0}(\mathbb{R}_+\,, B) \subseteq \mathcal{M}(\mathrm{C_0}(\mathbb{R}_+\,, B))/\,\mathrm{C_0}(\mathbb{R}_+\,, B) \to \mathcal{M}(\mathrm{Q}(\mathbb{R}_+\,, B))\,.$$

REMARK 7.1.4. The conditions (c), (d) and (e) are redundant in some cases, e.g. if A has real rank zero or B is a pi-sun algebra. *But (d) and (e) do not imply (c) in general:*

$\mathbb{K}$ is the only simple C^*-algebra that has an asymptotic morphism into $\mathbb{K}$ with (c).

For example let us consider only the requirements (a)–(d) for $B = \mathbb{K}$:

A non-zero, *simple*, and separable C^*–algebra A must be stably isomorphic to $\mathbb{K}$ or is stably projection-less, if A admits a non-zero C^*-morphism $h\colon A\colon\ \mathrm{Q}(\mathbb{R}_+\,,\mathbb{K})$. (In particular, that $\mathbb{K}$ is the only simple separable stable algebra which is SR-equivalent to $\mathbb{K}$.)

The closed ideal J of $\mathrm{Q}(\mathbb{R}_+;\mathbb{K})$ that is generated by $\mathbb{K}$ is Morita-equivalent to the commutative algebra $\mathrm{Q}(\mathbb{R}_+\,, \mathbb{C}) = \mathrm{C}(\beta\mathbb{R}_+ \setminus \mathbb{R}_+)$. In particular, every separable C^*-subalgebra of J is of type I, in particular it is very different from the huge algebra $\mathrm{Q}(\mathbb{R}_+\,; \mathbb{K})$, that has every separable C^*-algebra as a sub-quotient.

---

[3] Notice that the l.s.c. quasi-traces build a compact set with topology of point-wise convergence, because $[0, \infty]$ is compact.

On the other hand, the cone of every separable C^*-algebra is a C^*-subalgebra of $\mathrm{Q}(\mathbb{R}_+, \mathbb{K})$. In particular, $\mathrm{C}_0(\mathbb{R}_+, \mathcal{O}_2) \subset \mathrm{Q}(\mathbb{R}_+, \mathbb{K})$, and thus, (a), (b), (d), (e) (f), (g), (h) are satisfied for a c.c.p. lift V of the inclusion map, but (c) is not satisfied.

If B is stably isomorphic to a unital C^*-algebra B^{st} (its "Cuntz standard form") which contains unitally a copy of $\mathcal{O}_2$ then B has no semi-finite lower semi-continuous traces and then (c), (f), (g) and (e) follow from (a)-(b), because then $T^+(B) = 0$ and every $b \in \mathrm{C}_\mathrm{b}(\mathbb{R}_+, B)$ is in the ideal which is generated by B: Indeed, by Lemma ??, there exists a projection $p \in \mathrm{C}_\mathrm{b}(\mathbb{R}_+, \mathcal{O}_2 \otimes \mathbb{K})$ with $b - pbp \in \mathrm{C}_0(\mathbb{R}_+, B)$. Thus $pb - b \in \mathrm{C}_0(\mathbb{R}_+, B)$, and $p(t) = u(t)p_0u(t)$ for $p_0 \in \mathcal{O}_2 \otimes \mathbb{K} \subseteq B$.

....

Is above OK? Compare Chp. 9 ??

....

But here we add a few comments on the general case (and possible generalizations):

Since (b) implies that $h_V \colon a \in A \mapsto V(a) + \mathrm{C}_0(\mathbb{R}_+, B) \in Q(\mathbb{R}_+, B)$ is a C^*-morphism and that for every $\omega \in (\beta\mathbb{R}_+ \setminus \mathbb{R}_+)$ $\pi_\omega h_V \colon A \to \mathrm{C}_\mathrm{b}(\mathbb{R}_+, B)/J_\omega$ is a C^*-morphism (f) means just that $\pi_\omega h_V$ is a C^*-morphism with the same kernel as h_V, i.e. $\|h_V(a)\|_\omega = \|V(a)\|_\omega = \mathrm{dist}(V(a), \mathrm{C}_0(\mathbb{R}_+, B))$ for every ω in the corona of $\mathbb{R}_+$. E.g. if A is simple then h is zero or $\pi_\omega h_V$ is a monomorphism for every $\omega \in \beta\mathbb{R}_+ \setminus \mathbb{R}_+$.

If A has real rank zero then again (c), (d), (e), (g) and (h) follow from (a), (b) and (f) since every projection of $Q(\mathbb{R}_+, B \otimes \mathbb{K})$ is unitarily equivalent to a projection in $B \otimes \mathbb{K}$ by a unitary in the unitization of $Q(\mathbb{R}_+, B \otimes \mathbb{K})$ and ideals of A are determined by its projections. For $RR(A) = 0$ the topology on $T^+(A)$ is induced by the pairing with $K_0(A)$ thus (h) is satisfied. The same happens with the space of 2-quasi-traces, which gives (d) and (e) from (a),(b) and (f).

The further challenge of the theory of (our type of) asymptotic morphisms are variants of property (f). Here a lot of stronger or weaker versions are possible which will be discussed somewhere else.

Next Cor. cited in Chapter 10.

Corollary 7.1.5. *Suppose that A and B are C^*-algebras, where A is separable and B is a σ-unital and stable.*

Let $\varphi \colon A \to \mathrm{Q}(\mathbb{R}_+, B)$ and $\psi \colon A \to \mathrm{Q}(\mathbb{R}_+, B)$ C^*-morphisms that are unitarily equivalent by a unitary $W \in \mathcal{M}(\mathrm{Q}(\mathbb{R}_+, B))$.

Then φ and ψ are unitarily equivalent by a unitary $U \in \mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B))$ that is a finite product of exponentials $\exp(T_j)$, $j = 1, \ldots, n$, where $T_j \in \mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B))$ with $\|T_j\| < 1$, $T_j^* = -T_j$.

Desired: $T_j \in \mathrm{Q}(\mathbb{R}_+, B)$

PROOF. Let $W \in \mathcal{M}(\mathrm{Q}(\mathbb{R}_+, B))$ with $W^*\varphi(\cdot)W = \psi(\cdot)$.

Let $a_0 \in A_+$ a strictly positive contraction for A. Then $\varphi(a_0) + \psi(a_0)$ is a strictly positive element of $C^*(\varphi(A) \cup \psi(A))$. There exists contractions $e_0, e_1, e_2 \in \mathrm{C_b}(\mathbb{R}_+, B)_+$ such that, $e_i e_j = e_j e_i$ and $e_1(1 - e_0), e_2(1 - e_1) \in \mathrm{C}_0(\mathbb{R}_+, B)$, $e_3 := e_2 + \mathrm{C}_0(\mathbb{R}_+, B) \in \mathrm{Q}(\mathbb{R}_+, B)$ satisfies $e_3(\varphi(a_0) + \psi(a_0)) = \varphi(a_0) + \psi(a_0)$.

It implies that $e_3\varphi(\cdot) = \varphi(\cdot) = \varphi(\cdot)e_3$ and $e_3\psi(\cdot) = \psi(\cdot) = \psi(\cdot)e_3$. Let $f := e_3 W e_3$. Then $f \in \mathrm{Q}(\mathbb{R}_+, B)$ is a contraction with $f^*\varphi(\cdot)f = \psi(\cdot)$ and $f\psi(\cdot)f^* = \varphi(\cdot)$. It follows that $(1 - ff^*)\varphi(\cdot)ff^* = 0$ and ????

We can lift f to a contraction $g \in \mathrm{C_b}(\mathbb{R}_+, B)$ with $f = g + \mathrm{C}_0(\mathbb{R}_+, B)$ and $e_1 g = g = g e_1$.

Since B is stable and σ-unital, we get from

Lemma **??**

isometries $S, T \in \mathrm{C_b}(\mathbb{R}_+, \mathcal{M}(B))$ with $SS^* + TT^* = 1$ and $(1 - S)e_0, e_0(1 - S) \in \mathrm{C}_0(\mathbb{R}_+, B)$. It gives $T^*e_0 = 0 = e_0 T$. Let $U_0 := U(g)$ the Halmos unitary of g with respect to (S, T), cf. cf. Remark **??**. Then $U_0 \in \mathrm{C_b}(\mathbb{R}_+, \mathcal{M}(B))$ and $\pi_B(U_0(t)) = TS^* - ST^*$, i.e., $U_0 \in TS^* - ST^* + \mathrm{C_b}(\mathbb{R}_+, B)$. We get $U_0^* e_1 = U_0^* e_0 e_1 = Sge_0 + T(1 - g^*g)S^*e_0 = Sg = Se_0 g = g$,

Need $U_0^* e_1 = g$???? □

2. The asymptotic corona $\mathrm{Q}(X, A)$

Let us fix some notations: Throughout this section X denotes a locally compact Hausdorff space. In our later applications we use only *closed subsets* X of the plane $\mathbb{R} \times \mathbb{R} \cong \mathbb{C}$ that are not necessarily bounded.

Notice that a locally compact space X is a σ-compact space if and only if the C^*-algebra $\mathrm{C}_0(X)$ contains a strictly positive element $e \in \mathrm{C}_0(X)$: Let $X_1 \subseteq X_2 \subseteq \ldots$ be a sequence of open subsets of X with compact closures such that the closure of X_n is contained in X_{n+1} and $X = \bigcup X_n$.

By Urysohn Lemma, we find continuous functions $\mu_n \in \mathrm{C}_0(X)_+$ with $\|\mu_n\| = 1$, $\mu_n|\overline{X_n} = 1$, $\mu_n|(X \setminus X_{n+1}) = 0$. Then $\mu_n\mu_{n+1} = \mu_n$ and $e(x) := \sum_{n=1}^{\infty} 2^{-n}\mu_n \in \mathrm{C}_0(X)_+$, and $1 \geq e(x) > 0$ for every $x \in X$. Thus, $\mathrm{C}_0(X)$ *is σ-unital with strictly positive element e if X is σ-compact.*

Conversely, suppose that the C^*-algebra $\mathrm{C}_0(X)$ is σ-unital. There exists continuous function $e \in \mathrm{C}_0(X)_+$ that is a strictly positive element of norm one in the C^*-algebra $\mathrm{C}_0(X)$. The sets $U_n := e^{-1}((n^{-1}, 1])$ build a sequence of open subsets of X with $X = \bigcup X_n$, the closure of X_n is contained in compact set $C_n := e^{-1}([(n+1)^{-1}, 1])$. Thus X is σ-compact.

We consider from now on only σ-compact l.c. spaces X.

Let $\mathrm{C_b}(X)$ denote the C^*-algebra of bounded continuous functions on X. By βX we denote the **Stone-Čech compactification** of X, the **corona** $\gamma(X) :=$

$\beta(X) \setminus X$ consists of abstract limit points of the free ultra-filters on X. $\beta(X)$ and $\gamma(X)$ are compact and X is a dense open subset of βX.

In terms of C^*-algebras we have natural isomorphisms $\mathrm{C_b}(X) \cong C(\beta X) \cong \mathcal{M}(\mathrm{C_0}(X))$ and, therefore, $C((\beta X \setminus X)) \cong \mathrm{C_b}(X)/\mathrm{C_0}(X) \cong \mathcal{M}(\mathrm{C_0}(X))/\mathrm{C_0}(X)$. The free ultra-filters on X (i.e. the points of the corona of X) correspond one-to-one to the characters of $\mathrm{C_b}(X)$ which annihilate $\mathrm{C_0}(X)$, i.e. to the characters of $\mathrm{C_b}(X)/\mathrm{C_0}(X)$. In the sequel we consider frequently every continuous bounded function on X also as a continuous function on βX.

It follows that $\gamma(\mathbb{R}) = \beta\mathbb{R}\setminus\mathbb{R}$ is the disjoint union of the open connected subsets $\gamma(\mathbb{R}_-)$ and $\gamma(\mathbb{R}_+)$, where $\mathbb{R}_- = (-\infty, 0]$ and $\mathbb{R}_+ = [0, +\infty)$.

More simply expressed:
If f is a bounded continuous function on $\mathbb{R}_-$ and g a bounded continuous function on $\mathbb{R}_+$, then $h(t) := f(t)$ for $t \leq -1$, $j(t) := g(t)$ for $t \geq 0$, $h(t) := |t|f(-1)+(1-|t|)g(0)$ for $t \in [-1, 0]$ is a bounded continuous function with $h|\gamma(\mathbb{R}_-) = f|\gamma(\mathbb{R}_-)$ and $h|\gamma(\mathbb{R}_+) = g|\gamma(\mathbb{R}_+)$.

Now let A be a Banach space. By $\mathrm{C_b}(X, A)$ (resp. $\mathrm{C_0}(X, A)$) we denote the Banach space of bounded continuous functions $f \colon X \to A$ with $\|f\| = \sup\{\|f(x)\| \colon x \in X\}$ (resp. continuous functions $f \colon X \to A$ vanishing at infinity, i.e., on $\gamma(X)$).

If A is a C^*-algebra, then $\mathrm{C_0}(X, A)$ is an ideal of the C^*-algebra $\mathrm{C_b}(X, A)$, $\mathrm{C_b}(X)$ acts on $\mathrm{C_b}(X, A)$ by $(gf)(x) = g(x)f(x)$ for $f \in \mathrm{C_b}(X, A)$ and $g \in \mathrm{C_b}(X)$.

Definition 7.2.1. Let $f \in \mathrm{C_b}(X, A)$. We denote by $N(f) \in \mathrm{C_b}(X)$ the continuous function $N(f)(x) := \|f(x)\|$.

We call the Banach space $\mathrm{Q}(X, A) := \mathrm{C_b}(X, A)/\mathrm{C_0}(X, A)$ the **asymptotic corona of** A **with respect to** X, and $\mathrm{Q}(\mathbb{R}_+, A)$ the **asymptotic corona of** A.

If Y is a closed subset of $\beta(X)$ then

$$J_Y := \{f \in \mathrm{C_b}(X, A) \colon \ N(f)(y) = 0 \ \forall y \in Y\},$$

where we consider $N(f)$ as a function in $\mathrm{C}(\beta X)$. In particular, $J_X = \mathrm{C_0}(X, A)$.

More generally, we define **restrictions** $\mathrm{C_b}(X, A)|Y$ of $\mathrm{C_b}(X, A)$ to closed subsets Y of βX by

$$\mathrm{C_b}(X, A)|Y := \mathrm{C_b}(X, A)/J_Y \,.$$

In particular, $\mathrm{Q}(X, A) = \mathrm{C_b}(X, A)|\gamma(X)$. We write also $\mathrm{Q}(X, A)|Y := \mathrm{C_b}(X, A)|Y$ if $Y \subseteq \gamma(X)$.

The reader can easily check that:

(i) $N(f) \colon x \mapsto \|f(x)\|$ is in $\mathrm{C_b}(X) \cong \mathrm{C}(\beta X)$ if $f \in \mathrm{C_b}(X, A)$ and is $\mathrm{C_b}(X)_+$-homogeneous, i.e. $gN(f) = N(gf)$ if $f \in \mathrm{C_b}(X, A)$, $g \in \mathrm{C_b}(X)_+$.

(ii) $\mathrm{C_0}(X, A) = \mathrm{C_0}(X)\,\mathrm{C_b}(X, A)$, and, more generally,

$$J_Y = \mathrm{C_0}((\beta X) \setminus Y) \cdot \mathrm{C_b}(X, A)$$

if $Y \subseteq \gamma(X)$ ([4]).

Part (ii) can be seen (e.g. in the case of σ-compact X) as follows: Let $f \in J_Y$ and let $e \in \mathrm{C}_0(X)_+ \subseteq \mathrm{C}(\beta(X))$ a fixed continuous function with $e(x) > 0$ for $x \in X \setminus Y$, $e(y) = 0$ for $y \in \gamma(X)$ (i.e., take the above constructed strictly positive element $e \in \mathrm{C}_0(X)$ of the σ-unital C^*-algebra $\mathrm{C}_0(X \setminus Y)_+$ — with X replaced by $X \setminus Y$). $\mathrm{C}_0(X)_+$. Then $g = (N(f) + e)^{1/2} \in \mathrm{C}_0(\beta X \setminus Y)$. The function $f_1(x) := (N(f) + \delta)^{-1/2}(x) f(x)$ for $x \in X$ is continuous and satisfies $N(f_1) \leq N(f)^{1/2}$. In particular $f_1 \in J_Y$ and $g f_1 = f$.

LEMMA 7.2.2. *Let A a C^*-algebra, and X a locally compact, σ-compact and non-compact Hausdorff space.*

There are following natural isomorphisms and properties:

(i) $\mathrm{C}_0(X, A) \cong \mathrm{C}_0(X) \otimes A$ *by the a natural isomorphism that identifies $f(x)a$ and $f \otimes a$ for $a \in A$, $f \in \mathrm{C}_0(X)$. It defines a natural C^*-morphism from* $\mathrm{C_b}(X)$ *into the center of* $\mathcal{M}(\mathrm{C}_0(X, A))$.

(ii) $\mathcal{M}(\mathrm{C}_0(X, A))$ *is naturally isomorphic to the C^*-algebra* $\mathrm{C_{b,st}}(X, \mathcal{M}(A))$ *of bounded strictly (= *-strongly) continuous maps f from X into $\mathcal{M}(A)$.*

(iii) $\mathrm{C_b}(X, A)$ *is identical with the ideal of* $\mathcal{M}(\mathrm{C}_0(X, A))$ *given by*

$$\{\, f \in \mathcal{M}(\mathrm{C}_0(X, A))\,;\; gf \in \mathrm{C}_0(X, A) \quad \forall\; g \in \mathrm{C}_0(X)\}\,.$$

*In particular, the natural *-monomorphism from* $\mathrm{C_b}(X, A)$ *extends to a natural *-isomorphism*

$$\mathcal{M}(\mathrm{C_b}(X, A)) \cong \mathcal{M}(\mathrm{C}_0(X, A))\,.$$

(iv) $\mathrm{Q}(X, A) := \mathrm{C_b}(X, A)/\,\mathrm{C}_0(X, A)$ *is naturally isomorphic to an ideal of* $\mathcal{M}(\mathrm{C}_0(X, A))/\,\mathrm{C}_0(X, A)$.

And $\mathcal{M}(\mathrm{Q}(X, A)) = \mathcal{M}(\mathrm{C}_0(X, A))/\,\mathrm{C}_0(X, A)$.

The algebraic two-sided annihilator $\mathrm{Ann}(\mathrm{Q}(X, A))$ *of* $\mathrm{Q}(X, A)$ *in* $\mathcal{M}(\mathrm{C}_0(X, A))/\,\mathrm{C}_0(X, A) = \mathcal{M}(\mathrm{C_b}(X, A))/\,\mathrm{C}_0(X, A)$ *is identical with*

$$\{T + \mathrm{C}_0(X, A)\,;\; T \in \mathcal{M}(\mathrm{C}_0(X, A))\,,\; Tf, fT \in \mathrm{C}_0(X, A)\;\; \forall\, f \in \mathrm{C_b}(X, A)\}\,.$$

It is identical with the C^*-algebra $\big(\mathrm{C}_0(X) \cdot \mathcal{M}(\mathrm{C}_0(X, A))\big)/\,\mathrm{C}_0(X, A)$.

(v) *For $f, g \in \mathrm{Q}(X, A)_+$, $fg = 0$ there exists contractions $h_1, h_2 \in \mathrm{Q}(X, A)_+$ with $fh_1 = f$, $gh_2 = g$ and $h_1 h_2 = 0$.*

(vi) *For $f \in \mathrm{C_b}(X, A \otimes \mathbb{K})_+$ there exists an isometry $s \in \mathrm{C_b}(X, \mathcal{M}(\mathbb{K})) \subseteq \mathcal{M}(\mathrm{C}_0(X, A \otimes \mathbb{K}))$ such that $fs \in \mathrm{C}_0(X, A \otimes \mathbb{K})$.*

(vii) *If $M_1 \subset \mathcal{M}(\mathrm{C}_0(X, A))$ and $M_2 \subseteq \mathrm{C_b}(X, A)$ are countable subsets then there exist a positive contraction $e \in \mathrm{C_b}(X, A)$ such that $eb - be, c - ec, c - ce \in \mathrm{C}_0(X, A)$ for all $b \in M_1$ and $c \in M_2$.*

(viii) *Suppose that the C^*-algebra B contains a continuous path $t \in \mathbb{R}_+ \mapsto p(t) \in B$ in the projections of B such that $\lim_{t\to\infty} p(t)b = b$ for all $b \in B$.*

[4] The factorization holds for arbitrary l.c. X by Cohen factorization applied to the *non-degenerate* Banach $\mathrm{C}_0(\beta(X) \setminus Y)$-module J_Y.

Let $h\colon B \to \mathcal{M}(A)$ is non-degenerate C^*-morphism, and

$$h_X\colon \mathrm{C_b}(X, B) \to \mathrm{C_{b,st}}(X, \mathcal{M}(A)) \cong \mathcal{M}(\mathrm{C}_0(X, A))$$

its natural extension to $\mathrm{C_b}(X, B)$*.*

Then for every countable subset $M \subset \mathrm{C_b}(X, A)$ there exists a projection $p \in \mathrm{C_b}(X, B)$ such that $(1 - h_X(p))f, f(1 - h_X(p)) \in \mathrm{C}_0(X, A)$ for all $f \in M$.

`It is likely that` $\mathcal{M}(\mathrm{C_b}(X, B))/\,\mathrm{C}_0(X, B) \subseteq \mathcal{M}(\mathrm{Q}(X, B))$ `is not equal to` $\mathcal{M}(\mathrm{Q}(X, B))$`,` e.g. `if` $X = \mathbb{R}_+$ `and` B `is not` σ`-unital?`

`When` $\mathcal{M}(A)/J \subseteq \mathcal{M}(A/J)$ `??`
`Perhaps` $\mathcal{M}(A/J) \cong \mathcal{M}(A)/\mathcal{N}(A, J)$ `if` A `and` J `are` σ`-unital ??`

`Notice that` $J := \mathrm{C}_0(X, B)$ `is not` σ`-unital if` B `is not` σ`-unital!`

PROOF. (i): Easy to see, e.g. [**767**, vol.I,chp.IV.,thm.4.14], [**704**, sec. 1.22].

(ii): For $y \in X$ the $*$-epimorphism $f \in \mathrm{C}_0(X, A) \mapsto f(y) \in A$ defines a C^*-morphism $b \in \mathcal{M}(\mathrm{C}_0(X, A)) \mapsto b(y) \in \mathcal{M}(A)$. If $g \in \mathrm{C}_0(X)$, $a \in A$ then $(b(g \otimes a))(y) = g(y)b(y)a \in \mathrm{C}_0(X, A)$. Thus $y \mapsto b(y)$ is strongly continuous. The same happens for b^*, $y \mapsto (b(y))^* = b^*(y)$ since $\mathrm{C}_0(X) \odot A$ is dense in $\mathrm{C}_0(X, A) = \mathrm{C}_0(X) \otimes A$, for every $b \in \mathcal{M}(\mathrm{C}_0(X, A))$ there exists a strictly continuous function $x \mapsto b(x)$ with $\sup \|b(x)\| \leq \|b\|$ such that $(bf)(x) = b(x)f(x)$. Conversely a bounded strictly continuous map $x \mapsto b(x) \in \mathcal{M}(A)$ defines a multiplier of $\mathrm{C}_0(X, A)$ (respectively of $\mathrm{C_b}(X, A)$), because the A-valued functions $x \to b(x)a(x)$ and $x \to a(x)b(x)$ are in $\mathrm{C}_0(X, A)$ (respectively in $\mathrm{C_b}(X, A)$) if $x \to b(x) \in \mathcal{M}(A)$ is bounded and strictly continuous.

Parts (iii) and (iv) can be seen from (ii) and (i).

(v): It suffices to find a contraction $h_1 \in \mathrm{Q}(X, A)_+$ with $h_1 f = f$ and $h_1 g = 0$, because then one can use (g, h_1) in place of (f, g) to produce in the same way h_2 with $h_2 h_1 = 0$ and and $h_2 g = g$.

Let $b = b^* \in \mathrm{C_b}(X, A)$ with $b + \mathrm{C}_0(X, A) = f - g$. The the positive and the negative parts of b satisfy $b_+(x) = \max(0, b(x))$, $b_-(x) = \max(0, -b(x))$, $b_+ + \mathrm{C}_0(X, A) = f$ and $b_- + \mathrm{C}_0(X, A) = g$. Take a strictly positive contraction $e \in \mathrm{C}_0(X)_+$, i.e., $1 \geq e(x) > 0$ for all $x \in X$ and $\lim_{x \to \infty} e(x) = 0$.

Define $h(x) := e(x)^{-1} \min(b_+(x), e(x) \cdot 1)$, i.e., $h(x) = e(x)^{-1} b_+(x) - e(x)^{-1}(b_+(x) - e(x))_+$. This h is a positive contraction in $\mathrm{C_b}(X, A)$, and with $\|b_+(x)h(x) - b_+(x)\| \leq e(x)$ by spectral calculus, because $(b_+(x) - e(x))_+ \in C^*(b_+(x)) \subseteq A$, $x \mapsto (b_+(x) - e(x))_+$ is continuous and $t(1 - \varepsilon^{-1} \min(t, \varepsilon)) \leq \varepsilon$ for all $t \geq 0$ and $\varepsilon > 0$. Right from the definition we get $b_-(x)h(x) = 0$. Thus $h_1 := h + \mathrm{C}_0(X, A) \in \mathrm{Q}(X, A)$ has the desired properties.

(vi): `Combine proof with (viii). New text in Lemma:`

For $f \in \mathrm{C_b}(X, A \otimes \mathbb{K})_+$ there exists an isometry $s \in \mathrm{C_b}(X, \mathcal{M}(\mathbb{K})) \subseteq \mathcal{M}(\mathrm{C_0}(X, A \otimes \mathbb{K}))$ such that $fs \in \mathrm{C_0}(X, A \otimes \mathbb{K})$.

`Old proof:` Let $f \in \mathrm{C_b}(X, A \otimes \mathbb{K})$ and $X_1 \subseteq X_2 \subseteq \cdots$ a sequence of compact subsets of X such that X_n is contained in the *interior* of X_{n+1} and $\bigcup_n X_n = X$. We find projections $p_1 \leq p_2 \leq \ldots \in \mathbb{K}$ such that $\|f(x)1 \otimes p_n - f(x)\| < \frac{1}{n}$ for $x \in X_n$. Thus it suffices to find a strictly continuous map $x \mapsto s(x) \in \mathcal{L}(H) = \mathcal{M}(\mathbb{K})$ such that $s(x)$ is an isometry and $\|p_n s(x)\| \leq \frac{1}{n}$ for x in the closure of $X_{n+1} \setminus X_n$. Then $x \mapsto 1 \otimes s(x)$ is as desired.

For $X = \mathbb{R}_+$ and $A := \mathbb{C}$ this can be solved by Lemma 5.1.2(iv) with $X_n := [0, n]$: We find a norm-continuous map $t \in \mathbb{R}_+ \mapsto s_0(t)$ into the isometries of $\mathcal{M}(A)$ such that $\|p_n s_0(t)\| \leq \frac{1}{n}$ for $t \in [n, n+1]$.

For general X and A let $s(x) := s_0(t(x))$, where $t \colon X \to \mathbb{R}_+$ is a continuous function with $t(X \setminus X_n) \subseteq (n, \infty)$, e.g. $t(x) := \sum_n (1 - g_n(x))$ with a continuous functions $g_n \colon X \to [0,1]$ with $g_n | X_{n-1} = 1$ and $g_n | (X \setminus X_n^{\circ}) = 0$.

(vii): `stated text:`

If $M_1 \subseteq \mathcal{M}(\mathrm{C_0}(X, A))$ and $M_2 \subseteq \mathrm{C_b}(X, A)$ countable subsets. Then there exist a positive contraction $e \in \mathrm{C_b}(X, A)$ such that $eb - be, c - ec, c - ce \in \mathrm{C_0}(X, A)$ for all $b \in M_1$ and $c \in M_2$.

(viii): `stated text:`

Suppose that the C^*-algebra B contains a continuous path $t \in \mathbb{R}_+ \mapsto p(t) \in B$ in the projections of B such that $\lim_{t \to \infty} p(t)b = b$ for all $b \in B$.

If $h \colon B \to \mathcal{M}(A)$ is a non-degenerate C^*-morphism, and $h_X \colon \mathrm{C_b}(X, B) \to \mathrm{C_{b,st}}(X, \mathcal{M}(A)) \cong \mathcal{M}(\mathrm{C_0}(X, A))$.

Then for every countable subset $M \subseteq \mathrm{C_b}(X, A)$ there exists a projection $p \in \mathrm{C_b}(X, B)$ such that $(1 - h_X(p))f, f(1 - h_X(p)) \in \mathrm{C_0}(X, A)$ for all $f \in M$.

`To be filled in` ?? □

Remark 7.2.3. The following example shows that in general $\mathrm{C_b}(X, A)$ is strictly contained in the C^*-algebra of the bounded strictly continuous functions $f \in \mathrm{C_{b,st}}(X, \mathcal{M}(A))$ with $f(X) \subseteq A$, i.e., a bounded strictly continuous function f on X with values in A is not necessarily continuous. Let $X := \{0\} \cup \{1/n \colon n \in \mathbb{N}\} \subseteq [0,1]$. $A := \mathbb{K}$ and $f(0) := 0$, $f(1/n) = p_{nn}$.

Then X is compact and $\lim_{n \to \infty} p_{nn}$ converges strictly to zero in $\mathcal{M}(A)$. Thus, $f \in \mathrm{C_{b,st}}(X, \mathcal{M}(A))$. Clearly, $f \notin \mathrm{C}(X, \mathcal{M}(A))$, because certainly $f \notin \mathrm{C}(X, A)$.

Thus, f is in $\mathrm{C_{b,st}}(X, \mathcal{M}(A)) \cong \mathcal{M}(\mathrm{C}(X, A))$, has image in A, but f is not in $\mathrm{C_b}(X, A) = \mathrm{C}(X, A)$.

Lemma 7.2.4. *Let (Ω, ρ) be a compact metric space, X a locally compact σ-compact space and F a set of bounded nonnegative continuous functions on $\Omega \times X$, such that*

(i) $|f(\omega_1, x) - f(\omega_2, x)| \leq C\rho(\omega_1, \omega_2)$ *for all* $x \in X$, $f \in F$ *and* $\omega_1, \omega_2 \in \Omega$,

(ii) *For every bounded sequence* $f_1, f_2, \ldots \in F$ *and every countable covering* $\{U_n\}$ *of* X *by open subsets with compact closures (in* X*), there exist* $f \in F$ *and a locally finite decomposition* $\lambda_1, \lambda_2, \ldots \in \mathrm{C}_0(X)_+$ *of* 1*, such that for every* k *there exists* n_k *with support* $\lambda_k \subseteq U_{n_k}$ *and* $f(\omega, x) \leq \sum \lambda_k(x) f_{n_k}(\omega, x)$ *for* $x \in X$.

Let $f^*(x) := \sup\{f(\omega, x) \colon \omega \in \Omega\}$, $g(x) := \inf\{f^*(x) \colon f \in F\}$, h *a bounded continuous function on* X *such that* $g(x) < h(x)$ *for every* $x \in X$ *and* $Y \subset \beta X \setminus X$ *a compact subset of the corona.*

Then there exist $k_1, k_2 \in F$ *with* $k_1^* \leq h$*, and* $k_2^*(y) \leq \sup\{g(y) \colon y \in Y\}$ *for every* $y \in Y$.

It holds $\sup\{g(x) \colon x \in \beta X \setminus X\} \leq \lim_{n\to\infty}(\sup\{g(x) \colon x \in X \setminus X_n\})$ *where* $\overline{X_n} \subseteq X_{n+1} \subseteq \ldots X$ *are open subsets of* X *with compact closures such that* $X = \bigcup X_n$.

Remark 7.2.5. Here we consider only locally finite decompositions of 1 which are finite in a sufficiently small neighborhood every point of X, i.e. for every $x \in X$ there is neighborhood U of x such that only a finite number of the λ_k is nonzero on U.

Proof. By the Lipschitz-condition (i), the f^* are bounded continuous functions on X. $F^* = \{f^* \colon f \in F\}$ satisfies (i) and (ii) for $\Omega =$ point and F replaced by F^*. The conclusions do not require Ω. Therefore it is enough to prove the lemma in case of $\Omega =$ point, $f = f^*$ $\forall f \in F$. Since $g(x) < h(x)$ for $x \in X$ we find for every $x \in X$ an $f \in F$ and a neighborhood $U(x)$ of x such that $f(y) < h(y)$ for every $y \in U(x)$ and $U(x)$ has compact closure. Since X is locally compact we find a countable subsystem $(f_n, U(X_n))$ with $\bigcup U(X_n) = X$. If (λ_k) is the locally finite decomposition of unit subordinated to $\{U(x_n)\}$ such that support of λ_k is contained in some $U(x_{n_k})$ and such that there is $k_1 \in F$ with $k \leq \sum \lambda_k f_{n_k}$, then $g \leq k_1 \leq h$. If $\overline{X_n} \subseteq X_{n+1} \subseteq \ldots X$ is a covering of X by open subsets with compact closure, the a suitable construction of $h \geq g$ shows that $\sup\{g(x) \colon x \in \beta X \setminus X\} \leq \limsup C_n$ where $C_n = \sup\{g(x) \colon x \in \overline{X_{n+2}} \setminus X_n\}$. Now consider $Y \subseteq \beta X \setminus X$, compact, $C = \sup\{g(y) \colon y \in Y\}$.

Then for every $y \in Y$, $n \in \mathbb{N}$ there exists $f \in F \subseteq \mathrm{C_b}(Y) \cong C(\beta X)$, such that $f(y) < C + \frac{1}{n}$. Thus for every point $y \in Y$ there exists a neighborhood $U(y)$ of $y \in \beta X$ and $f \in F \subseteq C(\beta X)$ with $f(x) \leq C + \frac{1}{n}$ for $x \in U(y)$.

Since Y is compact we find a $y_1, \ldots, y_n \in Y$, $f_1, \ldots, f_n \in F$ with $f_k(x) \leq C + \frac{1}{n}$ for $x \in U(y_k)$ and $Y \subseteq U(y_1) \cup \ldots \cup U(y_n)$. In this way we find a sequence $g_1, g_2, \ldots \in F$ such that $\inf\{g_k(y) \colon k = 1, 2, \ldots\} \leq C$ for $y \in Y$. Let $\delta \in \mathrm{C}_0(X)_+$ with $\delta(x) > 0$ for every $x \in X$ (exists because X is σ-compact). By the first part of the proof it is enough to find a bounded continuous function k with $g \leq k \leq \inf\{g_k\} + \delta$ on X. Because then there is $k_1 \in F$ with $k_1 \leq k + \delta$ which implies $k_1(y) \leq g_n(y)$ for $y \in \beta X \setminus X$ and $n = 1, 2, \ldots$. Let $k = \mu_1 g_1 + \sum(\mu_{n+1} - \mu_n) \cdot \inf\{g_1, \ldots, y_n\}$

where $\mu_n(x) \in [0,1]$ for $x \in X_n$, $\mu_n(x) = 1$ on $\overline{X_n}$ and $\mu_n(x) = 0$ on $X \setminus X_{n+1}$ (use Urysohn Lemma). □

REMARK 7.2.6. If $X = \mathbb{N}$ and $\omega \in \gamma(\mathbb{N}) := \beta\mathbb{N} \setminus \mathbb{N}$ is a point of the corona $\gamma(\mathbb{N})$ of $\mathbb{N}$ the ω is called a "free" ultrafilter. $B_\omega = \mathrm{C_b}(\mathbb{N}, B)/J_{\{\omega\}} = l_\infty(B)/c_\omega(B)$ is then the well known (norm-)ultrapower of a Banach space B.

If X is locally compact, non-compact but σ-compact (e.g. $X = \mathbb{R}_+$) and $\omega \in \beta X \setminus X$ then in general there does not (!) exist a sequence $x_1, x_2, \ldots \in X$ and a (free) ultrafilter $\omega_1 \in \beta\mathbb{N} \setminus \mathbb{N}$ such that $\omega = \lambda(\omega)$ (where $\lambda\colon \beta\mathbb{N} \to \beta\mathbb{N}$ is induced by the map $n \mapsto x_n$). Therefore in the following proof one needs really our reduction to the bounded continuous functions on X (and not only ultrapower arguments or pure logical partition arguments).

Another technical problem is the following: If Ω is a compact metric space that contain infinitely many points, then the natural continuous epimorphism from $\beta(\mathbb{R}_+ \times \Omega)$ onto $\beta(\mathbb{R}_+) \times \Omega$ is not an isomorphism. Thus $\mathrm{C_b}(\mathbb{R}_+, \mathrm{C}(\Omega, A)) \not\cong \mathrm{C}(\Omega, \mathrm{C_b}(\mathbb{R}_+, A))$ in general. But always $\mathrm{C_b}(\mathbb{R}_+, \mathrm{C}(\Omega, A)) = \mathrm{C_b}(\mathbb{R}_+ \times \Omega, A)$.

. . . .

Suppose that B is a Banach space, $Z \subseteq \beta X$, $f \in \mathrm{C_b}(X, B)$. then $N(f)(y) := \|f(y)\|$ defines an element $N(f)$ of $\mathrm{C}(\beta X) \cong \mathrm{C_b}(X)$. Therefore $\|f\|_Y := \sup\{N(f)(y) \colon y \in Y\}$ is well defined for $Y \subseteq \beta X$ closed and $\|f\|_Y = \|\pi_Y(f)\| = \|f + J_Y\| = \mathrm{dist}(f, J_Y)$.

Suppose, A, B are Banach spaces, T is a set of linear contractions from A into B. T^X denotes the set of strongly continuous maps from X into T. The elements of T^X operate on $\mathrm{C_b}(X, B)$ as linear contractions, indeed: if $L := \{S(y)\}_{y \in X} \in T^X$, $f \in \mathrm{C_b}(X, B)$ then $g(y) := S(y)(f(y))$ defines an element $L(f) = g \in \mathrm{C_b}(X, B)$.

Let Ω be a compact metric space, $\gamma_1 \colon \Omega \to \mathrm{C_b}(X, A)$ and $Z \subseteq \beta X$ a subset of βX. For fixed Ω, γ_1 and γ_2, we define for $Z \subseteq \beta X$ closed, $L \in T^X$ $\mu(L, Z) := \sup\{\|L(\gamma_1(t)) - \gamma_2(t)\|_Z \colon t \in \Omega\}$ $\nu(Z) := \inf\{\mu(L, Z) \colon L \in T^X\}$.

With the above assumptions and notations we have:

PROPOSITION 7.2.7. *Assume that X is σ-compact and T is convex or that X is totally disconnected. Then*

(i) $\nu(Z) \le \sup\{\nu(\{\omega\}) \colon \omega \in Z\}$
(ii) $\nu(\beta X \setminus X) \le \lim_{n\to\infty}(\sup\{\nu(\{y\}) \colon y \in X \setminus X_n\})$
(iii) *If $Z \subseteq \beta X \setminus X$ is closed then there exists $L \in T^X$ with $\nu(Z) = \mu(L, Z)$, i.e. the infimum is attained.*
(iv) $\nu(X) \le \sup\{\nu(\{y\}) \colon y \in X\}$.

PROOF. The functions

$$g(y,t) := \|L(\gamma_1(t)) - \gamma_2(t)\|_y = \|L(y)(\gamma_1(t)(y)) - \gamma_2(t)(y)\|,$$

$y \in X$, $t \in \Omega$ satisfy the assumptions of Lemma **??** where we have to introduce on Ω the metric $\rho(t_1, t_2) = \rho_\Omega(t_1, t_2) + \|\gamma_1(t_1) - \gamma_1(t_2)\| + \|\gamma_2(t_1) - \gamma_2(t_2)\|$. In particular the family $\{g(y,t)\}$ is $\sigma - \mathrm{C}_0(X)$-subconvex in the variable $y \in X$.

But then (i)-(iii) follows from Lemma **??**, where for the proof of (iii) one has to use the family $\max\{0, g(y,t) - \nu(Z)\}$, which again satisfies the assumptions of Lemma **??**. □

Corollary 7.2.8. *Suppose that A and B are C^*-algebras, that X is σ-compact and that T is a set of c.p. contractions from A into B.*

Then, for each $\omega \in \beta(X)$, T^X defines a set of completely positive contractions $T^X|\omega$ from $A_\omega := \mathrm{C}_\mathrm{b}(X, A)/J_\omega$ into $B_\omega := \mathrm{C}_\mathrm{b}(X, B)/J_\omega$, given by the natural map $T^X \mapsto T^X|Y$ from $\mathrm{C}_{\mathrm{b,st}}(X, \mathcal{L}(A, B))$ in $\mathcal{L}(A_Y, B_Y)$ for closed $Y \subseteq \beta(X) \setminus X$.

The restriction of $T^X|Y$ to each separable closed subspace C of A_Y is point-norm closed in $\mathcal{L}(A_Y, B_Y)$.

If $T \subseteq \mathrm{CP}(A, B)$ is convex, (respectively inner-invariant, operator-convex or is a matrix operator-convex cone), then $T^X|Y$ is so as subset of $\mathrm{CP}(A_Y, B_Y)$.

$T^X|Y$ satisfies the assumptions (i)-(iii) of Lemma **??**.

???????

??

Transitivity needed???:

If T is convex, and for every $a \in A_+$ and $b \in B_+$ with $\|a\| = \|b\| = 1$ and $\varepsilon > 0$ there exists $V \in T$ with $\|V(a) - b\| < \varepsilon$, then $T^X|Y$ has this property for $a \in (A_Y)_+$ and $b \in (B_Y)_+$ with $\|a_\omega\| = \|b_\omega\|$ for all $\omega \in Y$.

In particular, if $C \subseteq A_\omega$ is a separable C^*-subalgebra and $V \colon C \to B_\omega$ is a nuclear contraction, then there exists an $L \in T^X$ such that for $V\pi_\omega(a) = \pi_\omega(L(a))$ if $a \in \mathrm{C}_\mathrm{b}(X, A)$ and $\pi_\omega(a) \in C$.

Corollary 7.2.9. *Let $Y \subseteq \beta X \setminus X$ be a compact subset, C a separable subspace of $\mathrm{C}_\mathrm{b}(X, A)/J_Y$ and $S \colon C \to \mathrm{C}_\mathrm{b}(X, B)/J_Y$ a linear map.*

Suppose that for each $\omega \in Y$, $\varepsilon > 0$ and every finite subset $F \subseteq C$ there exists a nuclear completely positive contraction $V_\omega \colon \pi_\omega(C) \to B_\omega$ such that

$$\|V_\omega(\pi_\omega(c)) - \pi_\omega(S(c))\| < \varepsilon$$

for all $c \in F$.

Then there exists a strongly continuous map $L \colon x \in X \mapsto L(x) \in \mathcal{L}(A, B)$ into the nuclear completely positive contractions from A into B such that

$$S(\pi_Y(a)) = \pi_Y(L(a)) \qquad \forall\ a \in \pi_Y^{-1}(C)\,.$$

Proof. Let Ω be a compact subset of C that generates C as a closed linear subspace. and let $\gamma_1 \colon \Omega \to \mathrm{C}_\mathrm{b}(X, A)$ a topological lift, i.e., $\pi_Y \gamma_1 = \mathrm{id}_\Omega$. Let $\gamma_2 \colon \Omega \to \mathrm{C}_\mathrm{b}(X, B)$ be a topological lift of $(S|\Omega) \colon \Omega \to \mathrm{C}_\mathrm{b}(X, B)/J_Y$. Moreover, let T be the convex set of nuclear completely positive contractions from A into B. Define $\nu(L, Y)$ and $\mu(Y)$ as explained above. We have to find $L \in T^X$ with $\nu(L, Y) = 0$ because then L is as desired (since $\pi_Y L$ and S are contractions).

By Proposition **??** (iii) and (i) it suffices to show that $\nu(\{y\}) = 0$ for each $y \in Y$. But that we have seen above in Corollary **??**. □

Now we get our asymptotic Weyl–von Neumann version of the Weyl–von Neumann–Voiculescu–Kasparov theorem:

THEOREM 7.2.10. *Let X be a locally compact σ-compact space, Y a closed subset of the corona $\beta X \setminus X$ of X, B a C^*-algebra and A a purely infinite simple C^*-subalgebra of B such that AB is dense in B. Moreover let C be a separable C^*-subalgebra of $\pi_Y(\mathrm{C_b}(X, A)) = \mathrm{C_b}(X, A)/J_Y$.*

If V is a completely positive contraction from C into $\pi_Y(\mathrm{C_b}(X, B))$ such that for each $\omega \in Y$ there exists a nuclear completely positive contraction $V_\omega \colon \pi_\omega(a) = \pi_\omega(V(a))$ for every $a \in C$, then there exists a contraction $d \in \mathrm{C_b}(X, B)$ such that $V(a) = \pi_Y(d)^* a \pi_Y(d)$ for every $a \in C$.

PROOF. The Theorem is the logical sum of Corollary **??** and Proposition **??**. □

LEMMA 7.2.11. *If $a \in \pi_Y(\mathrm{C_b}(X, A))_+$ satisfies $\|\pi_\omega(a)\| = 1$ for every $\omega \in Y$, then there exists $b \in \mathrm{C_b}(X, A)_+$ such that $\|\pi_x(b)\| = 1$ for every $x \in X$ and $a = \pi_Y(b)$.*

PROOF. Let $d \in A_+$ with $\|d\| = 1$ and let $c \in \mathrm{C_b}(X, A)_+$ be a contractive lift of a, i.e. $\pi_y(c) = a$, $c \geq 0$, $\|c(x)\| = \|\pi_x(c)\| \leq 1$ for every $x \in X$. Now let $g(x) := \|c(x)\|$ then $g \in \mathrm{C}(\beta X) \cong \mathrm{C_b}(X)$, $f(x) := c(x) + (1 - g(x))d$ is in $\mathrm{C_b}(X, A)$ and $\|f\| \leq 1$ and $1/2 \leq \max(g(x), 1 - g(x)) \leq \|f(x)\|$ for $x \in X$. Then $\pi_y(f) = a$ because $g(\omega) = 1$ for $\omega \in Y$. Thus $\|\pi_\omega(f)\| = 1$ for $\omega \in Y$, i.e. $h(\omega) = 1$ for $\omega \in Y$, where $h(x) := \|f(x)\|^{-1}$. □

Next:
Suppose $\mathrm{C_b}(X, A)$ is not s.p.i.

Conjecture (1):
Then there exists a separable C*-subalgebra B of A such that B has the same invariants:

$$\rho(a, b; B) = \rho(a, b; A)$$

for $a, b \in B_+$, where

$$\rho(a, b; C) := \inf\{\|d^* a^2 d - a^2\| + \|e^* b^2 e - b^2\| + \|d^* abe\|\,;\ e, d \in C\}$$

for $a, b \in C$.

Conjecture (2):
Let A a $C*$-algebra. Then
for every separable $C*$-subalgebra B of $\mathcal{M}(A)$
there exists a contraction $d \in A_+$ with
$BD \subseteq D$ for $D := \overline{dAd}$
and $\|b\| = \sup_n \|bd^{1/n}\|$ for all $b \in B$
such that

$$\rho(a, b; \mathcal{M}(A)) = \rho(\lambda(a), \lambda(b); \mathcal{M}(D))$$

for the faithful $C*$-morphism $\lambda \colon B \to \mathcal{M}(\overline{dAd})$
given by $\lambda(b)x := bx$ for $x \in D$ and $b \in B$

The σ-unitality of A and the σ-compactness
of X (used below) can be reduced if Conj. (1) and (2) hold.

If A is strongly p.i. and σ-unital and X is σ-compact,
then $\mathcal{M}(\mathrm{C}_0(X, A))$ is s.p.i. and above defined A_ω strongly p.i.

This special case follows also from:

''B s.p.i.'' and ''C exact'' imply ''$B \otimes C$ s.p.i.'' and
''$\mathcal{M}(\overline{b^*Bb})$ is s.p.i.'' for each $b \in B$
''A s.p.i.'' implies ''$A \otimes \mathrm{C}_0(X) = \mathrm{C}_0(X, A)$ s.p.i.''
implies ''$\mathcal{M}(\mathrm{C}_0(X, A))$ s.p.i.'' if X is σ-compact and A σ-unital

$\mathrm{C_b}(X, A)$ is ideal of $\mathrm{C_{b,st}}(X, \mathcal{M}(A)) \cong \mathcal{M}(\mathrm{C}_0(X, A))$,
because $f \in \mathrm{C_b}(X, A)$, if and only if,
$f \in \mathrm{C_{b,st}}(X, \mathcal{M}(A))$ and $gf \in \mathrm{C}_0(X, A)$ for all
$g \in \mathrm{C}_0(X) \cdot 1 \subseteq$ center of $\mathcal{M}(\mathrm{C}_0(X, A))$.

Property ''s.p.i.'' passes to ideals and quotients.

Corollary 7.2.12. *If A is simple and purely infinite then every fiber $A_\omega = \mathrm{C_b}(X, A)/J_\omega$ of $\mathrm{C_b}(X, A)$ $(\omega \in \beta X)$ is simple and purely infinite.*

In particular, $\mathrm{C_b}(X, A)$ is a continuous field over $\beta(X)$ with simple purely infinite fibres $A_x = A$ for $x \in X$ and A_ω for $\omega \in \beta(X) \setminus X$.

Proof. If $\omega \in X$ then J_ω is the kernel of the epimorphism $\pi_\omega \colon \mathrm{C_b}(X, A) \to A$.

If $\omega \in \beta(X) \setminus X$, then $J_\omega = \mathrm{C}_0(\beta(X) \setminus \{\omega\}) \cdot \mathrm{C_b}(X, A)$, because $f \in J_\omega$ if and only if $N(f) \in \mathrm{C_b}(X) \cong \mathrm{C_b}(\beta X)$ for the $N(f)(x) := \|f(x)\|$ has the property $N(f)(\omega) = 0$.

Consider for a, b in $(A_\omega)_+$, $\|a\| = \|b\| = 1$ the nuclear map $V \colon c \mapsto \rho(c)b$ where ρ is a pure state on A_ω with $\rho(a) = 1$.

By Lemma 7.2.11 and Corollary 7.2.9 there exist elements $c, d \in \mathrm{C_b}(X, A)$ with $\pi_\omega(c) = a$, $\pi_\omega(d) = b$, $\|c(x)\| = \|d(x)\| = 1$ for all $x \in X$.

Need reduction to σ-compact X !
if not supposed before.

For each compact subset $K \subseteq X$ and $\varepsilon > 0$ there is a contraction $f = f(K, \varepsilon) \in \mathrm{C}(K, A)$ with $\|f(x)^* c(x) f(x) - d(x)\| < \varepsilon$ for all $x \in K$

???????????? (cf. Corollary **??**).

Since X is σ-compact, we find continuous functions $g_0 = 0$ and $g_n \colon X \to [0, 1]$ with supports in compact sets K_n of X such that $g_{n+1}(x) = 1$ for $x \in K_n$ and $X = \bigcup K_n$. Let $G_1(x) := \sum_n (g_{2n}(x) - g_{2n-1}(x))^{1/2} f(K_{2n}, 1/n)(x)$ and $G_2(x) := \sum_n (g_{2n+1}(x) - g_{2n}(x))^{1/2} f(K_{2n+2}, 1/n)(x)$. Then $G_j \in \mathrm{C_b}(X, A)$ and $d - G_1^* c G_1 + G_2^* c G_2 \in \mathrm{C_0}(X, A)$. It follows that $y_1^* a y_1 + y_2^* a y_2 = b$ for the contractions $y_j := \pi_\omega(G_j)$. In particular, A_ω is simple.

Since A is naturally contained in A_ω and since A is purely infinite, A_ω is not isomorphic to the compact operators on a Hilbert space. Thus A_ω satisfies the assumptions of part (iv) of Proposition **??**, which implies that A_ω is purely infinite. □

Start of collections for Chapter 7

The *-epimorphism $b \mapsto b(t)$, for $b \in \mathrm{C}([0, 1], B)$, extends naturally to a *-epimorphism $\pi_t \colon \mathrm{C_b}(\mathbb{R}_+ \times [0, 1], B) \to \mathrm{C_b}(\mathbb{R}_+, B)$ by

$$\pi_t((b_s)_{s \in \mathbb{R}_+}) := (b_s(t))_{s \in \mathbb{R}_+} .$$

The π_t define evaluation semi-group morphisms

$$(\pi_t)_* \colon \mathrm{SR}(\mathcal{C}[0, 1]; A, B[0, 1]) \to \mathrm{SR}(\mathcal{C}; A, B)$$

that naturally define group morphisms

$$(\pi_t)_* \colon \mathrm{R}(\mathcal{C}[0, 1]; A, B[0, 1]) \to \mathrm{R}(\mathcal{C}; A, B) .$$

The following proposition confirms the homotopy invariance of the Rørdam groups.

Proposition 7.2.13. *If B is stable and σ-unital $h \colon A \to Q(\mathbb{R}_+, B[0, 1])$, satisfies $[h] \in \mathrm{SR}(\mathcal{C}[0, 1]; A, B[0, 1])$, then $[h_0] = [h_1]$ in $\mathrm{R}(\mathcal{C};\, A, B)$, where $[h_t] := (\pi_t)_*[h] \in \mathrm{R}(\mathcal{C};\, A, B)$ is defined by the evaluation semi-group morphism*

$$(\pi_t)_* \colon \mathrm{R}(\mathcal{C}[0, 1]; A, B[0, 1]) \to \mathrm{R}(\mathcal{C}; A, B) .$$

Lemma 7.2.14. *Suppose that X is a σ-compact locally compact space, B is a stable and σ-unital algebra, and that $D \subseteq \mathcal{M}(B)$ is non-degenerate (i.e. DB is dense in B).*

(i) *For every σ-unital C^*-subalgebra A of $\mathrm{Q}(X, B)$ there exists an contraction $f \in \mathrm{Q}(X, B)_+$ such that $fa = af = a$ for every $a \in A$.*
(ii) *For each $g \in \mathrm{C_b}(X, B)$ there exists a contraction $e \in \mathrm{C_b}(X, D)_+$ with $g - eg, g - ge \in \mathrm{C_0}(X, D)$.*

(iii) *For* $f \in Q(X, B)$ *there exists an isometry* T *in* $C_b(X, \mathcal{M}(B))/\, C_0(X, B)$ *such that* $T^* f T = 0$.
(iv) *Each* C^**-morphism* $h: D \to Q(X, B)$ *dominates zero in* $Q\big(X, \mathcal{M}(B)\big)$ *(and thus in* $C_b(X, \mathcal{M}(B))/\, C_0(X, B) \subseteq E_X$*).*

Recall that $Q(X, B) \subseteq C_b(X, \mathcal{M}(B))/\, C_0(X, B) \subseteq E_X$. Since the annihilator of $Q(X, B)$ in $C_b(X, \mathcal{M}(B))/\, C_0(X, B)$ is just $C_0(X, \mathcal{M}(B))/\, C_0(X, B)$, we have also that $Q(X, B)$ is naturally isomorphic to an ideal of $Q(X, \mathcal{M}(B))$.

PROOF. `to be filled in` ?? □

`Important !`
`Observation:`
`For all` C^*`-algebras` B `and l.c. Hausdorff spaces holds`

$$\mathcal{M}(C_0(X, B)) = \mathcal{M}(C_b(X, B))\,.$$

(1) $C_0(X, B)$ ideal of $C_b(X, B)$, $fg = 0$ for all $g \in C_0(X, B)$ implies that $f = 0$.

And $C_b(X, B)$ is non-degenerate C^*-subalgebra of $\mathcal{M}(C_0(X, B))$.

Induces faithful unital embedding of $\mathcal{M}(C_b(X, B))$ into $\mathcal{M}(C_0(X, B))$.

(2) Need that $C_b(X, B)$ is ideal of $\mathcal{M}(C_0(X, B))$ (then we are ready).

If $f \in C_b(X, B)$, $T \in \mathcal{M}(C_0(X, B))$ and $\psi \in C_0(X)$ then $T.(\psi.f) \in C_0(X, B)$ and $\psi.(T.f) = T.(\psi.f)$. Thus, $\psi T f \in C_0(X, B)$ for all $\psi \in C_0(X, B)$.

$g \in C_{b,st}(X, \mathcal{M}(B)) \cong \mathcal{M}(C_0(X, B))$ is in $C_b(X, B)$ if and only if $\psi \cdot g \in C_0(X, B)$ for all $\psi \in C_0(X)$.

PROPOSITION 7.2.15. *Suppose that* A *and* B *are stable and* σ*-unital, and that* X *is a* σ*-compact, locally compact, non-compact Hausdorff space.*

Then all "natural" definitions of inner equivalence of C^**-morphisms* $h_i: A \to Q(X, B)$, $i = 1, 2$, *define the same classes, i.e., precisely that the following properties* (i)–(v) *of* (h_1, h_2) *are all equivalent:*

(i) *There exists a unitary* u_1 *in the multiplier algebra* $\mathcal{M}(Q(X, B))$ *of* $Q(X, B)$ *such that* $u_1^* h_1(\cdot) u_1 = h_2$ *, i.e.,* $u_1^* h_1(a) u_1 = h_2(a)$ *for every* $a \in A$.
(ii) *There exists a unitary* u_2 *in* $E_X = \mathcal{M}(C_0(X, B))/\, C_0(X, B) = \mathcal{M}(C_b(X, B))/\, C_0(X, B)$ *such that* $u_2^* h_1(\cdot) u_2 = h_2$ *for every* $a \in A$.
(iii) *There exists a unitary* V_3 *in the* C^**-algebra* $C_b(X, \mathcal{M}(B))$ *of bounded norm-continuous functions on* X *with values in* $\mathcal{M}(B)$ *such that* $u_3^* h_1(\cdot) u_3 = h_2$ *for the unitary*

$$u_3 := \pi_{C_0(X,B)}(V_3) = V_3 + C_0(X, B)$$

in $C_b(X, \mathcal{M}(B))/\, C_0(X, B) \subseteq E_X$ *.*
(iv) *If* Y *is a* σ*-compact locally compact Hausdorff space such that the corona* $\beta(X) \setminus X$ *of* X *is an* open *subset of* $\beta(Y) \setminus Y$*, then there exists an unitary* $u_4 \in E_Y$ *such that* $u_4^* h_1(\cdot) u_4 = h_2$*, where we embed* $Q(X, B)$ *naturally as an ideal of* E_Y*.*

(v) *There exists a contraction* e *in* $\mathrm{Q}(X,B)$ *such that* $e^*h_1(\cdot)e = h_2$ *and* $eh_2(\cdot)e^* = h_1$.

In particular, we get for every C^*-morphism $h_0\colon A \to \mathrm{Q}(X,B)$ that the semigroups $S\big(h_0;\, A, \mathrm{Q}(X, \mathcal{M}(B))\big)$ $S\big(h_0;\, A, \mathcal{M}(\mathrm{Q}(X,B))\big)$, and $S(h_0;\, A, E_X)$ become naturally isomorphic semigroups if consider $\mathrm{Q}(X,B)$ as ideals in $\mathrm{Q}(X,\mathcal{M}(B))$ and in E_X.

If especially $X := \mathbb{R}_+$ and $Y := \mathbb{R}$, then $\beta(\mathbb{R}_+)\setminus\mathbb{R}_+$ is naturally homeomorphic to an open subset of $\beta(\mathbb{R})\setminus\mathbb{R} \cong (\beta(\mathbb{R}_-)\setminus\mathbb{R}_-) \biguplus \beta(\mathbb{R}_+)\setminus\mathbb{R}_+$. Let $h_0\colon A \to \mathrm{Q}(\mathbb{R}_+, B)$ a C^*-morphism with $[h_0] = [h_0] + [h_0]$ in $\mathrm{Hom}(A, E_{\mathbb{R}_+})$. Then $S\big(h_0\,;\, A, E_{\mathbb{R}}\big)$, $S\big(h_0\,;\, A, E_{\mathbb{R}_+}\big)$ and $S\big(h_0\,;\, A, \mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B))\big)$ are naturally isomorphic semigroups.

Proof. (i)⇒(v): Let $f \in A_+$ a strictly positive contraction. The element $h_0(f) + h_1(f)$ is a strictly positive element of $C^*(h_0(A) \cup h_1(A)) \subseteq \mathrm{Q}(X,B)$. Thus, by Lemma 7.2.14(i) there exists a positive contraction $C \in \mathrm{C_b}(X,B)$ with $cg = g = gc$ for $c := C + \mathrm{C_0}(X,B)$ and $g \in h_0(A) \cup h_1(A)$. Let $e := cu_1c$.

(iii)⇒(ii): Use that $\mathrm{C_b}(X,B) \subseteq \mathrm{C_b}(X,\mathcal{M}(B)) \subseteq \mathcal{M}(\mathrm{C_b}(X,B))$. The restriction of the *-monomorphism

$$\mathcal{M}(\mathrm{C_b}(X,B)) \to \mathcal{M}(\mathrm{Q}(X,B))$$

to the embedding of $\mathrm{C_b}(X,B)$ in $\mathrm{C_b}(X,\mathcal{M}(B))$ induces the quotient map $\mathrm{C_b}(X,B) \to \mathrm{Q}(X,B)$.

(ii)⇒(i): Consider the C^*-algebras

$$\mathrm{C_b}(X,B) \subseteq \mathrm{C_b}(X,\mathcal{M}(B)) \subseteq \mathrm{C_{b,st}}(X,\mathcal{M}(B)) \cong \mathcal{M}(\mathrm{C_0}(X,B))\,.$$

The C^*-algebra $\mathrm{C_b}(X,B)$ is an ideal of $\mathcal{M}(\mathrm{C_0}(X,B))$, because $f \in \mathrm{C_b}(X,B)$ if and only if $\psi\cdot f \in \mathrm{C_0}(X)$ for all functions $\psi \in \mathrm{C_0}(X) \cong \mathrm{C_0}(X)1 \subseteq \mathrm{C_{b,st}}(X,\mathcal{M}(B))$.

The induced C^*-morphism from $\mathcal{M}(\mathrm{C_0}(X,B))$ into $\mathcal{M}(\mathrm{C_b}(X,B))$ is faithful and unital and fixes $\mathrm{C_b}(X,B)$. It allows to identify the multiplier algebras $\mathcal{M}(\mathrm{C_0}(X,B))$ and $\mathcal{M}(\mathrm{C_b}(X,B))$ naturally, as

$$\mathrm{C_b}(X,B) \subseteq \mathrm{C_{b,st}}(X,B) = \mathcal{M}(\mathrm{C_0}(X,B)) = \mathcal{M}(\mathrm{C_b}(X,B))\,.$$

Since $\mathrm{Q}(X,B) = \mathrm{C_b}(X,B)/\,\mathrm{C_0}(X,B)$, we get also a natural unital C^*-morphism from $\mathcal{M}(\mathrm{C_b}(X,B))$ into $\mathcal{M}(\mathrm{Q}(X,B))$. The restriction of the corresponding *-morphisms

$$\mathcal{M}(\mathrm{C_0}(X,B)) = \mathcal{M}(\mathrm{C_b}(X,B)) \to \mathcal{M}(\mathrm{Q}(X,B))$$

to the embedding of $\mathrm{C_b}(X,B)$ in $\mathcal{M}(\mathrm{C_0}(X,B))$ induces the quotient map $\mathrm{C_b}(X,B) \to \mathrm{Q}(X,B)$. Thus, define unital C^*-morphisms into $\mathcal{M}(\mathrm{Q}(X,B))$ that is compatible with $\mathrm{C_b}(X,B) \to \mathrm{Q}(X,B)$. This shows that (i) follows from (ii) and (iii).

(v)⇒(iii):

`to be filled in` ??

(iv)⇔(i): In case $Y := X$ it is the same as the implication (ii)⇔(i), by the above proven equivalences of (i),(ii),(iii) and (v).

If the compact set $\beta(X) \setminus X$ is homeomorphic to an open subset of $\beta(Y) \setminus Y$, let $Z := (\beta(Y) \setminus Y) \setminus (\beta(X) \setminus X)$. It follows that Z is open and compact and $\mathrm{Q}(Y, B) = \mathrm{Q}(Y, B)|Z \oplus \mathrm{Q}(X, B)$. Thus $\mathcal{M}(\mathrm{Q}(X, B))$ is a quotient of $\mathcal{M}(\mathrm{Q}(Y, B))$. It shows that (iv) implies (i) in general, because $\mathrm{Q}(X, B) \subseteq \mathrm{Q}(Y, B) \subseteq E_Y$ is an ideal of E_Y, that defines the natural group morphism $\mathcal{U}(E_Y) \to \mathcal{U}(\mathrm{Q}(X, B))$.

`To be filled in`

???? The way from (iii) to (iv) goes over the natural C^*-morphisms

$$\mathrm{C_b}(Y, \mathcal{M}(B))/\,\mathrm{C_0}(Y, B) \to \mathrm{C_b}(X, \mathcal{M}(B))/\,\mathrm{C_0}(X, B)\,.$$

□

COROLLARY 7.2.16. *Suppose that A and B are stable, where B is σ-unital and A is separable.*

Let $h\colon A \to \mathrm{Q}(\mathbb{R}_+, B)$ be a C^*-morphism that dominates $h \oplus h$, and let $V\colon A \to \mathrm{Q}(\mathbb{R}_+, B)$ a completely positive contraction.

Further let $\Omega \subseteq A$ a (norm-)compact subset that generates a (norm-)dense linear subspace of A, $\gamma_0\colon \Omega \to \mathrm{C_b}(\mathbb{R}_+, B)$ a topological lift of $h|\Omega$ and $\gamma_1\colon \Omega \to \mathrm{C_b}(\mathbb{R}_+, B)$ a topological lift of $V|\Omega$.

The following are equivalent:

(i) *h dominates V by an isometry $S \in \mathrm{C_b}\big(\mathbb{R}_+, \mathcal{M}(B)\big)$.*
(ii) *h approximately 1-dominates V.*
(iii) *h dominates weakly approximately inner V (in the second conjugate of $\mathrm{Q}(\mathbb{R}_+, B)$.*
(iv) *h n-dominates V for some $n \in \mathbb{N}$.*
(v) *There exists a contraction $T \in \mathcal{M}\big(\mathrm{C_0}(\mathbb{R}_+, B)\big)$ such that*

$$T^*\delta_\infty\gamma_0(a)T - \gamma_1(a) \in \mathrm{C_0}(\mathbb{R}_+, B) \qquad \forall\, a \in A\,.$$

The criteria (v) is later needed only the case of constant $h\colon A \to B$.

PROOF. `to be filled in` ?? □

LEMMA 7.2.17. *Let h_1 and h_2 be C^*-morphisms from $A \otimes \mathcal{O}_2$ into a W^*-algebra N such that $h_1(a \otimes 1) = h_2(a \otimes 1)$ for every $a \in A$.*

Then h_1 and h_2 dominate weakly approximately inner each other.

In fact, h_1 and h_2 are unitarily homotopic in N (in norm-topology).

PROOF. Let $H(a) := h_1(a \otimes 1)$ and let M denote the W*-algebra generated by $H(A)$ with unit element $P = 1_M \in N$. Then there are unital C^*-morphisms $g_j\colon \mathcal{O}_2 \to PNP$ such that $H(a)g_j(b) = h_j(a \otimes b)$. It follows that $h_j(\mathcal{O}_2) \subseteq E := M' \cap PNP$. Notice that $\mathrm{K}_1(M' \cap PNP) = 0$ as it is for all W*-algebras, because every unitary is an exponential of a some T with $T^* = -T$ and $\|T\| \leq \pi$.

Any two unital *-morphisms from $\mathcal{O}_2$ into a unital C^*-algebra E with $\mathcal{U}(E) = \mathcal{U}_0(E)$ are point-norm homotopic. The latter implies stable unitary homotopy for copies of $\mathcal{O}_2$. Since id and δ_2 are unitary homotopic in $\mathcal{O}_2$, it follows that stable homotopy of unital copies of $\mathcal{O}_2$ implies that the copies unitarily homotopic in E.

The path of unitaries $t \mapsto U(t) + (1-p)$ defines a unitary homotopy from h_1 to h_2.

`To be filled in: Check again` ?? □

PROPOSITION 7.2.18. *Suppose that A and B are stable, where B is σ-unital and A is separable, X a non-compact locally compact σ-compact Hausdorff space, and that $h\colon A \to \mathrm{Q}(X,B)$ is a C^*-morphism which is unitarily equivalent to $h \oplus h$ by a unitary in $\mathcal{M}(\mathrm{Q}(X,B))$.*

Then there exists a C^*-morphism $k\colon A \otimes \mathcal{O}_2 \to \mathrm{Q}(X,B)$ such that

(i) *$k(a \otimes 1) = h(a)$ for all $a \in A$, and*
(ii) *k is unitarily equivalent to $k \oplus k$.*

A C^*-morphism k with properties (i) *and* (ii) *is unique up to unitary equivalence by a unitary in $\mathrm{Q}(X, \mathcal{M}(B))$.*

PROOF. `to be filled in` ?? □

COROLLARY 7.2.19. *Suppose that A and B are stable, where B is σ-unital and A is separable and exact, and that $h_i\colon A \to \mathrm{Q}(\mathbb{R}_+, B)$ are nuclear C^*-morphisms which are unitarily equivalent to $h_i \oplus h_i$, $i = 1, 2$.*

Furthermore, suppose that, for each closed ideal J of A, $h_1(J)$ and $h_2(J)$ generate the same ideal of $\mathrm{Q}(\mathbb{R}_+, B)$.

Then h_1 and h_2 are unitarily equivalent, by a unitary in $\mathrm{Q}\big(\mathbb{R}_+, \mathcal{M}(B)\big)$.

PROOF. `To be filled in` ?? □

`What happens if` $k\colon A \otimes \mathcal{O}_2 \hookrightarrow E$ `exists with` $k((\cdot) \otimes 1) = h_0(\cdot)$? `Is` $h_0 \sim h_0 \oplus h_0$ `in` $\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B))$?

COROLLARY 7.2.20. *Suppose that A is stable, separable and exact, that B is stable and σ-unital, and that $\mathrm{C}_0(\mathbb{R}, B)$ satisfies the WvN-property or that B is strongly purely infinite.*

Let $h_0\colon A \to B$ be a nuclear non-degenerate C^*-morphism from A into B such that $h_0 \oplus h_0$ is unitarily homotopic to h_0. And let $h\colon A \to B$ is a C^*-morphism that satisfies for each $J \in \mathcal{I}(B)$ that

$$h^{-1}(h(A) \cap J) = h_0^{-1}(h_0(A) \cap J)\,,$$

i.e., that $h(a)$ and $h_0(a)$ generate the same closed ideal of B for each $a \in A_+$.

Then h is unitarily homotopic to $h \oplus h_0$.

*In particular, every *-monomorphism $h\colon A \otimes \mathbb{K} \to B \otimes \mathbb{K}$ is unitarily homotopic to $h \oplus h_0$ if B is simple, purely infinite and σ-unital and A is unital and separable.*

PROOF. The equation shows that $h(A)$ generates B as a closed ideal, because $h_0(A)B$ is dense in B. Since A and B are stable and B is σ-unital, we get from

Proposition **??**

IN CHAPTERS 7 or 5 ??

that h is unitarily homotopic to a non-degenerate C^*-morphism from A into B, i.e., there is a norm-continuous path $t \in \mathbb{R}_+ \to U(t) \in \mathcal{M}(B)$ and a non-degenerate C^*-morphism $H \colon A \to B$ such that $\lim_{t\to\infty} U(t)^* h(a)U(t) = H(a)$ for each $a \in A$.

`to be filled in, check from here` **??**

Therefore, we can assume that $h(A)$ contains a strictly positive element of B.

Since $h_0 \oplus h_0$ is unitarily homotopic to h_0, it follows by

Proposition **??**,

that it suffices to show that h asymptotically absorbs h_0, i.e. that h dominates h_0 in the multiplier algebra $\mathcal{M}(\mathrm{Q}(\mathbb{R}_+, B)) \cong \mathrm{C}_{\mathrm{b,st}}(\mathbb{R}_+, B)$ of $\mathrm{Q}(\mathbb{R}_+, B)$.

If we want to adapt the proof of

Proposition **??**,

then we have to find a sequence of contractions $d_n \in B$, such that, for $a \in A$ and $j \in \{0, 1\}$,

$$\lim_{n\to\infty} \|d_n^* h(a)d_{n+j} - (1 - j)h_0(a)\| = 0\,.$$

Since $(h_0 \oplus h_0) \circ h^{-1} \colon h(A) \to B$ is residually nuclear by the assumptions, and since B is strongly p.i. (or has WvN-property), we find such a sequence,

cf. Remark **??**.

Thus h absorbs h_0 asymptotically and, therefore $h \oplus h_0$ is unitarily homotopic to h. □

PROOFS OF THEOREMS B(III) AND M(III): First, Theorem B(iii) is a special case of Theorem M(iii):

we have defined $h_0 \colon A\otimes\mathbb{K} \to B\otimes\mathbb{K}$ in Chapter 1 before Theorem B. If we replace A and B by its stabilizations, then with $N := \mathcal{O}_2 \otimes \mathbb{K}$, $\mathrm{Prim}(N) = \mathrm{Prim}(B) =$point, and the assumptions of Theorem M(iii) are satisfied.

We explain the assumptions of Theorem M in the special situation of part (iii): We suppose that A is a separable, stable and exact C^*-algebra, that B is strongly purely infinite, and that N is a strongly purely infinite separable stable C^*-subalgebra of B, such that NB is dense in B and that $\Psi_B := \Psi_0^{N,B}$ is an *isomorphism* from $\mathcal{I}(N) \cong \mathbb{O}(\mathrm{Prim}(N))$ onto $\mathcal{I}(B)$. The latter conditions imply that B is σ-unital and stable, and that, for every $I \in \mathcal{I}(N)$, there is a unique $J \in \mathcal{I}(B)$ with $I = J \cap N$.

Furthermore, there is given a lower semi-continuous action $\Psi_A \colon \mathbb{O}(X) \to \mathcal{I}(A)$ of $X := \mathrm{Prim}(N)$ on A with $\Psi_A(\emptyset) = 0$, $\Psi_A^{-1}(A) = X$, such that Ψ_A satisfies condition (ii) of Definition 1.2.6.

Here we assume the existence of a non-degenerate nuclear *-monomorphism $k\colon A\otimes\mathcal{O}_2 \to N$ such that $h_0 := k((.)\otimes 1)$ induces Ψ_A by $\Psi_A(Z_I) = h_0^{-1}(h_0(A)\cap I)$ for $I \in \mathcal{I}(N)$ and $Z_I \in \mathbb{O}(X)$ corresponding to I. The existence of h_0 follows from Theorem K, which will be shown in Chapter 12. The proof of Theorem K uses results of Chapter 3-6, of the first part of Chapter 9 and of Chapter 7 up to

Corollary ??.

For this h_0 we have $h_0(\Psi_A(Z)) = h_0(A) \cap \Psi_B(Z)$, because $N \cap \Psi_B(Z)$ is the closed ideal of N which corresponds to $Z \in \mathbb{O}(X)$. If $h\colon A \to B$ is a *-monomorphism, such that $h(\Psi_A(Z)) = h(A) \cap \Psi_B(Z)$ for $Z \in \mathbb{O}(X)$, then, for $J \in \mathcal{I}(B)$,

$$h^{-1}(h(A)\cap J) = h_0^{-1}(h_0(A)\cap J),$$

because Ψ_B maps $\mathbb{O}(X)$ onto $\mathcal{I}(B)$.

Thus, Corollary 7.2.20 applies, and h asymptotically dominates h_0. □

3. Remarks on the case of group actions

REMARK 7.3.1. Our Definition 7.1.1 of asymptotic $CP_{nuc}(A, B)$-morphisms does not work well in the case where a T_0 space X acts on A and B, as considered in Section 2 of Chapter 1, or in the case where, moreover, a locally compact group G acts Ψ_A-equivariant on A (via $\gamma_A\colon G \to \mathrm{Aut}(A)$) and Ψ_B-equivariant on B (via γ_B). Then it is useful to replace (a) by the following (a'):

(a') *For every $t \in \mathbb{R}_+$, every open subset $Z \subseteq X$ and every $g \in G$, $V(t)$ is Ψ-residually nuclear and $V(t)$ is asymptotically γ-equivariant.*
That means:
$V(t)(\Psi_A(Z)) \subseteq \Psi_B(Z)$ and the naturally induced completely positive contraction $[V(t)]_Z\colon A/\Psi_A(Z) \to B/\Psi_B(Z)$ is nuclear, and,
for every $g \in G$ and $a \in A$, $V(t)(\gamma_A(g)(a)) - (\gamma_B(g)V(t)(a))$ converges to zero if $t \to \infty$.

This is condition (a) in case of the cone $\mathcal{C}$ of Ψ-residually nuclear maps from A to B if the action of G is trivial on A and B.

If the actions of G are not trivial, i.e., if there exists a $g \in G$ such that $\gamma_A(g) \neq \mathrm{id}$ or $\gamma_B(g) \neq \mathrm{id}$, then also the definition of unitary homotopy should be stronger: We could require that $g \mapsto \mathcal{M}(\gamma_B(g))(u(t))$ is norm-continuous for every t and that $\lim_{t\to\infty} \|u(t) - \mathcal{M}(\gamma_B(g))(u(t))\| = 0$ in the for every $g \in G$.

One has to make some extra assumption on the actions of G on B such that that Cuntz addition makes sense:

There should exist norm-continuous maps $t \mapsto s_1(t)$, $t \mapsto s_2(t)$ from $\mathbb{R}_+$ into the isometries in $\mathcal{M}(B)$ such that $s_1(t)s_1(t)^* + s_2(t)s_2(t)^* = 1$, $\mathcal{M}(\gamma_B(g))(s_i(t)) - s_i(t)$ is in B for every $t \in \mathbb{R}_+$ and every $g \in G$, and tends to zero if $t \to \infty$ for every (fixed) $g \in G$.

The semigroup of asymptotically γ-equivariant Ψ-equivariant nuclear asymptotic morphisms will be denoted by $\mathrm{SR}^G(X,A,B)$. We write $\mathrm{R}^G(X,A,B)$ for its Grothendieck group, and $\mathrm{R}(X,A,B)$ if G is trivial.

Most of the theory ??????????????

`more ??? ??`

4. Collection of needed results.

`PLAN:`

General Plan for Chp. 7:

1. Asymptotic morphisms (def. and classes)

2. lifting of nuclear maps, cases where residually nuclear maps can be lifted, lifting by continuous families of approximately inner maps. When does a continuous family of approximately inner maps define a "locally" approximately inner map of $\mathrm{Q}(X,B)$?. Compare also the invertibility for $\mathrm{SExt}_{\mathrm{nuc}}(X;\, A,B)$ in Chapter 5.

3. "car:" Asymptotic Weyl - von Neumann theorem (for asymptotically residually nuclear maps $V\colon C\to \mathrm{Q}(X,B)$)

4. Absorption theorems for $h\colon A\to \mathrm{Q}(X,B)$, $k\colon A\to \mathrm{C}(Y,B),\ldots$

5. Asymptotic morphism as elements of

$$G(h_0;A,E_{\mathbb{R}})\cong G(h_0;A,\mathrm{Q}(\mathbb{R}_+,\mathcal{M}(B)))\cong G(h_0;A,\mathrm{C_b}(\mathbb{R}_+,\mathcal{M}(B))/\,\mathrm{C}_0(\mathbb{R}_+,B))$$

for $E_{\mathbb{R}}:=\mathcal{M}(\mathrm{C}_0(\mathbb{R},B))/\,\mathrm{C}_0(\mathbb{R},B)$, A separable, B σ-unital and stable.

$\mathrm{R}(\mathrm{Prim}(B);A,B)\cong G(h_0;A,E_{\mathbb{R}})$ if nuclear $h_0\colon A\hookrightarrow B$ with $[h_0\oplus h_0]=[h_0]$ defines the action.

$\mathrm{R}(\mathcal{C}(h_0);A,B)\cong G(h_0;A,E_{\mathbb{R}})$ if $h_0=h((\cdot)\otimes 1)$ for $h\colon A\otimes\mathcal{O}_2\to B$.

6. Existence of zero domination:

For every $h\colon A\to \mathrm{Q}(X,B)$ with stable B and σ-unital A there exist a positive contraction $e\in \mathrm{Q}(X,B)$ and isometries $S,T\in \mathrm{C_b}(X,\mathcal{M}(B))$ with $SS^*+TT^*=1$, $\eta(T)^*e\eta(T)=0$, $h(a)=h(a)e=eh(a)$ for all $a\in A$, where $\eta\colon \mathrm{C_b}(X,\mathcal{M}(B))\to \mathcal{M}(\mathrm{Q}(\mathbb{R}_+,B))$

<== *here* $X=\mathbb{R}_+$?

*denotes the natural *-morphism induced by the natural embedding*

$$\mathrm{C_b}(X,\mathcal{M}(B))\hookrightarrow \mathrm{C_{b,st}}(X,\mathcal{M}(B))\cong\mathcal{M}(\mathrm{C}_0(X,B))\,.$$

In particular, $h\colon A\to \mathrm{Q}(X,B)$ dominates zero in $\mathrm{Q}(X,\mathcal{M}(B))$.

7. Asymptotic unitary equivalence of "stable" monomorphisms to "non-degenerate" monomorphisms (see also Chapter 5)

`to be added:`

`refprop:7.Y1.chp9`

For a C^*-algebra F, let

$$\mathrm{Q}(\mathbb{R}_+, F) := \mathrm{C_b}(\mathbb{R}_+, F)/\,\mathrm{C_0}(\mathbb{R}_+, F)\,.$$

PROPOSITION 7.4.1. *$\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(F))$ is in a natural way a C^*-subalgebra of the multiplier algebra of $\mathrm{Q}(\mathbb{R}_+, F)$.*

If F is stable or unital, then, for every separable subset Y of $\mathrm{Q}(\mathbb{R}_+, F)$ and every unitary v in the multiplier algebra of $\mathrm{Q}(\mathbb{R}_+, F)$ there is a unitary $u \in \mathrm{Q}(\mathbb{R}_+, \mathcal{M}(F))$ with $u^*bu = v^*bv$ for every $b \in Y$.

In general (for every σ-unital F), if $A \subseteq \mathrm{Q}(\mathbb{R}_+, F)$ is a separable C^*–subalgebra of $\mathrm{Q}(\mathbb{R}_+, F)$ and v is a unitary in the connected component of 1 in $\mathcal{M}(D)$ for $D := \overline{A\,\mathrm{Q}(\mathbb{R}_+, F)A}$, then there is a unitary $u \in \mathrm{Q}(\mathbb{R}_+, \mathcal{M}(F))$ with $uD + Du \subseteq D$ such that $v = u + \mathrm{Ann}(A)$.

`ref{lem:7.Y2.chp9} or ref{prop:7.Y2.chp9}`

PROPOSITION 7.4.2. *Suppose that $\mathcal{M}(B)$ contains a copy of $\mathcal{O}_2$ unitally, that A is a C^*–algebra, and that $h_0 \colon A \hookrightarrow \mathrm{Q}(\mathbb{R}_+, B)$ is a *-monomorphism. If $h_0 \oplus h_0$ is unitarily equivalent to h_0 in $\mathcal{M}(\mathrm{Q}(\mathbb{R}_+, B))$ then there is a *-monomorphism $h \colon A \otimes \mathcal{O}_2 \hookrightarrow \mathrm{Q}(\mathbb{R}_+, B)$ with $h(a \otimes 1) = h_0(a)$ for $a \in A$ such that $h \oplus h$ is unitarily equivalent to h by a unitary in $\mathcal{M}(\mathrm{Q}(\mathbb{R}_+, B))$.*

If A is σ-unital and stable and $k \colon A \otimes \mathcal{O}_2 \to \mathrm{Q}(\mathbb{R}_+, B)$ satisfies $k(a \otimes 1) = h_0(a)$ for $a \in A$, then k is unitarily equivalent to h by a unitary in $\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B))$.

In particular, then $h \oplus h$ is unitarily equivalent to h in $\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B))$.

For the two latter statements it is only needed that A is σ-unital and the unitary group of $D := \overline{h_0(A)\,\mathrm{Q}(\mathbb{R}_+, B)h_0(A)}$ is connected. ¡== for unital A or ???

`or:`

... $\mathcal{U}(\mathcal{M}(\overline{h_0(A)\,\mathrm{Q}(\mathbb{R}_+, B)h_0(A)}))$ is connected ?? **??**

`reflem:7.Y3.chp10?  also:  chp9?`

COROLLARY 7.4.3. *Suppose A is stable and separable, that B is stable, and that h_0 and k_0 are nuclear *-monomorphisms from A into $\mathrm{Q}(\mathbb{R}_+, B)$, such that h_0 and k_0 "extend" to C^*-morphisms h and k from $A \otimes \mathcal{O}_2$ into $\mathrm{Q}(\mathbb{R}_+, B)$.*

Then h and $h \oplus h$ (respectively k and $k \oplus k$) are unitarily equivalent in $\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B))$.

If for every $I \in \mathcal{I}(\mathrm{Q}(\mathbb{R}_+, B))$,

$$h_0^{-1}(h_0(A) \cap I) = k_0^{-1}(k_0(A) \cap I)\,.$$

Then h and k are unitarily equivalent by a unitary in $\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B))$.

*In particular, if $h, k \colon A \otimes \mathcal{O}_2 \to B$ are nuclear *-monomorphisms that induce the same map from $\mathcal{I}(B)$ to $\mathcal{I}(A)$, then h and k are unitarily homotopic.*

`ref{lem:7.??}(??)`

By Lemma lem:7.??(??), (see ref in chp 9) k_0 comes from $k\colon D\otimes\mathcal{O}_2 \to B$, D, B stable, D separable , B σ-unital *there exists a contraction* $g_1 \in \mathrm{C_b}(\mathbb{R}, 1_B \otimes \mathbb{K})_+$ *such that* $g_1(x) = 0$ *for* $x \leq 0$ *and* $\lim_{x\to+\infty} g_1(x)k_0(a) = k_0(a)$ *for every* $a \in D$, *because* $k_0(D)$ *is separable.*

`refcor:7.Y7.chp9`

Corollary 7.4.4. *Suppose that A is separable and stable, B is σ-unital and stable and that $h, k\colon A \otimes \mathcal{O}_2 \to B$ are *-monomorphisms. Let $h_0 := h((.) \otimes 1)$ and $k_0 := k((.) \otimes 1)$.*

If there are approximately inner completely positive maps $V_n, W_n\colon B \to B$ such that $V_n \circ h_0$ converges in point-norm to k_0 and $W_n \circ k_0$ converges in point-norm to h_0, then h and k are unitarily homotopic.

`next:  reflem:7.Y3.chp9`

Corollary 7.4.9. *Suppose that $B \cong B \otimes \mathcal{O}_\infty \otimes \mathcal{O}_\infty \cdots$ and that B is stable. Let $G = \mathrm{Q}(\mathbb{R}_+, B)$ or $G := B_\omega$ and $A \subseteq G$ separable. There is a *-monomorphism h from $A \otimes \mathcal{O}_\infty \otimes \mathbb{K}$ into G with $h(a \otimes 1 \otimes e_{1,1}) = a$.*

`ref; cor:7.Y2.chp12`

COROLLARY 7.4.10. *G as in Corollary 7.4.9 $A \subseteq G$ separable. The approximately inner completely positive contractions $T \colon D \to G$ are one-step inner, i.e., there is a contraction $d \in G$ such that $T(b) = d^* bd$.*

`ref; prop:7.Y1.chp12:`

PROPOSITION 7.4.11. *Suppose that $A_1, A_2, \ldots$ are separable C*-algebras with $A_k \cong A_k \otimes \mathcal{O}_\infty \otimes \mathcal{O}_\infty \otimes \ldots$, and let $D := \prod_\omega (A_k)$.*

*Then if $B \subseteq D$ is separable, there exists a *-monomorphism φ from $B \otimes \mathcal{O}_\infty$ into D, such that $\varphi(b \otimes 1) = b$ for $b \in B$.*

`ref; lem:7.Y6.chp9`

LEMMA 7.4.12. *Let $a = (a_1, a_2) \in \mathrm{Q}(\mathbb{R}, B) \cong \mathrm{Q}(\mathbb{R}_-, B) \oplus \mathrm{Q}(\mathbb{R}_+, B)$ a positive contraction, then there exist a positive contraction $b = (b_1, b_2) \in \mathrm{Q}(\mathbb{R}, B)$ with $b_1 = 0$ and $b_2 a_2 = a_2$.*

LEMMA 7.4.13. *Every non-zero projection in $\mathrm{C_b}(\mathbb{R}, \mathcal{O}_2 \otimes \mathbb{K})$ is equivalent to $1 \otimes e_{1,1} \in \mathcal{O}_2 \otimes \mathbb{K}$ by unitaries in the unitization of $\mathrm{C_b}(\mathbb{R}, \mathcal{O}_2 \otimes \mathbb{K})$.*

PROPOSITION 7.4.14. ***(Compare also 7.4.18)***

Suppose that $\mathcal{O}_2 \otimes \mathbb{K} \subseteq \mathcal{M}(B)$ non-degenerate with $(\mathcal{O}_2 \otimes \mathbb{K}) \cap B = 0$. Define F by $\mathrm{C_b}(\mathbb{R}, \mathcal{O}_2 \otimes \mathbb{K}) \cong F \subseteq \mathrm{C_b}(\mathbb{R}, \mathcal{M}(B))$. For every projection $q \in F_1 \cong \mathrm{C_b}(\mathbb{R}, \mathcal{O}_2 \otimes \mathbb{K})$, and every element $f_1 \in \mathrm{C_b}(\mathbb{R}, B)$ there exists a projection p in F_1 such that $pf_1p - f_1 \in \mathrm{C_0}(\mathbb{R}, B)$, $q \leq p$ and $q \neq p$.

`ref; {prop:7.Y5.chp9}(??), {prop:7.Y5new.chp9}(??),`

PROPOSITION 7.4.15. *Suppose B is stable and σ-unital, and that D separable, stable and* exact.

Let $E_\mathbb{R} := \mathcal{M}(B \otimes \mathrm{C_0}(\mathbb{R}))/B \otimes \mathrm{C_0}(\mathbb{R})$ and $h_0 \colon D \to E_\mathbb{R}$ defined by ...????????????? is nuclear.

??

Let $k \in \mathrm{Hom}(X; D, \mathrm{Q}(\mathbb{R}_+, B))$.

(i) *The map k has unitary equivalence class $[k]$ in $S(h_0, D, E_\mathbb{R})$, if an only if k is nuclear, where $\mathrm{Q}(\mathbb{R}_+, B) \subseteq \mathrm{Q}(\mathbb{R}, B) \subseteq E_\mathbb{R}$ naturally.*
(ii) $\mathrm{R}(X; D, B) = [h_0] + S(h_0, D, E_\mathbb{R}) = [h_0] + S(h_0, D, \mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B)))$.
(iii) *If h is nuclear as a map from D to $\mathrm{Q}(\mathbb{R}_+, B)$, and if h is also Ψ-equivariant, then h is dominated by $h_0 \colon D \to \mathrm{Q}(\mathbb{R}_+, B)$.*

The point is, that nuclear asymptotically equivariant h is residually nuclear ??????

`really needed in chp. 9:`

Let $h \colon D \to \mathrm{Q}(\mathbb{R}_+, B)$. Suppose that $H_\mathbb{R}$ dominates $h + \beta h_0$, i.e., there exists an isometry $T \in E_{\mathbb{R}}$ with $T^* H_0(.)T = h + \beta h_0$. Then $h \in S(h_0\,;\, D, \mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B)))$, i.e., h_0 dominates h if and only if $H_{\mathbb{R}}$ dominates $h + \beta h_0$.

(True for any $h_0 \colon D \to B$ non-degenerate with $h_0 \oplus h_0 \sim h_0$, i.e., H_0 pseudo-dominates h, if and only if, H_0 dominates h, if and only if, h_0 dominates h.)

`ref; prop:7.Y5.chp9`

By Proposition 7.4.15, $S(h_0, D, E_{\mathbb{R}})$ is nothing else the semigroup of unitary equivalence classes of Ψ-residually nuclear C^*-morphisms h from D into $\mathrm{Q}(\mathbb{R}_+, B)$, where $\Psi_A(J)$ and $\Psi_{\mathrm{Q}(\mathbb{R}_+,B)}$ are defined as above.

`next: Proof of Thm. B(iii),`
`also Proof of Corollary 7.4.16`

Corollary 7.4.16. *The absorption result (iii) of Theorem B:*

Suppose that B is simple, purely infinite, unital and contains a copy of $\mathcal{O}_2 \subseteq B$ unitally.

*Let A a unital separable exact C^*–algebra and let $k_1 \colon A \to \mathcal{O}_2$, $k_2 \colon \mathcal{O}_2 \otimes \mathcal{O}_2 \to \mathcal{O}_2$ unital *-monomorphisms, and $k_0 := k_2(k_1(\cdot) \otimes 1)$.*

*Then, for every unital *-monomorphism $h \colon A \to \mathrm{Q}(\mathbb{R}_+, B)$, $[h \oplus k_0] = [h]$.*

More generally, $\mathrm{R}(D, (\mathcal{O}_2 \otimes \mathcal{O}_2 \otimes \cdots) \otimes \mathbb{K}) = 0$ for every stable separable C^*-algebra D.

Lemma 7.4.17. *Let $h \colon D \to B \otimes \mathbb{K}$ a C^*-morphism where D is σ-unital. Then there exists a contraction $g_1 \in \mathrm{C_b}(\mathbb{R}, 1_{\mathcal{M}(B)} \otimes \mathbb{K})_+$ such that $g_1(x) = 0$ for $x \leq 0$ and $\lim_{x \to +\infty} g_1(x)h(a) = h(a)$ for every $a \in D$.*

(because $h(D)$ is σ-unital)

`Next proposition, see chp9, but only the prop is cited:`

Let $G_2 := \epsilon(\mathcal{O}_2 \otimes \mathbb{K}) \subseteq \mathcal{M}(B)$. Then $G_2 \cong \mathcal{O}_2 \otimes \mathbb{K}$, $G_2 \cap B = 0$ and $G_2 \cdot B$ is dense in B. Let $F_1 := \mathrm{C_b}(\mathbb{R}, G_2) \subseteq \mathcal{M}(\mathrm{C_0}(\mathbb{R}, B))$. Certainly $\tilde{\beta}(F_1) \subseteq F_1$.

$F_1 \cap \mathrm{C_0}(\mathbb{R}, B) = 0$ and therefore $F := \pi_{SB}(F_1) \subseteq E_{\mathbb{R}}$ is a C^*-subalgebra of $E_{\mathbb{R}}$ which is isomorphic to $\mathrm{C_b}(\mathbb{R}, \mathcal{O}_2 \otimes \mathbb{K})$ and satisfies $\beta(F) = F$.

$H_0'(D)G_2 \subseteq B$ implies that $F_1 H_0'(D) \subseteq \mathrm{C_b}(\mathbb{R}, B)$ and thus $F H_0(D) \subseteq J + \beta J$.

Proposition 7.4.18. *For every projection $q \in F_1$, and every element $f_1 \in \mathrm{C_b}(\mathbb{R}, B)$ there exists a projection p in F_1 such that $p f_1 p - f_1 \in \mathrm{C_0}(\mathbb{R}, B)$, $q \leq p$ and $q \neq p$.*

Let* $k_0 := k((\cdot) \otimes 1) \in \mathrm{Hom}_n\, uc(D, B)$*,* $X := \mathrm{Prim}(N)$ *and define actions* Ψ_A *(respectively* Ψ_B*) of* X *on* A *(respectively on* B*) by* $\Psi_A(J) := k_0^{-1}(k_0(A) \cap J)$ *and* $\Psi_B(J) :=$ *the closed ideal of* B *generated by* $J \in \mathcal{I}(N) \cong \mathbb{O}(\mathrm{Prim}(N))$.

Then $\mathrm{CP_{rn}}(\Psi) = \mathcal{C}(k_0) \subseteq \mathrm{CP}(A, B)$ *and*

$$\mathrm{SR}(X;\, D, B) \;=\; \mathrm{SR}(\mathrm{CP_{nuc}}(\Psi);\, D, B) \;=\; S(k_0;\, D, \mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B)))\,.$$

`??`

`Next taken from chap.9.  Need this here ??`

The reader can see, that $X := \mathrm{Prim}(N)$ acts on B upper semi-continuously by Ψ_B where $\Psi_B(J)$ is the closed ideal of B generated by the closed ideal J of N. The T_0 space X acts lower semi-continuously on D by Ψ_D, and, moreover, the action Ψ_D is monotone upper semi-continuous, i.e., satisfies also condition (ii) of Definition 1.2.6. Here $\Psi_D(J)$ for $J \in \mathcal{I}(N)$ is defined by

$$\Psi_D(J) := k_0^{-1}(k_0(D) \cap J)\,.$$

The later in Chapter 12 given proof of Theorem K shows that $k_0\colon D \to B$ (and $k\colon D \otimes \mathcal{O}_2 \to B$) can be constructed up to unitary homotopy from the actions Ψ_D and Ψ_B of X on D, respectively on B.

LEMMA 7.4.24. *Suppose that D is separable and stable, B is σ-unital and stable and that $h_0 \in \mathrm{Hom}(D,B)$ is non-degenerate and is unitarily equivalent to $h_0 \oplus h_0$.*

Let $\mathcal{C} := \mathcal{C}(h_0) \subseteq \mathrm{CP}(D,B)$, the point-norm closed matrix operator-convex cone generated by h_0.

Then a c.p. contraction $T\colon D \to \mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B))$ is dominated by h_0 in $\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B)))$, if and only if, there is a point-norm continuous map $t \in \mathbb{R}_+ \mapsto V_t \in \mathcal{C}$ such that $V\colon D \to \mathrm{C}(\mathbb{R}_+, B)$ satisfies $\|V\| \leq 1$, $V(a)(t) := V_t(a)$ and $V(a) + \mathrm{C}_0(\mathbb{R}_+, B) = T(a)$ for all $a \in D$.

If $T \in \mathrm{CP}(D,B)$ is a c.p. contraction, then h_0 dominates T in $\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B))$, if and only if, $T \in \mathcal{C}$.

In particular, $h \in \mathrm{Hom}(D,B)$ satisfies $h \in \mathcal{C}$, if and only if, $[h] \in \mathrm{SR}(\mathcal{C};\, D, B)$, if and only if, $[h] \in \mathrm{Gr}\big(h_0;\, D,\, \mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B))\big)$.

The natural group homomorphism

$$G(h_0;\, D, \mathcal{M}(B)) \to G(h_0;\, D, \mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B)))$$

is neither surjective nor injective in general, e.g. for $D = \mathcal{O}_2 \otimes \mathbb{K}$, $B = \mathcal{O}_2 \otimes \mathcal{O}_2 \otimes \mathbb{K}$ and $h_0(\cdot) := 1 \otimes (\cdot)$.

PROOF. $T \in \mathrm{CP}(D, \mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B)))$ is dominated by h_0 in $\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B)) \supset B$, if and only if, there is a norm continuous map $t \in \mathbb{R}_+ \mapsto S(t) \in \mathcal{M}(B)$ into the isometries in $\mathcal{M}(B)$ with $s^* h_0(\cdot) s = T$ for $s := S + \mathrm{C}_0(\mathbb{R}_+, \mathcal{M}(B))$. Let $V_t(a) := S(t)^* h_0(a) S(t)$, then $V_t \in \mathcal{C} = \mathcal{C}(h_0)$ and $V(a) + \mathrm{C}_0(\mathbb{R}_+, B) = T(a)$ for all $a \in A$ (because $\mathrm{C}_\mathrm{b}(\mathbb{R}_+, B))) \cap \mathrm{C}_0(\mathbb{R}_+, \mathcal{M}(B)) = \mathrm{C}_0(\mathbb{R}_+, B)$ and $\mathrm{C}_\mathrm{b}(\mathbb{R}_+, B)$ is an ideal of $\mathrm{C}_\mathrm{b}(\mathbb{R}_+, \mathcal{M}(B)))$.

If $T \in \mathrm{CP}(D,B)$ (in addition), this means that T is the limit of $V_t := S(t)^* h_0(\cdot) S(t)$ in point-norm. Since $\mathcal{C}$ is closed in point-norm topology, this implies $T \in \mathcal{C}$.

More arguments:
The assumption implies that there are norm continuous paths

$$t \in [0,\infty) \mapsto S_k(t) \in \mathcal{M}(B)$$

(for $k \in \{1,2\}$) of isometries, defining a path of copies of $\mathcal{O}_2$ in $\mathcal{M}(B)$ that commutes with $h_0(D)$ in $\mathrm{C}_\mathrm{b}(\mathbb{R}_+, \mathcal{M}(B))$ modulo $\mathrm{C}_0(\mathbb{R}_+, B)$.

If $T \in \mathcal{C}$ then there exist point-norm approximation $b_n^* h(\cdot) b_n$ of T in $\mathrm{CP}(D,B) \subseteq \mathcal{L}(D,B)$ with suitable b_n. With approximately central unit of D one can manage that $\|b_n\| \leq 1$. This allows to replace the sequence by a norm-continuous path of isometries in $\mathrm{C}_\mathrm{b}(\mathbb{R}_+, \mathcal{M}(B))$.

Conversely, if there is contraction $V\colon D \to \mathrm{C}_\mathrm{b}(\mathbb{R}_+, B)$ with $V_t(\cdot) := V(\cdot)(t) \in \mathcal{C}$, then there is a norm-continuous map $t \in \mathbb{R}_+ \mapsto S(t) \in \mathcal{M}(B)$ into the isometries in $\mathcal{M}(B)$, such that $\lim_{t\to\infty} \|V(a)(t) - S(t)^* h_0(a) S(t)\| = 0$ for all $a \in D$.

??

`Give reference for construction of` $S(t)$
`Perhaps as in above blue part?`

Let $h \in \mathrm{Hom}(D, B)$. By Definition **??**of $[h] \in \mathrm{SR}(\mathcal{C};\, D, B)$, if and only if, there is a map $t \in [0, \infty) \mapsto V_t \in \mathcal{C}$, such that $\lim_{t\to\infty} \|V_t(a) - h(a)\| = 0$ for every $a \in D$. Thus $h \in \mathcal{C}$.

If $h \in \mathcal{C}$, then $T := h$ is dominated by h_0 in $\mathrm{Q}(\mathbb{R}_+;\, \mathcal{M}(B))$

(but in general not directly in $\mathcal{M}(B)$ itself, h_0 dominates h only asymptotical inside $\mathcal{M}(B)$). □

`Next cited from chp.8:`
If an element $b \in \mathcal{M}(SB)/SB$ has a representative $c \in \mathrm{C}_{\mathrm{b,st}}(\mathbb{R}, \mathcal{M}(B))$ such that $c(t) \in B$ for every t. that it even does not say that c is in $\mathrm{C}_{\mathrm{b}}(\mathbb{R}, B)$ (as we have seen in Chapter 7).

`Next definition cited from chp.8:`
$\mathrm{SR}(X; A, B) := \mathrm{Hom}_{\mathrm{nuc}}(X; A, \mathrm{Q}(\mathbb{R}_+, B))$ for stable separable A and σ-unital stable B.
`for the action` Ψ `of` X `on` $\mathrm{Q}(\mathbb{R}_+, B)$
one has to take $\Psi(U) := \mathrm{Q}(\mathbb{R}_+, B)\Psi_B(U)\,\mathrm{Q}(\mathbb{R}_+, B)$

(or less controlled, but NOT $\Psi(U) = \mathrm{Q}(\mathbb{R}_+, \Psi_B(U))$???)

`Somewhere in Chp.7: following should appear for use in Chp.9:`
$\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(F))$ is a unital C^*-subalgebra of the multiplier algebra $\mathcal{M}(\mathrm{Q}(\mathbb{R}_+, F))$ of $\mathrm{Q}(\mathbb{R}_+, F)$.

5. Related questions

Question:
Let $h_j\colon A \to M$ weakly nuclear C^*-morphisms ($j = 1, 2$), where A is separable and exact and M is a semi-finite W*-algebra and $\|h_1(a)p\| = \|h_2(a)p\|$ for all central projections p of M and all $a \in A$, that the neutral ???? elements e_j of the weak closures of $h_j(A)$ are unitarily equivalent in M, and that $\tau(h_1(a)) = \tau(h_2(a))$ for all $a \in A_+$ and all l.s.c. additive traces $\tau\colon M_+ \to [0, \infty]$ (possibly degenerate).

Is h_1 unitarily homotopic to h_2?

Are they (at least) weakly approximately unitarily equivalent?

(There should be a reduction to the case of countably decomposable M and then to M with separable pre-dual.)

If the image of h_1 has only trivial intersection with the Brauer-ideal of M (i.e., the norm-closed ideal generated by the finite projections in M), then one has only to check that the infinite repeats $\delta_\infty \circ h_j$ are unitarily homotopic to h_j (if $e_1 = e_2 = 1_M$) and then apply Theorem M (here δ_∞ is in $\mathrm{End}(M)$).

CHAPTER 8

The isomorphism of $\mathrm{KK}(\mathcal{C};\, A, B)$ and $\mathrm{Ext}(S\mathcal{C};\, A, SB)$

We have reassuring good news for those readers who are interested *only* in Theorem A and Corollaries C, D, F, G, H and J, and only in the *nuclear* case of Theorem I:
Their proofs only use the triviality of $\mathrm{Ext}^{-1}(A, \mathcal{O}_2)$ and the special case of Theorem B in the introductory Chapter 1, where A is *nuclear*. In this cases we have obviously the identities $\mathrm{Ext}_{\mathrm{nuc}}(A, B) = \mathrm{Ext}^{-1}(A, B)$ and $\mathrm{KK}(A, B) = \mathrm{KK}_{\mathrm{nuc}}(A, B)$. The reader can see that our proof of Theorem B in this special cases involves only the usual KK- and Ext-theory of Kasparov. So, the reader can find the needed facts for this very special case and the here indicated approach in text books, e.g. in [**73**], *except some elementary observations in Sections 3 of this chapter*

`Is Section 3 all?`

needed for the proofs of Theorems B and its generalization M in Chapter 9.

In this Chapter 8 we describe our viewpoint on a (weakly) *nuclear* version of Kasparov's KK-theory, and its isomorphism to $\mathrm{Ext}_{\mathrm{nuc}}(A, SB)$, but in a more general context that covers also our $\mathcal{C}$-equivariant group $\mathrm{Ext}(\mathcal{C}\,;\, A, SB)$ – just by the anyway needed more refined and general terminology. The needed definitions and facts about $\mathrm{Ext}_{\mathrm{nuc}}(A, B)$ and generalizations in different directions like $\mathrm{Ext}(X;\, A, B)$ and $\mathrm{Ext}(\mathcal{C};\, A, B)$ can be found in Chapters 3 and 5. We generalize the ordinary KK-functor in the following direction:
We introduce KK-groups $\mathrm{KK}(\mathcal{C};\, A, B)$ depending on (non-degenerate) countably generated point-norm closed matrix operator-convex cones (m.o.c.c.) $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ (cf. Chapter 3). It has the property, that the Kasparov product allows to define a bi-additive map

$$\mathrm{KK}(\mathcal{C}_1\,;\, A, B) \times \mathrm{KK}(\mathcal{C}_2\,;\, B, C) \to \mathrm{KK}(\mathcal{C}_3\,;\, A, C)$$

if $\mathcal{C}_2 \circ \mathcal{C}_1 \subseteq \mathcal{C}_3$ and A and B are both separable, and C is σ-unital. A special case is our *residually nuclear* KK-group $\mathrm{KK}_{\mathrm{nuc}}(X;\, A, B)$ that corresponds to a well-defined m.o.c. cone $\mathcal{C} := \mathrm{CP}_{\mathrm{rn}}(X;\, A, B) \subseteq \mathrm{CP}(A, B)$, the cone $\mathrm{CP}_{\mathrm{rn}}(X;\, A, B) := \mathrm{CP}_{\mathrm{rn}}(X;\, \Psi_A, \Psi_B)$ of Ψ-*residually nuclear* c.p. maps for given actions $\Psi_A \colon \mathbb{O}(X) \to \mathcal{I}(A)$ of a T_0 space X on A and Ψ_B of X on B (under the additional assumption that $\mathrm{CP}_{\mathrm{rn}}(X;\, A, B)$ for the actions Ψ_A and Ψ_B is non-degenerate), see Chapters 1 and 3 for the

`give Refs.  for actions and its cones`

definitions of this actions and the related m.o.c. cones. The group $\mathrm{KK}_{\mathrm{nuc}}(A,B)$ of Skandalis [**726**] – even if they are defined directly as the homotopy classes given by elements in $\mathbb{E}(A, B[0,1])$ ...

is the same as our $\mathrm{KK}(\mathcal{C}\,;\, A, B)$ for the special case of the m.o.c. cone $\mathcal{C} := \mathrm{CP}_{\mathrm{nuc}}(A,B) \subseteq \mathrm{CP}(A,B)$ (?? `check def in [726] again !` ??),

if A is separable and B is σ-unital, because then $\mathrm{CP}_{\mathrm{nuc}}(A,B)$ is countably generated as matrix operator convex cone.

If A and B are both separable, then $\mathcal{C} := \mathrm{CP}(A,B)$ is itself countably generated and the usual Kasparov group $\mathrm{KK}(A,B)$ is the same as $\mathrm{KK}(\mathrm{CP}(A,B)\,;\, A, B)$.
`Check next! But next is true if` B `is not` σ`-unital!:`
(Notice that $\mathrm{CP}(A,B)$ is not countably generated – which is equal to singly generated – as matrix operator-convex cone if $A := \mathbb{K}(\ell_2(\mathbb{N}))$ or $A := \mathbb{C}$ and B is not separable.)

But $\mathrm{CP}(\mathbb{C}, B) \cong B_+$ is generated as m. o. c. cone by the element $\mathbb{C} \ni z \mapsto ze \in B$ if $e \in B_+$ is a strictly positive element of B. But what happens if $A := \mathrm{C}_0(0,1]$?

All results of this chapter can be obtained by modifying the proofs of the corresponding results for the usual (non-nuclear) KK-theory, but use our observations on operator-convex cones in Chapter 3. We apply the $\mathrm{Ext}(\mathcal{C};\, \cdot, \cdot)$-groups defined in Chapter 5 to give other proofs, which are more "elementary" (or "constructive") and allow to control all identifications and constructions which are needed during our proofs of Theorems B and M, cf. Lemma 8.3.2. In fact, we need to work only with *unitary* homotopy, because this is automatically $\mathcal{C}$-equivariant, and we prove later that $\mathcal{C}$-equivariant homotopy can be realized by unitary homotopy (modulo stabilization). This is also important for the X-equivariant theory $\mathrm{KK}_{\mathrm{nuc}}(X\,;\, A, B) := \mathrm{KK}(\mathcal{C}\,;\, A, B)$ given by the m.o.c. cone for $\mathcal{C} := \mathrm{CP}_{\mathrm{rn}}(X\,;\, \Psi_A, \Psi_B\,;\, A, B)$.

The major results of this chapter are the homotopy invariance of $\mathrm{KK}(\mathcal{C}\,;\, A, B)$, the observations in Section 5 (that are needed in Chapter 9) and the related "controlled" isomorphism

$$\mathrm{Ext}\big(\mathcal{C} \otimes \mathrm{CP}(\mathbb{C}, \mathrm{C}_0(\mathbb{R}));\, A, B \otimes \mathrm{C}_0(\mathbb{R})\big) \cong \mathrm{KK}(\mathcal{C};\, A, B)\,,$$

that gives in particular $\mathrm{Ext}_{\mathrm{nuc}}(X;\, A, SB) \cong \mathrm{KK}_{\mathrm{nuc}}(X;\, A, B)$ for actions Ψ_A and Ψ_B of a T_0-space X on A respectively B if the cone $\mathrm{CP}_{\mathrm{rn}}(X;\, A, B)$ is non-degenerate and countably generated, cf. Chapters 1 and 5.

In Chapters 9 and 12 we use results on $\mathrm{KK}_{\mathrm{nuc}}(X;\, A, B)$ and $\mathrm{Ext}_{\mathrm{nuc}}(X;\, A, B)$ in the case where X is often the primitive ideal space of a separable C^*-algebra. The definitions can be found in Chapters 1 and 5. The necessary changes from the theory of $\mathrm{KK}_{\mathrm{nuc}}(A,B)$ and $\mathrm{Ext}_{\mathrm{nuc}}(A,B)$ to this general $\mathrm{KK}_{\mathrm{nuc}}(X;\, .,.)$- and $\mathrm{Ext}_{\mathrm{nuc}}(X;\, .,.)$-theories or even to $\mathrm{KK}(\mathcal{C}\,;\, A, B)$ and $\mathrm{Ext}(\mathcal{C}\,;\, A, B)$ are often straight-forward, up to more complicate notations:
Then one has only to replace the emphasized words *"nuclear"* by the words *"Ψ-residually nuclear"*, respectively by *"$\mathcal{C}$-compatible"*, if we consider the more flexible

theory of the groups $\mathrm{KK}(\mathcal{C}\,;\, A, B)$. Therefore we discuss sometimes only properties of the $\mathrm{KK}_{\mathrm{nuc}}$-theory because of simpler notation. All differences to the basic theory appears by a pre-selection of suitably chosen sub-classes of Kasparov modules. If this choice has been made, only two general conditions define the appropriate equivalence relation that makes the direct module-sum to the addition on the corresponding classes that build the elements of the KK-groups. The formed Grothendieck group defines in the case of $\mathcal{C} = \mathrm{CP}(A, B)$ the relation $\sim_c$ on the Kasparov modules considered by G. Kasparov and J. Cuntz.

The prove of the (operator-) homotopy invariance of J. Cuntz and G. Skandalis carries over almost verbatim to $B \mapsto \mathrm{KK}(\mathcal{C}; A, B)$. The full homotopy invariance can then derived by the ideas of A. Connes ...

`Check next statement!!`

A modification of parts of our proof of Theorem B can be used to show that $\mathcal{O}_\infty$*-stabilized unsuspended weakly nuclear* $\otimes\mathcal{O}_\infty$ `necessary?`

E-theory is equivalent to $\mathrm{KK}_{\mathrm{nuc}}$-theory in separable case with trivial grading (an observation of N.Ch. Phillips, cf. Remark 8.3.6).

`Check ???  At some points we could use that` $A' \cap \mathrm{Q}(B)$ `with` $\mathrm{Q}(B) := \mathcal{M}(B)/B$
`is s.p.i. if` $A \hookrightarrow \mathrm{Q}(B)$ `is nuclear`
`and` B `is s.p.i. and` σ`-unital.`

`Then` $A' \cap \mathrm{Q}(B)$ `should be` K_1`-bijective.`

`VERY IMPORTANT!!!`
`We need !!!  and use later that:`

$\mathrm{KK}(\mathcal{C};\, A, B)$ is naturally isomorphic to the kernel of the natural map

$$\mathrm{K}_1\big((\pi_B \circ H_{\mathcal{C}})(A)' \cap \mathrm{Q}(B)\big) \to \mathrm{K}_1(\mathrm{Q}(B)) \cong \mathrm{K}_0(B)$$

if A is separable and stable and B is σ-unital and stable (and all is trivially graded).

And that the "natural" isomorphisms $\mathrm{KK}(\mathcal{C}[0,1]\,;\, A, B[0,1]) \cong \mathrm{KK}(\mathcal{C}\,;\, A, B)$ and $\mathrm{KK}([0,1]\mathcal{C}\,;\, A[0,1], B) \cong \mathrm{KK}(\mathcal{C}\,;\, A, B)$. given by evaluations at points $t \in [0,1]$.

(– The latter are the homotopy invariances of $\mathrm{KK}(\mathcal{C};\cdot,\cdot)$ and works as in the case $\mathcal{C} = \mathrm{CP}(\cdot,\cdot)$ using the G. Kasparov product construction modified by A. Connes ... –).

Claimed in Chapter 5:
There are natural isomorphisms $\mathrm{KK}(A, B) \cong \mathrm{Ext}(A, SB)$ and $\mathrm{KK}(A, B) \cong \ker\big(\mathrm{K}_1(H_0(A)' \cap \mathrm{Q}(B)) \to \mathrm{Q}(B) \cong \mathrm{K}_0(B)\big)$ for separable stable σ-unital A and B.

This should come from Cuntz picture for trivially graded A and B: $\mathrm{KK}^1(\mathcal{C};\, A, B)$ is defined for separable A and σ-unital B and countably generated m.o.c. cone $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ as equivalence classes $[(\psi, P)]$ in the set of all pairs

$\{(\psi, P)\,;\ \psi\colon A \to \mathcal{M}(B\otimes\mathbb{K}), P = P^* = P^2 \in \mathcal{M}(B\otimes\mathbb{K})\}$ with the properties: ψ is a C^*-morphism, $d^*\psi(\cdot)d \in \mathcal{C}$ for all $d \in B\otimes\mathbb{K}$ and $P\psi(a) - \psi(a)P \in B\otimes\mathbb{K}$.

Can all reduce to case $E := \widehat{\mathbb{H}}_B := \mathbb{H}_B \oplus \mathbb{H}_B^{op}$. It has the "standard even" grading if B is trivially graded. And this induces on $\mathcal{L}(\widehat{\mathbb{H}}_B) \cong \mathcal{M}(B\otimes\mathbb{K})$ the standard even grading.

If E is any trivially graded Hilbert B-module then $E\oplus E^{op}$ induces the standard even grading on $M_2(\mathcal{L}(E))$.

We should start with "Fredholm picture" in case of trivially graded separable A and stable σ-unital trivially graded B:

Triples $(E^{(0)}\oplus E^{(1)}, \phi_0\oplus\phi_1, T)$ with $T \in \mathcal{L}(E^{(0)}, E^{(1)})$ and relations:

$T\phi_0(a) - \phi_1(a)T \in \mathbb{K}(E^{(0)}, E^{(1)})$ for all $a \in A$, $1 - T^*T \in \mathbb{K}(E^{(0)})$ and $1 - TT^* \in \mathbb{K}(E^{(1)})$.

The ϕ_* should satisfy $\langle \phi_*(\cdot)e, e\rangle \in \mathcal{C}$.

Then try to "absorb" the ϕ_* and $E^{(*)}$ by $H_{\mathcal{C}}\colon A \to \mathcal{M}(B)$ and $E \cong B$ in case of stable σ-unital B.

Should get new $T \in \mathcal{M}(B)$ with $[T, H_{\mathcal{C}}(a)] \in B$, $(1 - T^*T)H_{\mathcal{C}}(a) \in B$ $(1 - TT^*)H_{\mathcal{C}}(a) \in B$ for all $a \in A$. ... ???

Is this all at the beginning?

If one can make ????????????

Also very important:

There are natural isomorphisms

$$\mathrm{Ext}(\mathcal{C};\, A, B) \cong \ker(\mathrm{K}_0(H_0(A)' \cap \mathrm{Q}(B)) \to \mathrm{K}_0(\mathrm{Q}(B)) \cong \mathrm{K}_1(B))$$

for separable stable σ-unital A and σ-unital stable B.

$\Leftarrow$ `This has been shown in Chp. 3 or 5 ??? Where? Ref.?`

1. Some basics on KK and Ext

`Think about interchanging the role of` $\mathcal{L}(E)$ `and` $\mathcal{B}(E)$`,`
`or use` $\mathbb{B}(E)$ `and` $\mathbb{L}(E)$ `!!??`

The nuclear KK-theory $\mathrm{KK}_{\mathrm{nuc}}(A, B)$ was defined by Skandalis [**726**]. But we use at the beginning a *different* definition that is more algebraic and refers not explicit to any sort of homotopy invariance. It allows us to give later a "constructive" proof of the existence of a functor isomorphism:

$$\mathrm{Ext}(\mathcal{C};\, A\otimes\mathbb{K}, B) \cong \mathrm{KK}(\mathcal{C};\, A, B_{(1)}) \tag{1.1}$$

in case where A and B are *trivially graded*, i.e., the corresponding $\mathbb{Z}_2$-actions on A and B are given by the identity map, A is separable, B is σ-unital, stable and $B_{(1)}$ denotes the graded algebra $B_{(1)} := B\oplus B$ with the **standard odd grading** $\beta((a, b)) := (b, a)$. In particular $\mathrm{Ext}_{\mathrm{nuc}}(A\otimes\mathbb{K}, B) \cong \mathrm{KK}_{\mathrm{nuc}}(A, B_{(1)})$.

It implies then that $\mathrm{Ext}(S\mathcal{C};\, A, SB) = \mathrm{KK}(\mathcal{C};\, A, B)$ for trivially graded separable stable C^*-algebras A and B.

The natural isomorphism $B_{(1)} \cong B \otimes (\mathbb{C}_{(1)})$ of graded C^*-algebras allows to extend an operator-convex cone $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ naturally to a cone $\mathcal{C} \subseteq \mathrm{CP}(A, B_{(1)})$: Simply take the m.o.c. cone-tensor product $\mathcal{C} \otimes \mathrm{CP}(\mathbb{C}, \mathbb{C} \oplus \mathbb{C})$, i.e., the smallest point-norm closed hereditary sub-cone of $\mathrm{CP}(A, B_{(1)})$ containing the c.p. maps $V \otimes W$ with $V \in \mathcal{C}$ and $W \in \mathrm{CP}(\mathbb{C}, \mathbb{C} \oplus \mathbb{C}) \cong \mathbb{R}_+ \oplus \mathbb{R}_+$.

Recall that the "tensor"-cones are in general not completions of algebraic tensor products – see Definition 3.6.16: Here this "m.o.c.cone-tensor-product" is – as a set – the same as the set of maps $a \in A \mapsto (V_1(a), V_2(a)) \in B_1$ with $V_1, V_2 \in \mathcal{C} \subseteq \mathrm{CP}(A, B)$.

We have to consider $\mathbb{Z}_2$-graded C^*-algebras, because we need formula (1.1) and its consequences concerning the very important homotopy invariance. But the reader should notice that the groups $\mathrm{Ext}_{\mathrm{nuc}}(A, SB)$ and $\mathrm{KK}_{\mathrm{nuc}}(A, B)$ are in general not isomorphic for non-trivially graded separable C^*-algebras A and B.

`Check again ??:`

G. Skandalis [**726**] requires homotopy invariance as a part of his *definition* of $\mathrm{KK}_{\mathrm{nuc}}(A, B)$ right from the beginning, so he was in the comfortable situation that he didn't need to *prove* the formula (1.1). But for us this is a non-obvious key observation, that must be proven, because it is then often used in our proofs, e.g. in Section 5 that establish the applicability the abstract results in Chapter 4 and allow with them together to show in Chapter 9 that

`?? in the general case that we consider ??`

Need: For stable separable C^*-algebras A and B and countable generated non-degenerate m.o.c. cone $\mathcal{C}$ for the canonical $H_{\mathcal{C}} \colon A \to \mathcal{M}(B)$ holds (in the trivially graded case):

The group $\mathrm{KK}(\mathcal{C}\,;\; A, B)$ is naturally isomorphic to the kernel of the natural morphism

$$\mathrm{K}_1\big((\pi_B \circ H_{\mathcal{C}})(A)' \cap \mathrm{Q}^{\mathrm{s}}(B)\big) \;\to\; \mathrm{K}_1\big(\mathrm{Q}^{\mathrm{s}}(B)\big) \cong \mathrm{K}_0(B)\,.$$

A hint is: [**73**, subsec. 17.5.1] but then add the infinite repeat of $\phi_0 \oplus \phi_1$ to it and use suitable unitaries in $\mathcal{M}(B)$ to correct the formula ...

`To be carried out in detail.`

In case of $\mathrm{Ext}(\mathcal{C}\,;\; A, B)$ it is not difficult to see that $\mathrm{Ext}(\mathcal{C}\,;\; A, B)$ is isomorphic to the kernel of

$$\mathrm{K}_0\big((\pi_B \circ H_{\mathcal{C}})(A)' \cap \mathrm{Q}^{\mathrm{s}}(B)\big) \;\to\; \mathrm{K}_0\big(\mathrm{Q}^{\mathrm{s}}(B)\big) \cong \mathrm{K}_0(B)\,.$$

We define $\mathrm{KK}_{\mathrm{nuc}}(A, B)$ as one of our more general groups $\mathrm{KK}(\mathcal{C};\, A, B)$ – specialized to the case where $\mathcal{C} := \mathrm{CP}_{\mathrm{nuc}}(A, B)$. They have a completely algebraic definition and that does not impose any sort of homotopy invariance *in itself*. We shall later *prove* the homotopy invariance of our $\mathrm{KK}(\mathcal{C};\, A, B)$ by modifications of ideas of G. Kasparov (discussed and modified by A. Connes, G. Skandalis, J. Cuntz, N. Higson and others).

We work with an "algebraic" definition that does not refer to "homotopy invariance" because the homotopy invariance of the purely algebraic defining relations proves also the homotopy invariance of *our* $\mathrm{Ext}_{\mathrm{nuc}}(A, B)$ groups (and of our groups $\mathrm{Ext}(\mathcal{C};\, A, B)$, $\mathrm{Ext}_{\mathrm{nuc}}(X;\, A, B)$ etc.) with help of *our* definition of $\mathrm{KK}(\mathcal{C};\, A, B)$. It is not a triviality.

Even the much weaker (since as a relation stronger) *operator-homotopy invariance* of the equivalence classes that build the elements of in $\mathrm{KK}(\mathcal{C};\, A, B)$ is not evident. The proof of the homotopy invariance from stronger more algebraic definitions is the core of the application of generalized $\mathrm{KK}(\mathcal{C};\, \cdot, \cdot)$ to classification of non-simple C^*-algebras.

The so-called "degenerate" Kasparov modules represent zero automatically in any version of KK-theory that is a quotient of the Grothendieck group of a sub-semigroup of the semigroup of unitary equivalence classes of Kasparov modules, because the "degenerate" Kasparov modules can be defined equivalently by its property that *their infinite direct sum is again a Kasparov module* ([1]). The proof of the operator homotopy can be done by modifications of the techniques of G. Kasparov (respectively of J. Cuntz and G. Skandalis) in the proof of the homotopy invariance of the below defined $\mathrm{KK}_c(A, B)$-functor for graded separable A and σ-unital graded B, where KK_c can be defined equivalently by the *cobordism*-picture, cf. [**73**, def. 17.10.2, thm. 17.10.7] ([2]). After introduction of the Kasparov products up to operator homotopy (!), the proof of [**73**, thm. 18.5.3] carries over to our situation and establishes the general homotopy invariance, where one can use that Kasparov products define the functor $\mathrm{KK}_{\mathrm{nuc}}$ to as an KK-"ideal" in the KK-category. See below lemmata for a more details.

The way *from* operator homotopy invariance to the existence of Kasparov products (and then to homotopy invariance) can be found also in [**389**, chp. 2].

We use the approach of Kasparov to show that our $\mathrm{KK}_{\mathrm{nuc}}$-bi-functor (respectively our $\mathrm{KK}(\mathcal{C};\, \cdot, \cdot)$ bi-functor – generalizing our $\mathrm{KK}_{\mathrm{nuc}}(X;\, \cdot, \cdot)$ bi-functor for actions Ψ of $\mathbb{O}(X)$ on ideal lattices) is homotopy invariant. But one has to be careful because *in general the identity maps* id_A *does not represent an element of* $\mathrm{KK}_{\mathrm{nuc}}(A, A)$, and the relations are calculated up to stabilization with *nuclear* Kasparov modules and not up to stabilization with general Kasparov modules. But with this in mind, one can go through the textbooks and over-carry step by step every argument to the case of $\mathrm{KK}_{\mathrm{nuc}}$ (or even to $\mathrm{KK}(\mathcal{C};\, \cdot, \cdot)$, and thus especially to $\mathrm{KK}_{\mathrm{nuc}}(X;\, \cdot, \cdot)$, if one uses the natural extension of the actions Ψ of X on A to an action $\Psi \otimes C\colon U \to \Psi(U) \otimes C$ on $A \otimes C$, for $C := \mathrm{C}_0((0, 1])$, $\mathrm{C}_0(\mathbb{R})$, $\mathbb{K}$, $\mathrm{C}([0, 1])$ or $\mathcal{O}_\infty$ –).

---

[1] Note that the infinite sums are again weakly *nuclear*, or more generally $\mathcal{C}$-*compatible*.

[2] Note that [**73**, def. 17.10.1] must require $[p, F]\phi(A) \subseteq \mathbb{K}(E)$ in addition, cf. [**187**, def. 3.1].

Let us recall some *general definitions* concerning graded Hilbert modules used in the "algebraic" definition of $\mathrm{KK}(\mathcal{C};\cdot,\cdot)$-theory:

We prefer a picture (– the original picture of Kasparov himself –) that requires to use *graded* σ-unital algebras for the most basic results, in particular, *all* C^*-*algebras* $A, B, \ldots$ *in question are supposed to be* σ-*unital*, of course except the related algebras $\mathcal{M}(A)$, ... , etc.

Suppose that A and B are $\mathbb{Z}_2$-graded C^*-algebras, with grading automorphisms $\beta_A \in \mathrm{Aut}(A)$ and $\beta_B \in \mathrm{Aut}(B)$. We drop the indices A and B, if it is obvious where β acts. Thus, always $\beta^2 = \mathrm{id}$. Further we suppose that $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ is a (non-degenerate) point-norm closed matrix operator-convex (m.o.c.) cone with the (minimally necessary) property that $\beta_B \circ \mathcal{C} \circ \beta_A \subseteq \mathcal{C}$.

In general a $\mathbb{Z}_2$-grading of a vector space V is given by a linear operator $\beta \colon V \to V$ with $\beta^2 = \mathrm{id}_V$.

`compare def.s with book:`

An element $v \in V$ has *degree* $\deg(v) = 0$ if $v = \beta(v)$ and $\deg(v) = 1$ if $v = -\beta(v)$. We use also the notation ∂v for $\deg(v)$.

`Is notation` ∂v `really better?  Not misleading?`

The vector space V is the direct sum $V = V^{(0)} + V^{(1)} \cong V^{(0)} \oplus V^{(1)}$ of its linear subspaces $V^{(0)} = \{v \in V\,;\ \deg(v) = 0\}$ and $V^{(1)} = \{v \in V\,;\ \deg(v) = 1\}$. Thus $\beta(v) = \beta(v_0 + v_1) = v_0 - v_1$ for the unique decomposition $v = v_0 + v_1$ with $\deg(v_0) = 0$ and $\deg(v_1) = 1$.

The graded tensor product $V \otimes W$ of graded vector spaces V, W is usually given by $\beta_V \otimes \beta_W$? **??**

A **Hilbert** B**-module** E is a complete normed right B-module together with positive definite hermitian B-module form $(x, y) \in E \times E \mapsto \langle x, y\rangle \in B$ that is linear in the second variable and anti-linear (conjugate-linear) in the first variable and satisfies $\|x\|^2 = \|\langle x, x\rangle\|$ for all $x \in E$.

We denote by $\mathbb{K}(E)$ the closed linear span of the "B-rank-one" operators:

$$x \in E \mapsto y\langle z, x\rangle \in E\,.$$

It is a C^*-algebra and an essential ideal in the C^*-algebra $\mathcal{L}(E)$ of bounded and $\langle .,.\rangle$-adjoint-able B-module endomorphisms of E. Moreover $\mathcal{L}(E)$ is naturally isomorphic to the multiplier C^*-algebra (real or complex) $\mathcal{M}(\mathbb{K}(E))$ of $\mathbb{K}(E)$. During Chapter 8 we denote by $\mathcal{B}(E)$ the Banach algebra of *all* bounded linear operators on E with the usual operator norm. Then our $\mathcal{L}(E)$ is the subalgebra of $T \in \mathcal{B}(E)$ with $T(x \cdot b) = (Tx) \cdot b$ for $x \in E$ and $b \in B$. The norms on $\mathcal{L}(E)$ are the usual operator norms. $\mathcal{L}(E)$ does not coincide with $\mathcal{B}(E)$ if $B \neq \mathbb{C}$.

Assume that B is $\mathbb{Z}_2$-graded by a C^*-algebra automorphism β_B of order 2. A Hilbert B-module E is **graded** by β_E, if β_E is an isometry with $\beta_E^2 = \mathrm{id}$ and

$\beta_E(xb) = \beta_E(x)\beta_B(b)$ for $x \in E$, $b \in B$. One can easily see that the isometry property $\|\beta_E(x)\| = \|x\|$ ($x \in E$) of β_E is equivalent to invariance property $\beta_B(\langle x, y\rangle) = \langle \beta_E(x), \beta_E(y)\rangle$ for $x, y \in E$, e.g. simply by composing both sides with positive functionals on B, and using the trapezoid rule and that $\|\langle x, x\rangle\| = \|x\|^2$.

The grading β_E *induces* on the C^*-algebra $\mathcal{L}(E)$ the grading $F \to \beta_E \circ F \circ \beta_E$. By E^{op} we denote the **opposite** Hilbert B-module of E, that is the same B-module as E with the new "opposite" grading $-\beta_E$.

An **isomorphism** of graded Hilbert B-modules $\lambda\colon E_1 \to E_2$ is an isometric B-module map from E_1 onto E_2 that satisfies $\lambda \circ \beta_{E_1} = \beta_{E_2} \circ \lambda$ ([3]). The *isomorphism classes* of (over B) countably generated graded Hilbert B-modules build a *set*, if B is σ-unital, because they are isomorphic to orthogonally complemented grading invariant closed subspaces of $\widetilde{\mathcal{H}}_B := \mathcal{H}_B \oplus_B (\mathcal{H}_B)^{op}$, cf. [**73**, thm.14.6.1], by Kasparov's stabilization theorem [**?**], (or, by the almost equivalent Brown stable isomorphism theorem, [**107**]).

The **direct sum** $E \oplus_\infty E'$ of Hilbert B-modules E and E' with norm $\|(x, y)\|_\infty := \max(\|x\|, \|y\|)$ is a Hilbert $B \oplus B$-module, and therefore has also the *diagonal* right B-module structure. If we consider $E \oplus_\infty E'$ as a right *Banach* B-module, then $E \oplus_\infty E'$ is naturally and bounded (but not isometrically!) B-module isomorphic to the **Hilbert B-module sum** $E \oplus_B E'$ with B-valued form $\langle (x_1, y_1), (x_2, y_2)\rangle := \langle x_1, x_2\rangle + \langle y_1, y_2\rangle$. Up to unitary equivalence, $\oplus_B$ is associative and commutative, $\mathcal{L}(E) \oplus_\infty \mathcal{L}(E') \subset \mathcal{B}(E \oplus_\infty E')$ and $\mathcal{L}(E) \oplus_\infty \mathcal{L}(E')$ is a unital C^*-subalgebra of $\mathcal{L}(E \oplus_B E')$.

Some minimal basics on *graded* tensor products of operator-convex cones and on natural extension are needed during this Chapter 8:
We denote by $A \mathbin{\widehat{\otimes}} B$ the (outer) **graded tensor product** of $\mathbb{Z}_2$-graded C^*-algebras A and B. The **outer graded tensor product** of graded Hilbert A-modules E_1 and graded Hilbert B-modules E_2 will be denoted by $E_1 \widehat{\otimes} E_2$ and is a Hilbert $A \widehat{\otimes} B$-module.

Since we have *to define* the groups KK($\mathcal{C}$; $A\widehat{\otimes}C$, $B\widehat{\otimes}D$) for $\mathbb{Z}_2$*-graded separable nuclear* C^*-algebras C and D, we must "extend" a given matrix operator-convex cone $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ to an m.o.c. cone $\mathcal{C}_{C,D} \subseteq \mathrm{CP}(A\widehat{\otimes}C, B\widehat{\otimes}D)$:
Simply, let $\mathcal{C}_{C,D} := \mathcal{C} \mathbin{\widehat{\otimes}} \mathrm{CP}(C, D)$, where $\mathcal{C} \mathbin{\widehat{\otimes}} \mathrm{CP}(C, D) \subseteq \mathrm{CP}(A\widehat{\otimes}C, B\widehat{\otimes}D)$ denotes the point-norm closed m.o.c. cone that is generated by the graded Hilbert $(A\widehat{\otimes}C, B\widehat{\otimes}D)$-module $(E_1\widehat{\otimes}E_2, \phi_1\widehat{\otimes}\phi_2\colon A\widehat{\otimes}C \to \mathcal{L}(E_1\widehat{\otimes}E_2))$ for a graded Hilbert (A, B)-module $(E_1, \phi_1\colon A \to \mathcal{L}(E_1))$ and a graded Hilbert (C, D)-module $(E_1, \phi_2\colon C \to \mathcal{L}(E_2))$ that generates $\mathcal{C}$ (respectively generates $\mathrm{CP}(C, D)$) in the sense of Definition 3.6.25. (Please observe that the notation $\mathcal{C} \mathbin{\widehat{\otimes}} \mathrm{CP}(C, D)$ does not say that it is a sort of "completion" of the linear span of some kind of tensor

[3] The grading λ is $\mathbb{C}$-linear by the Cohen factorization theorem, because every Hilbert B-module is non-degenerate, and it holds automatically $\langle \lambda(x), \lambda(y)\rangle = \langle x, y\rangle$ for $x, y \in E_1$, because, if $a, b \in B_+$ and $\|c^*ac\| = \|c^*bc\|$ for all $c \in B$ then $a = b$, – as application of pure states to $b - a$ shows by using the "excision" Lemma **??**.

products: It is only "generated" as point-norm closed m.o.c. cone by tensor products $V \otimes W$ with $V \in \mathcal{C}$ and $W \in \mathrm{CP}(C, D)$. See Chapter 3 for more details.

Let us consider an easy example:

Example 8.1.1. We consider the groups $\mathrm{KK}(\mathcal{C};\, \mathrm{C}[0,1], \mathbb{C})$ that are used in the proof of the later considered "homotopy invariance". Where $\mathcal{C} \subseteq \mathrm{CP}(\mathrm{C}[0,1], \mathbb{C}) \cong \mathrm{C}[0,1]^*_+$ is any point-norm closed m.o.c. cone ...

The minimal point-norm closed *non-degenerate*

??????

$\mathrm{CP}(\mathbb{C}, \mathbb{C}) = \mathbb{R}_+ \cdot \mathrm{id}_{\mathbb{C}} \cong \mathbb{R}_+$

matrix operator-convex cone $\mathcal{C}_{\min} \subseteq \mathrm{CP}(\mathrm{C}[0,1]) := \mathrm{CP}_{[0,1]}(\mathrm{C}[0,1], \mathrm{C}[0,1])$ on $\mathrm{C}[0,1]$ are the "inner" c.p. maps, i.e., is here – with other words – simply the set of all multiplication maps $V_g(f) := gf$ with positive elements $g \in \mathrm{C}[0,1]_+$. Thus $\mathcal{C}_{\min}(\mathrm{C}[0,1]) \cong \mathrm{C}[0,1]_+$ by an isometric identification $\|V_g\| = \|g\|$.

Indeed ????: $\mathrm{CP}(\mathrm{C}[0,1], \mathrm{C}[0,1])$ is natural isomorphic to the set of weakly continuous maps

$$[0,1] \ni t \mapsto \mu_t \in \mathrm{C}[0,1]^*_+$$

from $[0,1]$ into the finite positive measures on $[0,1]$.

Let $\mathcal{C} \subseteq \mathrm{CP}(\mathrm{C}[0,1], \mathrm{C}[0,1])$ is a point-norm closed m.o.c. cone, then for each $t \in [0,1]$ there exists $V \in \mathcal{C}$ and $f \in \mathrm{C}[0,1]_+$ such that $V(f)(t) > 1$. By continuity of $V(f)(\cdot)$, order monotony of V and we find an open intervall $I = (\alpha, \beta) \subseteq [-1, 2]$ and $\gamma > 0$ such that $t \in I$ and $V(1)(s) > \gamma$ for $s \in I$. The compactness of $[0,1]$ shows then that there is $\mu > 0$ finite sum of such kind of $V \in \mathcal{C}$ is a $W_0 \in \mathcal{C}$ with $W_0(1)(t) \geq \mu$. It shows that there exists $W \in \mathcal{C}$ with with $W(1) = 1$.

The only point-norm closed non-degenerate m.o.c. cone $\mathcal{C} \subseteq \mathrm{CP}(\mathrm{C}[0,1], \mathbb{C}) = \mathrm{C}[0,1]^*_+$ is $\mathrm{C}[0,1]^*_+$ itself ??

Seems to be ... wrong ...????

It implies that $\mathrm{KK}(\mathcal{C};\, \mathrm{C}[0,1], \mathbb{C}) = \mathrm{KK}(\mathrm{C}[0,1], \mathbb{C}) \cong \mathbb{Z}$ and then for all non-degenerate point-norm m.o.c. cones $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ and, – as we see later – that

$$\mathrm{KK}(\mathcal{C}[0,1]\,;\; A, B[0,1]) \cong \mathrm{KK}(\mathcal{C}\,;\; A, B)$$

via any of the evaluation maps $\{V_t\} \in \mathcal{C}[0,1] \to V_0 \in \mathcal{C}$ and $\{b(t)\} \in B[0,1] := \mathrm{C}([0,1], B) \mapsto b(0) \in B$.

(Compare Definition 3.6.16 for the notations.)

For our later applications on the study of $\mathrm{KK}(\mathcal{C}; A, B)$ and $\mathrm{Ext}(\mathcal{C}; A, B)$ in the trivially graded cases, we need only the below listed cases (I) and (II), where the graded tensor products of algebras and the outer graded tensor-products of its Hilbert modules become naturally isomorphic to the usual spatial C^*-algebra- and Hilbert module- tensor products, then with grading automorphisms on the tensor product given by the tensor product of the grading automorphisms:

(I) A and B are graded, $\mathcal{C} \circ \beta_A \subseteq \mathcal{C}$ and $\beta_B \circ \mathcal{C} \subseteq \mathcal{C}$,
and C, D are trivially graded separable nuclear algebras.

(II) A and B are trivially graded and C, D are graded separable nuclear algebras.

In case (I) we need only $\mathrm{C}[0,1]$, $\mathrm{C}_0(\mathbb{R}_+)$, $\mathrm{C}_0(\mathbb{R})$, $\mathrm{C}_0(\mathbb{R}^2)$, $\mathbb{C}$ and $\mathbb{K}$ in place of C or D for our applications, and in case of (II) the later application for the proofs of Theorems **??** require only the cases $(C, D) = (\mathbb{C}_{(1)}, \mathrm{C}_0(\mathbb{R}))$ and $(C, D) = (\mathrm{C}_0(\mathbb{R}), \mathbb{C}_{(1)})$.

The below given construction of the group morphisms

$$\tau_B\colon \mathrm{KK}(C, D) \to \mathrm{KK}(\mathrm{CP}_{\mathrm{in}}(B, B) \otimes \mathrm{CP}(C, D)\,;\; B\widehat{\otimes}C, B\widehat{\otimes}D)$$

becomes natural for all graded B, C and D.

In general, $A\widehat{\otimes}\mathbb{C}_{(1)} \cong A \rtimes_\beta \mathbb{Z}_2 \subseteq A \otimes M_2$ for the $\mathbb{Z}_2$-action defined by the β and with grading $\beta \circ \widehat{\beta}$ on $A \rtimes_\beta \mathbb{Z}_2$ on the right side, where $\widehat{\beta}$ is just the dual $\mathbb{Z}_2$-action on $A \rtimes_\beta \mathbb{Z}_2$ of the action $\beta\colon \mathbb{Z}_2 \to \mathrm{Aut}(A)$. It is a C^*-morphism that maps $a \in A$ to $a \in A$ and $\varepsilon := (1, -1)$ to the $\mathbb{Z}_2$-generator in $\mathbb{Z}_2 \subseteq \mathcal{M}(A \rtimes_\beta \mathbb{Z}_2)$. In the special case $\mathcal{C} = \mathrm{CP}_{\mathrm{rn}}(X;\, A, B) := \mathrm{CP}_{\mathrm{rn}}(X;\, \Psi_A, \Psi_B;\, A, B)$ we define a matrix o.c. cone by

$$\mathcal{C}_{C,D} := \mathrm{CP}_{\mathrm{rn}}(X\,;\; A\,\widehat{\otimes}\, C\,,\; B\,\widehat{\otimes} D) := \mathrm{CP}_{\mathrm{rn}}(X;\, \Psi_{A\widehat{\otimes}C}, \Psi_{B\widehat{\otimes}D})$$

for the actions $\Psi_{A\widehat{\otimes}C}(U) := \Psi_A(U)\widehat{\otimes}C$ with $U \in \mathbb{O}(X)$ and (similar) $\Psi_{B\widehat{\otimes}F}$ For simplicity, we assume here that actions Ψ_A and Ψ_B are invariant under the gradings on A and B, e.g. $\beta_A(\Psi_A(U)) = \Psi_A(U)$ for $U \in \mathbb{O}(X)$.

We know from Chapter 3 that for *nuclear* C and D, a c.p. map $V \in \mathrm{CP}(A\,\widehat{\otimes}\, C\,,\; B\,\widehat{\otimes}\, D)$ is in $\mathcal{C}_{C,D} := \mathcal{C}\widehat{\otimes}\, \mathrm{CP}(C, D)$ if and only if

$$a \in A \mapsto (\mathrm{id}_B \,\widehat{\otimes} \rho)(V(a\widehat{\otimes}e)) \in B$$

is in $\mathcal{C}$ for each $e \in C_+$ with $\beta_C(e) = e$ and for each positive functional $\rho \in D^*$ with $\rho \circ \beta_D = \rho$:
See Proposition **??** for the case of trivially graded C and D. The graded case can be reduced to the case of an even grading by the embedding of C and D into $C \rtimes \mathbb{Z}_2$ respectively $D \rtimes \mathbb{Z}_2$ (with the grading given by the self-adjoint unitary that generates the copy of $\mathbb{Z}_2$ in $\mathcal{M}(C \rtimes \mathbb{Z}_2)$). Then the arguments are similar to those in the proof of Proposition **??** (using that the point-norm closed m.o.c. cones are just the point-norm closed convex cones that are hereditary in $\mathrm{CP}(A\widehat{\otimes}C, B\widehat{\otimes}D)$, then properties of hereditary cones).

In case $C := \mathbb{C}$, $D := C_0(Y)$ (with Y a locally compact Hausdorff space), a map $V \in \mathrm{CP}(A, \mathrm{C}_0(Y, B))$ is in $\mathcal{C}_{C,D}$, if and only if, there is a point-strongly continuous map $W\colon y \in Y \mapsto \mathrm{CP}(A, B) \subseteq \mathcal{L}(A, B)$ with $W(y) \in \mathcal{C}$, the map $y \mapsto \|W(y)(a)\|$ is in $\mathrm{C}_0(Y)$ for every $a \in A$ and $W(y)(a) = V(a)(y)$. In this case we write also $\mathcal{C}(Y)$ ($\mathcal{C}[Y]$ or simply $\mathcal{C}$) if $\mathcal{C}_{C,D} = \mathcal{C} \otimes \mathrm{CP}(\mathbb{C}, \mathrm{C}_0(Y))$ for $C = \mathbb{C}$ and $D = \mathrm{C}_0(Y)$. Thus, the extensions $\mathcal{C} \curvearrowright \mathcal{C}_{C,D}$ are rather natural ([4]). $\mathrm{KK}_{\mathrm{nuc}}$-theory is the special case of $\mathrm{KK}(\mathcal{C};\, \cdot, \cdot)$-theory where $\mathcal{C} = \mathrm{CP}_{\mathrm{nuc}}(A, B)$,

Check if this is equivalent to the Def. of Skandalis [726]

and it is the special case of $\mathrm{KK}(X;\, \cdot, \cdot)$-theory where X is a singleton, i.e., $X = \{p\}$ with action on A given by $\Psi_A(\emptyset) = 0$, $\Psi_A(\{p\}) = A$ (and similar on B). In the same way $\mathrm{Ext}_{\mathrm{nuc}}(\cdot, \cdot)$ is a special case of $\mathrm{Ext}_{\mathrm{nuc}}(X;\, \cdot, \cdot)$ or of $\mathrm{Ext}(\mathcal{C};\, \cdot, \cdot)$. If A is separable and B is nuclear and separable, then $\mathrm{KK}(\mathcal{C};\, A, B) = \mathrm{KK}_{\mathrm{nuc}}(X;\, A, B)$ for $\mathcal{C} := \mathrm{CP}_{\mathrm{rn}}(X;\, A, B)$

read again !!!!!! more precise? ??

(where X and non-degenerate actions Ψ_A and Ψ_B of X on A and B are given) and $X := \mathrm{Prim}(B)$, with natural action on B and lower semi-continuous action of $\mathrm{Prim}(B)$ defined by a "universal" Hilbert A-B-module $H_0\colon A \to \mathcal{L}(\mathcal{H}_B)$ (as defined in Chapters 3 and 5, where we have to use that the corresponding cone is separating and non-degenerate by the existence of a *regular* Abelian subalgebra in B (in the sense of Definition B.4.1) using [**464**] and [**359**]).

A triple $\mathcal{E} = (E, \phi, F)$ is called a **Kasparov module** (more precisely: Kasparov (A, B)–module) if E is a graded right Hilbert B-module that is *countably generated* over B, $\phi\colon A \to \mathcal{M}(\mathbb{K}(E)) \cong \mathcal{L}(E)$ is a grading preserving C^*-morphism, and $F \in \mathcal{L}(E)$ is an operator of degree 1 such that $F\phi(a) - \phi(\beta_A(a))F$ ([5]), $(1 - F^2)\phi(a)$ and $(F^* - F)\phi(a)$ are in $\mathbb{K}(E)$ for every $a \in A$. The Kasparov module (E, ϕ, F) is **degenerate** if $F\phi(a) - \phi(\beta_A(a))F$, $(1 - F^2)\phi(a)$ and $(F^* - F)\phi(a)$ are all zero.

If the B-module E is trivially graded, then this definition implies that $F = 0$ and $\phi(A) \subseteq \mathbb{K}(E)$ and that $(E, 0, 0)$ is the only degenerate Kasparov module.

The Kasparov module $\mathcal{E} = (E, \phi, F)$ is **isomorphic** to $\mathcal{E}' = (E', \phi', F')$ (denoted by $\mathcal{E}' \approx_u \mathcal{E}$) if there is an isometric B-module map $U\colon E \to E'$ from E onto E' such that $U\beta_E = \beta_{E'}U$ (i.e., U is of even degree), $\phi'(\cdot)U = U\phi(\cdot)$ and $F'U = UF$. It is easy to see that the isometric B-module morphism U preserve the values of the B-valued hermitian form: $\langle Ux, Uy \rangle = \langle x, y \rangle$ for $x, y \in E$. By definition, the Kasparov modules $\mathcal{E}$ and $\mathcal{E}'$ are **unitary equivalent** if they are isomorphic in this way.

The **sum** $\mathcal{E}' \oplus \mathcal{E}$ of Kasparov A-B-modules $\mathcal{E}'$ and $\mathcal{E}$ is defined by the B-module sum

$$\mathcal{E}' \oplus \mathcal{E} := (E' \oplus_B E, \phi' \oplus \phi, F' \oplus F).$$

A Kasparov module (E_1, ϕ_1, F_1) is a **compact perturbation** of the Kasparov module (E, ϕ, F) if $E_1 = E$, $\phi_1 = \phi$ and $(F - F_1)\phi(a)$ is in $\mathbb{K}(E)$ for every $a \in A$. It suffices here to consider only $a \in A$ of degree $\partial(a) = 0$, because it is obvious that

---

[4] See Chapter 3 for a Definition of tensor products of matrix operator-convex cones. We write also $\mathcal{C}$ instead of $\mathcal{C}_{C,D}$ to relax notation.

[5] Because $\partial(F) = 1$, $F\phi(a) - \phi(\beta_A(a))F = [F, \phi(a)]_{gr}$ for the graded commutator $[\cdot, \cdot]_{gr}$.

$A^{(0)}$ contains an approximate unit of A. Occasionally we use then the terminology "**ϕ-compact perturbation**" to underline the difference to perturbations by elements of $\mathbb{K}(E)$, or by generalized "compact" operators on the Banach space E.

The equivalence relation $\sim_{scp}$ which is generated by (unitary) isomorphisms and compact perturbations is compatible with the addition of Kasparov modules. Therefore the addition ?????? defines on the $\sim_{scp}$-classes of Kasparov modules the structure of a semigroup $\mathbb{E}(A, B)/\sim_{scp}$. The relation $\sim_{cp}$ of [**73**, def.17.2.4] is weaker, because the $\sim_{cp}$-classes allow addition of degenerate Kasparov modules. But $\sim_{cp}$ and $\sim_{scp}$ generate the same "stable" relation on $\mathbb{E}(A, B)$.

2. Isomorphism of Ext($\mathcal{C}$; A, B) and KK($\mathcal{C}$; $A, B_{(1)}$)

Notice that the below considered natural map from KK($\mathcal{C}$; $A, B_{(1)}$) to Ext($\mathcal{C}$; A, B)

`Or: from` Ext($\mathcal{C}$; A, B) `to` KK($\mathcal{C}$; $A, B_{(1)}$)?

becomes in general only in the special case of separable trivially graded A and trivially graded σ-unital B an isomorphism.

The here first considered algebras $A, A_1, \ldots, B, C, D, \ldots$ are σ-unital C^*-algebras. We start with some general considerations that require to consider also graded algebras. Thus, the algebras may have grading automorphisms $\beta_A, \beta_{A_1}, \ldots, \beta_B, \ldots$, and then we require that $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ is a point-norm closed matrix operator-convex cone with $\beta_B \circ \mathcal{C} \circ \beta_A \subseteq \mathcal{C}$ (cf. Chapter 3, Section on m.o.c.c. operations and equivariant m.o.c. cones **??** for notations).

Definition 8.2.1. A Kasparov module $(E, \phi, F) \in \mathbb{E}(A, B)$ is called **nuclear** (respectively **Ψ-residually nuclear**, **$\mathcal{C}$-compatible**) if the C^*-morphism

$$\phi \colon A \to \mathcal{M}(\mathbb{K}(E)) = \mathcal{L}(E)$$

is weakly *nuclear* in the sense Definition B.7.6 (respectively is weakly Ψ-*residually nuclear*, respectively is weakly $\mathcal{C}$-*compatible*). Equivalently, this means that the c.p. maps $a \in A \mapsto \langle \phi(a)x, x\rangle \in B$ are *nuclear* (respectively are Ψ-residually nuclear, respectively are in $\mathcal{C}$) for every $x \in E$.

In fact all KK-groups come from first selecting an m.o.c. cone $\mathcal{C}$ and then considering only the $\mathcal{C}$-compatible Kasparov modules, because $\mathrm{KK}(A, B) = \mathrm{KK}(\mathcal{C}\,;\ A, B)$ with $\mathcal{C} = \mathrm{CP}(A, B)$, $\mathrm{KK}_{\mathrm{nuc}}(A, B) = \mathrm{KK}(\mathrm{CP}_{\mathrm{nuc}}\,;\ A, B)$, $\mathrm{KK}(\Psi\,;\ A, B) = \mathrm{KK}(\mathrm{CP}(\Psi\,;\ A, B)\,;\ A, B)$, where $\mathrm{CP}(\Psi\,;\ A, B) \subseteq \mathrm{CP}(A, B)$ denotes the m.o.c. cone of Ψ-equivariant c.p. maps, and, finally, the Ψ-residually nuclear KK-groups are $\mathrm{KK}(\mathcal{C}\,;\ A, B)$ with m.o.c. cone $\mathcal{C}$ defined by the "Ψ-residually nuclear" maps

$$\mathcal{C} := \mathrm{CP}_{\mathrm{nuc}}(\Psi\,;\ A, B) \subseteq \mathrm{CP}(\Psi\,;\ A, B) \subset \mathrm{CP}(A, B)\,.$$

This theory can be considered as a refinement of the original Kasparov theory.

Examples of *nuclear* Kasparov (A, B)-modules (respectively of $\mathcal{C}$-compatible Kasparov modules) are the modules $(E, 0, F)$ for arbitrary Hilbert B-modules E

and arbitrary $F \in \mathcal{L}(E)$ of degree one, and the **difference construction** $(B, \phi, 0)$ for a *nuclear* C^*-morphism $\phi\colon A \to B$ (respectively for $\psi \in \mathrm{Hom}(A, B) \cap \mathcal{C}$), where B is considered as right B-module.

The category of *nuclear* (respectively of *$\mathcal{C}$-compatible*) Kasparov (A, B)-modules is invariant under Hilbert B-module addition, because

$$\phi \oplus \phi'\colon A \to \mathcal{M}\big(\mathbb{K}(E \oplus_B E')\big)$$

is again weakly nuclear (resp. is again weakly $\mathcal{C}$-compatible) if ϕ and ϕ' are weakly nuclear (resp. are weakly $\mathcal{C}$-compatible). If (E, ϕ, F) is nuclear (respectively $\mathcal{C}$-compatible) and $(E, \phi, F) \sim_{scp} (E', \phi', F')$, then (E', ϕ', F') is also nuclear (respectively $\mathcal{C}$-compatible). It follows that the $\sim_{scp}$-classes of *nuclear* (respectively $\mathcal{C}$-compatible) Kasparov A–B-modules build a sub-semigroup $\mathbb{E}_{\mathrm{nuc}}(A, B)/\sim_{scp}$ (respectively a sub-semigroup $\mathbb{E}(\mathcal{C};\, A, B)/\sim_{scp}$) of the semi-group $\mathbb{E}(A, B)/\sim_{scp}$ (with Hilbert B-module sum as addition).

Definition 8.2.2. We define the **nuclear Kasparov group** $\mathrm{KK}_{\mathrm{nuc}}(A, B)$ as the *Grothendieck group of* $\mathbb{E}_{\mathrm{nuc}}(A, B)/\sim_{scp}$:

$$\mathrm{KK}_{\mathrm{nuc}}(A, B) := \mathrm{KK}(\mathcal{C};\, A, B) = \mathrm{Gr}(\mathbb{E}_{\mathrm{nuc}}(A, B)/\sim_{scp}) = \mathrm{Gr}(\mathbb{E}(\mathcal{C};\, A, B)/\sim_{scp})\,,$$

for $\mathcal{C} := \mathrm{CP}_{nuc}(A, B)$. The more general **$\mathcal{C}$-equivariant Kasparov group** $\mathrm{KK}(\mathcal{C};\, A, B)$ is the *Grothendieck group of* of $\mathbb{E}(\mathcal{C};\, A, B)/\sim_{scp}$:

$$\mathrm{KK}_{\mathrm{nuc}}(A, B) := \mathrm{Gr}(\mathbb{E}(\mathcal{C};\, A, B)/\sim_{scp})\,.$$

The X-equivariant KK-groups and residually nuclear KK-groups are defined by

$$\mathrm{KK}(X;\, A, B) := \mathrm{KK}(\mathcal{C};\, A, B) \quad \text{for } \mathcal{C} := \mathrm{CP}(X;\, A, B)\,,$$

and

$$\mathrm{KK}_{\mathrm{nuc}}(X;\, A, B) := \mathrm{KK}(\mathcal{C};\, A, B) \quad \text{for } \mathcal{C} := \mathrm{CP}_{\mathrm{rn}}(X;\, A, B)\,.$$

More precisely, $\mathrm{KK}(X;\, A, B)$ and $\mathrm{KK}_{\mathrm{nuc}}(X;\, A, B)$ depend on the actions $\Psi_A\colon \mathbb{O}(X) \to \mathcal{I}(A)$ and $\Psi_B\colon \mathbb{O}(X) \to \mathcal{I}(B)$, that define the related point-norm closed m.o.c. cones $\mathrm{CP}(X, \Psi_A, \Psi_B;\, A, B)$ and $\mathrm{CP}_{\mathrm{rn}}(X, \Psi_A, \Psi_B;\, A, B)$, cf. Chapter 3. But there are other natural and functorial constructions of m.o.c. cones $\mathcal{C}$ from "actions" Ψ_A and Ψ_B of X on A and B. The m.o.c. cones $\mathrm{CP}_{\mathrm{rn}}(X, \Psi_A, \Psi_B;\, A, B) \subseteq \mathrm{CP}_{\mathrm{nuc}}(A, B)$ of Ψ_A-Ψ_B–residually nuclear maps play an important role in our applications.

If A and B are trivially graded and if $h\colon A \to B \otimes \mathbb{K} = B \widehat{\otimes} \mathbb{K}$ is a *nuclear* C^*-morphism (respectively if $h \in \mathrm{Hom}(A, B \otimes \mathbb{K}) \cap \mathcal{C}$), we can define $[h - 0] \in \mathrm{KK}_{\mathrm{nuc}}(A, B)$ (respectively $[h - 0] \in \mathrm{KK}(\mathcal{C};\, A, B)$) as the class which is represented by the **difference construction**

$$(\mathcal{H}_B, h\colon A \to B \otimes \mathbb{K}, 0)\,,$$

where $\mathcal{H}_B$ denotes the Hilbert B-module

$$\mathcal{H}_B := \{(b_1, b_2, \ldots)\colon\, b_n \in B, \sum_n b_n^* b_n \in B\}.$$

with trivial grading, and where we use the natural isomorphism $B \otimes \mathbb{K} \cong \mathbb{K}(\mathcal{H}_B)$.

It can be shown (as in the non-nuclear theory) that the bi-functor $\mathrm{KK}_{\mathrm{nuc}}(A, B)$ is stable, and with help of Kasparov products, that our $\mathrm{KK}_{\mathrm{nuc}}$ groups are *homotopy invariant*, hence, are the same as the $\mathrm{KK}_{\mathrm{nuc}}$-groups of Skandalis [**726**] (at least if A is exact). Therefore, they satisfy variants of *Bott Periodicity, 6-term exact sequences for semi-split exact sequences, ...* But in case of the $\mathrm{KK}(\mathcal{C};\, \cdot, \cdot)$-theory the situation is more complicate, because this are in essence functors from a "category" of point-norm closed m.o.c. cones $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ into Abelian groups, and the C^*-algebras play only a formal role as a sort of indices.

The way to homotopy invariance for *our* functors $\mathrm{KK}_{\mathrm{nuc}}(A, B) := \mathrm{KK}(\mathcal{C};\, A, B)$ in case that $\mathcal{C} := \mathrm{CP}_{\mathrm{nuc}}(A, B)$ and the much more general $\mathrm{KK}(\mathcal{C};\, A, B)$ is the following:
Our definitions of $\mathrm{KK}_{\mathrm{nuc}}(A, B)$ is the *weakly nuclear* variant (respective $\mathcal{C}$-compatible variant) of the cobordism-class $\sim_c$ definition for KK, cf. [**73**, defs. 17.2.4, 17.3.1, 17.10.2]. Indeed, weakly *nuclear* (respectively $\mathcal{C}$-*compatible*) Kasparov modules $\mathcal{E}_1$ and $\mathcal{E}_2$ define the same element of $\mathrm{KK}_{\mathrm{nuc}}(A, B)$, if and only if, there exists a *nuclear* (respectively $\mathcal{C}$-*compatible*) Kasparov module $\mathcal{E}_3$ such that $\mathcal{E}_1 \oplus \mathcal{E}_3$ is isomorphic to a compact perturbation of $\mathcal{E}_2 \oplus \mathcal{E}_3$. This is the equivalence relation $\sim_c$ of [**73**, def. 17.2.4] (in case where $\mathcal{C} := \mathrm{CP}(A, B)$). More precisely, the relation $\sim_c$ in [**73**] is the stabilization of the relation $\sim_{cp}$ that allows also addition of degenerate elements. "Degenerate" Kasparov modules become zero even for the stabilization of the relation $\approx_u$ of unitary equivalence in [**73**, def.17.2.1], but here automatic *inside* $\mathbb{E}_{\mathrm{nuc}}(A, B)$ (respectively inside the semigroup $\mathbb{E}(\mathcal{C};\, A, B)$): The difference between the *nuclear* (respectively our more general $\mathcal{C}$-compatible) case and the usual KK-theory relation $\sim_c$ is, that the added module $\mathcal{E}_3$ has to be a *nuclear* (respectively a $\mathcal{C}$-compatible) Kasparov module as well.

We say that Kasparov modules (E, ϕ, F_0) and (E, ϕ, F_1) are **operator homotopic** if there exists a norm-continuous map $t \in [0, 1] \mapsto F(t) \in \mathcal{L}(E)$ such that $F(0) = F_0$, $F(1) = F_1$ and that $(E, \phi, F(t))$ is a Kasparov module for every $t \in [0, 1]$.

The same arguments as in [**73**, sec. 17.10] show that operator homotopic *nuclear* (respectively $\mathcal{C}$-compatible) Kasparov modules define the same element of *our* group $\mathrm{KK}_{\mathrm{nuc}}(A, B)$ (respectively of $\mathrm{KK}(\mathcal{C};\, A, B)$).

The result that operator homotopic $\mathcal{C}$-compatible Kasparov modules are stably equivalent, implies that the Kasparov product is well-defined and is invariant under operator homotopy. In fact, the proofs in [**73**] or in [**389**, sec. 2.2] show that Kasparov products $\mathcal{E}_1 \otimes \mathcal{E}_2$ of representatives $\mathcal{E}_1$ and $\mathcal{E}_2$ of elements $[\mathcal{E}_1] \in \mathrm{KK}_{\mathrm{nuc}}(B, C)$ and $[\mathcal{E}_2] \in \mathrm{KK}(C, D)$ define up to operator homotopy an element of $\mathrm{KK}_{\mathrm{nuc}}(B, C)$ if B and C are separable. One has also that the Kasparov product defines a bi-additive map

$$\mathrm{KK}(A, B) \times \mathrm{KK}_{\mathrm{nuc}}(B, C) \to \mathrm{KK}_{\mathrm{nuc}}(A, C)$$

for σ-unital A, B and C and separable B. Its values are in $\mathrm{KK}_{\mathrm{nuc}}(B, D)$ respectively $\mathrm{KK}_{\mathrm{nuc}}(A, C)$, and if $A = B$ or $D = C$ the multiplication with $[\mathrm{id}_B - 0]$ or $[\mathrm{id}_C - 0]$

gives the identity homomorphism of $\mathrm{KK}_{\mathrm{nuc}}(B, C)$. Therefore, *our* $\mathrm{KK}_{\mathrm{nuc}}$-functor *is homotopy* invariant and coincides with the $\mathrm{KK}_{\mathrm{nuc}}$-functor of Skandalis [**726**].
There are natural homomorphisms from $\mathrm{KK}_{\mathrm{nuc}}(A, B)$ into $\mathrm{KK}(A, B)$, as the definition tells us ([6]).
Certainly, $\mathrm{KK}_{\mathrm{nuc}}(A, B) = \mathrm{KK}(A, B)$ if A or B is nuclear, because then every Kasparov (A, B)-module is nuclear.

We outline now the changes of the Kasparov approach, that are necessary in the case of $\mathrm{KK}(\mathcal{C};\, A, B)$. Recall the other equivalence relations $\sim_c$, $\sim_{cp}$, $\sim_s$, $\sim_{soh}$, $\sim_{oh}$ and $\sim_h$ and on $\mathbb{E}(\mathcal{C};\, A, B)$ that are defined as in [**73**, chp. 17] on all elements of $\mathbb{E}(A, B)$ by

($\sim_{cp}$:) $\mathcal{E}_0 \sim_{cp} \mathcal{E}_1$ if there are *degenerate* $\mathcal{E}_2, \mathcal{E}_3 \in \mathbb{E}(\mathcal{C};\, A, B)$, such that $\mathcal{E}_0 \oplus \mathcal{E}_2 \sim_{scp} \mathcal{E}_1 \oplus \mathcal{E}_3$.

($\sim_c$:) $(E_0, \phi_0, F_0) \sim_c (E_1, \phi_1, F_1)$ if $[(E_0, \phi_0, F_0)] = [(E_1, \phi_1, F_1)]$ in

$$\mathrm{KK}(\mathcal{C};\, A, B) = \mathrm{Gr}(\mathbb{E}(\mathcal{C};\, A, B)/\sim_{scp})\,.$$

`In [73, chp. 17]: ''stabilized version of` $\sim_{cp}$`''`

($\sim_{soh}$:) $(E_0, \phi_0, F_0) \sim_{soh} (E_1, \phi_1, F_1)$ if there is a C^*-morphism $\psi\colon A \to \mathcal{L}(E)$ and an operator-norm continuous map $t \in [0, 1] \mapsto F(t) \in \mathcal{L}(E)$ such that $(E, \psi, F(t)) \in \mathbb{E}(\mathcal{C};\, A, B)$ for every $t \in [0, 1]$ and that (E_i, ϕ_i, F_i) is (unitarily) isomorphic to $(E, \phi, F(i))$ for $i = 0, 1$.

($\sim_{oh}$:) $(E_0, \phi_0, F_0) \sim_{oh} (E_1, \phi_1, F_1)$ if there are *degenerate* $\mathcal{E}_2, \mathcal{E}_3 \in \mathbb{E}(\mathcal{C};\, A, B)$, a Hilbert B-module E, a C^*-morphism $\psi\colon A \to \mathcal{L}(E)$ and a norm-continuous map $t \in [0, 1] \mapsto F(t) \in \mathcal{L}(E)$ such that $(E, \psi, F(t)) \in \mathbb{E}(\mathcal{C}\,;\, A, B)$ for every $t \in [0, 1]$ and that $(E_i, \phi_i, F_i) \oplus \mathcal{E}_{i+2}$ is (unitarily) isomorphic to $(E, \phi, F(i))$ for $i = 0, 1$.

($\sim_h$:) It is the equivalence relation that is *generated* by the reflexive, but not necessarily transitive ???, relation $\sim_{h_0}$:
$(E_0, \phi_0, F_0) \sim_{h_0} (E_1, \phi_1, F_1)$ if there exists

$$(E, \psi, F) \in \mathbb{E}(\mathcal{C} \otimes \mathrm{CP}(\mathbb{C}, \mathrm{C}[0, 1])\,;\, A,\, B \otimes \mathrm{C}([0, 1]))$$

such that (E_i, ϕ_i, F_i) is isomorphic to $(E(i), \psi_i, F(i))$ for $i = 0, 1$.

Straight calculations show that all this relations are *compatible with addition* in $\mathcal{E}(\mathcal{C};\, A, B)/\approx_u$.

The relation $\sim_{cp}$ is an equivalence relation on $\mathbb{E}(\mathcal{C};\, A, B)$, because the degenerate Kasparov modules in $\mathbb{E}(\mathcal{C};\, A, B)/\sim_{scp}$ build a sub-semigroup of $\mathbb{E}(\mathcal{C};\, A, B)/\sim_{scp}$.

The relation $\sim_{oh}$ is an equivalence relation, because the degenerate Kasparov modules in $\mathbb{E}(\mathcal{C};\, A, B)/\sim_{soh}$ build a sub-semigroup of $\mathbb{E}(\mathcal{C};\, A, B)/\sim_{soh}$.

[6] We don't know if this homomorphisms are injective in general and if their images are naturally complemented in $\mathrm{KK}(A, B)$.

Notice that the Kasparov module (E, ψ, F) in the definition of $\sim_h$ can be considered as a "continuous" family $\{(E(t), \psi_t, F(t))\}_{0\leq t\leq 1}$ in $\mathbb{E}(\mathcal{C};\, A, B)$, if we consider the $B[0,1]$-module E as a complemented $B[0,1]$-submodule of $\widehat{\mathcal{H}}_{B[0,1]} \cong \mathrm{C}([0,1], \widehat{\mathcal{H}})$

but the unitary equivalences at the endpoints can not be specified ?????????

See proofs of part (vii) of Lemma 8.2.3.

Temporary, we define semi-groups

$$\mathrm{KK}_*(\mathcal{C};\, A, B) := \mathbb{E}(\mathcal{C};\, A, B)/\sim_*$$

for $* = h, oh, cp, c$.

Lemma 8.2.3. *Suppose that A and B are σ-unital and graded, $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ is countably generated point-norm closed operator convex cone, with $\mathcal{C} \circ \beta_A \subseteq \mathcal{C}$ and $\beta_B \circ \mathcal{C} \subseteq \mathcal{C}$.*

Then:

(i) *The unitary equivalence classes $\mathbb{E}(\mathcal{C};\, A, B)/\approx_u$ build an Abelian semi-group under addition of Kasparov modules.*

(ii) *The relations $\sim_h$, $\sim_{oh}$, $\sim_c$, $\sim_{cp}$, $\sim_{scp}$ and $\approx_u$ (respectively the relations $\sim_{oh}$, $\sim_{soh}$ and $\sim_{scp}$) are successively stronger, and are equivalence relations on $\mathbb{E}(\mathcal{C};\, A, B)$ that are all compatible with addition in $\mathbb{E}(\mathcal{C};\, A, B)/\approx_u$.*

Thus, the set of equivalence classes $\mathbb{E}(\mathcal{C};\, A, B)/\sim_*$ are semi-groups, and there are natural semi-group epimorphisms from $\mathbb{E}(\mathcal{C};\, A, B)/\approx_u$ onto $\mathbb{E}(\mathcal{C};\, A, B)/\sim_*$ for each of the above listed equivalence relation $\sim_*$.

If $\mathcal{C}' \subseteq \mathcal{C}$, then there are natural morphisms from $\mathbb{E}(\mathcal{C}';\, A, B)/\sim_*$ into $\mathbb{E}(\mathcal{C};\, A, B)/\sim_*$.

(iii) *$\mathrm{KK}_*(\mathcal{C};\, A, B) := \mathbb{E}(\mathcal{C};\, A, B)/\sim_*$ are groups for $* = oh, h$ and there are natural semigroup epimorphisms*

$$\mathrm{KK}_c(\mathcal{C};\, A, B) \to \mathrm{KK}_{oh}(\mathcal{C};\, A, B) \to \mathrm{KK}_h(\mathcal{C};\, A, B)\,.$$

The natural epimorphism $\mathbb{E}(\mathcal{C};\, A, B)/\sim_{scp} \to \mathbb{E}(\mathcal{C};\, A, B)/\sim_{cp}$ defines a group isomorphism $\mathrm{Gr}(\mathbb{E}(\mathcal{C};\, A, B)/\sim_{scp}) \cong \mathrm{Gr}(\mathbb{E}(\mathcal{C};\, A, B)/\sim_{cp})$.

$\mathrm{KK}_c(\mathcal{C};\, A, B)$ is a sub-semigroup of $\mathrm{Gr}(\mathbb{E}(\mathcal{C};\, A, B)/\sim_{cp}))$, and the kernel of $\mathrm{KK}_c(\mathcal{C};\, A, B) \to \mathrm{KK}_{oh}(\mathcal{C};\, A, B)$ consists of the classes $[(E, \phi, F)]_c$ such that there is a degenerate element $(E_0, \phi_0, F_0) \in \mathbb{E}(\mathcal{C};\, A, B)$ with $(E, \phi, F) \oplus (E_0, \phi_0, F_0) \sim_{soh} (E_0, \phi_0, F_0)$.

(iv) *If $f \in \mathrm{Hom}(B, C)$ is a grading preserving epimorphism, let $f_*\mathcal{C} := \mathcal{C}(f)\circ\mathcal{C}$ the point-norm closed matrix operator-convex cone generated by $f \circ \mathcal{C} := \{f \circ V\,;\ V \in \mathcal{C}\}$. Then*

$$f_*[(E, \phi, F)] := [(E\widehat{\otimes}_f C, \phi(\cdot)\widehat{\otimes}_f 1, F\widehat{\otimes}_f 1)]$$

defines semigroup morphism $f_*\colon \mathbb{E}(\mathcal{C}\,;\, A, B)/\approx_u \to \mathbb{E}(f_*\mathcal{C}\,;\, A, C)/\approx_u$ *that is compatible with all relations* $\sim_*$.

(v) *If* $g \in \mathrm{Hom}(D, A)$ *is grading preserving let* $g^*\mathcal{C} := \{V \in \mathrm{CP}(D, B)\,;\ V \circ g \in \mathcal{C}\}$, *then*

$$g^*[(E, \phi, F)] := [(E, \phi \circ g, F)]$$

defines semigroup morphism $g^*\colon \mathbb{E}(g^*\mathcal{C}\,;\, D, B)/\approx_u \to \mathbb{E}(\mathcal{C}\,;\, A, B)/\approx_u$ *that is compatible with all relations* $\sim_*$.

(vi) *Let* $\mathrm{CP_{in}}(B, B) \subseteq \mathrm{CP}(B, B)$ *denote the cone of all approximately inner c.p. maps of* B.

If C *and* D *are separable nuclear graded* C^**-algebras, then the map*

$$[(E, \phi, F)] \mapsto \big[(B \widehat{\otimes} E, id_B \widehat{\otimes} \phi, 1 \widehat{\otimes} F)\big]$$

maps $\mathbb{E}(C, D)/\approx_u$ *into* $\mathbb{E}(\mathrm{CP_{in}}(B, B) \widehat{\otimes}\, \mathrm{CP}(C, D);\ B \widehat{\otimes} C,\ B \widehat{\otimes} D)$ *and defines a morphism*

$$\tau_B\colon\ \mathrm{KK}(C, D) \to \mathrm{KK}_{oh}(\mathrm{CP_{in}}(B, B) \widehat{\otimes}\, \mathrm{CP}(C, D);\ B \widehat{\otimes} C, B \widehat{\otimes} D)$$

with $\tau_B([k - 0]) = [(\mathrm{id}_B \widehat{\otimes} k) - 0]$ *for grading preserving* $k \in \mathrm{Hom}(C, D)$.

In particular, $[\chi_t] = [\chi_t - 0] \in \mathrm{KK}(\mathrm{C}([0, 1]), \mathbb{C})$ *for* $\chi_t(f) := f(t)$ *maps to*

$$\tau_B([\chi_t]) = [\chi_t^B] \in \mathrm{KK}_{oh}(\mathrm{CP_{in}}(B, B) \widehat{\otimes}\, \mathrm{CP}(\mathrm{C}[0, 1], \mathbb{C});\ B \widehat{\otimes}\, \mathrm{C}([0, 1]), B)\,,$$

where χ_t^B *denotes the epimorphism* $\chi_t^B\colon f \in \mathrm{C}([0, 1], B) \mapsto f(t) \in B$ *(*$t \in [0, 1]$*).*

Since $[\chi_t] = [\chi_0]$ *by* [**73**, lem.18.5.2]*,it follows that* $[\chi_0^B] = [\chi_t^B]$ *for* $t \in [0, 1]$.

(vii) *Let* $\widehat{\mathcal{H}}_B := \mathcal{H}_B \oplus_B \mathcal{H}_B$ *with grading* $\beta_\infty \oplus (-\beta_\infty)$*, where* $\beta_\infty(x_1, x_2, \ldots) := (\beta_B(x_1), \beta_B(x_2), \ldots)$ *for* $(x_1, x_2, \ldots) \in \mathcal{H}_B \cong (B \otimes \mathbb{K})(1 \otimes p_{11})$.

There is a construction $\lambda =: \lambda_B$ *that assigns to each class* $[\mathcal{E}] = [(E, \phi, F)] \in \mathbb{E}(\mathcal{C};\, A, B)/\approx_u$ *a special class* $\lambda([\mathcal{E}]) \in \mathbb{E}(\mathcal{C};\, A, B)/\approx_u$ *that has representative* $(\widehat{\mathcal{H}}_B, \psi, U)$ *with* $U = U^* = U^{-1}$*, such that* λ *is additive,* $\mathcal{E} \sim_{cp} \lambda(\mathcal{E})$ *in* $\mathbb{E}(\mathcal{C};\, A, B)$*,* $\lambda(\mathcal{E})$ *is degenerate if* $\mathcal{E}$ *is degenerate,* $\lambda(\mathcal{E}_1) \sim_{scp} \lambda(\mathcal{E}_2)$ *if* $\mathcal{E}_1 \sim_{scp} \mathcal{E}_2$*, and* $\mathcal{E} = (E, \phi, F) \in \mathbb{E}(\mathcal{C}[0, 1];\, A, B[0, 1])$ *implies*

$$(p_t)_*(\lambda_{B[0,1]}[\mathcal{E}]) = \lambda_B((p_t)_*[\mathcal{E}])\,.$$

Moreover, if $E \cong \widehat{\mathcal{H}}_B$ *then* ψ *is unitarily equivalent to* $\phi \oplus 0$ *by an unitary* $W \in \mathcal{L}(\widehat{\mathcal{H}}_B)$ *of degree zero, and, if* $F = F^* = F^{-1}$ *then* $\lambda(\widehat{\mathcal{H}}_B\,, \phi, F)$ *is isomorphic to* $(\widehat{\mathcal{H}}_B\,, \phi \oplus_{s,t} 0, F \oplus_{s,t} (-F))$ *for (any) isometries* $s, t \in \mathcal{L}(\widehat{\mathcal{H}}_B)$ *of even degree.*

In particular, all equivalence-operations for the relations $\sim_*$ *can be elaborated inside the class of special Kasparov modules* $(\widehat{\mathcal{H}}_B, \psi, F)$ *with* $F = F^* = F^{-1}$.

(viii) *If* $\mathcal{M}(B)$ *contains isometries* s, t *of even degree with* $ss^* + tt^* = 1$*, then addition in* $\mathbb{E}(\mathcal{C};\, A, B)/\approx_u$ *is compatible with*

$$\epsilon\colon B \oplus_\infty B \to B\,,\quad \epsilon(a, b) \mapsto sas* + tbt^*\,,$$

i.e., the composition $\epsilon^* \circ \Sigma$ *of the map*

$$\Sigma\colon [\mathbb{E}(A,B)] \times [\mathbb{E}(A,B)] \to [\mathbb{E}(A, B\oplus B)]$$

given by

$$\Sigma\colon ((E_1,\phi_1,F_1),(E_2,\phi_2,F_2)) \mapsto (E_1 \oplus_\infty E_1, \phi_1(\cdot)\oplus\phi_2(\cdot), F_1\oplus F_2)$$

with ϵ^* *defines the addition in* $\mathbb{E}(A,B)/\!\approx_u$*. In particular,* $2[\mathcal{E}] = \delta^*[\mathcal{E}]$ *in* $\mathbb{E}(\mathcal{C};\, A,B)/\approx_u$ *for* $\mathcal{E}\in\mathbb{E}(\mathcal{C};\, A,B)$ *and* $\delta(b) := sbs^* + tbt^*$*.*

Proof. (i): The unitary equivalence classes $\mathbb{E}(\mathcal{C};\, A,B)/\approx_u$ build an Abelian semigroup under addition of Kasparov modules, because $\mathbb{E}(A,B)/\approx_u$ is an Abelian semigroup (is in particular a *set*), the sum of $\mathcal{C}$-compatible Kasparov (A,B)-modules is $\mathcal{C}$-compatible, and the class of $\mathcal{C}$-compatible Kasparov modules is invariant under unitary equivalence.

(ii): It is easy to check that $\approx_u$, $\sim_{scp}$ and $\sim_{soh}$ are equivalence relations on $\mathbb{E}(\mathcal{C}\,;\, A,B)$ that are compatible with sums of Kasparov modules.

If $(E,\phi,F')\in\mathbb{E}(A,B)$ is a ϕ-compact perturbation of $(E,\phi,F)\in\mathbb{E}(\mathcal{C};\, A,B)$, then $(E,\phi,F(t))$ is in $\mathbb{E}(\mathcal{C};\, A,B)$ for $F(t) := tF + (1-t)F'$, thus $(E,\phi,F')\sim_{soh}$ (E,ϕ,F) in $\mathbb{E}(\mathcal{C};\, A,B)$, i.e., $\sim_{scp}$ is stronger than $\sim_{soh}$ on $\mathbb{E}(\mathcal{C};\, A,B)$.

Thus $\sim_{soh}$, $\sim_{scp}$ and $\approx_u$ are successively stronger equivalence relations $\sim_*$ on $\mathbb{E}(A,B)$ that are compatible with the property that $(E,\phi,F)\sim_* (E',\phi',F')$ and $(E,\phi,F)\in\mathbb{E}(\mathcal{C};\, A,B)$ implies $(E',\phi',F')\in\mathbb{E}(\mathcal{C};\, A,B)$.

It is easy to see, that the *infinite repeat* $\mathcal{E}_\infty := (E\otimes\ell_2;\, \phi(\cdot)\otimes 1, F\otimes 1)$ is a Kasparov (A,B)-module, if and only if, $\mathcal{E} = (E,\phi,F)$ is a *degenerate* Kasparov module. Then $\mathcal{E}_\infty\oplus\mathcal{E}\approx_u\mathcal{E}_\infty$, and $\mathcal{E}$ is a degenerate element in $\mathbb{E}(\mathcal{C};\, A,B)$ if and only if $\mathcal{E}_\infty$ is in $\mathbb{E}(\mathcal{C};\, A,B)$.

compare above and below! ??

Infinite (B-module) sums $(E,\phi,F)\oplus(E,\phi,F)\oplus\cdots\cong(\mathcal{H}\otimes E, 1\otimes\phi, 1\otimes F)$ of *degenerate* Kasparov modules $(E,\phi,F)\in\mathbb{E}(\mathcal{C};\, A,B)$ are degenerate Kasparov modules in $\mathbb{E}(\mathcal{C};\, A,B)$, and $(E,\phi,F)\oplus(\mathcal{H}\otimes E,1\otimes\phi,1\otimes F)$ is unitary isomorphic to $(\mathcal{H}\otimes E,1\otimes\phi,1\otimes F)$, i.e., $[(E,\phi,F)] = 0$ in $\mathrm{Gr}(\mathbb{E}(\mathcal{C};\, A,B)/\sim_{scp})$ Thus $\mathcal{E}\oplus(E,\phi,F)\sim_c\mathcal{E}$ for every $\mathcal{E}\in\mathbb{E}(\mathcal{C};\, A,B)$. If follows that $\sim_c$ is stronger than $\sim_{oh}$. Hence, there is a natural semigroup epimorphisms $\mathrm{KK}_c(\mathcal{C};\, A,B)\to\mathrm{KK}_{oh}(\mathcal{C};\, A,B)$.

Since the classes of degenerate modules in $\mathbb{E}(\mathcal{C};\, A,B)$ build the sub-semigroups of $\mathbb{E}(\mathcal{C};\, A,B)/\sim_{scp}$ and $\mathbb{E}(\mathcal{C};\, A,B)/\sim_{sop}$ of elements that are additively absorbed by some other element, we get that $\sim_{op}$ and $\sim_{cp}$ are successively stronger additive equivalence relations on $\mathbb{E}(\mathcal{C};\, A,B)$ that are weaker than $\sim_{sop}$ respectively $\sim_{scp}$. Furthermore, $\mathrm{KK}(\mathcal{C}\,;\, A,B) = \mathrm{Gr}(\mathbb{E}(\mathcal{C}\,;\, A,B)/\sim_{cp})$,

$$\mathrm{Gr}(\mathbb{E}(\mathcal{C}\,;\, A,B)/\sim_{soh}) = \mathrm{Gr}(\mathbb{E}(\mathcal{C}\,;\, A,B)/\sim_{oh})\,,$$

and there is semigroup monomorphism $\mathrm{KK}_c(\mathcal{C};\, A, B) \hookrightarrow \mathrm{KK}(\mathcal{C};\, A, B)$, and semigroup epimorphisms

$$\mathbb{E}(\mathcal{C};\, A, B)/\sim_{cp} \to \mathrm{KK}_c(\mathcal{C};\, A, B) \to \mathrm{KK}_{oh}(\mathcal{C};\, A, B)$$

and a semigroup morphism $\mathrm{KK}_{oh}(\mathcal{C};\, A, B) \to \mathrm{Gr}(\mathbb{E}(\mathcal{C};\, A, B)/\sim_{soh})$ such that its image generates $\mathrm{Gr}(\mathbb{E}(\mathcal{C};\, A, B)/\sim_{soh})$. All its images are sub-semigroups that generate the groups.

??????????????????????

The relation $\sim_{soh}$ is stronger than $\sim_{oh}$ by definition, and $\mathrm{KK}_{oh}(\mathcal{C};\, A, B) = \mathbb{E}(\mathcal{C};\, A, B)/\sim_{oh}$ is a group ???? (if we include unitary equivalence and calculate modulo addition of a degenerate module in $\mathbb{E}(\mathcal{C};\, A, B)$), because $\sim_{oh}$ is compatible with unitary equivalence, compact perturbation and addition of degenerate elements.

???????????????????.

??

The relation $\sim_h$ is an equivalence relation, because homotopy $\sim_{h_0}$ is reflexive and $\approx_u$ is an equivalence relation. Since homotopy "inside" $\mathbb{E}(\mathcal{C};\, A, B)$ are additive as elements of $\mathbb{E}(\mathcal{C} \otimes \mathrm{CP}(\mathbb{C}, \mathrm{C}[0,1]);\, A, B \otimes \mathrm{C}[0,1])$, and since unitary equivalence is compatible with addition of Kasparov modules, we get that $\sim_h$ is compatible with addition in $\mathbb{E}(\mathcal{C};\, A, B)/\approx_u$. Thus $\mathrm{KK}_h(\mathcal{C};\, A, B) := \mathbb{E}(\mathcal{C};\, A, B)/\sim_h$ is a commutative semi-group.

The relation $\sim_{soh}$ is stronger than $\sim_h$ on $\mathbb{E}(\mathcal{C};\, A, B)$, because an operator homotopy $t \mapsto (E, \phi, F(t))$ in $\mathbb{E}(\mathcal{C};\, A, B)$ defines an element $(E \otimes \mathrm{C}[0,1], \phi(\cdot) \otimes 1, F)$ in $\mathbb{E}(\mathcal{C}([0,1]);\, A, \mathrm{C}([0,1], B))$ that defines a homotopy between $(E, \phi, F(0))$ and $(E, \phi, F(1))$. Here:

$$F := \{F(t)\} \in \mathrm{C}([0,1], \mathcal{M}(\mathbb{K}(E))) \subseteq \mathrm{C}_{\mathrm{b,st}}([0,1], \mathcal{M}(\mathbb{K}(E))) \cong \mathcal{L}(E \otimes \mathrm{C}[0,1])$$

By definition of the relation $\sim_{oh}$, $\mathcal{E} \sim_{oh} (\{0\}, 0, 0)$ if $\mathcal{E} \in \mathbb{E}(\mathcal{C}\,;\, A, B)$ is *degenerate*.

The same happens also for $\sim_h$, because the homotopy connecting degenerate $\mathcal{E} := (E, \phi, F) \in \mathbb{E}(A, B)$ and the 0-module $0 := (\{0\}, 0, 0)$, that is given the proof of [**73**, prop.17.2.3], is in $\mathbb{E}(\mathcal{C}([0,1]);\, A, \mathrm{C}([0,1, B))$ if $\mathcal{E} \in \mathbb{E}(\mathcal{C};\, A, B)$. Thus $\sim_{oh}$ is stronger than $\sim_h$.
Finally, there are natural semigroup epimorphisms

$$\mathbb{E}(\mathcal{C};\, A, B)/\approx_u \to \mathrm{KK}_c(\mathcal{C};\, A, B) \to \mathrm{KK}_{oh}(\mathcal{C}\,;\, A, B) \to \mathrm{KK}_h(\mathcal{C};\, A, B)\,.$$

If $(E, \phi, F) \in \mathbb{E}(\mathcal{C}\,;\, A, B)$ then $(E, \phi \circ \beta_A, -F) \in \mathbb{E}(\mathcal{C};\, A, B)$, because $\mathcal{C} \circ \beta_A \subseteq \mathcal{C}$ by our assumptions.

The sum $(E, \phi, F) \oplus (E, \phi \circ \beta_A, -F)$ is operator-homotopic to a degenerate element (cf. [**73**, prop.17.3.3]). Thus, the semigroups $\mathrm{KK}_{oh}(\mathcal{C}\,;\, A, B)$ and $\mathrm{KK}_h(\mathcal{C}\,;\, A, B)$ are groups, and the above natural semigroup morphism $\mathrm{KK}_{oh}(\mathcal{C}\,;\, A, B) \to \mathrm{Gr}(\mathbb{E}(\mathcal{C}\,;\, A, B)/\sim_{sop})$ is an isomorphism of groups.

`to be filled in: proof of 8.2.3`

Let $\sim_{soh}$ denote the equivalence relation generated by $\approx_u$ and operator homotopies $t \in [0,1] \mapsto (E, \phi, F(t)) \in \mathbb{E}(\mathcal{C}_2\,; B, C)$. Then $\sim_{soh}$ is compatible with addition and is stronger than $\sim_{oh}$.

Since $\mathrm{KK}_{oh}(\mathcal{C}\,; B, C) = \mathbb{E}(\mathcal{C}_2\,; B, C)/\sim_{oh}$ is a group, we get that there is a natural epimorphism from $\mathrm{Gr}(\mathbb{E}(\mathcal{C}_2\,; B, C)/\sim_{soh})$ onto $\mathrm{KK}_{oh}(\mathcal{C}; B, C)$. This must be an isomorphism, because $0 = [\mathcal{E}] \in \mathrm{Gr}(\mathbb{E}(\mathcal{C}_2\,; B, C)/\approx_u)$ for every "degenerate" $\mathcal{E} \in \mathbb{E}(\mathcal{C}_2\,; B, C)$.

If $\mathcal{C}_1 \subseteq \mathcal{C}_2$, then (obviously) $\mathbb{E}(\mathcal{C}_1\,; B, C) \subseteq \mathbb{E}(\mathcal{C}_2\,; B, C)$.

For the relations $\sim_* = \approx_u, \sim_{scp}$ or $\sim_{soh}$ It is easy to see, that elements $\mathcal{E}_j \in \mathbb{E}(\mathcal{C}_1\,; B, C)$ $(j = 1, 2)$ satisfy $\mathcal{E}_1 \sim_* \mathcal{E}_2$ in $\mathbb{E}(\mathcal{C}_1\,; B, C)$, if and only if, $\mathcal{E}_1 \sim_* \mathcal{E}_2$ in $\mathbb{E}(\mathcal{C}_2\,; B, C)$.

Thus $\mathbb{E}(\mathcal{C}_1\,; B, C)/\sim_*$ is a subgroup of $\mathbb{E}(\mathcal{C}_2\,; B, C)/\sim_*$. If we apply the Grothendieck functor, we get natural semigroup morphisms $\mathrm{KK}_c(\mathcal{C}_1\,; B, C) \to \mathrm{KK}_c(\mathcal{C}_2\,; B, C)$ and $\mathrm{KK}_{oh}(\mathcal{C}_1\,; B, C) \to \mathrm{KK}_{oh}(\mathcal{C}_2\,; B, C)$.

In the case of the relation $\sim_* = \sim_h$, one has at least that $\mathcal{E}_1 \sim_h \mathcal{E}_2$ in $\mathbb{E}(\mathcal{C}_1\,; B, C)$ implies that $\mathcal{E}_1 \sim_h \mathcal{E}_2$ in $\mathbb{E}(\mathcal{C}_2\,; B, C)$, because $\mathbb{E}(\mathcal{C}_1 \otimes \mathrm{CP}(\mathbb{C}, \mathrm{C}[0,1])\,; B, \mathrm{C}([0,1], C))$ is contained in $\mathbb{E}(\mathcal{C}_2 \otimes \mathrm{CP}(\mathbb{C}, \mathrm{C}[0,1])\,; B, \mathrm{C}([0,1], C))$.

??

Thus, if $\mathcal{C}_1 \subseteq \mathcal{C}_2$, there are natural semigroup morphisms

$$\mathrm{KK}_*(\mathcal{C}_1\,; B, C) \to \mathrm{KK}_*(\mathcal{C}_2\,; B, C)\,.$$

This semi-group morphisms are in general neither injective nor surjective.

??

semigroup epimorphisms

$$\mathrm{KK}_c(\mathcal{C}_2\,; B, C) \to \mathrm{KK}_{oh}(\mathcal{C}_2\,; B, C) \to \mathrm{KK}_h(\mathcal{C}_2\,; B, C)\,.$$

The natural injections $B \cong C \otimes p_{11} \subseteq B$ and $C \cong C \otimes p_{11} \subseteq C \otimes \mathbb{K}$ define isomorphisms from $\mathrm{KK}_{oh}(\mathcal{C}_3\,; B \otimes \mathbb{K}, C)$ onto $\mathrm{KK}_{oh}(\mathcal{C}_2\,; B, C)$ respectively from $\mathrm{KK}_{oh}(\mathcal{C}_2\,; B, C)$ onto $\mathrm{KK}_{oh}(\mathcal{C}_4\,; B, C \otimes \mathbb{K})$, where the m.o.c. cones $\mathcal{C}_3 \subseteq \mathrm{CP}(B \otimes \mathbb{K}, C)$ and $\mathcal{C}_4 \subseteq \mathrm{CP}(B, C \otimes \mathbb{K})$ are the natural extensions of $\mathcal{C}_2 \subseteq \mathrm{CP}(B, C)$ to the stabilizations.

`more???`

(vi): Let χ_t^B denote the epimorphisms $\chi_t^B \colon f \in \mathrm{C}([0,1], B) \mapsto f(t) \in B$ $(t \in [0,1])$, and let $\mathrm{CP}_{\mathrm{in}}(B, B) \subseteq \mathrm{CP}(B, B)$ denote the cone of approximately inner c.p. maps of B, and $\mathcal{S} := \mathrm{CP}_{\mathrm{in}}(B, B) \otimes \mathrm{CP}(\mathrm{C}[0,1], \mathbb{C})$. Then the difference construction $(B\,, \chi_t^B\,, 0)$ is an Element in ([7])

$$\mathbb{E}\big(\mathcal{S};\, \mathrm{C}([0,1], B), B\big) = \mathbb{E}\big(\mathrm{CP}_{\mathrm{in}}(B, B) \otimes \mathrm{CP}(\mathrm{C}[0,1], \mathbb{C})\,; B \otimes \mathrm{C}[0,1],\, B\big)\,.$$

We denote by $[\chi_t^B - 0] := [(B, \chi_t^B\,, 0)]$ its class in $\mathrm{KK}(\mathrm{CP}_{\mathrm{in}}(B, B); B \otimes \mathrm{C}([0,1]), B)$.

[7]The equation expresses only our conventions on notations, i.e., it is a trivial identity!

Since by ??? **??**

$$\mathcal{C} = (\mathcal{C} \otimes \mathrm{CP}(\mathbb{C}, \mathrm{C}[0,1])) \circ (\mathrm{CP}_{\mathrm{in}}(B,B) \otimes \mathrm{CP}(\mathrm{C}[0,1], \mathbb{C}))$$

holds for all point-norm closed matrix operator-convex cones $\mathcal{C} \subseteq \mathrm{CP}(A,B)$, one has only to check that, for all σ-unital B and all $t \in [0,1]$ holds $[\chi_0^B - 0] = [\chi_t^B - 0]$ in $\mathrm{KK}(\mathrm{CP}_{\mathrm{in}}(B,B);\, B \otimes \mathrm{C}[0,1], B)$.

The cone $\mathrm{CP}_{\mathrm{in}}(B,B)$ is singly generated by $\{\mathrm{id}_B\}$. Thus, our theory applies to $\mathrm{KK}(\mathrm{CP}_{\mathrm{in}}(B,B);\, B \otimes \mathrm{C}[0,1], B)$.

$$(E, \phi, F) \mapsto (B \widehat{\otimes} E, \mathrm{id}_B \widehat{\otimes} \phi, 1_{\mathcal{M}(B)} \widehat{\otimes} F)$$

defines an additive map from $\mathbb{E}(C,D)$ into $\mathbb{E}(\mathrm{CP}_{\mathrm{in}}(B,B) \otimes \mathrm{CP}(C,D);\, B \otimes C, B \otimes D)$ for *trivially graded* nuclear C and D (where e.g. the graded tensor product $(B \widehat{\otimes} C, \beta)$ coincides with $(B \otimes C, \beta_B \otimes \mathrm{id}_C)$). It induces a group morphism $\tau_B \colon \mathrm{KK}(C,D) \to \mathrm{KK}(\mathrm{CP}_{\mathrm{in}}(B,B);\, B \otimes C, B \otimes D)$. Obviously, $\tau_B([\psi - 0]) = \tau_B([(D,\psi,0)]) = [(B \otimes D;\, \mathrm{id} \otimes \psi, 0)] = [(\mathrm{id} \otimes \psi) - 0]$ if $\psi \in \mathrm{Hom}(C,D)$.

We have the identities $[(\mathbb{C}, \chi_t, 0)] = [\chi_t - 0] = [\chi_0 - 0]$ in $\mathrm{KK}_{oh}(C[0,1], \mathbb{C})$ for all $t \in [0,1]$, where $\chi_t \colon f \in \mathrm{C}[0,1] \mapsto f(t) \in \mathbb{C}$, cf. [**73**, lem.18.5.2].

It is not difficult to see that the original proof of Kasparov of $[\chi_0^B - 0] = [\chi_t^B - 0]$ in $\mathrm{KK}(B \otimes \mathrm{C}[0,1], B)$ works also in $\mathrm{KK}(\mathrm{CP}_{\mathrm{in}}(B,B);\, B \otimes \mathrm{C}[0,1], B)$, because $(B, \chi_t^B, 0) = (B \otimes \mathbb{C}, \mathrm{id}_B \otimes \psi_t, 0)$ for the morphism $\psi_t \colon g \in C[0,1] \mapsto g(t) \in \mathbb{C}$.

(vii): Let E^{op} denote the Hilbert B-module E with grading $-\beta_E$. Then $\widehat{\mathcal{H}}_B \cong \mathcal{H}_B \oplus_B \mathcal{H}_B$. We use that there are unitary grading-preserving B-module isomorphisms $E \oplus_B \widehat{\mathcal{H}}_B \cong \widehat{\mathcal{H}}_B$ (Kasparov stabilization, [**73**, thm.14.6.1], [**389**, thm.1.2.12], $\widehat{\mathcal{H}}_B \oplus_B (\widehat{\mathcal{H}}_B)^{op} \cong \widehat{\mathcal{H}}_B$.

We define $\lambda[(E,\phi,F)]$ for $[\mathcal{E}] = [(E,\phi,F)] \in \mathbb{E}(\mathcal{C};\, A, B)/\approx_u$ by the operations $\lambda = \lambda_2 \circ \lambda_1$:

$$\lambda_1([E,\phi,F]) := (E \oplus_B \widehat{\mathcal{H}}_B\,, \phi \oplus 0\,, G_1(F) \oplus 0)\,,$$

where $G_1(F) := g((F^* + F)/2)$ for the function $g(t) = t$ on $|t| \le 1$ and $g(t) := t/|t|$ for $|t| > 1$. Then $G_1(F) = G_1(F)^*$ and $\|G_1(F)\| \le 1$.

Note that $(E, \phi, G_1(F))$ is degenerate if (E,ϕ,F) is degenerate, $G_1(F_1 \oplus F_2) = G_1(F_1) \oplus G_1(F_2)$, $G_1(U^*FU) = U^* G_1(F) U$ for unitaries U, $G_1(F_2)$ is a ϕ-compact perturbation of $G_1(F_1)$ if F_2 is a ϕ-compact perturbation of F_1. and $G_1(F)(t) = G_1(F(t))$ for $F = \{F(t)\} \in \mathcal{L}(E)$ if $E = \{E(t)\}$ is a Hilbert $B[0,1]$-module. Since $\mathcal{E} \oplus (\widehat{\mathcal{H}}_B, 0, 0) \in \mathbb{E}(\mathcal{C};\, A, B)$, it follows from the arguments in [**73**, 17.4] that $\lambda =: \lambda_B$ has the quoted properties.

One can now go a step further and build from $(E, \phi, G) \in \mathbb{E}(\mathcal{C};\, A, B)$ with $E := \widehat{\mathcal{H}}_B$, $G = G^*$ and $\|G\| \le 1$ the Kasparov module

$$\lambda_2\big(E, \phi, (E \oplus_B E^{op}, \phi \oplus 0, U(G)\big) \in \mathbb{E}(\mathcal{C};\, A, B)$$

with $U(G) \in \mathcal{M}_2(\mathcal{L}(E)) \cong \mathcal{L}(E \oplus_B E^{op})$ where $U(G)$ is the (selfadjoint) Halmos unitary $U(G)$ of G with $U(G)_{11} := G$, $U(G)_{22} := -G$ and $U(G)_{12} = U(G)_{21} := (1 - G^2)^{1/2}$. Straight calculations show $U(G)(\beta_E(x), -\beta_E(y)) = ((-\beta_E) \oplus$

$\beta_E)(U(G)(x,y))$ (i.e., $U(G)$ has odd degree), and $U(G)$ is a $(\phi \oplus 0)$-compact perturbation of $G \oplus -G$. The graded commutator $U(G)(\phi(a) \oplus 0) - (\phi(\beta_A(a)) \oplus 0)U(G)$ is given by the 2×2-matrix with diagonal entries $G\phi(a) - \phi(\beta_A(a))G$ and 0 and with off-diagonal entries $(1 - G^2)^{1/2}\phi(a)$ and $-(\phi(\beta_A(a))(1 - G^2)^{1/2})$, thus is in $\mathbb{K}(E \oplus E^{op}) \cong M_2(\mathbb{K}(E))$ (and is zero if (E, ψ, G) is degenerate). Now one can use again that $E \oplus E^{op} \cong \widehat{\mathcal{H}}_B$. The operation λ_2 also plays nicely together with unitary equivalence, (Cuntz-)addition, ϕ-compact perturbation, operator homotopy and homotopy (all inside the class of Kasparov $\mathcal{C}$-modules with self-adjoint contractive ψ-derivation G).

??

(ix): ?????????????????? □

LEMMA 8.2.4. *Suppose that A and B are trivially graded and stable, A is separable, B is σ-unital, and that $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ is a non-degenerate point-norm closed m.o.c. cone that is countably generated.*

Let $B_{(1)}$ denote $B \oplus B$ with odd grading $\beta_{B \oplus B}(a, b) = (b, a)$.

Let $H\colon A \to \mathcal{M}(B)$ defined by $\mathcal{C}$ such that $\delta_\infty \circ H$ is unitarily equivalent to H and is non-degenerate.

Let s, t isometries in $H(A)' \cap \mathcal{M}(B)$ with $ss^* + tt^* = 1$.

$H_1 := H(\cdot) \oplus H(\cdot)\colon A \to \mathcal{M}(B \oplus B) = \mathcal{M}(B) \oplus \mathcal{M}(B)$.

(o) $\mathrm{CP}_{\mathrm{nuc}}(A, B)$ *is countably generated if A is separable and B is σ-unital.*

(i) *There is a natural grading preserving isomorphism $B_{(1)} \cong B \widehat{\otimes} \mathbb{C}_{(1)}$, and the graded standard Hilbert $B_{(1)}$-module $\widehat{\mathcal{H}}_{B_{(1)}}$ is isomorphic to the $B \oplus B$-module $B \oplus B$ with standard odd grading $S(x, y) = (y, x)$.*

Furthermore, $\mathbb{K}(B_{(1)}) \cong B_{(1)}$, and $\mathcal{L}(B_{(1)}) = \mathcal{M}(B_{(1)}) = \mathcal{M}(B)_{(1)}$. (i.e., $\mathcal{M}(B) \oplus \mathcal{M}(B)$ with standard odd grading).

There is a grading-preserving unitary $B_{(1)}$-module monomorphism γ from $B_{(1)} \oplus_{B_{(1)}} B_{(1)}$ onto $B_{(1)}$ that induces the Cuntz addition $\oplus$ on $\mathcal{M}(B) \oplus \mathcal{M}(B)$, i.e.,

$$\mathcal{M}(\gamma)((F_1, G_1) \oplus_{B \oplus B} (F_2, G_2)) = (sF_1s^* + tF_2t^*, sG_1s^* + tG_2t^*)$$

for $(F_1, G_1), (F_2, G_2) \in \mathcal{M}(B) \oplus \mathcal{M}(B)$.

The morphism $H_1\colon a \in A \mapsto H(a) \oplus H(a) \in \mathcal{M}(B) \oplus \mathcal{M}(B)$ defines a degenerate element $(B_{(1)}, H_1, 1 \oplus (-1)) \in \mathbb{E}(\mathcal{C};\, A, B_{(1)})$.

(iii) *The isomorphism classes of the Kasparov $B_{(1)}$-modules $(B_{(1)}, H_1, U)$, with self-adjoint unitary U define a sub-semigroup $\mathcal{S}_p$ of $\mathbb{E}(\mathcal{C};\, A, B_{(1)})/\approx_u$, such that the in $\mathbb{E}(\mathcal{C};\, A, B_{(1)})/\approx_u$ defined addition*

$$[(B_{(1)}, H_1, U_1)] + [(B_{(1)}, H_1, U_2)] := [(B_{(1)}, H_1, U_3)]$$

is realized by Cuntz addition $(U_1, U_2) \mapsto U_3 := SU_1S^* + TU_2T^*$, where $S := (s, s)$ and $T = (t, t)$.

It holds $U = (1-2p, 2p-1)$ *with* $(1-U)/2 =: p = p^* = p^2$ *if and only if* $[p, H(A)] \subseteq B$.

The semigroup morphism from $\mathcal{S}_p$ *into*

$$\mathrm{KK}_h(\mathcal{C};\, A, B_{(1)}) := \mathbb{E}(\mathcal{C};\, A, B_{(1)})/\sim_h$$

is an epimorphism.

(iv) *If we consider* B *as graded Hilbert* B*-module with even grading given by the symmetry* $I = ss^* - tt^* \in \mathcal{M}(B)$*, then* $\widehat{\mathcal{H}}_B \cong B$*. If* $V \in \mathcal{M}(B)$ *is a selfadjoint unitary, then* (B, H, V) *is in* $\mathbb{E}(\mathcal{C};\, A, B)$ *if and only if* $U := s^*Vt$ *is a unitary with* $[U, H(A)] \subseteq B$*. Then* $V = sUt^* + tU^*s^*$.

The isomorphism classes of the Kasparov B*-modules*

$$(B, H, sUt^* + tU^*s^*)\,,$$

where U *is a unitary in* $\mathcal{M}(B)$ *with* $[U, H(A)] \subseteq B$ *build a sub-semigroup* $\mathcal{S}_u$ *of* $\mathbb{E}(\mathcal{C};\, A, B)/\approx_u$*, such that the addition*

$$[(B, H, sU_1t^* + tU_1^*s^*)] + [(B, H, sU_2t^* + tU_2^*s^*)] = [(B, H, sU_3t^* + tU_3^*s^*)]$$

in $\mathbb{E}(\mathcal{C};\, A, B_{(1)})/\approx_u$ *is realized by Cuntz addition*

$$(U_1, U_2) \mapsto U_3 := sU_1s^* + tU_2t^*\,.$$

The semigroup morphism from $\mathcal{S}_u$ *into*

$$\mathrm{KK}_h(\mathcal{C};\, A, B) := \mathbb{E}(\mathcal{C};\, A, B)/\sim_h$$

is an epimorphism.

Proof. (o): ?????????????

The m.o.c. cone $\mathrm{CP}_{\mathrm{nuc}}(A, B)$ is countably generated if A is separable and B is σ-unital, because it is generated by the c.p. map $V_{\varphi,e}(a) := \varphi(a)e$, where $e \in B_+$ is a strictly positive contraction and $\varphi \in A_+^*$ is a faithful positive functional.

(i): Since B is stable, there are isometries $s_1, s_2, \ldots \in \mathcal{M}(B)$ with $\sum s_n s_n^*$ strictly convergent to 1, cf. Remark 5.1.1(8). Then $\mu(b) := (s_1 b, s_2 b, \ldots)$ defines an isometric B-module isomorphism from B onto $\mathcal{H}_B$ with inverse $\mu^{-1}(b_1, b_2, \ldots) = \sum_n s_n^* b_n$.

$\mathcal{H}_{B_{(1)}}$ is $\mathcal{H}_{B\oplus B}$ with grading given by

$$((x_1, y_1), (x_1, y_2), \ldots) \mapsto ((y_1, x_1), (y_1, x_2), \ldots)\,,$$

and $\mathcal{H}_{B\oplus B}$ is $B \oplus B$-module isomorphic to $\mathcal{H}_B \oplus_\infty \mathcal{H}_B$ by

$$((x_1, y_1), (x_1, y_2), \ldots) \mapsto ((x_1, x_2, \ldots), (y_1, y_2, \ldots))$$

This isomorphism becomes grading-preserving if we take on $\mathcal{H}_B \oplus_\infty \mathcal{H}_B$ the standard odd grading $(x, y) \mapsto (y, x)$. It follows that $\mathcal{H}_{B_{(1)}}$ is isomorphic to $B \oplus B$ with odd grading $\beta(x, y) = (y, x)$.

Thus $\widehat{\mathcal{H}}_{B_{(1)}} \cong (B \oplus B) \oplus_{B\oplus B} (B \oplus B)$ with grading $\beta((x_1, y_1), (x_2, y_2)) := ((y_1, x_1), (-y_2, -x_2))$.

Since B is stable, $\mathcal{M}(B)$ contains a copy

$$C^*(s,t\,;\, ss^* + tt^* = s^*s = t^*t = 1)$$

of $\mathcal{O}_2$ unitally. The map $\nu((x_1, y_1), (x_1, y_2)) := (sx_1 + tx_2, sy_1 - ty_2)$ defines a grading preserving $B_{(1)}$-module map from $(B \oplus B) \oplus_{B \oplus B} (B \oplus B)$ with grading β onto $B_{(1)}$.

Clearly $\mathcal{L}(B_{(1)}) = \mathcal{M}(B_{(1)}) = \mathcal{M}(B)_{(1)}$ and $\mathbb{K}(B_{(1)}) = B_{(1)}$.

Since B is trivially graded, the graded tensor product $B \widehat{\otimes} \mathbb{C}_{(1)}$ is isomorphic to $B \otimes (\mathbb{C} \oplus \mathbb{C})$ with grading $\mathrm{id}_B \otimes \alpha$, where $\alpha(z_1, z_2) = (z_2, z_1)$ is the grading of $\mathbb{C}_{(1)}$. Thus, $B \widehat{\otimes} \mathbb{C}_{(1)} \cong B_{(1)}$ in this case.

(ii):

(iii):

(iv): □

The next proposition implies that relations $\sim_c$, $\sim_{oh}$ and $\sim_h$ on $\mathbb{E}(\mathcal{C};\, A, B)$ are the same if A is separable and B is σ-unital. We use the above introduced conventions on the extensions of the m.o.c. cone $\mathcal{C}$.

PROPOSITION 8.2.5. *Suppose that A, B, C are σ-unital graded C^*-algebras, where A is* separable, *and let $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ and $\mathcal{C}_1 \subseteq \mathcal{C}_2 \subseteq \mathrm{CP}(B, C)$ denote non-degenerate countably generated point-norm closed matricial operator-convex cones with $\mathcal{C} \circ \beta_A \subseteq \mathcal{C}$, $\beta_B \circ \mathcal{C} \subseteq \mathcal{C}$, $\mathcal{C}_j \circ \beta_B \subseteq \mathcal{C}_j$ and $\beta_C \circ \mathcal{C}_j \subseteq \mathcal{C}_j$ for $j = 1, 2$.*

(i) *The Kasparov product*

$$[(E', \phi', F')] \circ [(E, \phi, F)] = [(E' \widehat{\otimes}_B E\,,\ \phi(\cdot) \widehat{\otimes}_B 1\,,\,, F' \sharp F)]$$

defines a bi-additive map

$$\mathrm{KK}_{oh}(\mathcal{C};\, A, B) \times \mathrm{KK}_{oh}(\mathcal{C}_2, B, C) \mapsto \mathrm{KK}_{oh}(\mathcal{C}_2 \circ \mathcal{C};\, A, C)\,.$$

The natural injections $B \cong C \otimes p_{11} \subseteq B$ and $C \cong C \otimes p_{11} \subseteq C \otimes \mathbb{K}$ define isomorphisms from $\mathrm{KK}_{oh}(\mathcal{C}_2\,;\ B \otimes \mathbb{K}, C)$ onto $\mathrm{KK}_{oh}(\mathcal{C}_2\,;\ B, C)$ respectively from $\mathrm{KK}_{oh}(\mathcal{C}_2\,;\ B, C)$ onto $\mathrm{KK}_{oh}(\mathcal{C}_2\,;\ B, C \otimes \mathbb{K})$.

(ii) *The Kasparov $\mathcal{C}$-group $\mathrm{KK}(\mathcal{C};\, A, B) := \mathrm{Gr}(\mathbb{E}(\mathcal{C};\, A, B)/ \sim_{scp})$ is homotopy invariant in the – stronger – sense that the natural epimorphisms*

$$\mathrm{KK}_c(\mathcal{C};\, A, B) \to \mathrm{KK}_{oh}(\mathcal{C};\, A, B) \to \mathrm{KK}_h(\mathcal{C};\, A, B)$$

and the natural monomorphism $\mathrm{KK}_c(\mathcal{C};\, A, B) \hookrightarrow \mathrm{KK}(\mathcal{C};\, A, B)$ are isomorphisms.

The groups $\mathrm{KK}(\mathcal{C} \otimes \mathrm{CP}(\mathrm{C}[0,1], \mathbb{C});\, \mathrm{C}([0,1], A), B)$, $\mathrm{KK}(\mathcal{C};\, A, B)$ and $\mathrm{KK}(\mathcal{C}([0,1]);\, A, \mathrm{C}([0,1], B))$ are naturally isomorphic.

In particular, our above defined bi-functor

$$\mathrm{KK}_{\mathrm{nuc}}(A, B) = \mathrm{KK}(\mathrm{CP}_{\mathrm{nuc}}(A, B);\, A, B)$$

is homotopy invariant, and coincides with the $\mathrm{KK}_{\mathrm{nuc}}$*-functor of Skandalis* [**726**]. *Therefore* $\mathrm{KK}_{\mathrm{nuc}}(A, B)$ *is stable and is half exact (on semi-split short exact sequences) in each variable.*

(iii) *There are natural isomorphisms*

$$\mathrm{KK}(\mathcal{C};\, A, B_{(1)}) \cong \mathrm{KK}(\mathcal{C};\, A, SB) \cong \mathrm{KK}(\mathcal{C};\, SA, B),$$
$$\mathrm{KK}(\mathcal{C};\, A \otimes \mathbb{K}, B) \cong \mathrm{KK}(\mathcal{C};\, A, B) \cong \mathrm{KK}(\mathcal{C};\, A, B \otimes \mathbb{K})\,.$$

In particular,

$$\mathrm{KK}_{\mathrm{nuc}}(A, B_{(1)}) \cong \mathrm{KK}_{\mathrm{nuc}}(A, SB) \cong \mathrm{KK}_{\mathrm{nuc}}(SA, B)\,.$$

PROOF. To deduce the ???????

??

By the Kasparov product construction of an connection $F_1 \sharp F_2$, the Kasparov module $(E_1 \widehat{\otimes}_B E_2\,,\ \phi_1 \widehat{\otimes}_B \mathrm{id}_{E_2}\,,\ F_1 \sharp F_2)$ exists (in $\mathbb{E}(A, C)$) for $(E_1, \phi_1, F_1) \in \mathbb{E}(A, B)$ and $(E_2, \phi_2, F_2) \in \mathbb{E}(B, C)$, because A is separable. It is an element in $\mathbb{E}(\mathcal{C}_2 \circ \mathcal{C};\, A, C)$, if $(E_1, \phi_1, F_1) \in \mathbb{E}(\mathcal{C};\, A, B)$ and $(E_2, \phi_2, F_2) \in \mathbb{E}(\mathcal{C}_2\,;\, B, C)$, cf. Proposition **??** where $\mathcal{C}_2 \circ \mathcal{C}$ denotes the m.o.c. cone that is generated by the compositions $W \circ V$ for $V \in \mathcal{C}$ and $W \in \mathcal{C}_2$.

Since the connection $F_1 \sharp F_2$ is uniquely defined up to operator homotopy, it defines the desired bi-additive map from $\mathrm{KK}_{oh}(\mathcal{C};\, A, B) \times \mathrm{KK}_{oh}(\mathcal{C}_2\,;\, B, C)$ into $\mathrm{KK}_{oh}(\mathcal{C}_2 \circ \mathcal{C};\, A, C)$.

(ii): By definition two elements $\mathcal{E}_j = (E_j, \phi_j, F_j) \in \mathbb{E}(\mathcal{C};\, A, B)$ $(j = 0, 1)$ are **cobordant** in $\mathbb{E}(\mathcal{C};\, A, B)$, if there are (E, ϕ, G) in $\mathbb{E}(\mathcal{C};\, A, B)$ and a partial isometry $v \in \mathcal{L}(E) = \mathcal{M}(\mathbb{K}(E))$ of degree 0, commuting with $\phi(A)$, such that $[v, G]\phi(A) \subseteq \mathbb{K}(E)$ and that the "restricted" Kasparov modules $(E, \phi, G)_{1-vv^*} := (pE, \phi(\cdot)|pE, pG|pE)$ and $(E, \phi, G)_{1-v^*v}$ are (unitary) equivalent to $\mathcal{E}_0$ respectively $\mathcal{E}_1$.
Then the system (E, ϕ, G, v) is a $\mathcal{C}$–**cobordism** between $\mathcal{E}_0$ respectively $\mathcal{E}_1$ (inside $\mathbb{E}(\mathcal{C};\, A, B)$).

Inspections of the arguments in the proofs of [**73**, sec.17.10] shows that the relation $\sim_c$ on $\mathbb{E}(\mathcal{C};\, A, B)$ is equivalent to the relation "*cobordant*" on $\mathbb{E}(\mathcal{C};\, A, B)$, and that the relations $\sim_c$ is the same as $\sim_{oh}$.

Indeed, the cobordism between 0 and (E, ϕ, F) for a degenerate $(E, \phi, F') \in \mathbb{E}(\mathcal{C};\, A, B)$ that is operator homotopic to (E, ϕ, F) is given by $(E \widehat{\otimes} \ell_2, \phi \widehat{\otimes} 1, G, 1 \widehat{\otimes} T)$ (where $T \in \mathcal{L}(\ell_2)$ is the Toeplitz operator and G is suitable). It is also $\mathcal{C}$–cobordism in $\mathbb{E}(\mathcal{C};\, A, B)$ between 0 and (E, ϕ, F).

(Note that it suffices to prove that elements $\mathcal{E} \in \mathbb{E}(\mathcal{C};\, A, B)$ which are operator homotopic to a degenerate element in $\mathcal{E} \in \mathbb{E}(\mathcal{C};\, A, B)$ are also cobordant to $(0, 0, 0)$, because this implies that $\mathrm{KK}_c(\mathcal{C};\, A, B)$ is a group with the same representatives $(-\mathcal{E})$ for the inverse elements of $[\mathcal{E}]_c$ as for $[\mathcal{E}]_{oh}$, and then, that $\mathcal{E}' \sim_{oh} \mathcal{E}$ implies that $\mathcal{E}' \oplus (-\mathcal{E}) \oplus \mathcal{E}_1 \sim_{soh} \mathcal{E}_2$ for degenerate $\mathcal{E}_1$ and $\mathcal{E}_2$. Thus $\mathcal{E}' \oplus (-\mathcal{E}) \sim_c 0$ and $\mathcal{E} \oplus (-\mathcal{E}) \sim_c 0$. Hence $\mathcal{E}' \sim_{oh} \mathcal{E}$ implies $\mathcal{E}' \sim_c \mathcal{E}$ by the cancelation property of $\sim_c$.

The relation $\sim_{op}$ is different from $\sim_c$ because $\mathbb{E}_{\mathrm{nuc}}(\mathcal{C};\, A, B)/\sim_{op}$ has in general not cancelation.)

Since $\mathrm{KK}_c(\mathcal{C};\, A, B)$ is a sub-semigroup of

$$\mathrm{KK}(\mathcal{C};\, A, B) := \mathrm{Gr}\big(\mathbb{E}(\mathcal{C};\, A, B)/\sim_{scp}\big)$$

that generates $\mathrm{KK}(\mathcal{C};\, A, B)$, it follows that the natural group morphism

$$\mathrm{KK}(\mathcal{C};\, A, B) \to \mathrm{KK}_{oh}(\mathcal{C};\, A, B)$$

is an isomorphism, i.e., our *maximal* group $\mathrm{KK}(\mathcal{C};\, A, B) = \mathrm{Gr}\big(\mathbb{E}(\mathcal{C};\, A, B)/\sim_{scp}\big)$ is naturally isomorphic to

$$\mathrm{KK}_{oh}(\mathcal{C};\, A, B) := \mathrm{Gr}(\mathbb{E}(\mathcal{C};\, A, B)/\sim_{oh}))$$

if A is separable and B is σ-unital.

If the invariance of the classes in $\mathrm{KK}(\mathcal{C};\, A, B)$ under unitary homotopy of its representatives in $\mathbb{E}(\mathcal{C};\, A, B)$ is established for all separable A and all σ-unital B and all (point-norm closed non-degenerate) operator-convex cones $\mathcal{C} \subseteq \mathrm{CP}(A, B)$, then Kasparov's proof of the homotopy-invariance works also for $\mathrm{KK}(\mathcal{C};\, A, B)$ and its special cases $\mathrm{KK}_{\mathrm{nuc}}(A, B)$ and $\mathrm{KK}_{\mathrm{nuc}}(X;\, A, B)$:

Then one can use the (formally larger) classes of Kasparov modules $(E, \phi, F) \in \mathbb{E}(\mathcal{C};\, A, B)$ given by by the equivalence relation $\sim_{oh}$ (i.e., given by unitary isomorphisms and operator homotopy) on $\mathbb{E}(\mathcal{C};\, A, B)$.

This allows to use Kasparov products to show finally the homotopy invariance. The Kasparov product reduces its proof to Lemma 8.2.3(vi) as follows:

`shorten/complete above and below given arguments` ??

The homotopy invariance of $\mathrm{KK}(\mathcal{C};\, A, B) = \mathrm{KK}_{oh}(\mathcal{C};\, A, B)$ finally follows from Lemma 8.2.3(vi). Indeed, let

$$\mathcal{E} := (E, \phi, F) = \{(E_t, \phi_t, F_t)\} \in \mathbb{E}(\mathrm{CP}(\mathbb{C}, \mathrm{C}[0,1]) \otimes \mathcal{C};\, A, \mathrm{C}([0,1], B))\,.$$

The Kasparov modules $(E_t, \phi_t, F_t) = \chi_t^B(E, \phi, F)$ define the same element $[(E_t, \phi_t, F_t)] = (\chi_t^B)_*[(E, \phi, F)]$ of $\mathrm{KK}(\mathcal{C};\, A, B)$ for $t \in [0,1]$.

This is because, for $t \in [0,1]$, $[\chi_t - 0] = [\chi_1 - 0] \in \mathrm{KK}(\mathrm{C}[0,1], \mathbb{C})$ and $(\chi_t^B)_*[(E, \phi, F)]$ is the the same as the Kasparov product

$$[\mathcal{E}] \otimes_{B \otimes \mathrm{C}[0,1]} [(B, \chi_t^B, 0)] = [\mathcal{E}] \otimes \tau_B([\chi_t - 0])\,.$$

Notice here that the smallest point-norm closed m.o.c. cone $\mathcal{C}_{\min}(\mathrm{C}[0,1], \mathbb{C})$ that contains all characters

$$\chi_t \colon f \in \mathrm{C}[0,1] \mapsto f(t) \in \mathbb{C}$$

is nothing else all of $\mathrm{CP}(\mathrm{C}[0,1], \mathbb{C}) \cong \mathrm{C}[0,1]^*_+$

The m.o.c. cone $\mathrm{CP}_{in}(B, B)$ of all approximately inner c.p. maps V from B to B is generated by the identity map id_B of B, and has the property that for each point-norm closed m.o.c. cone $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ holds $\mathrm{CP}_{in}(B, B) \circ \mathcal{C} = \mathcal{C}$.

check above and below formula!

Let $\mathcal{C}^{(1)} := \mathrm{CP}_{in}(B,B)\widehat{\otimes}\,\mathrm{CP}(\mathrm{C}[0,1],\mathbb{C}) \subseteq B\otimes$?????? the m.o.c. cone tensor product generated by $\{\, \mathrm{id}_B \otimes \chi_t \,\}$ in $\mathrm{CP}(B\otimes \mathrm{C}[0,1], B)$, i.e., the point-norm closed m.o.c. cone that is generated by $\mathrm{id}_B \otimes \mathrm{CP}(\mathrm{C}[0,1],\mathbb{C})$ and $\mathrm{CP}(\mathrm{C}[0,1],\mathbb{C})$.

This construction reduces the proof of homotopy invariance of general $\mathrm{KK}(\mathcal{C};\, A, B)$ to the check of the homotopy invariance of $\mathrm{KK}(\mathcal{C}^{(1)};\, B[0,1], B)$, which in turn reduces to $\mathrm{KK}(\mathrm{C}[0,1],\mathbb{C}) \cong \mathbb{Z}$.

(iii): ????????

Part (i????) of ??????????

implies in particular, that our $\mathrm{KK}_{\mathrm{nuc}}$-groups are the same as those of Skandalis, [**726**]. Then periodicity (ii) comes now in the same way as it comes for Kasparov's KK-functor.

But there is ???????????? □

The following Proposition 8.2.6 is crucial for the later needed corollaries of the homotopy invariance of *our* groups $\mathrm{Ext}(\mathcal{C};\, A, B)$. Therefore, we give a detailed proof, that uses the natural isomorphism $\mathrm{KK}_c(\mathcal{C};\, A, B_{(1)}) \cong \mathrm{KK}_h(\mathcal{C};\, A, B_{(1)})$ and the isomorphism from $\mathrm{Ext}(\mathcal{C};\, A, B)$ onto the *kernel* ([8]) of the group homomorphism

$$\mathrm{K}_0(H_0(A\otimes\mathbb{K})'\cap \mathrm{Q}^{\mathrm{s}}(B)) \to \mathrm{K}_0(\mathrm{Q}^{\mathrm{s}}(B))\,.$$

PROPOSITION 8.2.6. *Suppose that A is separable and stable, that B is σ-unital and stable, that both are trivially graded, and let $\mathcal{C} \subseteq \mathrm{CP}(A,B)$ a point-norm closed matrix operator-convex cone that is countably generated, non-degenerate and faithful.*

(i) $\mathrm{Ext}(\mathcal{C};\, A, B)$ *is* naturally *isomorphic to* $\mathrm{KK}(\mathcal{C};\, A, B_{(1)})$, *such that the isomorphism $\Phi(\mathcal{C};\, A, B)$ from $\mathrm{Ext}(\mathcal{C};\, A, B)$ onto $\mathrm{KK}(\mathcal{C};\, A, B_{(1)})$ satisfies*

$$\Phi(\delta\circ\mathcal{C};\, A, C)\circ \delta_* = (\delta_{(1)})_* \circ \Phi(\mathcal{C}\,; A, B)$$

and

$$\Phi(\mathcal{C}\circ\gamma;\, A_1, B)\circ \gamma^* = \gamma^* \circ \Phi(\mathcal{C}\circ\gamma;\, A_1, B)$$

for isomorphisms $\delta\colon B\to C$ and $\gamma\colon A_1 \to A$.

In particular, $\mathrm{Ext}_{\mathrm{nuc}}(A,B)$ *is naturally isomorphic to* $\mathrm{KK}_{\mathrm{nuc}}(A, B_{(1)})$.

(ii) $\mathrm{Ext}(\mathcal{C}(\mathbb{R}_+);\, A, \mathrm{C}_0(\mathbb{R}_+, B)) \cong 0$.

In particular, $\mathrm{Ext}_{\mathrm{nuc}}(A, \mathrm{C}_0(\mathbb{R}_+, B)) \cong 0$.

(iii) $\mathrm{KK}(\mathcal{C}(\mathbb{R}_+);\, A, \mathrm{C}_0(\mathbb{R}_+, B)) \cong 0$.

(iv) *Let $H_0\colon A \to \mathrm{Q}^{\mathrm{s}}(B)$ the canonical C^*-morphism associated to $\mathcal{C}$ and $S, T \in H(D)'\cap \mathcal{M}(B)$ isometries with $SS^* + TT^* = 1$. Consider the isometries $s := \pi_B(S)$ and $t := \pi_B(T)$ in $H_0(A)'\cap \mathrm{Q}^{\mathrm{s}}(B)$.*

[8] Notice that $\mathrm{Ext}(A,B)$ is not equal to $\mathrm{K}_0(H_0(A\otimes\mathbb{K})'\cap \mathrm{Q}^{\mathrm{s}}(B))$ itself. But one can calculate $\mathrm{Ext}(A,B)$ as quotient by its subgroup $\mathrm{K}_0(\mathrm{Ann}(H_0(A\otimes\mathbb{K}), \mathrm{Q}^{\mathrm{s}}(B)))$. Use Lemma 4.2.20(o) to compare it with our definition.

Then there exists a constant $\gamma(\mathcal{C}) < \infty$ *such that for each unitary* $u \in \mathcal{U}_0(H_0(D)' \cap \mathrm{Q}^{\mathrm{s}}(B))$ *the geodesic distance* $\mathrm{cel}(sus^* + tt^*)$ *of the unitary* $sus^* + tt^*$ *to* 1 *inside* $\mathcal{U}_0(H_0(D)' \cap \mathrm{Q}^{\mathrm{s}}(B))$*, satisfies*

$$\mathrm{cel}(sus^* + tt^*) \leq \gamma(\mathcal{C})\,.$$

PROOF. Recall that $\mathcal{C} := \mathrm{CP}_{\mathrm{nuc}}(A, B)$ is singly generated, non-degenerate and faithful if A is separable and B is σ-unital, because $V := \rho(\cdot)b_0$ is a generates $\mathrm{CP}_{\mathrm{nuc}}(A, B)$ as m.o.c. cone if $\rho \in A^*_+$ is a faithful positive functional on A and $b_0 \in B_+$ is a strictly positive element. (The more general m.o.c. cones $\mathrm{CP}_{\mathrm{rn}}(X; A, B)$ are often not countably generated despite $\mathrm{CP}_{\mathrm{rn}}(X;\, A, B)$ itself is a matrix-hereditary sub-cone of $\mathrm{CP}_{\mathrm{nuc}}(A, B)$.)

Notice that $\mathrm{CP}_{\mathrm{nuc}}(A, B) \otimes \mathrm{CP}(C, D) = \mathrm{CP}_{\mathrm{nuc}}(A \otimes C, B \otimes D)$ for all nuclear C^*-algebras C and D by the local characterization in Proposition ??, and that $\mathrm{KK}_{\mathrm{nuc}}(A, B \widehat{\otimes} C) = \mathrm{KK}\big(\mathrm{CP}_{\mathrm{nuc}}(A, B \otimes C);\, A, B \widehat{\otimes} C\big)$ for all (graded) separable nuclear C. Further recall that

$$\mathrm{Ext}_{\mathrm{nuc}}(A, B) := \mathrm{Gr}(\mathrm{SExt}_{\mathrm{nuc}}(A, B)) \cong \mathrm{Ext}(\mathrm{CP}_{\mathrm{nuc}}(A, B);\, A, B)\,,$$

with $\mathrm{SExt}_{\mathrm{nuc}}(A, B) := [\mathrm{Hom}_{\mathrm{l\text{-}nuc}}(A, \mathrm{Q}(B \otimes \mathbb{K}))] \cong \mathrm{SExt}(\mathrm{CP}_{\mathrm{nuc}}(A, B);\, A, B)$, and $\mathrm{KK}_{\mathrm{nuc}}(A, B) = \mathrm{KK}(\mathrm{CP}_{\mathrm{nuc}}(A, B);\, A, B)$ right from the definitions.

We proceed with the $\mathrm{KK}(\mathcal{C};\, \cdot, \cdot)$ and $\mathrm{Ext}(\mathcal{C};\, \cdot, \cdot)$ for general countably generates point norm closed m.o.c. cones $\mathcal{C} \subseteq \mathrm{CP}(A, B)$.

It follows that there is a natural isomorphism from $\mathrm{KK}(\mathcal{C};\, A, B_{(1)})$ onto $\mathrm{Ext}(\mathcal{C};\, A, B)$ for separable stable A, σ-unital stable B, (both trivially graded), with countably generated non-degenerate and faithful m.o.c. cone $\mathcal{C} \subseteq \mathrm{CP}(A, B)$. It covers also the cases $\mathcal{C} := \mathrm{CP}_{\mathrm{nuc}}(A, B)$ and $\mathcal{C} := \mathrm{CP}_{\mathrm{rn}}(X; A, B)$, i.e., it suffices to consider the (more general) case of a non-degenerate faithful countably generated m.o.c. cone $\mathcal{C}$ in place of $\mathrm{CP}_{\mathrm{nuc}}(A, B)$.

(i): Life could be easier if a simply and elementary argument would show that the stabilization $\sim$ of the relation that are given by unitary equivalence and by ψ-"compact" perturbations on the below considered pairs (ψ, q) with $\psi\colon A \to \mathcal{M}(B)$ weakly $\mathcal{C}$-compatible and $q \in \mathcal{M}(B)$ a projection with $q\psi(a) - \psi(a)q \in B$ (equipped with with Cuntz addition $\oplus := \oplus_{S,T}$ with a suitable copy $C^*(S, T)$ of $\mathcal{O}_2$) are the same as the stabilization of relations induced on them by considering them *modulo* $B \otimes \mathbb{K}$ (up to unitary equivalence), i.e., as the corresponding classes of elements that build *our* $\mathrm{Ext}(\mathcal{C};\, A, B)$ defined in Definition 5.8.2. The critical point is, that one has to make sure that the relation $\sim$ is weak enough such that $\pi_B(p_1\phi_1(\cdot)p_1) = \pi_B(p_2\phi_2(\cdot)p_2)$ implies $(\phi_1, p_1) \sim (\phi_2, p_2)$.

In our approach we use that $\mathrm{KK}_c(\mathcal{C};\, A, B_{(1)}) = \mathrm{KK}_h(\mathcal{C};\, A, B_{(1)})$ to get the relation $(\psi_1, p_1) \sim (\psi_2, p_2)$ from the homotopy invariance of $\mathrm{KK}_c(\mathcal{C};\, A, B_{(1)})$.

`check next remark, give cross-ref`

By Lemma 5.9.14, the general defining relations for classes of representing elements (ϕ, p) that build the elements of $\mathrm{Ext}(\mathcal{C};\, A, B)$ are:

$$(\phi_0, p_0) \sim (\phi_1, p_1) \quad \Leftrightarrow \quad \exists\, (\psi_0, 1), (\psi_1, 1),\, \exists\, U \in \mathcal{M}(B): \tag{2.1}$$

$$\forall a \in A: \quad p_0\phi_0(a)p_0 \oplus \psi_0(a) - U^*(p_0\phi_1(a)p_0 \oplus \psi_1(a))U \in B\,. \tag{2.2}$$

Here $\oplus$ means Cuntz-addition in $\mathcal{M}(B)$.

`From Lemma 5.9.14:` Recall:

Let $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ is a countably generated point-norm closed matrix operator-convex cone. We denote by $\mathcal{S}$ the set of pairs (φ, p), where $\varphi\colon A \to \mathcal{M}(B)$ is a C^*-morphism with $b^*\varphi(\cdot)b \in \mathcal{C}$ for all $b \in B$ and $p \in \mathcal{M}(B)$ is a projection that satisfies $\varphi(a)p - p\varphi(a) \in B$ for all $a \in A$.

We denote by $[\mathcal{S}]$ the set of unitary equivalence classes $[(\varphi, p)]$ by unitaries in $\mathcal{M}(B)$.

An element $(\varphi, p) \in \mathcal{S}$ is **degenerate** if $p\varphi(a) = \varphi(a)p$ for all $a \in A$.

(i) $[\mathcal{S}]$ is a commutative semigroup (with Cuntz-Addition on maps and projections).
(ii) The map $[\varphi, p] \mapsto \pi_B(\varphi(\cdot)p) \in \mathrm{Hom}(A, \mathrm{Q}(B))$ defines an additive semigroup morphism ϑ from $[\mathcal{S}]$ onto $\mathrm{SExt}(\mathcal{C};\, A, B)$. The image of ϑ contains $[0] + \mathrm{SExt}(\mathcal{C};\, A, B)$.
(iii) The map $\mathcal{S} \to \mathrm{Ext}(\mathcal{C};\, A, B)$ induces an equivalence relation $\sim$ on $\mathcal{S}$ that is compatible with Cuntz addition and is generated by the following operations and relations:
  (a) unitary equivalence by unitaries in $\mathcal{M}(B)$, i.e., $(\varphi, p) \sim (\psi, q)$ if there is a unitary $u \in \mathcal{M}(B)$ with $\psi = u^*\varphi(\cdot)u$ and $q = u^*pu$,
  (b) addition $(\varphi \oplus \psi, p \oplus q)$ of *degenerate* elements $(\psi, q) \in \mathcal{S}$ to elements $(\varphi, p) \in \mathcal{S}$, i.e., $(\varphi \oplus \psi, p \oplus q) \sim (\varphi, p)$, and
  (c) unitary perturbation: $(\varphi, p) \sim (\varphi, q)$ if there is $b^* = b \in \mathcal{M}(B)$ such that $\varphi(a)b - b\varphi(a) \in B$ and $(p - e^{-ib}qe^{ib})\varphi(a) \in B$ for all $a \in A$.
(iv) The natural semigroup morphism from $\mathrm{SExt}(\mathcal{C};\, A, B)$ into $\mathrm{Ext}(\mathcal{C};\, A, B)$ is an epimorphism.
(v) If $\mathcal{C}$ is countably generated and non-degenerate, and if $H\colon A \otimes \mathbb{K} \to \mathcal{M}(B)$ is as in Corollary 5.4.4, then the unitary equivalence classes $[(H(\cdot), p)] \in [\mathcal{S}]$ with $p = TT^*$ for some isometry $T \in \mathcal{M}(B)$ build a sub-semigroup $[\mathcal{P}]$ of $[\mathcal{S}]$ such that ϑ maps $[\mathcal{P}]$ onto $\mathrm{Ext}(\mathcal{C}; A, B)$.

Recall that almost directly from the definitions one can see that there are natural isomorphisms $\mathrm{Ext}(\mathcal{C};\, A, B) \cong \mathrm{Ext}(\mathcal{C};\, A \otimes \mathbb{K}, B \otimes \mathbb{K})$ (in particular this happens for $\mathrm{Ext}_{\mathrm{nuc}}$), see cf. Proposition 5.9.25.

One direction of the proof (such as in [**73**, 17.6]) is almost trivial, as the reader can see from the last part of our proof. But for the other direction we make two times very essential use of the homotopy invariance of $\mathrm{KK}(\mathcal{C};\, A, B_{(1)})$, and use the trivial isomorphism $\mathrm{C}([0,1], B_{(1)}) \cong \mathrm{C}([0,1], B)_{(1)}$. Our proof is a compromise between the suggestions in [**73**] before [**73**, prop. 17.6.5] and the detailed exposition in [**389**, chp. 3] (both for ordinary KK and Ext).

We make use of the *stability* of the bi-functors $\mathrm{KK}(\mathcal{C};\,\cdot,\cdot)$ and $\mathrm{Ext}(\mathcal{C};\,\cdot,\cdot)$ to get a constructive picture, that allows to see the $\mathcal{C}$-compatibility of all constructions. In particular, *we suppose from now on that B is stable and σ-unital*, and let $D := A\otimes\mathbb{K}$, $E := \mathrm{Q}(B) := \mathcal{M}(B)/B$ that is naturally isomorphic to $\mathrm{Q}^{\mathrm{s}}(B)$ (because B is stable).

Remark 5.8.7 and ?????????????????? **??**

show that there are natural isomorphisms

$$\mathrm{Ext}_{\mathrm{nuc}}(A,B)\cong\mathrm{Ext}_{\mathrm{nuc}}(D,B)\cong G(H_0\,;\,D,E)\,,$$

respectively,

$$\mathrm{Ext}(\mathcal{C};\,A,B)\cong\mathrm{Ext}(\mathcal{C}\otimes\mathrm{CP}(\mathbb{K},\mathbb{C});\,D,B)\cong G(H_0\,;\,D,E)\,,$$

where $\mathcal{C}$ is naturally extended to $D = A\otimes\mathbb{K}$ as $\mathcal{C}\otimes\mathrm{CP}(\mathbb{K},\mathbb{C})\subseteq\mathrm{CP}(D,B)$, $H_0 = \pi_B\circ H_1$, and $H_1\colon D\to\mathcal{M}(B)$ is an infinite repeat of a faithful non-degenerate representation of D in $\mathcal{M}(\mathbb{K})\subseteq\mathcal{M}(B)$ (compare Corollary 5.4.10 in case $\mathcal{C} = \mathrm{CP}_{\mathrm{nuc}}(D,B)$), or where $H_1\colon D\to\mathcal{M}(B)$ is constructed from the countably generated cone $\mathcal{C}$ by Corollary 5.4.4. Thus, there is a copy of $\mathcal{O}_2$ unitally contained in the commutant of $H_1(D)$ in $\mathcal{M}(B)$ by Lemma 5.1.2(ii), i.e., $H_0(D)'\cap E$ contains a unitally liftable copy of $\mathcal{O}_2$. By Proposition 4.4.3(i), $G(H_0\,;\,D,E)$ is naturally isomorphic to the kernel of $\mathrm{K}_0(H_0(D)'\cap E)\to\mathrm{K}_0(E)$.

Furthermore, since $C := H_0(D)'\cap E$ contains a unitally liftable copy of $\mathcal{O}_2$, every element of this kernel has a representative $q = p+B\in C$ which comes from a projection $p\in\mathcal{M}(B)$, because $q = q'\oplus 1\oplus 0$ is unitarily equivalent to $1\oplus 0$ by a unitary $u\in\mathcal{U}_0(E) = \pi_B(\mathcal{U}(\mathcal{M}(B)))$ if $[q'] = 0$ in E, but $[q] = [q']$ in $\mathrm{K}_0(C)$, cf. Lemma 4.2.6(iv,b).

Thus the representatives are projections $p\in\mathcal{M}(B)$ with $pH_1(a)-H_1(a)p\in B$ for every $a\in D$. By Lemma 4.2.6(i), the addition in $\mathrm{K}_0(H_0(D)'\cap E)$ coincides with the Cuntz addition (if we use a unital copy of $\mathcal{O}_2$ in E that commutes element-wise with $H_0(D)$). Let

$$\mathcal{P} := \{p\in\mathcal{M}(B)\,;\;\, p = p^* = p^2\,,\;\,[p,H_1(a)]\in B\;\;\forall\, a\in A\,\}\,.$$

The set $\mathcal{P}$ is closed under Cuntz addition defined by a unital copy of $\mathcal{O}_2$ in $H_1(D)'\cap\mathcal{M}(B)$, and it is invariant under unitary equivalence by unitaries in the commutant of $H_1(D)$ in $\mathcal{M}(B)$ and, more generally, by unitaries in $\pi_B^{-1}(H_0(D)'\cap\mathrm{Q}^{\mathrm{s}}(B))$. Therefore, the unitary equivalence classes of projections in $\mathcal{P}$ by unitaries in $H_1(D)'\cap\mathcal{M}(B)$ build a semigroup by Proposition 4.3.2. This semigroup maps additively *onto* $\mathrm{Ext}(\mathcal{C};\,D,B)$ (respectively onto $\mathrm{Ext}_{\mathrm{nuc}}(D,B)$) by the above consideration.

We are now going to describe the equivalence relation which is induced by this additive map into $\mathrm{K}_0(C)$:

By Lemma 4.2.6(iv,b), two representatives p and p' define the same element of $\mathrm{K}_0(H_0(D)' \cap E)$ if and only if the Cuntz sums $0 \oplus p \oplus 1$ and $0 \oplus p' \oplus 1$ are unitarily equivalent modulo B by a unitary $u \in \mathcal{M}(B)$ that can be connected to 1 by a norm-continuous path $\xi \in [0,1] \mapsto u(\xi) \in \mathcal{M}(B)$ of unitaries $u(\xi)$ which all commute element-wise with the image of H_1 modulo B. Another *equivalent condition* is: $0 \oplus p \oplus 1$ and $0 \oplus p' \oplus 1$ are (norm-)homotopic in the set $\mathcal{P}$ (the projections q of $\mathcal{M}(B)$ with $qH_1(a) - H_1(a)q \in B$ for every $a \in D$). (Because the latter implies that their images in $C := H_0(D)' \cap E$ are homotopic inside the projections of C.)

But a more delicate description of the equivalence relation on $\mathcal{P}$ induced by $\mathcal{P} \to \mathrm{K}_0(H_0(D)' \cap E)$ comes from Propositions 5.5.12 and 4.4.3:
The *-morphism $H_0\colon D \to E$ dominates zero, because $H_1(D) + B$ is stable, cf. Proposition 5.5.12(ii). Projections $p, p' \in \mathcal{P}$ define the same class in $\mathrm{K}_0(H_0(D)' \cap E)$, if and only if, there is a unitary $u \in \mathcal{M}(B)$ such that $[u, H_1(a)]$ and $(u^*(p' \oplus 1 \oplus 0)u - (p \oplus 1 \oplus 0))H_1(a)$ are in B for every $a \in D$, cf. Proposition 4.4.3(iii).

By obvious reasons (e.g. consider the given map from $\mathcal{P}$ into $\mathrm{K}_0(H_0(D)' \cap E)$ itself), the corresponding equivalence relations on $\mathcal{P}$ are *compatible* with Cuntz addition.

Now we define a semigroup epimorphism from $([\mathcal{P}], +)$ onto $\mathrm{KK}_{\mathrm{nuc}}(A, B_{(1)}) = \mathrm{KK}_{\mathrm{nuc}}(D, B_{(1)})$. (We show later that this map induces the same equivalence relations as the map from $[\mathcal{P}]$ to $\mathrm{K}_1(C)$.)

As in [**73**, 17.6.4], one can see that the elements of $\mathrm{KK}(\mathcal{C};\, D, B_{(1)})$ (respectively of $\mathrm{KK}_{\mathrm{nuc}}(D, B_{(1)})$) can be represented by $(\mathcal{H}_B \oplus_\infty \mathcal{H}_B, \phi, G)$ where

$$\mathcal{H}_B := \{(b_1, b_2, \ldots)\,;\ b_n \in B, \sum b_n^* b_n \in B\}$$

and the grading is given by $\beta(x, y) = (y, x)$ for $x, y \in \mathcal{H}_B$, ϕ is weakly $\mathcal{C}$-compatible (respectively is *nuclear*), and G is a selfadjoint unitary in $\mathcal{L}(\mathcal{H}_B \oplus_\infty \mathcal{H}_B) = \mathcal{M}(B) \oplus \mathcal{M}(B) = \mathcal{M}(B)_{(1)}$ of degree one. Thus, $G = (U, -U)$, $U = U^* = U^{-1} \in \mathcal{M}(B)$, and $\phi(a)(x, y) = (\phi_1(a)x, \phi_2(a)y)$ satisfies $\psi := \phi_1 = \phi_2$.

The passage to a *selfadjoint* unitary $G \in \mathcal{M}(B)_{(1)}$ respects unitary isomorphism classes and is additive on $\mathbb{E}(\mathcal{C};\, D, B_{(1)})/\approx_u$ (respectively in $\mathbb{E}_{\mathrm{nuc}}(D, B_{(1)})/\approx_u$), the operation is compatible with "compact" perturbations and transforms each homotopy into a homotopy. The same happens with the passage from a graded $B_{(1)}$-module E and $\phi\colon D \to \mathcal{L}(E)$ to $\psi\colon D \to \mathcal{H}_B \oplus \mathcal{H}_B$ with help of Kasparov stabilization: $(E, \phi, F) \oplus ((\mathcal{H}_B)_{(1)}, 0, 1) \approx ((\mathcal{H}_B)_{(1)}, \phi', F')$ for suitable weakly $\mathcal{C}$-compatible $\phi'\colon D \to \mathcal{L}((\mathcal{H}_B)_{(1)})$

???????.

??

But then Hilbert B-module addition becomes Cuntz addition with a unital copy of $\mathcal{O}_2$ with degree zero generators. Thus the equivalence relations from our definition becomes unitary equivalence with an unitary of degree zero and compact perturbation, i.e., passage to an selfadjoint unitary F' with degree $= 1$ and $(F' -$

$F)\phi(D) \subseteq B$. $\mathrm{KK}(\mathcal{C};\, D, B)$ is then again the Grothendieck group of the semigroup which is defined by this equivalence classes.

It follows $\mathcal{L}(\mathcal{H}_B \oplus \mathcal{H}_B) = \mathcal{M}(B) \oplus \mathcal{M}(B)$, $\phi = \psi \oplus \psi$ and $F = (1-2q, 2q-1)$, where $\psi\colon D \to \mathcal{M}(B)$ is a weakly *nuclear* (possibly degenerate) C^*-morphism and q is a projection in $\mathcal{M}(B)$ with $q\psi(a) - \psi(a)q$ for all $a \in D$. Conversely (E, ϕ, F) is in $\mathbb{E}_{\mathrm{nuc}}(D, B)$ if $E := \mathcal{H}_B \oplus \mathcal{H}_B$, $\phi := \psi \oplus \psi$ and $F = (1-2q, 2q-1)$ for every pair (ψ, q) with *weakly nuclear* (respectively $\psi \in \mathcal{C}$) $\psi\colon D \to \mathcal{M}(B)$ and projection $p \in \mathcal{M}(B)$ such that $q\psi(a) - \psi(a)q$ for all $a \in D$.

The addition in $\mathrm{KK}(\mathcal{C};\, D, B_{(1)})$ agrees under this identification with the Cuntz addition of the projections q and of the homomorphisms ψ. Isomorphisms become unitary equivalences and "compact" perturbation means passage to a projection $p' \in \mathcal{M}(B)$ with $(p' - p)\psi(D) \in B$. Therefore $(H_1, 1)$ and $(H_1, 0)$ represent the zero element, and we can represent the elements of $\mathrm{KK}(\mathcal{C};\, D, B_{(1)})$ by the elements $(\psi \oplus H_1, q \oplus 1)$. Let $\psi_\tau\colon D \to \mathcal{M}(B)$ be a point-norm continuous family of *weakly nuclear* C^*-morphisms and let $p \in \mathcal{M}(B)$ be a projection such that $\psi_\tau(a) - \psi_0(a)$ and $[\psi_0(a), p]$ are in B for all $a \in D$ and $\tau \in [0,1]$. Then the homotopy invariance of the $\mathrm{KK}_{\mathrm{nuc}}$-functor implies that (ψ_0, p) and (ψ_1, p) represent the same element of $\mathrm{KK}(\mathcal{C};\, D, B_{(1)})$.

By Theorem 5.6.2(ii) – applied to $C := H_1(A)$ and $T = \psi \circ (H_1^{-1})$ –, we find a norm-continuous map $t \mapsto U(t)$ into the unitaries of $\mathcal{M}(B)$ such that $U(t)^* H_1(a) U(t) - (\psi(a) \oplus H_1(a)) \in B$ for $t \in \mathbb{R}_+$ and

$$\lim_{t\to\infty} \|U(t)^* H_1(a) U(t) - (\psi(a) \oplus H_1(a))\| = 0$$

for $a \in A$. Thus $(U(0)^* H_1 U(0), q \oplus 1)$ and $(\psi \oplus H_1, q \oplus 1)$ represent the same element of $\mathrm{KK}(\mathcal{C};\, D, B_{(1)}) \cong \mathrm{KK}(\mathcal{C};\, A, B_{(1)})$. But $(U(0)^* H_1 U(0), q \oplus 1)$ is unitarily equivalent to (H_1, p) where $p := U(0)(q \oplus 1)U(0)^*$, and p is in $\mathcal{P}$. Thus every element of $\mathrm{KK}(\mathcal{C};\, D, B_{(1)})$ can be represented by (H_1, p), where $p \in \mathcal{P}$.

Conversely, the maps

$$p \in \mathcal{P} \mapsto (H_1, p) \mapsto (\mathcal{H}_B \oplus \mathcal{H}_B, H_0 \oplus H_0, (1-2p, 2p-1))$$

define together an additive map from $\mathcal{P}$ onto $\mathbb{E}(\mathcal{C};\, D, B_{(1)})$.

If we use the copy of $\mathcal{O}_2$ in the commutant of $H_1(D)$, then $(H_1, p \oplus 1 \oplus 0)$ is nothing else $(H_1 \oplus H_1 \oplus H_1, p \oplus 1 \oplus 0)$, and represents therefore the same element of $\mathrm{KK}(\mathcal{C};\, D, B_{(1)})$ as it (H_1, p) does.

Let $p, p' \in \mathcal{P}$. If $t \in [0,1] \mapsto u(t)$ is a norm-continuous map into the unitaries which element-wise commutes with $H_1(D)$ modulo B, and if $u(0) = 1$ $p' - u(1)^* p u(1) \in B$ then (H_1, p) and (H_1, p') define the same element of $\mathrm{KK}(\mathcal{C};\, D, B_{(1)})$ because it defines a homotopy in the *nuclear* Kasparov modules followed by a "compact" perturbation.

So far we have seen that $p \in \mathcal{P} \mapsto (\mathcal{H}_B \oplus \mathcal{H}_B, H_1 \oplus H_1, (1-2p, 2p-1))$ defines a group epimorphism from $\mathrm{Ext}_{\mathrm{nuc}}(D, B)$ onto $\mathrm{KK}(\mathcal{C};\, D, B_{(1)})$.

It remains to show that the kernel is trivial, i.e., that $[p] = 0$ in $\mathrm{K}_0(H_0(D)' \cap \mathrm{Q}^{\mathrm{s}}(B))$ if (H_1, p) represents the zero of $\mathrm{KK}(\mathcal{C};\, D, B_{(1)})$.

If (H_1, p) represents zero, then there is a pair (ψ, q) and a unitary $u_0 \in \mathcal{M}(B)$ such that $H_1 \oplus \psi = u_0 \psi u_0^*$ and $u_0 q u_0^*$ is a $H_1 \oplus \psi$-"compact" perturbation of $p \oplus q$. We add to this relations the pair $(H_1, 1)$. By Proposition 4.3.2 and Theorem 5.6.2(ii) (applied to $C := H_1(A)$ and $T := \psi \circ H_1^{-1}$), we find then unitaries u_1 and u_2 such that $H_1 \oplus (\psi \oplus H_1) = u_1(\psi \oplus H_1)u_1^*$, $u_2^* H_1(a) u_2 - (\psi \oplus H_1)(a) \in B$ for $a \in D$, and such that $u_1(q \oplus 1)u_1^*$ is a $H_1 \oplus (\psi \oplus H_1)$-"compact" perturbation of $p \oplus (q \oplus 1)$.

Now we consider the relations modulo B in $E := \mathrm{Q}^{\mathrm{s}}(B) := \ cM(B)/B$, and let $v_j := \pi_B(u_j)$, $\varphi := \pi_B \circ \psi$, $p' := \pi_B(p)$ and $q' := \pi_B(q)$. Note that $H_0 \oplus H_0 = H_0$, if we use a copy of $\mathcal{O}_2$ in $H_0(D)' \cap \mathrm{Q}^{\mathrm{s}}(B)$. We get $v_2^* H_0 v_2 = \varphi \oplus H_0$, $v_1^*(1 \oplus v_2)^* H_0 (1 \oplus v_2) v_1 = v_2^* H_0 v_2$ and

$$\big((q' \oplus 1) - v_1^*(p' \oplus (q' \oplus 1))v_1\big) \cdot v_2^* H_0 v_2 = \{0\}\,.$$

It follows that the unitary $w := (1 \oplus v_2) v_1 v_2^*$ and the projection $r := v_2(q' \oplus 1)v_2^*$ are in $H_0(D)' \cap E$, and that $(r - w^*(p' \oplus r)w) H_0(D) = \{0\}$. Let $p_1 := w^*(p' \oplus r)w$. If π denotes the quotient map, then It gives $[p_1] = [r] = 0$ in $K_0(\mathrm{Q}^{\mathrm{s}}(B))$ and $(p_1 - r)) H_0(D) = 0$, $[\pi(p)] = [p'] = [p_1] - [r]$ in $\mathrm{K}_0(H_0(D)' \cap \mathrm{Q}^{\mathrm{s}}(B))$.

By Proposition 4.4.3(iii), $[p_1] = [r]$ in $\mathrm{K}_0(H_0(D)' \cap \mathrm{Q}^{\mathrm{s}}(B))$, because H_0 dominates zero. Thus $[\pi(p)] = 0$ in $\mathrm{K}_0(H_0(D)' \cap \mathrm{Q}^{\mathrm{s}}(B))$.

(ii): The functor

$$Y \mapsto \mathrm{Ext}(\mathcal{C}(Y);\, A, \mathrm{C}_0(Y, B)) \cong \mathrm{KK}(\mathcal{C}(Y);\, A, \mathrm{C}_0(Y, B)_{(1)})$$

is homotopy invariant, because $\mathrm{C}_0(Y, B)_{(1)} = \mathrm{C}_0(Y, B_{(1)})$ and the map $Y \mapsto \mathrm{KK}(\mathcal{C}(Y);\, A, \mathrm{C}_0(Y, C))$ is homotopy invariant for each non-degenerate point-norm closed m.o.c. cone $\mathcal{C} \subseteq \mathrm{CP}(A, C)$ for any graded σ-unital graded C^*-algebra C, by Proposition 8.2.5.

(iii): $\mathrm{Ext}(\mathcal{C}(\mathbb{R}_+);\, A, \mathrm{C}_0(\mathbb{R}_+, B)) \cong 0$ follows from (ii), because $\mathrm{C}_0(\mathbb{R}_+, B_{(1)})$ is a contractible.

(iv):

TEXT of (iv):

Let $H_0 \colon A \to \mathrm{Q}^{\mathrm{s}}(B)$ denote the canonical C^*-morphism associated to $\mathcal{C}$ and $S, T \in H(D)' \cap \mathcal{M}(B)$ isometries with $SS^* + TT^* = 1$. Consider the isometries $s := \pi_B(S)$ and $t := \pi_B(T)$ in $H_0(A)' \cap \mathrm{Q}^{\mathrm{s}}(B)$.

Then there exists a constant $\gamma(\mathcal{C}) < \infty$ such that for each unitary $u \in \mathcal{U}_0(H_0(D)' \cap \mathrm{Q}^{\mathrm{s}}(B))$ the geodesic distance $\mathrm{cel}(sus^* + tt^*)$ of the unitary $sus^* + tt^*$ to 1 inside $\mathcal{U}_0(H_0(D)' \cap \mathrm{Q}^{\mathrm{s}}(B))$, satisfies

$$\mathrm{cel}(sus^* + tt^*) \leq \gamma(\mathcal{C})\,.$$

Proof, To be filled in ?? □

Next Corollary 8.2.7 is important and has to be checked: ?? Move parts of the Cor. (8.b2) to proof !!!

Recall Definitions (4.2) and (4.3) for a C^*-subalgebra $C \subseteq D$ of a C^*-algebra D and an ideal $I \lhd D$ of D: The *derivation C^*-subalgebra* $\mathrm{Der}(C, I) \subseteq E$ is defined by

$$\mathrm{Der}(C, I) := \{e \in D\, ;\; ea - ae \in I \;\; \forall\, a \in C\}\,,$$

and the *normalizer C^*-subalgebra* $\mathcal{N}(C, I) \subseteq E$ is defined as the hereditary C^*-subalgebra

$$\mathcal{N}(C, I) := \{e \in D\, ;\; ea, ae \in I \;\; \forall\, a \in C\}\,.$$

The definitions show that $I \subseteq \mathcal{N}(C, I)$ and that $\mathcal{N}(C, I)$ is a closed ideal of $\mathrm{Der}(C, I)$.

Corollary 8.2.7. *Suppose that A and B are stable C^*-algebras (with trivial gradings $\beta_A = \mathrm{id}_A$ and $\beta_B = \mathrm{id}_B$), A is separable, B is σ-unital and that $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ is a non-degenerate m.o.c. cone that is countably generated.*

Let $H\colon A \to \mathcal{M}(B)$ a non-degenerate C^*-morphism with $\delta_\infty \circ H$ unitarily equivalent to H such that $V_b\colon\; a \in A \mapsto b^* H(a) b$ is in $\mathcal{C}$ for each $b \in B$ and the c.p. maps $\{V_b\, ;\; b \in B\}$ generate $\mathcal{C}$, existing by Corollary 5.4.4.

Further let $S, T \in H(A)' \cap \mathcal{M}(B)$ two isometries with $SS^* + TT^* = 1$ that exist by Remark 5.1.1(8).

Define $H_0\colon A \to \mathcal{M}(B)/B = \mathrm{Q}^{\mathrm{s}}(B)$ by $H_0 := \pi_B \circ H$.

The group $\mathrm{KK}(\mathcal{C};\, A, B)$ is natural isomorphic to the kernel of the group morphism

$$\mathrm{K}_1\big(H_0(A)' \cap \mathrm{Q}^{\mathrm{s}}(B)\big) \to \mathrm{K}_1\big(\mathrm{Q}^{\mathrm{s}}(B)\big) \cong \mathrm{K}_0(B)\,.$$

Alternatively, with $D := \mathcal{M}(B)$ and $C := H(A)$ and $I := B$, we get

$$\mathrm{KK}(\mathcal{C};\, A, B) \cong \mathrm{K}_1\big(\mathrm{Der}(H(A), B)\big)\,.$$

The elements of $\mathrm{KK}(\mathcal{C};\, A, B)$ can be represented by unitaries in $u \in \mathcal{M}(B)$ that satisfy $u \in \mathrm{Der}(H(A), B)$.

Next has to be checked again!
It would be a dream. But not reality?

Two unitaries $u, v \in \mathrm{Der}(H(A), B)$ define the same element of $\mathrm{KK}(\mathcal{C}\,;\, A, B)$, if and only if, there exist $n \in \mathbb{N}$ and $f_1, \ldots, f_n \in \mathrm{Der}(H(A), B)$ with $f_j^* = -f_j$ $(j = 1, \ldots, n)$ and

$$(u^* v) \oplus_{S,T} 1 = \exp(f_1) \cdot \ldots \cdot \exp(f_n)\,.$$

In particular, $u \in \mathcal{U}\big(\mathrm{Der}(H(A), B)\big)$ represents the zero element, if and only if, there exist $n \in \mathbb{N}$ and $f_1, \ldots, f_n \in \mathrm{Der}(H(A), B)$ with $f_j^* = -f_j$ $(j = 1, \ldots, n)$ and

$$u \oplus_{S,T} 1 = \exp(f_1) \cdot \ldots \cdot \exp(f_n)\,.$$

Proof. A description that is a straight reformulation of the picture coming from the use of Kasparov modules and generalized Fredholm operators is given by classes of elements $F \in \mathrm{Der}(H(A), B)$ with $1 - F^*F, 1 - FF^* \in \mathcal{N}(H(A), B)$, i.e., $F + \mathcal{N}(H(A), B)$ is a unitary in $\mathrm{Der}(H(A), B)/\mathcal{N}(H(A), B)$ and $[F] = [G]$ for $G \in \mathrm{Der}(H(A), B)$ with $1 - G^*G, 1 - GG^* \in \mathcal{N}(H(A), B)$ if and only if $(G^*F \oplus_{S,T} 1) + \mathcal{N}(H(A), B)$ is in $\mathcal{U}_0(\mathrm{Der}(H(A), B)/\mathcal{N}(H(A), B))$. The addition is defined by $[F_1] + [F_2] := [F_1F_2]$.

Equivalently expressed:
$V_j := F_j + \mathcal{N}(H(A), B)$ are unitaries in $\mathrm{Der}(H(A), B)/\mathcal{N}(H(A), B)$.

And $[F_1] = [F_2]$ if and only if $(1 \oplus V_2) - (1 \oplus V_1) \in \mathcal{N}(H(A), B)$

???

Other approach ???

$F_1, F_2 \in \mathrm{Der}(H(A), B)$ with $1 - F_j^*F_j, 1 - F_jF_j^* \in \mathcal{N}(H(A), B)$ for some unitary $F_j + B = V_j \in \mathcal{M}(B)/B$, and $[F_1] = [F_2]$ if and only if

$$1 - (V_1^*V_2 \oplus 1) \in \mathrm{Ann}(H_0(A), \mathrm{Q^s}(B))$$

with $\oplus = \oplus_{\pi_B(S),\pi_B(T)}$, i.e., $(V_1 \oplus 1) - (V_2 \oplus 1) \in \mathrm{Ann}(H_0(A), \mathrm{Q^s}(B))$.

The equivalence follows from the fact that the hereditary C^*-subalgebra $\mathcal{N}(H(A), B)$ contains B and $\pi_B(\mathcal{N}(H(A), B)) = \mathrm{Ann}(H_0(A), \mathrm{Q^s}(B))$.

`to be filled in` ??

By assumptions, A and B are σ-unital, A is stable and H_0 is non-degenerate. It follows that the σ-unital C^*-subalgebras B, $H(A)$ and $H(A) + B$ of $\mathcal{M}(B)$ are stable by Remark 5.1.1(9).

It follows from ???? Prop. **?? ??** that there exist an isometry $S_1 \in \mathcal{M}(B)$ with $S_1^*H(A)S_1 \subseteq B$. Thus, $V := \pi_B(S_1) \in \mathrm{Q^s}(B)$ is an isometry, $V^*V = 1$, that satisfies $V^*H_0(A)V = \{0\}$. In particular, $\mathrm{Ann}(H_0(A)) := \mathrm{Ann}(H_0(A), \mathrm{Q^s}(B))$ is a full hereditary C^*-subalgebra of $\mathrm{Q^s}(B)$. It follows

$$\mathrm{K}_*\big((H_0(A)' \cap \mathrm{Q^s}(B))/\,\mathrm{Ann}(H_0(A))\big) \cong \mathrm{kernel}\{\mathrm{K}_*\big(H_0(A)' \cap \mathrm{Q^s}(B)\big) \to \mathrm{K}_*(\mathrm{Q^s}(B))\}\,.$$

We use that $\mathcal{N}(H(A), B)$ is a full hereditary C^*-subalgebra of $\mathcal{M}(B)$ and contains B. If we apply Lemma 4.2.20 to them we obtain that there is a natural isomorphism from $\mathrm{K}_*\big(\mathrm{Der}(H(A), B)/\mathcal{N}(H(A), B)\big)$ onto the *kernel* of the homomorphism $\mathrm{K}_*(\mathrm{Der}(H(A), B) \to \mathrm{K}_*(\mathcal{M}(B)))$ induced by the inclusion $\mathrm{Der}(H(A), B) \subseteq \mathcal{M}(B)$.

Using that $B \subseteq \mathcal{N}(H(A), B) \subseteq \mathrm{Der}(H(A), B)$ we obtain that

$$\mathrm{Der}(H(A), B)/B = H_0(A)' \cap \mathrm{Q^s}(B) \tag{2.3}$$

$$\mathcal{N}(H(A), B)/B = \mathrm{Ann}(H_0(A), \mathrm{Q^s}(B))\,. \tag{2.4}$$

Above we have seen that $\mathrm{Ann}(H_0(A), \mathrm{Q^s}(B))$ is full in $\mathrm{Q^s}(B)$. All this together yields

$$\mathrm{Der}(H(A), B)/\mathcal{N}(H(A), B) \cong (H_0(A)' \cap \mathrm{Q^s}(B))/\,\mathrm{Ann}(H_0(A), \mathrm{Q^s}(B))$$

and that $\mathrm{Ann}(H_0(A), \mathrm{Q^s}(B))$ is a full hereditary C^*-subalgebra of $\mathrm{Q^s}(B)$ ... MORE !!! ??? □

3. $\mathrm{Ext}(S\mathcal{C};\, A, SB)$ and $\mathrm{KK}(\mathcal{C};\, A, B)$ considered as K_1-groups

We fix now a σ-unital C^*-algebra B – later we suppose in addition that B is stable (which plays in the formal *notation* no role). The separability is then needed for emphour interpretation of the Kasparov product.

$\mathcal{C}$-compatible we need ????

Let A an arbitrary *separable* C^*-algebra and $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ a non-degenerate *countably generated* point-norm closed matricial operator-convex cone ("m.o.c. cone"). We define point-norm closed m.o.c. cones $\mathcal{C}(Y) := \mathcal{C} \otimes \mathrm{CP}(\mathbb{C}, \mathrm{C}_0(Y))$ and $\mathcal{C}(Z, Y) := \mathcal{C} \otimes \mathrm{CP}(\mathrm{C}_0(Z), \mathrm{C}_0(Y)) \subseteq \mathrm{CP}(\mathrm{C}_0(Z, A), \mathrm{C}_0(Y, B))$ for the *natural extensions* of $\mathcal{C}$ to the tensor products $\mathrm{C}_0(Z, A) = A \otimes \mathrm{C}_0(Z)$ with help of the algebras $\mathrm{C}_0(Z)$. This is compatible with our in Section 1 introduced canonical extensions $\mathcal{C}_{D,E} := \mathcal{C} \otimes \mathrm{CP}(D, E)$ of $\mathcal{C}$ to a m.o.c. cone in $\mathrm{CP}(A \otimes D, B \otimes E)$. In case $Y = \mathbb{R}$ we write sometimes $S\mathcal{C}$ in place of $\mathcal{C}(\mathbb{R})$, but mostly we simply drop the specification to the spaces Y and Z and write simply $\mathcal{C}$ in place of $\mathcal{C}(Y)$ or $\mathcal{C}(Z, Y)$, – if it is visible to which considered spaces the m.o.c. cone has to be canonically extended.

Recall from Chapter 3, Section **??**, that the possible extension of $\mathcal{C}$ to a point-norm closed m.o.c. cone in $\mathrm{CP}(A \otimes M, B \otimes N)$ is *unique* if M and N are simple and nuclear (cf. Chapter 3 `exact refs ??`). This applies in particular to the case where $M = \mathbb{K}$ and $N = \mathbb{K}$. We write also $\mathcal{C}$ for this extension $\mathcal{C} \otimes \mathrm{CP}(\mathbb{K}, \mathbb{K}) \subseteq \mathrm{CP}(A \otimes \mathbb{K}, B \otimes \mathbb{K})$.

It is important to understand clearly that the definitions in Chapter 3 give not "tensor products" in the usual algebraic or topological sense, because it are only point norm closed m.o.c. cones that are "generated" by a set $\mathcal{S}$ of tensor products, and the algebraic hull of this "tensors" is usually not dense in $\mathcal{C}(\mathcal{S})$.

Our below given results show that we only need to know that our functors $Y \mapsto \mathrm{KK}_{\mathrm{nuc}}(A, \mathrm{C}_0(Y, B))$, or $Y \mapsto \mathrm{KK}_{\mathrm{nuc}}(X;\, A, \mathrm{C}_0(Y, B))$ respectively $Y \mapsto \mathrm{KK}(\mathcal{C}(Y);\, A, \mathrm{C}_0(Y, B))$ exists (and are homotopy invariant with respect to the locally compact spaces Y) to get the needed facts for our later applications of $\mathrm{Ext}_{\mathrm{nuc}}$, $\mathrm{Ext}_{\mathrm{nuc}}(X;\, \cdot, \cdot)$, $\mathrm{Ext}(\mathcal{C};\, A, \cdot)$ and to the Rørdam groups $\mathrm{R}(\mathcal{C};\, A, \cdot)$ in the proofs of Theorems B and M.

For the proofs of the general results in Chapter 9 we even need only that $\mathrm{Ext}(\mathcal{C}(\mathbb{R}_+);\, A, \mathrm{C}_0(\mathbb{R}_+, B)) = 0$ (respectively $\mathrm{Ext}_{\mathrm{nuc}}(A, \mathrm{C}_0(\mathbb{R}_+, B)) = 0$, respectively $\mathrm{Ext}_{\mathrm{nuc}}(X;\, A, \mathrm{C}_0(\mathbb{R}_+, B)) = 0$). In fact, it would be enough to know that

$$\mathrm{Ext}\big(\mathcal{C}(S^1, \mathbb{R}_+)\, ;\, D \otimes \mathrm{C_b}(S^1)\, ,\, B \otimes \mathrm{C}_0(\mathbb{R}_+)\big) = 0$$

for $D = A \otimes \mathbb{K}$, because e.g. $\mathrm{Ext}_{\mathrm{nuc}}(A, B) = \mathrm{Ext}(\mathcal{C};\, A, B)$ take $\mathcal{C} = \mathrm{CP}_{\mathrm{nuc}}(A, B)$, and for $\mathrm{Ext}_{\mathrm{nuc}}(X;\, A, B)$ take the cone $\mathrm{CP}_{\mathrm{rn}}(X;\, A, B)$ of Ψ_A-Ψ_B-residually nuclear maps from A to B, where A is separable, B is σ-unital, and the action Ψ_B is (downward !) induced by an action of X on a separable non-degenerate C^*-subalgebra $N \subseteq \mathcal{M}(B)$ (which makes sure that $\mathrm{CP}_{\mathrm{rn}}(X;\, A, B)$ is countably generated, cf. Chapter 3).

We know from Prop./Cor. in Chapter 3

`Give exact references !!! ??`

and Corollary 5.4.4 how to find a non-degenerate C^*-morphism $H\colon A \otimes \mathbb{K} \to \mathcal{M}(B \otimes \mathbb{K})$ which determines the point-norm closure of $\mathcal{C}$ – in the case of, closed with respect to the point-norm topology, countably generated and non-degenerate matrix operator-convex cones $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ and of separable A and σ-unital B.

`find ref's for above ??? ??`

For example, if A and B are both separable, then $\mathcal{C} = \mathrm{CP}(A, B)$ satisfies our requirements on $\mathcal{C}$, but $\mathrm{CP}(A, B)$ is in general not singly generated if A is separable and B is only σ-unital.

We know from Corollary 5.6.1, cf. also Remark 5.1.1(8) and Lemma 5.1.2, that we can find a strictly continuous unital *-monomorphism $\mathcal{M}(\mathbb{K}) \hookrightarrow \mathcal{M}(B \otimes \mathbb{K})$ and

Next H_1 is only related to $\mathcal{C} := \mathrm{CP}_{\mathrm{nuc}}(D, B)$.
we use also the universal $H_1\colon D := A \otimes \mathbb{K} \to\to \mathcal{M}(B)$ in ''general position'' in the sense of Definition 3.3.1,
related to some specified $\mathcal{C} \subseteq \mathrm{CP}(A, B)$
that is ''non-degenerate'' and countably generated.

(... and) for $D := A \otimes \mathbb{K}$ a faithful *-monomorphism $H_1\colon D \to \mathcal{M}(\mathbb{K}) \subseteq \mathcal{M}(B \otimes \mathbb{K})$ such that H_1 is universal for the cone $\mathrm{CP}_{\mathrm{nuc}}(D, B)$ and that there is a copy of $\mathcal{O}_2$ unitally contained in $H_1(D)' \cap \mathcal{M}(\mathbb{K}) \subseteq \mathcal{M}(B \otimes \mathbb{K})$. Here $D := A \otimes \mathbb{K}$.

The general bi-module to be considered for non-degenerate m.o.c. cones $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ is given by the universal $H_0\colon D \to \mathcal{M}(B \otimes \mathbb{K})$ in general position – in the sense of Definition 3.3.1, with the property the c.p. maps $d \in D \mapsto e^* H_0(d) e \in B \otimes \mathbb{K}$ generates the natural extension of $\mathcal{C}$ to $\mathcal{C} \otimes \mathrm{CP}(\mathbb{K}, \mathbb{K}) \subseteq \mathrm{CP}(A \otimes \mathbb{K}, B \otimes \mathbb{K})$.

To simplify notation, let us assume again that B is stable in this section, i.e., that $B \cong B \otimes \mathbb{K}$. Further we suppose from now on that B is σ-unital, that $A \cong D := A \otimes \mathbb{K}$ is stable and separable.

We know that there is a given non-degenerate C^*-morphism $H\colon D \to \mathcal{M}(B)$ with $\delta \circ H$ unitarily equivalent to H, such that H corresponds to a non-degenerate countably generated m.o.c. cone $\mathcal{C}$ in the sense of Corollary 5.4.4. We fix H and $\mathcal{C}$ from now on.

Suppose from now on that Y is a closed subspace of $\mathbb{R}^2$. There is a natural unital strictly continuous embedding

$$\mathcal{M}(B) \cong 1 \otimes \mathcal{M}(B) \subseteq \mathrm{C}_{\mathrm{b,st}}(Y \cup \{\infty\}, \mathcal{M}(B)) \subseteq \mathcal{M}(\mathrm{C}_0(Y, B)) .$$

Let $E_Y := \mathcal{M}(\mathrm{C}_0(Y, B))/\, \mathrm{C}_0(Y, B)$ and $H_Y(a) := \pi_{\mathrm{C}_0(Y,B)}(H(a)) \in E_Y$ for $a \in D$. Then $B \cong \mathrm{C}_0(\{0\}, B)$, $H_0 := H_{\{0\}} = \pi_B \circ H$, $H_Y(D)' \cap E_Y$ contains a unital copy of $\mathcal{O}_2$ that comes from a copy of $\mathcal{O}_2$ which is unitally contained in $(1 \otimes H(D))' \cap \mathcal{M}(\mathrm{C}_0(Y, B))$. In particular, $[H_Y \oplus H_Y] = [H_Y]$ for the unitary equivalence classes. Further let $\mathcal{C} \subseteq \mathrm{CP}(D, B)$ denote the point-norm closed m.o. convex cone, that is generated by the maps $V_b \colon a \in D \mapsto b^* H(a) b$ ($b \in B$), and let

$$\mathcal{C}(Y) := \mathcal{C} \otimes \mathrm{CP}(\mathbb{C}, \mathrm{C}_0(Y)) \;\subseteq\; \mathrm{CP}(D, B \otimes \mathrm{C}_0(Y))$$

denote the natural extension of $\mathcal{C}$ to a cone in $\mathrm{CP}(D, \mathrm{C}_0(Y, B))$ (cf. Definition 3.6.16 and Corollary 3.6.20. Don't mix it up with a sort of completion of algebraic sums of tensors!).

Then $\mathrm{Ext}(\mathcal{C}(Y);\, A, \mathrm{C}_0(Y, B)) \cong G(H_Y\,; D, E_Y\,)$ by Proposition **??** and Corollary 5.4.4 by putting $\mathcal{C}(Y)$ and $H_Y \colon D \to E_Y$ in place of $\mathcal{C}$ and $H \colon D \to \mathcal{M}(B)$.

Now we introduce a construction that is needed in the proof of Lemma 8.3.2 and Corollary 8.3.3. The Lemma 8.3.2 will be used in the proof of Theorems B(i,ii) and M(i,ii) in Chapter 9.

Note that $\mathrm{Q^s}(SB) = \mathrm{Q^s}(\mathrm{C}_0(\mathbb{R}, B)) = E_{\mathbb{R}}$ is naturally isomorphic to the pull-back construction of the split epimorphisms $\pi_0^+ \colon E^{(+)} \to E^{(0)}$ and $\pi_0^- \colon E^{(-)} \to E^{(0)}$ at $t = 0$, where $E^{(+)} := E_{\mathbb{R}_+} = \mathrm{Q^s}(\mathrm{C}_0(\mathbb{R}_+, B))$, $E^{(-)} := E_{\mathbb{R}_-} = \mathrm{Q^s}(\mathrm{C}_0(\mathbb{R}_-, B))$ and $E^{(0)} := E_{\{0\}} = \mathrm{Q^s}(B)$:

This results from the natural isomorphism $\mathrm{C}_{\mathrm{b,st}}(Y, \mathcal{M}(B)) \cong \mathcal{M}(\mathrm{C}_0(Y, B))$ in cases $Y = \mathbb{R}$, $Y = \mathbb{R}_+$, $Y = \mathbb{R}_-$ and $Y = \{0\}$, by dividing by $\mathrm{C}_0(Y, B)$. The restriction and evaluation maps are induced by the corresponding restriction and evaluation of strictly continuous functions:

$H \colon D \to \mathcal{M}(B) \cong 1 \otimes \mathcal{M}(B)$ goes into the constant functions of $\mathrm{C}_{\mathrm{b,st}}(Y, \mathcal{M}(B))$ and then down to $E_Y = \mathrm{Q^s}(\mathrm{C}_0(Y, B))$. Therefore we must not always distinguish the various restrictions of "constant" elements in $\mathcal{M}(B) \subseteq \mathrm{C_b}(Y, \mathcal{M}(B)) \subseteq \mathrm{C}_{\mathrm{b,st}}(Y, \mathcal{M}(B))$.

But the reader should not misunderstand the terminology "constant", "restriction" and "evaluation": The point-"evaluations" $\pi_t(b)$ can all be zero but $b \in \mathrm{Q^s}(SB)$ is non-zero, because that says only that b has a representative $c \in \mathrm{C}_{\mathrm{b,st}}(\mathbb{R}, \mathcal{M}(B))$ such that $c(t) \in B$ for every t. In particular this happens for all $c \in \mathrm{C_b}(\mathbb{R}, B)$.

Notice that the C^*-subalgebra of elements

$$c \in \mathcal{M}(\mathrm{C_b}(X, B)) \cong \mathrm{C}_{\mathrm{b,st}}(X, \mathcal{M}(B)) \cong \mathcal{M}(\mathrm{C}_0(X, B))$$

with $\pi_x(c) \in B$ for all $x \in X$ for a non-discrete second countable locally compact Hausdorff spaces X is always bigger than $\mathrm{C_b}(X, B)$ if B is σ-unital and stable.

The criterium for $c \in \mathrm{C_b}(X, B)$ is $\pi_x(c) \in B$ for all $x \in X$ *and* $x \mapsto \|\pi_x(c)\|$ is an upper semi-continuous

As we have seen in Chapter 7, this does not imply that c is in $\mathrm{C_b}(\mathbb{R}, B)$, and, in particular, it does not mean that c is in $\mathrm{C_0}(\mathbb{R}, B)$. For example, the natural embedding $\epsilon\colon \mathcal{M}(B) \to \mathrm{Q^s}(\mathrm{C_0}(Y, B))$ of the constant functions into the stable corona of $\mathrm{C_0}(Y, B)$ will be defined as $b \in \mathcal{M}(B) \mapsto b + \mathrm{C_0}(Y, B)$, i.e. $\epsilon(\mathcal{M}(B)) = \mathcal{M}(B) + \mathrm{C_0}(Y, B)$. It is faithful for $Y = \mathbb{R}$ and $Y = \mathbb{R}_+$, but the kernel of $\pi_t \circ \epsilon$ is B for every $t \in Y$. But this is just the nice property that we can *explore* now:

Remark 8.3.1. The algebra $E_{\mathbb{R}} := \mathrm{Q^s}(SB)$ is a weak variant of a sort of "pull-back" of epimorphisms $\pi_0^+\colon E^{(+)} \to E^{(0)}$ and $\pi_0^-\colon E^{(-)} \to E^{(0)}$ if B is σ-unital, where we use the natural identities and epimorphisms from $\mathcal{M}(\mathrm{C_0}(\mathbb{R}_-, B)) = \mathcal{M}(\mathrm{C_b}(\mathbb{R}_-, B)) \to \mathcal{M}(B)$ and $\mathcal{M}(\mathrm{C_0}(\mathbb{R}_+, B)) = \mathcal{M}(\mathrm{C_b}(\mathbb{R}_-, B)) \to \mathcal{M}(B)$

We can define for unitaries U in $\mathcal{M}(B)$ that commute element-wise modulo B with $H(D)$, i.e., with $UH(d) - H(d)U \in B$ for all $d \in D$, in an almost trivial way a weakly *nuclear* (respectively weakly $\mathcal{C}$-*compatible*) extensions $h_U\colon D \to E_{\mathbb{R}}$ if H is weakly *nuclear* (respectively H is weakly $\mathcal{C}$-*compatible*).

More generally, we find in $\mathrm{Ext}(\mathcal{C}_H\,;\, D, SB) = G(H_{\mathbb{R}}\,;\, D, E_{\mathbb{R}})$ extensions by the following method:

$E_{\mathbb{R}}$ is in a natural way isomorphic to the subalgebra of $E^{(-)} \oplus E^{(+)}$ which consists of the pairs (e, f) with $\pi_0^-(e) = \pi_0^+(f)$, i.e., $e = \pi_-(g_-) := \pi_B(g_-(0))$, $f = \pi_+(g_+) := \pi_B(g_+(0))$ for

$$g_\alpha \in \mathrm{C_{b,st}}(\mathbb{R}_\alpha, \mathcal{M}(B)) \cong \mathcal{M}(\mathrm{C_0}(\mathbb{R}_\alpha, B))$$

$(\alpha \in \{+,-\})$, and the restriction maps $g_\alpha \mapsto g_\alpha|0 := g_\alpha(0)$. Notice that $\pi_B(g_-(0)) = \pi_B(g_+(0))$ is equivalent to $g_+(0) - g_-(0) \in B$.

Is $E_{\mathbb{R}}$ really the pull-back of $E^{(-)}$ and $E^{(+)}$?
Is $C^{(0)} := H_{\mathbb{R}}(D)' \cap \mathcal{M}(SB)$ the pull-back of C_+ and C_- with restriction epimorphisms $C_\alpha \to C|0$ $(\alpha \in \{-,+\})$, for

$$C_\alpha^{(0)} := H_{\mathbb{R}_\alpha}(D)' \cap \mathcal{M}(\mathrm{C_0}(\mathbb{R}_\alpha, B))$$

and

$$C^{(0)}|0 = H(D)' \cap \mathcal{M}(B)\,.$$

The map $c \in C^{(0)} \to c(0) \in C^{(0)}|0$ is a splitting epimorphism via $\lambda\colon C^{(0)}|0 \to C^{(0)}$ defined by $\lambda(d)(t) := d \in C^{(0)}|0$ for all $t \in \mathbb{R}$.

Is it the same for $\mathcal{D}_X := \mathrm{Der}(H_X(D); \mathrm{C_0}(X, B))$, with $X = \mathbb{R}$, $X = \mathbb{R}_+$ $X = \mathbb{R}_-$ or $X = \{0\}$?

What about $\mathrm{Der}(H_{\mathbb{R}}(D);K)/\,\mathrm{C}_0(\mathbb{R},B)$ with

$$K := \{f \in \mathrm{C_b}(\mathbb{R},B)\,;\, \lim_{t\to-\infty} \|f\| = 0\}\,.$$

Let $U \in \mathrm{Der}(H(D),B) \subseteq \mathcal{M}(B)$ a unitary, and let $h_U^{\alpha}\colon D \to E^{(\alpha)}$, for $\alpha \in \{+,-\}$, be defined by $h_U^{(-)}(a) := H(a)|\mathbb{R}_-$ and $h_U^{(+)}(a) := UH(a)U^*|\mathbb{R}_+$ for $a \in D$, where we use the natural inclusions of $\mathcal{M}(B)$ into $E_{\mathbb{R}}$, $E^{(-)}$ and $E^{(+)}$.

Then $\pi_0^+ h_U^{(+)}(a) = H(a) = \pi_0^- h_U^{(-)}(a)$ for $a \in D$. Thus, $h_U^{(+)}$ and $h_U^{(-)}$ define a homomorphism $h_U\colon D \to E_{\mathbb{R}}$.

If we use the – a bit inaccurate – restriction notation, we can express this by $h_U(a)|\mathbb{R}_- = H(a)|\mathbb{R}_-$ and $h_U(a)|\mathbb{R}_+ = UH(a)U^*|\mathbb{R}_+$ for $a \in D$.

It turns out that h_U has a completely positive contractive lift $T\colon D \to \mathcal{M}(SB) \cong \mathrm{C_{b,st}}(\mathbb{R},\mathcal{M}(B))$ that is 2-step-dominated by $H\colon D \to \mathcal{M}(B) \subseteq \mathrm{C_{b,st}}(\mathbb{R},\mathcal{M}(B))$:
Let $f \in \mathrm{C_b}(\mathbb{R})$ be defined by $f(t) := 0$ for $t \le 0$, $f(t) := t$ on $[0,1]$ and $f(t) := 1$ for $t \ge 1$, further let $T(d)(t) := (1-f(t))H(d) + f(t)UH(d)U^*$.

Thus $T(\cdot) = e_1^* H(\cdot) e_1 + e_2^* H(\cdot) e_2$ for $e_1 := \sqrt{1-f}$ and $e_2 := U^*\sqrt{f}$, and T is weakly *nuclear* if H is weakly *nuclear* (respectively T is weakly $\mathcal{C}$-*compatible* if H is weakly $\mathcal{C}$-*compatible*).

If $\mathcal{M}(B)$ contains a copy of $\mathcal{O}_2$ unitally and if $[H] = [H] + [H]$ (which is the case by our assumptions), then there are isometries $s_1, s_2 \in H(D)' \cap \mathcal{M}(B)$ which are canonical generators of $\mathcal{O}_2$, cf. Proposition 4.3.5(iii). Then $T(\cdot) = I_U^* H(\cdot) I_U$ for the isometry $I_U = (1-f)^{1/2}s_1 + f^{1/2}s_2U^*$.

Since $UH(d)U^* - H(d) \in B$, $T(d) - H(d)$ is an element of the ideal $I_1 := \{b \in \mathrm{C_b}(\mathbb{R},B)\colon b(t) = 0\,\forall t \le 0\}$, and $T(d) - UH(d)U^*$ is a element of the ideal $I_2 := \{b \in \mathrm{C_b}(\mathbb{R},B)\colon b(t) = 0\,\forall t \ge 1\}$. But $(I_1 + SB)/SB = \mathrm{Q}(\mathbb{R}_+,B)$ and $(I_2+SB)/SB = \mathrm{Q}(\mathbb{R}_-,B)$, where we identify $\mathrm{Q}(\mathbb{R},B)$ naturally with $\mathrm{Q}(\mathbb{R}_-,B) \oplus_{\ell_\infty} \mathrm{Q}(\mathbb{R}_+,B)$ and consider it as an ideal of $E_{\mathbb{R}}$. The natural epimorphism $E_{\mathbb{R}} \to E^{(-)}$ maps $\mathrm{Q}(\mathbb{R}_+,B)$ to zero and $E_{\mathbb{R}} \to E^{(+)}$ maps $\mathrm{Q}(\mathbb{R}_-,B)$ to zero.

One can see that $T(d) + SB = h_U(d)$, because this equality can be calculated separately in $E^{(-)}$ and $E^{(+)}$.

So, if $H(D)' \cap \mathcal{M}(B)$ contains a unital copy of $\mathcal{O}_2$ and if the unitary group of $\mathcal{M}(B)$ is connected, we get a map $U \mapsto h_U$ from the intersection $\mathcal{U}_0(\mathrm{Q}(B)) \cap H_0(D)'$ into $S(H_{\mathbb{R}}\,;\,D,E_{\mathbb{R}})$, where $H_0 := \pi_B \circ H$.

Thus we have seen that, in the case where B is stable and σ-unital and D is stable and separable, for every unitary $U \in \mathcal{M}(B)$ with $UH(d) - H(d)U \in B$ for all $d \in D$,
the homomorphism h_U defines an element $[h_U]$ of $S(H_{\mathbb{R}}\,;\,D,E_{\mathbb{R}})$ and satisfies $h_U(d) - H(d) \in J$ for every $d \in D$, where J is the ideal of $\mathrm{Q^s}(SB)$ which is defined by $\mathrm{Q}(\mathbb{R}_+,B)$.

It follows that $[h_U \oplus H_{\mathbb{R}}]$ is an element of $\mathrm{Ext}(\mathcal{C}(H);\, D, SB) = G(H_{\mathbb{R}}\,;\, D, E_{\mathbb{R}})$.

With the above introduced notations J, E_Y, H_Y, $F(Y)$ and H_0 we get the following lemma.

LEMMA 8.3.2. *Suppose that D is separable and stable, that B is σ-unital and stable, and that $H\colon D \to \mathcal{M}(B)$ is a non-degenerate faithful C^*-morphism with $\delta_\infty \circ H$ unitarily equivalent to H.*

Furthermore, suppose that the following groups for $\mathbb{R}_+ := [0,\infty)$ are trivial:

$$\mathrm{Ext}(\mathcal{C};\, D, \mathrm{C}_0(\mathbb{R}_+, B)) \;=\; G(H_{\mathbb{R}_+}\,;\, D, E_{\mathbb{R}_+}) \;=\; \{[H_{\mathbb{R}_+}]\} \;\cong\; 0\,.$$

Let $[g], [T] \in S(H_{\mathbb{R}}\,;\, D, E_{\mathbb{R}})$ with $[T] = [H_{\mathbb{R}}]$, and let $s_1, s_2 \in E_{\mathbb{R}}$ canonical generators of a copy of $\mathcal{O}_2$ that is unitally contained in $E_{\mathbb{R}}$. Then:

(i) *There exists a unitary $u \in E_{\mathbb{R}}$ such that*

$$u^*T(a)u - (g(a) \oplus_{s_1,s_2} T(a)) \in J \quad \textit{for every } a \in D\,,$$

where J is the image of the natural embedding of $\mathrm{Q}(\mathbb{R}_+, B)$ into

$$\mathrm{Q}(\mathbb{R}, B) \subseteq E_{\mathbb{R}}\,.$$

(ii) *If $\sigma\colon \mathbb{R} \to \mathbb{R}$ is an order preserving homeomorphism of $\mathbb{R}$, then $[\widehat{\sigma} \circ (g \oplus T)] = [g \oplus T]$ in $S(H_{\mathbb{R}}\,;\, D, E_{\mathbb{R}})$.*

This applies to the case where $H\colon D \to \mathcal{M}(B)$ corresponds to a countably generated non-degenerate m.o.c. cone $\mathcal{C}$ – as e.g. to $\mathcal{C} := \mathrm{CP}_{\mathrm{nuc}}(A, B)$ if A is separable and B is σ-unital – because then $\mathrm{Ext}(\mathcal{C};\, D, \mathrm{C}_0(\mathbb{R}_+, B)) \cong 0$, by Corollary 5.9.21 and Proposition 8.2.6.

PROOF. We keep the notations of Remark 8.3.1. The Cuntz addition will be taken at first with respect to fixed isometries s_1 and s_2 in $H_{\mathbb{R}}(D)' \cap E_{\mathbb{R}}$ which generate a copy of $\mathcal{O}_2$ in $H_{\mathbb{R}}(D)' \cap E_{\mathbb{R}}$. Then $H_{\mathbb{R}} \oplus H_{\mathbb{R}} = H_{\mathbb{R}}$.

We show at the end of the proof of Part (i) the independence of the result from the chosen representatives H for for $[H_{\mathbb{R}}]$ in $G(H_{\mathbb{R}};\, D, E_{\mathbb{R}})$ and from the chosen isometries s_1, s_2 in $H_{\mathbb{R}}(D)' \cap E_{\mathbb{R}}$ with $s_1s_1^* + s_2s_2^* = 1$.

(i): Recall that $\mathrm{C}_0(\mathbb{R}_\alpha, B) \cong \mathrm{C}_0((0,1], B)$,

$$E^{(\alpha)} := E_{\mathbb{R}_\alpha} = \mathrm{Q}^{\mathrm{s}}(\mathrm{C}_0(\mathbb{R}_\alpha, B))$$

for $\alpha \in \{-,+\}$ and $E^{(0)} = \mathrm{Q}^{\mathrm{s}}(B)$.

If $g\colon D \to E_{\mathbb{R}} := \mathrm{Q}^{\mathrm{s}}(SB)$ defines an element in $S(H_{\mathbb{R}}\,, D, E_{\mathbb{R}})$, then this means that there is an isometry $s \in E_{\mathbb{R}}$ with $s^*H_{\mathbb{R}}(d)s = g(d)$ for all $d \in D$, i.e., such $ss^* \in H_{\mathbb{R}}(D)' \cap E_{\mathbb{R}}$.

In fact we know at the beginning only that, by definition of $\mathrm{SExt}(\mathcal{C}[\mathbb{R}];\, D, SB)$,

unify notations for $\mathcal{C}[X]$!!!

there is a c.p. contraction $V \colon D \to \mathcal{M}(SB)$ with $\pi_{SB} \circ V = g$ and $a^* V(\cdot) a \in \mathcal{C}[\mathbb{R}]$ for each $a \in \mathrm{C}_0(\mathbb{R}, B) =: SB$. From that we have obtained in Chapters 3 and 4 that there exists an isometry $T \in \mathcal{M}(SB)$ with $T^* H(d) T - V(d) \in SB$ for all $d \in D$. Thus $s = \pi_{SB} \circ T$ has the desired property.

If we restrict now $g(d)$ and s to $\mathbb{R}_-$ and $\mathbb{R}_+$, we get isometries $s^- \in E^{(-)}$, $s^+ \in E^{(+)}$ and homomorphisms $g^- \colon D \to E^{(-)}$ and $g^+ \colon D \to E^{(+)}$ such that $(s^\alpha)^* H_\alpha s^\alpha = g^\alpha$ for $\alpha \in \{+,-\}$ where $H_+ := H_{[0,\infty)}$ and $H_- := H_{(-\infty,0]}$ are the "restrictions" of $H_\mathbb{R}$. Thus $[g^\alpha] \oplus [H_\alpha] \in G(H_\alpha, D, E^{(\alpha)})$ for $\alpha \in \{+,-\}$. By the definition of $E^{(+)}$ and $E^{(-)}$ and by assumption, we get $[g^\alpha \oplus H_\alpha] = [H_\alpha]$. But this means that there are unitaries $U^+ \in E^{(+)}$ and $U^- \in E^{(-)}$ such that $g^\alpha \oplus H_\alpha = (U^\alpha)^* H_\alpha U^\alpha$ for $\alpha \in \{+,-\}$.

If we let $H_0 := \pi_B \circ H$ we get in particular

$$(\pi_0^+(U^+))^* H_0 \pi_0^+(U^+) = (\pi_0^-(U^-))^* H_0 \pi_0^-(U^-)$$

at zero. From now on we use the shorter (but by Remark 8.3.1 somehow inaccurate) notation

$$U^+(0) := \pi_0^+(U^+) \quad \text{and} \quad U^-(0) := \pi_0^-(U^-).$$

Thus $U^+(0) U^-(0)^* \in \mathrm{Q^s}(B)$ is a unitary in the commutant $H_0(D)' \cap \mathrm{Q^s}(B)$ of $H_0(D)$ in $\mathrm{Q^s}(B)$. $U^-(0)$ is in the image of the unitaries of $E^{(-)}$ by π_0^- and $U^+(0)$ is in the image of the unitaries of $E^{(+)}$ by π_0^+.

We have $\mathrm{K}_*(\mathcal{M}(\mathrm{C}_0(\mathbb{R}_+, B))) = 0$, because B is stable. This follows from Lemma 5.1.2(ii) as in the proof of Lemma 4.6.5(ii), or from the contractibility of the unitary groups of multiplier algebras of stable algebras, [**557**], [**180**]. Since $\mathrm{C}_0(\mathbb{R}_+, B) \cong \mathrm{C}_0(\mathbb{R}_-, B)$ is contractible, we get $\mathrm{K}_1(E^{(+)}) = 0$ and $\mathrm{K}_1(E^{(-)}) = 0$ from the 6-term exact sequence of K-theory. Therefore the epimorphisms π_0^+, respectively π_0^-, maps unitaries of $E^{(+)}$, respectively of $E^{(-)}$, into the unitaries u of $E^{(0)} := \mathrm{Q^s}(B)$ with $[u] = 0$ in $\mathrm{K}_1(\mathrm{Q^s}(B))$. Thus $[U^+(0) U^-(0)^*] = [U^+(0)] - [U^-(0)] = 0$ in $\mathrm{K}_1(\mathrm{Q^s}(B))$, and, therefore, by Lemma 4.2.6(v,2), $(U^-(0) U^-(0)^*) \oplus 1$ is in the connected component of 1 in the unitaries of $\mathrm{Q^s}(B)$. Let $V \in \mathcal{M}(B)$ a unitary lift of $(U^+(0) U^-(0)^*) \oplus 1$. Then $H(a) V - V H(a) \in B$ for $a \in D$, and we can form the *-monomorphism $h_V \colon D \to E_\mathbb{R}$ with $[h_V] \in S(H_\mathbb{R}, D, E_\mathbb{R})$ and $h_V(a) - H_\mathbb{R}(a) \in J$.

Let $W := V + \mathrm{C}_0(\mathbb{R}_+, B)$ in $E^{(+)}$, then

$$\pi_0^+(W) = \pi_B(V) = (U^+(0) U^-(0)^*) \oplus 1\,.$$

The unitaries $(U^- \oplus 1) \in E^{(-)}$ and $W^*(U^+ \oplus 1) \in E^{(+)}$, satisfy

$$U^-(0) \oplus 1 = \pi_0^-(U^- \oplus 1) = \pi_0^+(W)^* (U^+(0) \oplus 1) = \pi_0^+(W^*(U^+ \oplus 1)).$$

Therefore they define a unitary $u_0 \in E_\mathbb{R} \subseteq E^{(-)} \oplus E^{(+)}$.

Let $w \in \mathcal{O}_2$ with $w^*((a \oplus b) \oplus c) w = a \oplus (b \oplus c)$, and let $u := u_0 w$. For the Cuntz addition $\oplus$ and its transformation rules we refer to Chapter 4 for every details.

Since $H_0 \oplus H_0 = H_0$, we get from our definition of h_V in Remark 8.3.1 that

$$g^-(a) \oplus H_-(a) = w^*(U^- \oplus 1)^*(h_V(a)|\mathbb{R}_-)(U^- \oplus 1)w$$

and

$$g^+(a) \oplus H_+(a) = w^*(U^+ \oplus 1)^* V^*(h_V(a)|\mathbb{R}_+)V(U^+ \oplus 1)w\,.$$

This means that $g \oplus H_0 = u^* h_V u$ with $u \in \mathcal{U}(E_{\mathbb{R}})$ as above defined. Therefore, $(g(a) \oplus H_0(a)) - u^* H_0(a) u = u^*(h_V(a) - H_0(a))u$ is in J for $a \in D$.

We show the independence from the particular choice of $T \in [H_{\mathbb{R}}]$ and from the generators s_1, s_2 of $\mathcal{O}_2$: Let $T\colon D \to \mathrm{Q}^{\mathrm{s}}(SB)$ another representative of $[H_{\mathbb{R}}]$ and t_1, t_2 isometries in $E_{\mathbb{R}} = \mathrm{Q}^{\mathrm{s}}(SB)$ which generate a copy of $\mathcal{O}_2$. Then there are unitaries $u_1, u_2 \in E_{\mathbb{R}}$ such that $T = u_1^* H_{\mathbb{R}} u_1$ and $u_2 t_j = s_j$, $j = 1, 2$. Thus, with $\oplus = \oplus_{s_1,s_2}$, $g \oplus_{t_1,t_2} T = (1 \oplus u_1)^* u_2 (g \oplus H_{\mathbb{R}}) u_2^* (1 \oplus u_1)$. If $u^* h_V u = g \oplus H_{\mathbb{R}}$, then $u_3^*(u_1^* h_V u_1) u_3 = g \oplus_{t_1,t_2} T$ for $u_3 := u_1^* u u_2^* (1 \oplus u_1)$, and $T(a) - u_1^* h_V(a) u_1 \in J$ for $a \in D$, because J is an ideal.

(ii): Let $\sigma_s(t) := st + (1-s)\sigma(t)$ for $s \in [0,1]$ and $t \in \mathbb{R}$. Since $\sigma\colon \mathbb{R} \to \mathbb{R}$ is order preserving, the σ_s define a homotopy $s \to \rho_s := \widehat{\sigma_s}|\,\mathrm{C}_0(\mathbb{R}, B) \in \mathrm{Aut}(\mathrm{C}_0(\mathbb{R}, B))$ between $\widehat{\sigma}|\,\mathrm{C}_0(\mathbb{R}, B) = \rho_0$ and $\mathrm{id} = \rho_1$, where $\widehat{\sigma_s}(f) := f \circ \sigma_s$ for $f \in \mathrm{C}_{\mathrm{b,st}}(\mathbb{R}, \mathcal{M}(B)) \cong \mathcal{M}(\mathrm{C}_0(\mathbb{R}, B))$. Then $[\widehat{\sigma_s} \circ h] = (\rho_t)_*([h])$ in $\mathrm{Ext}(\mathcal{C}(\mathbb{R});\, D, SB) \cong \mathrm{KK}(\mathcal{C};\, D, (SB)_{(1)})$, by definition of $(\rho_t)_* \in \mathrm{Aut}(\mathrm{Ext}(\mathcal{C}(\mathbb{R});\, A, B))$.

Let $\tau_s := (\rho_s)_{(1)}$, i.e., $\tau_s(f, g) := (f \circ \sigma_s, g \circ \sigma_s)$. Then $t \to \tau_s \in \mathrm{Aut}(\mathrm{C}_0(\mathbb{R}, B)_{(1)})$ is a (grading-preserving) homotopy between id and τ_1.

If $\Phi = \Phi(\mathcal{C};\, D, SB)$ denotes the natural isomorphism from $\mathrm{Ext}(\mathcal{C}(\mathbb{R});\, D, SB)$ onto $\mathrm{KK}(\mathcal{C};\, D, (SB)_{(1)})$, then $(\tau_s)_* \circ \Phi = \Phi \circ (\rho_s)_*$.

Since $(\tau_1)_* = (\tau_0)_*$ by homotopy invariance of $\mathrm{KK}(\mathcal{C};\, D, (SB)_{(1)})$, we get $[\widehat{\sigma} \circ h] = (\rho_0)_*([h]) = (\rho_1)_*([h]) = [h]$ for $[h] \in G(H_{\mathbb{R}}\,;\, D, E_{\mathbb{R}})$. Since $h = g \oplus T$ satisfies $[h] \in G(H_{\mathbb{R}}\,;\, D, E_{\mathbb{R}})$, we can see that $[\widehat{\sigma} \circ (g \oplus T)] = [g \oplus T]$ in $S(H_{\mathbb{R}}\,;\, D, E_{\mathbb{R}})$. □

In principle, Proposition 8.2.6, and Remark 5.8.7

Check ref. to 5.8.7

imply our below given Corollary 8.3.3 via Bott periodicity.

But we give a proof which uses only the homotopy invariance of $\mathrm{KK}(\mathcal{C};\, \cdot, \cdot)$ alone to derive that $\mathrm{Ext}(\mathcal{C}(\mathbb{R}_+);\, A, \mathrm{C}_0(\mathbb{R}_+, B)) = 0$ and use the simple construction of Remark 8.3.1, because our explicit constructions on the level of Busby invariants and unitaries are needed in Chapter 9 to show that Theorem 4.4.6 yields the proofs of Theorems B(i,ii) and M(i,ii).

Corollary 8.3.3. *Suppose that D is separable, B is σ-unital and that both are stable and trivially graded. Let $\mathcal{C} \subseteq \mathrm{CP}(D, B)$ a non-degenerate point-norm closed countably generated m.o.c. cone.*

*Let $E := \mathrm{Q}(B) := \mathcal{M}(B)/B \cong \mathrm{Q}^{\mathrm{s}}(B)$, and let $H_0 := \pi_B \circ H\colon D \to E$ be a *-monomorphism that comes from a faithful non-degenerate *-representation $H\colon D \to$*

$\mathcal{M}(B)$ with the property that $\delta_\infty \circ H$ is unitarily equivalent to H and that the maps $a \in D \mapsto b^* H(a) b \in B$ generate $\mathcal{C}$ ([9]).

(i) *There is a natural isomorphism θ from the kernel of $\mathrm{K}_1(H_0(D)' \cap E) \to \mathrm{K}_1(E)$ onto $\mathrm{KK}(\mathcal{C};\, A, B)$.*

(ii) *In particular, $\mathrm{K}_*(H_{\mathbb{R}_+}(D)' \cap \mathrm{Q^s}(\mathrm{C}_0(\mathbb{R}_+, B))) = 0$ where $H_{\mathbb{R}_+}(a)$ means the "restriction" of $H_0(a) \in \mathcal{M}(B) \subseteq E_{\mathbb{R}} = \mathcal{M}(\mathrm{C}_0(\mathbb{R}, B))/\mathrm{C}_0(\mathbb{R}, B)$ to $\mathbb{R}_+$.*

(iii) *The map*

$$[g] \in G(H_0\,,\, D, \mathrm{Q^s}(SB)) \to [U^+(0)U^-(0)^*] \in \mathrm{K}_1(H_0(D)' \cap E),$$

where $U^-(0), U^+(0) \in E$ are as in the proof of Lemma 8.3.2, defines a group isomorphism ι from $\mathrm{Ext}(\mathcal{C};\, D, SB) = G(H_0\,;\, D, \mathrm{Q^s}(SB))$ onto the kernel of $\mathrm{K}_1(H_0(D)' \cap E) \to \mathrm{K}_1(E)$.

(iv) *Let $h\colon D \to B$ be a C^*-morphism in $\mathcal{C}$, C_h the extension of D by SB given by the mapping cone construction for h, and let $[h - 0]$ denote the element of $\mathrm{KK}(\mathcal{C};\, A, B)$ that is represented by the difference construction $(B, h, 0)$.*

Then the isomorphism $\theta \circ \iota$ from $\mathrm{Ext}(\mathcal{C};\, A, SB)$ onto $\mathrm{KK}(\mathcal{C};\, A, B)$ maps the class $[C_h] \in \mathrm{Ext}(\mathcal{C};\, A, SB)$ of C_h to $[h-0] \in \mathrm{KK}(\mathcal{C};\, A, B)$, i.e., $\theta \circ \iota([C_h]) = [h - 0]$.

Proof. (i): Let $H_0(a) := H_1(a) + B$, $\mathrm{Q}(B) := \mathcal{M}(B)/B \cong \mathrm{Q^s}(B)$ and let $C := H_0(D)' \cap \mathrm{Q^s}(B)$. Recall that $H_1(D)' \cap \mathcal{M}(B)$ contains a copy of $\mathcal{O}_2$ unitally, and that $\mathrm{K}_*(H_1(D)' \cap \mathcal{M}(B)) = 0$.

By E_0 we denote the Hilbert B-module $\mathcal{H}_B \oplus \mathcal{H}_B^{op}$, i.e., $\mathcal{H}_B \oplus \mathcal{H}_B$ with grading $\beta_{E_0}\colon (x, y) \mapsto (x, -y)$. Then naturally $\mathcal{L}(E_0) \cong M_2(\mathcal{M}(B))$ with grading $Z \mapsto \beta Z \beta$, $\beta := \mathrm{diag}(1, -1)$ and $\mathbb{K}(E_0) \cong M_2(B)$ under this isomorphism. We define $\phi_0\colon D \to \mathcal{L}(E_0)$ by $\phi_0(a) := \mathrm{diag}(H_1(a), H_1(a))$ for $a \in D$.

For a unitary $U \in \mathcal{M}(B)$ let $F(U) \in \mathcal{L}(E_0)$ denote the selfadjoint unitary which is given by the off-diagonal 2×2-matrix with entries $F(U)_{11} = F(U)_{22} = 0$, $F(U)_{12} = U$ and $F(U)_{21} = U^*$. Then

$$F(U)\phi_0(a) - \phi_0(a)F(U) = F(1)\,\mathrm{diag}\big(U^*H_1(a) - H_1(a)U^*, UH_1(a) - H_1(a)U\big)\,.$$

Thus, $(E_0, \phi_0, F(U))$ is a $\mathcal{C}$-compatible Kasparov module, if and only if, $U \in \mathcal{U}(H_1(D), B)$, with notation of Lemma 4.6.6. In particular, the product $U_0U_2U_1^*$ is in $\mathcal{U}(H_1(D), B)$ if $U_0, U_1, U_2 \in \mathcal{M}(B)$ are unitaries and if

$$(E_0, \mathrm{diag}(U_0^*H_1U_0, U_1^*H_1U_1), F(U_2))$$

is a Kasparov module. The latter is isomorphic to $(E_0, \phi_0, F(U_0U_2U_1^*))$ via $\mathrm{diag}(U_0, U_1)$.

[9] See Corollary 5.4.4. In the special $\mathcal{C} = \mathrm{CP_{nuc}}(A, B)$, $H = \mathcal{M}(\gamma) \circ \rho$ for a non-degenerate *-morphism $\gamma\colon \mathbb{K} \to \mathcal{M}(B)$ and any faithful $\rho\colon D \hookrightarrow \mathcal{M}(\mathbb{K})$ with $\rho(D) \cap \mathbb{K} = 0$.

We define a Hilbert B-module isomorphism $T_0\colon E_0 \oplus_B E_0 \to E_0$ from the Hilbert B-module sum $E_0 \oplus_B E_0$ onto E_0, by

$$T_0\colon ((x_1, y_1), (x_2, y_2)) \mapsto (s_1 x_1 + s_2 x_2, s_1 y_1 + s_2 y_2)\,.$$

Then $T_0^*(\phi_0 \oplus \phi_0)T_0 = \phi_0$ and $T_0^*(F(U_1) \oplus F(U_2))T_0 = F(U_1 \oplus_{s_1,s_2} U_2)$ for unitaries U_1 and U_2 in $\mathcal{M}(B)$. By Lemma 4.6.6, $\mathcal{U}(H_1(D), B)$ is closed under Cuntz addition.

It follows that $\theta_0\colon U \mapsto (E_0, \phi_0, F(U))$ is an additive map from $\mathcal{U}(H_1(D), B)$ with Cuntz addition into the semigroup $\mathbb{E}(\mathcal{C};\, D, B)/\approx$ of isomorphism classes of elements of $\mathbb{E}(\mathcal{C};\, D, B)$.

Since $1 \oplus 1 = 1$, we get that $\theta_0(1)$ represents the zero of $\mathrm{KK}(\mathcal{C};\, D, B)$. Therefore, $\theta_0(U)$ and $\theta_0(U \oplus 1)$ represent the same element of $\mathrm{KK}(\mathcal{C};\, D, B)$.

A simple calculation shows that $\theta_0(U)$ is a compact perturbation of $\theta_0(U')$ in the sense of Definition 8.2.1 if and only if $(U' - U)H_1(D) \subseteq B$.

If $t \mapsto U(t)$ is a continuous map from $[0, 1]$ into $\mathcal{U}(H_1(D), B)$, then $t \mapsto \theta_0(U(t))$ defines an operator homotopy in $\mathbb{E}(\mathcal{C};\, D, B)$, and, therefore, $\theta_0(U(0))$ and $\theta_0(U(1))$ represent the same element of $\mathrm{KK}(\mathcal{C};\, D, B)$ by the (operator) homotopy invariance of $\mathrm{KK}(\mathcal{C};\, \cdot, \cdot)$.

By Lemma 4.6.6, it follows that $\theta_0(U_1)$ and $\theta_0(U_2)$ represent the same element of $\mathrm{KK}(\mathcal{C};\, D, B)$ if $[U_1 + B] = [U_2 + B]$ in $\mathrm{K}_1(H_0(D)' \cap \mathrm{Q^s}(B))$.

This means that $\theta([U + B]) := [\theta_0(U)]$ defines a group homomorphism θ from the kernel of $\mathrm{K}_1(H_0(D)' \cap E) \to \mathrm{K}_1(E)$ into $\mathrm{KK}(\mathcal{C};\, D, B) \cong \mathrm{KK}(\mathcal{C};\, A, B)$. It remains to show:

(1) θ is an epimorphism, i.e., every element of $\mathrm{KK}(\mathcal{C};\, D, B)$ can be represented by $\theta_0(U)$ for a suitable $U \in \mathcal{U}(H_1(D), B)$.
(2) $[\theta_0(U)] = 0$ in $\mathrm{KK}(\mathcal{C};\, D, B)$ implies $[U + B] = 0$ in $\mathrm{K}_1(C)$.

(1): For trivially graded D and σ-unital trivially graded B, one can use Kasparov's stabilization theorem to obtain a representative (E, ϕ, F) of an element of $\mathrm{KK}(\mathcal{C};\, D, B)$, such that the Hilbert B-module E is isomorphic to the above considered "universal" graded Hilbert B-module E_0, cf. . [**73**, 17.4.1].

An element of $\mathrm{KK}(\mathcal{C};\, D, B) \cong \mathrm{KK}(\mathcal{C};\, A, B)$ with representing element (E, ϕ, F) can be also represented by $\mathcal{C}$-compatible Kasparov modules $(E \oplus E^{op}, \phi \oplus 0, G(F))$ with $G(F) = G(F)^* = G(F)^{-1}$. Here E^{op} is the Hilbert B-module E with the new grading operator $-\beta_E$, and $G(F) \in \mathcal{L}(E \oplus E^{op}) \cong M_2(\mathcal{L}(E))$ is given by the matrix with entries $G(F)_{11} = F_1$, $G(F)_{22} = -F_1$ and $G(F)_{12} = G(F)_{21} = (1 - F_1^2)^{1/2}$, where $F_1 := f((F^* + F)/2)$ is a contractive selfadjoint ϕ-"compact" perturbation of F, and $f \in \mathrm{C_b}(\mathbb{R})$ is given by $f(t) = t$ for $t \in [0, 1]$, $f(t) = -1$ for $t \leq -1$ and $f(t) = 1$ for $t \geq 1$.

$(E \oplus_B E^{op}, \phi \oplus 0, G(F))$ represents the same element of $\mathrm{KK}(\mathcal{C};\, D, B)$ because $(E \oplus_B E^{op}, \phi \oplus 0, G(F))$ is a compact perturbation of the sum of (E, ϕ, F) and $(E^{op}, 0, -F)$ (see [**73**, 17.4.2, 17.4.3, 17.6] for more details).

The passage to this special representatives is functorial in $\mathbb{E}(\mathcal{C};\, D, B)$ in the sense that it is operator homotopy preserving and is additive modulo addition of trivial elements of form $(E', 0, F')$ and compact perturbation. If (E, ϕ, F') is a ϕ-"compact" perturbation of of (E, ϕ, F), then

Is this correct needed?:

$(E \oplus_B E^{op}, \phi \oplus 0, G(F')) \sim_{cp} (E \oplus_B E^{op}, \phi \oplus 0, G(F))$.

Since we did start with a *$\mathcal{C}$-compatible* Kasparov module (E, ϕ, F) such that E is isomorphic to our above defined E_0 by a grading preserving isometric B-module isomorphism, we have that $E \oplus_B E^{op}$ is isometrically and grading preserving B-module isomorphic to E_0.

Thus we find for each element of $\mathrm{KK}(\mathcal{C};\, D, B)$ a representing *$\mathcal{C}$-compatible* Kasparov module $(E_0\,, \phi, G)$ with $G = G^* = G^{-1}$.

Since the degree of $\phi(a)$ is zero and the degree of G is one, the representative has the form $\phi(a) = \mathrm{diag}(\psi_0(a), \psi_1(a))$ with *weakly $\mathcal{C}$-compatible* *-morphisms $\psi_0, \psi_1 \colon D \to \mathcal{M}(B)$ and $G = F(U)$ for a unitary $U \in \mathcal{M}(B)$.

T_0 defines an isomorphism from the sum of $(E_0\,, \mathrm{diag}(\psi_0, \psi_1), F(U))$ and of $\theta_0(1)$ onto

$$(E_0\,, \mathrm{diag}(\psi_0 \oplus H_1, \psi_1 \oplus H_1), F(U \oplus 1)). \tag{*}$$

Since $\theta_0(1)$ represents the zero, every element of $\mathrm{KK}(\mathcal{C};\, D, B)$ is represented by a Kasparov module of form (*).

The *homotopy invariance* of $\mathrm{KK}(\mathcal{C};\, D, B)$ yields the following:
Let $\tau \mapsto \psi_0^{(\tau)} \colon D \to \mathcal{M}(B)$ and $\tau \mapsto \psi_1^{(\tau)} \colon D \to \mathcal{M}(B)$ be a point-norm continuous families of weakly *$\mathcal{C}$-compatible* C^*-morphisms, and let $U \in \mathcal{M}(B)$ be a unitary such that $U\psi_1^{(0)}(a) - \psi_0^{(0)}(a)U \in B$ for all $a \in D$. Suppose that $\psi_0^{(\tau)}(a) - \psi_0^{(0)}(a)$ and $\psi_1^{(\tau)}(a) - \psi_1^{(0)}(a)$ are in B for all $a \in D$ and $\tau \in [0, 1]$. Then $(E_0, \mathrm{diag}(\psi_0^{(0)}, \psi_1^{(0)}), U)$ and $(E_0, \mathrm{diag}(\psi_0^{(1)}, \psi_1^{(1)}), U)$ represent the same element of $\mathrm{KK}(\mathcal{C};\, D, B)$.

By Theorem 5.6.2(ii) (applied to $C := H_1(D)$ and $T := \psi \circ H_1^{-1}$), we find norm-continuous maps $t \mapsto U_0(t)$ and $t \mapsto U_1(t)$ into the unitaries of $\mathcal{M}(B)$ such that, for $k \in \{0, 1\}$, $t \in \mathbb{R}_+$ and $a \in A$,

$$U_k(t)^* H_1(a) U_k(t) - (\psi_k(a) \oplus H_1(a)) \in B$$

and

$$\lim_{t \to \infty} \| U_k(t)^* H_1(a) U_k(t) - \big(\psi_k(a) \oplus H_1(a)\big) \| = 0\,.$$

Thus

$$\big(E_0, \mathrm{diag}(U_0(0)^* H_1 U_0(0), U_1(0)^* H_1 U_1(0)), F(U \oplus 1)\big) \tag{**}$$

and (*) represent the same element of $\mathrm{KK}(\mathcal{C};\, D, B) = \mathrm{KK}(\mathcal{C};\, A, B)$.

(**) is isomorphic to $\theta_0(U_1)$, where $U_1 := U_0(0)(U \oplus 1)U_1(0)^*$, and U_1 is a unitary in $\mathcal{U}(H_1(D), B)$, because (**) is a Kasparov module. Thus, every element of $\mathrm{KK}(\mathcal{C};\, D, B) \cong \mathrm{KK}(\mathcal{C};\, A, B)$ can be represented by a *$\mathcal{C}$-compatible* Kasparov module $\theta_0(U)$, where $U \in \mathcal{U}(H_1(D), B)$, and θ is an epimorphism.

(2): Suppose that $[\theta_0(U)] = 0$ in KK($\mathcal{C}$; D, B).

By Definition 8.2.1, $[\theta_0(U)] = 0$ means that there exist a *$\mathcal{C}$-compatible* Kasparov module (E, ϕ, F) and a compact perturbation (E, ϕ, F') of it, such that $\theta_0(U) \oplus (E, \phi, F)$ is isomorphic to (E, ϕ, F') via a grading preserving B-module unitary I. In particular $F' = I^{-1}(F(U) \oplus F)I$. If we add trivial Kasparov modules, take the above listed $\phi \oplus 0$-"compact" perturbations and pass to isomorphic Kasparov modules (isomorphic in the strong sense of Definition 8.2.1), then we can assume moreover that $E = E_0$, $F = F(V_1)$, $F' = F(V_2)$ for unitaries V_1 and V_2 in $\mathcal{M}(B)$, as we have shown above. Then $\phi = \mathrm{diag}(\psi_0, \psi_1)$ for weakly *$\mathcal{C}$-compatible* C^*-morphisms ψ_0 and ψ_1 from D into $\mathcal{M}(B)$.

By stability of B, there exists a sequence of isometries $t_1, t_2, \ldots$ in $\mathcal{M}(B)$ such that $\sum t_n t_n^*$ converges strictly to 1, cf. Remark 5.1.1(8). Let λ be the infinite repeat of the Cuntz sum $(\psi_0 \oplus \psi_1) \oplus H_1$ i.e., $\lambda := \delta_\infty((\psi_0 \oplus \psi_1) \oplus H_1)$, where $\oplus = \oplus_{s_1,s_2}$.

Then λ is a strictly continuous C^*-morphism from D into $\mathcal{M}(B)$.

The series $\sum((t_n \oplus t_n) \oplus t_n)t_n^*$ and converges strictly to a unitary in $\mathcal{M}(B)$. Therefore λ is unitarily equivalent to the Cuntz sum of the infinite repeats of ψ_0, of ψ_1 and of H_1. It follows that $\psi_0 \oplus \lambda$, $\psi_1 \oplus \lambda$ and $H_1 \oplus \lambda$ are unitarily equivalent to λ.

Now Corollary 5.6.1 applies to the C^*-subalgebra $C := H_1(D)$ of $\mathcal{M}(B)$ and to $T = \lambda \circ H_1^{-1}$. Thus there is a unitary v in $\mathcal{M}(B)$ such that $v^*\lambda(a)v - H_1(a) \in B$ for $a \in D$.

Let $\chi := v^*\lambda v$. Then again $\chi \oplus \psi_0$ and $\chi \oplus \psi_1$ are unitarily equivalent to χ. By Lemma 4.6.5(ii), the relative commutant of $\chi(D)$ in $\mathcal{M}(B)$ has trivial K-theory, in particular, $[V + B] = 0$ in $\mathrm{K}_1(C)$ if V is a unitary in $\mathcal{M}(B)$ which commutes element-wise with $\chi(D)$. By Lemma 5.1.2, χ is unitarily equivalent to $\chi \oplus \chi$, because χ is an infinite repeat.

We add the Kasparov module $(E_0, \mathrm{diag}(\chi, \chi), F(1))$ to $(E_0, \phi, F(V_j))$, $j = 1, 2$. Then we use our above defined isomorphism T_0 from $E_0 \oplus E_0$ onto E_0, and pass to equivalent Kasparov modules, where we use the above described transformation rules for $U \mapsto F(U)$.

Then we get unitaries U_1, U_2, U_3 and U_4 in $\mathcal{M}(B)$ such that

$(E_0, \mathrm{diag}(\chi, \chi), F(U_j))$ are Kasparov modules for $j = 1, 2$,

$\chi(D)(U_1 - U_2) \subseteq B$,

$U_3^*(H_1 \oplus \chi)U_3 = \chi$, $U_4^*(H_1 \oplus \chi)U_4 = \chi$ and $U_3^*(U \oplus U_1)U_4 = U_2$.

In particular $V := U_3^* U_4$ commutes element-wise with the image of χ, and, therefore, $[V + B] = 0$ in $\mathrm{K}_1(C)$.

Since $H_1 \oplus H_1 = H_1$ and $\chi(d) - H_1(d) \in B$ for $d \in D$, we get that the U_k are in $\mathcal{U}(H_1(D), B)$ for $k = 1, 2, 3, 4$.

Let u_0, u_1, u_2, u_3, u_4 denote the images of U, U_1, U_2, U_3, U_4 in $C = H_0(D)' \cap E$.

Then $[u_1] = [u_2]$ in $\mathrm{K}_1(C)$ by Lemma 4.6.6.

$$[u_0] + [u_1] = [u_3^*(u_0 \oplus u_1)u_3] + [u_3^* u_4] = [u_2]\,.$$

Thus $[U + B] = [u_0] = 0$ in $\mathrm{K}_1(H_0(D)' \cap E)$.

(ii): Let $E^{(+)} := \mathrm{Q}^{\mathrm{s}}(\mathrm{C}_0(\mathbb{R}_+, B))$. In the proof of Lemma 8.3.2 we have seen that $\mathrm{K}_*(E^{(+)}) = 0$.

`Is this CONCLUSION ‘‘thus’’ correct? ??`

Thus,

by Propositions 4.4.3(i) and 8.2.6,

$$\mathrm{K}_0(H_{\mathbb{R}_+}(D)' \cap E^{(+)}) = \mathrm{KK}(\mathcal{C};\, D, \mathrm{C}_0(\mathbb{R}_+, B)_{(1)}) = 0\,.$$

By Part (i) and Proposition 8.2.5(ii),

$$\mathrm{K}_1(H_{\mathbb{R}_+}(D)' \cap E^{(+)}) = \mathrm{KK}(\mathcal{C};\, D, \mathrm{C}_0(\mathbb{R}_+, B)) = 0\,.$$

(iii): Let $E := \mathrm{Q}^{\mathrm{s}}(B)$, $C := H_0(D)' \cap E$, $E_{\mathbb{R}} := \mathrm{Q}(SB)$ $E^{(\alpha)} := \mathrm{Q}^{\mathrm{s}}(\mathrm{C}_0(\mathbb{R}_\alpha, B))$ for $\alpha \in \{+, -\}$.

Since $G(H_{\mathbb{R}}, D, E_{\mathbb{R}}) = [H_{\mathbb{R}}] + S(H_{\mathbb{R}}, D, E_{\mathbb{R}})$, from the proof of Lemma 8.3.2 we get the existence of unitaries $U^+ \in E^{(+)}$ and $U^- \in E^{(-)}$ such that

$$g^\alpha = (U^\alpha)^* H_\alpha U^\alpha\,,$$

where $g^\alpha(a) := g(a)|\mathbb{R}_\alpha$, $H_\alpha := H_{\mathbb{R}_\alpha}$ for $\alpha \in \{+, -\}$. Here we use the "restriction" notation as explained in Remark 8.3.1.

We have seen in the proof of Lemma 8.3.2 that $U^+(0)(U^-(0))^*$ is a unitary in C such that $[U^+(0)(U^-(0))^*]$ is in the kernel of the natural group homomorphism from $\mathrm{K}_1(C)$ into $\mathrm{K}_1(E)$. Here $U^+(0) := \pi_0^+(U^+)$ and $U^-(0) := \pi_0^-(U^-)$ for the natural epimorphisms $\pi_0^\alpha \colon E^{(\alpha)} \to E$, where $\alpha \in \{+, -\}$.

If $U_1^+ \in E^{(+)}$ and $U_1^- \in E^{(-)}$ are other unitaries with $g^\alpha = (U_1^\alpha)^* H_\alpha U_1^\alpha$ for $\alpha \in \{+, -\}$. Then $U_1^+(U^+)^*$ is in ????? $H_+(D)' \cap E^{(+)}$. By part (ii), the K_1-images of the natural epimorphism from $H_+(D)' \cap E^{(+)}$ into $C = H_0(D)' \cap E$ is zero. This implies that $[U_1^+(0)(U^+(0))^*] = 0$ in $\mathrm{K}_1(C)$. Similarly, $[U^-(0)(U_1^-(0))^*] = 0$ in $\mathrm{K}_1(C)$. Thus $[U^+(0)(U^-(0))^*] = [U_1^+(0)(U_1^-(0))^*]$ in $\mathrm{K}_1(C)$.

Therefore $\iota([g]) := [U^+(0)(U^-(0))^*]$ is a well-defined map from $G(H_{\mathbb{R}}, D, E_{\mathbb{R}}) = \mathrm{Ext}(\mathcal{C};\, D, SB)$ into the kernel of $\mathrm{K}_1(C) \to \mathrm{K}_1(E)$.

If g and h are representatives of elements in $G(H_{\mathbb{R}}, D, E_{\mathbb{R}})$ and if $U_1^+, U_2^+ \in E^{(+)}$ and $U_1^-, U_2^- \in E^{(-)}$ are unitaries with $h^\alpha = (U_2^\alpha)^* H_\alpha U_2^\alpha$ and $g^\alpha = (U_1^\alpha)^* H_\alpha U_1^\alpha$ for $\alpha \in \{+, -\}$. Then $U^\alpha := U_1^\alpha \oplus U_2^\alpha \in E^{(\alpha)}$ are unitaries with $(g \oplus h)^\alpha = (U_1^\alpha)^* H_\alpha U_1^\alpha$. Thus $\iota([g] + [h]) = [(U_1^+(0)(U_1^-(0))^*) \oplus (U_2^+(0)(U_2^-(0))^*)]$, which is $\iota([g]) + \iota([h])$ in $\mathrm{K}_1(C)$. Therefore, ι is a group homomorphism.

By Lemma 4.6.6, ι is an epimorphism, because for $U \in \mathcal{U}(H_1(D), B)$ and h_U in Remark 8.3.1 we have, for $g = h_U \oplus H_{\mathbb{R}}$, $U^+ = U \oplus 1$ and $U^- = 1$, and therefore $\iota[h_U \oplus H_{\mathbb{R}}] = [U + B]$.

Suppose that $\iota([g]) = [U^+(0)U^-(0)^*] = 0$ in $\mathrm{K}_1(H_0(D)' \cap E)$. By Lemma 4.2.6(v,2), the unitary $V := (U^+(0)U^-(0)^*) \oplus 1$ is in the connected component of 1 in the unitaries of C. Thus there is a continuous map $t \in [0,1] \to U(t)$ into the unitaries of $\mathcal{M}(B)$ such that $U(0) = 1$, $U(1)+B = V$ and $U(t)+B \in C$ for $t \in [0,1]$. Thus $U(t) \in \mathcal{U}(H_1(D), B)$ for $t \in [0,1]$. Let $U := U(1)$ and $W \in \mathrm{C_b}(\mathbb{R}, \mathcal{M}(B)) \subseteq \mathcal{M}(SB)$ the unitary which is defined by $W(t) := 1$ for $t \le 0$, $W(t) := U(t)$ for $t \in [0,1]$, and $W(t) = U$ for $t \ge 1$. Then, for the lift T of h_U in Remark 8.3.1, we get that $T(a)(t) - W(t)^* H_1(a) W(t) \in B$ for $t \in \mathbb{R}$ and $T(a)(t) - W(t)^* H_1(a) W(t) = 0$ for t not in $[0,1]$. Thus $h_U = w^*(H_\mathbb{R})w$ for $w := W + \mathrm{C}_0(\mathbb{R}, B)$. In the proof of Lemma 8.3.2 we have seen that $[g \oplus H_\mathbb{R}] = [h_U]$. Since $[g] \in G(H_\mathbb{R}, D, E_\mathbb{R})$, we get $[g] = [g \oplus H_\mathbb{R}] = [h_U] = [w^* H_\mathbb{R} w] = [H_\mathbb{R}] = 0$.

Thus ι is an isomorphism from $\mathrm{Ext}(\mathcal{C};\, A \otimes \mathbb{K}, SB) \cong G(H_\mathbb{R}, D, \mathrm{Q^s}(SB))$ onto the kernel of natural homomorphism from $\mathrm{K}_1(H_0(D)' \cap \mathrm{Q^s}(B))$ into $\mathrm{K}_1(\mathrm{Q^s}(B))$.

(iv): To simplify notation, we assume that B is stable. We keep the notations $E^{(-)}$, $E^{(+)}$ of Remark 8.3.1, but don't use the notation $E_\mathbb{R}$ used there for $\mathrm{Q^s}(SB) = \mathcal{M}(SB)/SB$. Let $C := H_0(D)' \cap E$.

If $h\colon D \to B$ is a *-morphism in $\mathcal{C}$, then the mapping cone C_h is represented as an element of $S(H_\mathbb{R}\,;\, D, \mathrm{Q^s}(SB))$ by

$$g_h\colon a \in D \mapsto (0, h(a)) \in 0 \oplus B \subset \mathrm{Q}(\mathbb{R}_-, B) \oplus \mathrm{Q}(\mathbb{R}_+, B) = \mathrm{Q}(\mathbb{R}, B) \subseteq E^{(-)} \oplus E^{(+)}.$$

The corresponding element of $G(H_\mathbb{R}, D, \mathrm{Q^s}(SB)) = \mathrm{Ext}(\mathcal{C};\, A \otimes \mathbb{K}, SB)$ is $[g_h \oplus H_\mathbb{R}]$. If we apply Theorem 5.6.2(ii) to $C := H_1(D)$ and separately to $T = 0$ and $T = hH_1^{-1}$, we get norm-continuous maps $t \mapsto U_0(t)$ and $t \mapsto U_1(t)$ from $\mathbb{R}_+$ into the unitaries of $\mathcal{M}(B)$, such that $\lim_{t\to\infty} \|(h \oplus H_1)(a) - U_0(t)^* H_1(a) U_0(t)\| = 0$, $(h \oplus H_1)(a) - U_0(t)^* H_1(a) U_0(t) \in B$, $\lim_{t\to\infty} \|(0 \oplus H_1)(a) - U_1(t)^* H_1(a) U_1(t)\| = 0$ and $(0 \oplus H_1)(a) - U_1(t)^* H_1(a) U_1(t) \in B$ for $a \in D$, $t \in \mathbb{R}_+$.

Let us consider U_0 as a unitary in $\mathrm{C_b}(\mathbb{R}_+, \mathcal{M}(B)) \subseteq \mathcal{M}(\mathrm{C}_0(\mathbb{R}_+, B))$ and $V(t) := U_1(-t)$ for $t \le 0$ as a unitary V in $\mathcal{M}(\mathrm{C}_0(\mathbb{R}_-, B))$.

Let $U^+ := \pi^+(U_0)$, $U^- := \pi^-(V)$. Then $(g_h \oplus H_\mathbb{R})|\mathbb{R}_\alpha = (U^\alpha)^* H_\alpha U^\alpha$ for $\alpha \in \{+,-\}$, $U^+(0) = \pi_0^+(U^+) = U_0(0) + B$ and $U^-(0) = \pi_0^-(U^-) = U_1(0) + B$. Thus $\iota([g_h \oplus H_0]) = [U_0(0)U_1(0)^* + B]_C \in \mathrm{K}_1(C)$.

By construction of θ, we have that $\theta([U_0(0)U_1(0)^* + B]_C)$ is represented by $(E_0, \phi_0, F(U_0(0)U_1(0)^*))$.

Let $(\mathcal{H}_B, h, 0)$ the *$\mathcal{C}$-compatible* Kasparov module obtained by the difference construction. Since the derivative F of the module is zero, the construction in the proof of part (i) produces for the class of $(\mathcal{H}_B, h, 0)$ in $\mathrm{KK}(\mathcal{C};\, D, B)$ the representative $(E_0, \mathrm{diag}(h, 0), F(1))$, because $F(1) = G(0)$, where the notation is as in the proof of part (i).

In the proof of part (i) we have seen, that the Kasparov module $(E_0, \phi_0, F(1))$ represents zero. If we add it to $(E_0, \mathrm{diag}(h, 0), F(1))$, we get $(E_0, \mathrm{diag}(h \oplus H_1, 0 \oplus H_1), F(1))$.

By homotopy invariance of $\mathrm{KK}(\mathcal{C};\cdot,\cdot)$, $(E_0, \mathrm{diag}(U_0^* H_1 U_0, U_1^* H_1 U_1), F(1))$ represents the same element, where $U_0 := U_0(0)$ and $U_1 := U_1(0)$ are the unitaries in $\mathcal{M}(B)$ which come from the above considered paths $U_0(t)$ and $U_1(t)$ in $\mathcal{U}(H_1(D), B)$.

In the proof of part (i) we have seen that the latter Kasparov module is isomorphic to $(E_0, \phi_0, F(U_0 U_1^*))$, which represents $\iota([U_0 U_1^*])$. Hence, $\iota \circ \theta([C_h]) = [h - 0]$. □

`Change following to` $\mathcal{C}$`-picture !?`

Corollary 8.3.4. *Suppose that A is separable, that B is σ-unital and stable, and that both are trivially graded. Let $D := A \otimes \mathbb{K}$, $E_{\mathbb{R}} := \mathrm{Q}^{\mathrm{s}}(SB)$, and let $H_{\mathbb{R}} \colon D \to E_{\mathbb{R}}$ be a *-monomorphism which comes from a faithful non-degenerate *-representation of $H \colon D \hookrightarrow \mathcal{M}(B) \subseteq E_{\mathbb{R}}$ in "general position", i.e., with $\delta_\infty \circ H$ is unitarily homotopic to H.*

(i) *For every $t \in [0,1]$, the natural group homomorphism*

$$\pi_t \colon G(H_{\mathbb{R}\times[0,1]}, D, \mathrm{Q}^{\mathrm{s}}(S\,\mathrm{C}([0,1], B))) \to G(H_{\mathbb{R}}, D, E_{\mathbb{R}}),$$

which is induced by the natural epimorphism from $\mathrm{Q}^{\mathrm{s}}(S\,\mathrm{C}([0,1],B))$ onto $E_{\mathbb{R}}$ is an isomorphism and is therefore independent of $t \in [0,1]$.

(ii) *If σ is an orientation preserving homeomorphism of $\mathbb{R}$ and $\widehat{\sigma}$ the automorphism of $E_{\mathbb{R}} := \mathrm{Q}^{\mathrm{s}}(SB)$ which is naturally induced by σ, then $[\widehat{\sigma} \circ h] = [h]$ in $\mathrm{Ext}_{\mathrm{nuc}}(A \otimes \mathbb{K}, SB)$ for every representing C^*-morphism $h \colon D \to E_{\mathbb{R}}$ of an element of $\mathrm{Ext}_{\mathrm{nuc}}(A \otimes \mathbb{K}, SB)$.*

Proof. (i): It follows from the natural isomorphisms $G(H_0, D, E_{\mathbb{R}}) = \mathrm{Ext}_{\mathrm{nuc}}(D, SB) \cong \mathrm{KK}_{\mathrm{nuc}}(D, B)$ (including $G\big(H_{\mathbb{R}\times[0,1]}, D, \mathrm{Q}^{\mathrm{s}}(S\,\mathrm{C}([0,1],B))\big) \cong \mathrm{KK}_{\mathrm{nuc}}(D, \mathrm{C}([0,1],B)))$ and the homotopy invariance of $\mathrm{KK}_{\mathrm{nuc}}$.

(ii): Since σ is a strictly increasing continuous function from $\mathbb{R}$ into $\mathbb{R}$, for every $f \in SB \cong \mathrm{C}_0(\mathbb{R}, B)$, the definition $g(t,s) := f(st + (1-s)\sigma(t))$ defines an element g in

$$S\,\mathrm{C}([0,1], B) \cong \mathrm{C}_0(\mathbb{R} \times [0,1], B)\,.$$

Let $V \colon D \to \mathcal{M}(SB)$ be a completely positive

weakly *nuclear*, respectively $\mathcal{C}$-compatible,

contractive lift of $h \colon D \to \mathrm{Q}^{\mathrm{s}}(SB)$.

The curvature $d \mapsto V(d^*d) - V(d)^*V(d)$ of V maps D into $SB = \mathrm{C}_0(\mathbb{R}, B)$. Under the natural identifications of $\mathrm{C}_{\mathrm{b,st}}(\mathbb{R}, \mathcal{M}(B))$ with $\mathcal{M}(SB)$, respectively of $\mathrm{C}_{\mathrm{b,st}}(\mathbb{R} \times [0,1], \mathcal{M}(B))$ with $\mathcal{M}(S\,\mathrm{C}([0,1],B))$, we let

$$\widetilde{V}(t,s)(d) := V(st + (1-s)\sigma(t))(d)$$

for $t \in \mathbb{R}$, $s \in [0,1]$, $d \in D$. Then $\widetilde{V}$ is

`check again?:`

weakly *nuclear*, respectively $\mathcal{C}$-compatible,

and the curvature $d \mapsto \widetilde{V}(d^*d) - \widetilde{V}(d)^*\widetilde{V}(d)$ of $\widetilde{V}$ maps D into $\mathrm{C}_0(\mathbb{R}\times[0,1], B) = S\,\mathrm{C}([0,1], B)$. Thus it defines a

weakly *nuclear*, respectively $\mathcal{C}$-compatible,

liftable C^*-morphism $k\colon D \to \mathrm{Q^s}(S\,\mathrm{C}([0,1], B))$.

The natural epimorphisms from $\mathrm{Q^s}(S\,\mathrm{C}([0,1], B))$ onto $\mathrm{Q^s}(SB)$ at zero and at one map k into $\widehat{\sigma}h$ and h, respectively. Thus k defines an element $[k]$ of $\mathrm{Ext}_{\mathrm{nuc}}(D, S\,\mathrm{C}_0([0,1], B))$. with $\pi_1([k]) = [h]$ and $\pi_0([k]) = [\widehat{\sigma}h]$. Therefore, by (i), $[h] = [\widehat{\sigma} \circ h]$ in $\mathrm{Ext}_{\mathrm{nuc}}(D, SB)$, respectively is in $\mathrm{Ext}(\mathcal{C};\, D, SB)$. □

Remark 8.3.5. The natural map γ from $\mathrm{KK}_{\mathrm{nuc}}(A, B)$ to $\mathrm{Hom}(\mathrm{K}_*(A), \mathrm{K}_*(B))$ is defined as $(\gamma(x))(y) := y \otimes_A x \in \mathrm{K}_*(B)$ for $y \in \mathrm{K}_*(A)$, $x \in \mathrm{KK}_{\mathrm{nuc}}(A, B)$, where we denote by $y \otimes_A x$ the Kasparov product of x and y, and $\mathrm{K}_0(.)$ and $\mathrm{K}_1(.)$ are naturally identified with $\mathrm{KK}(\mathbb{C}, .)$ and $\mathrm{KK}(\mathrm{C}_0(\mathbb{R}), .)$ respectively.

In terms of $\mathrm{Ext}_{\mathrm{nuc}}(A, SB)$ this means equivalently, that γ maps the class with representative $g\colon D \to \mathrm{Q^s}(SB)$ into the connecting maps

$$\delta_*\colon\ \mathrm{K}_*(A) \to \mathrm{K}_{(*+1)\mathrm{mod}2}(SB)$$

of the six term exact sequence for the extension of $A \otimes \mathbb{K}$ by SB which is defined by g. Then use $\mathrm{K}_*(B) \cong \mathrm{K}_{(*+1)\mathrm{mod}2}(SB)$.

Both descriptions of γ allow to see that $\gamma([h - 0]) = \mathrm{K}_*(h)$ if $h\colon A \otimes \mathbb{K} \to B$ is a *nuclear* C^*-morphism.

Remark 8.3.6. By Bott periodicity of $\mathrm{KK}_{\mathrm{nuc}}$ and by the isomorphism (1.1), the similar notion of a *strictly nuclear* E-theory is functorial equivalent to $\mathrm{KK}_{\mathrm{nuc}}$ (See further below). But E-theory is not useful for the proof of (1.1) and its consequences. Note that $\mathrm{E}_{\mathrm{nuc}}(A, B) = \mathrm{E}(A, B)$ if A is nuclear, but in general this equation does hold for nuclear B and non-nuclear A.

Even in the trivially graded case there is no direct proof of the isomorphism

$$\mathrm{Ext}_{\mathrm{nuc}}(A, SB) \cong \mathrm{E}_{\mathrm{nuc}}(A, B)$$

by using directly the weakly nuclear version $\mathrm{SR}(\mathrm{CP}_{\mathrm{nuc}};\, SA, S^2B)$ of $[[SA \otimes \mathbb{K}, S^2B]]$ as defined in the beginning of Chapter 7. Therefore we outline here *another proof*:

Suppose that B is a stable σ-unital C^*-algebra and denote by π_s ($s \in [0,1]$) the natural epimorphism

$$\pi_s\colon\ \mathrm{Q}(\mathbb{R}_+, S\,\mathrm{C}([0,1], B)) \to \mathrm{Q}(\mathbb{R}_+, SB)\,.$$

But notice that a weakly nuclear asymptotic morphism $h = \{V(t)\colon A \otimes \mathbb{K} \to B\}$ in the sense of of Definition 7.1.1(a,b) represents in general *not* an element of the Rørdam semigroup (with the additional requirement (c) of Definition 7.1.1 and with $\mathcal{C} := CP(A \otimes \mathbb{K}, B \otimes \mathbb{K})$). This can be seen easily in the case $A = \mathrm{C}_0(\mathbb{R}, \mathcal{O}_\infty)$ and $B = \mathrm{C}_0(\mathbb{R}) \otimes \mathbb{K}$. Note, that the nuclearity of $V(t)$ is required for each $t \in \mathbb{R}_+$, but the uniform nuclearity on $\mathbb{R}_+$ is *not* required.

We say that weakly nuclear asymptotic morphisms $h_0 = \{V_0(t)\}$ and $h_1 = \{V_1(t)\}$ from $SA \otimes \mathbb{K}$ into SB are **asymptotical homotopic** if there is a weakly nuclear asymptotic morphism $h = \{V(t)\}$ from $SA \otimes \mathbb{K}$ into $\mathrm{C}([0,1], SB)$ such that $h_0 = \pi_0 \circ h$ and $h_1 = \pi_1 \circ h$.

As in [**165**] or [**163**, chp.II.B], one can see that the classes of asymptotically homotopic weakly nuclear asymptotic homomorphisms from $SA \otimes \mathbb{K}$ into $SB \otimes \mathbb{K}$ form a group $E_{nuc}(A, B)$ under Cuntz addition.

The generalized mapping cone construction, cf. Chapters 1 and 9, yields a group homomorphism from $E_{nuc}(A, B)$ into $\mathrm{Ext}_{\mathrm{nuc}}(SA \otimes \mathbb{K}, S^2B)$.

Conversely the natural asymptotic morphism from $SA \otimes \mathbb{K}$ into SB which corresponds to an extension (extension-class) $0 \to SB \to E \to A \otimes \mathbb{K} \to 0$ in $\mathrm{Ext}_{\mathrm{nuc}}(A \otimes \mathbb{K}, SB)$ is a weakly nuclear asymptotic morphism. It defines a group homomorphism from $\mathrm{Ext}_{\mathrm{nuc}}(A \otimes \mathbb{K}, SB)$ to $E_{nuc}(A, B)$.

The composition maps are equivalent (i.e. are element-wise homotopic) to the natural map $E_{nuc}(A, B) \to E_{nuc}(SA, SB)$, respectively to

$$\mathrm{Ext}_{\mathrm{nuc}}(A \otimes \mathbb{K}, SB) \to \mathrm{Ext}_{\mathrm{nuc}}(SA \otimes \mathbb{K}, S^2B)\,.$$

Thus Proposition 8.2.5(iii) and Corollary 8.3.3(iii) imply that *there is a natural isomorphism* $\mathrm{KK}_{\mathrm{nuc}}(A, B) \cong E_{nuc}(A, B)$ *for separable* A *and* σ*-unital* B.

4. The residually nuclear case

REMARK 8.4.1. Suppose that A, B are stable, where A is separable and B is σ-unital. They are assumed to be trivially graded.

Furthermore, we suppose that X is the primitive ideal space of a separable C^*-algebra C. We can then replace C by $F \otimes C$ with same primitive ideal space, where we let $F := \mathbb{K} \otimes \mathcal{O}_2 \otimes \mathcal{O}_2 \otimes \ldots$. Then, in addition, C is stable and $C \cong C \otimes \mathcal{O}_2$.

Suppose now that there are given monotonous actions Ψ_A and Ψ_B of X on A and B, respectively, cf. Definition 1.2.6.

The group $\mathrm{KK}_{\mathrm{nuc}}(X;\, A, B)$ is defined in Definition 1.2.10 as $\mathrm{KK}(\mathcal{C};\, A, B)$ for the cone $\mathcal{C}$ of Ψ_A-Ψ_B–residually nuclear maps.

$\mathrm{Ext}_{\mathrm{nuc}}(X;\, A, B) \cong G(H_0;\, A, B)$ and $S(H_0, A, B)$ are defined in Chapter 5.

Note that here $H_0 \colon A \to \mathcal{M}(B)$ denotes the “universal” non-degenerate weakly Ψ-residually nuclear C^*-morphism from A to $\mathcal{M}(B)$ such that $\delta_\infty H_0$ is unitarily equivalent to H_0.

`or is it only approximately unitary equivalent`
`with respect to the strict topology on` $\mathcal{M}(B)$ `...?`
`See def. in chp. 5 !!`

The existence and uniqueness of H_0 is assured if the m.o.c. cone of Ψ-residually maps from $A \to \mathcal{M}(B)$ has a countable generating set (as it is e.g. in the case where A and B are separable).

We list now the non-trivial changes of the above considered case X =point (with trivial action $\Psi_A(X) = A$, $\Psi_A(\emptyset) = \{0\}$).

In the beginning of the proof of Proposition 8.2.5(iii):

By Section 9, for D separable and stable and B σ-unital and stable, $\mathrm{Ext}_{\mathrm{nuc}}(X; D, B) = G(H_0; D, E)$ where $E := Q(B)$, $H_0 = \pi_B \circ H_1$ and $H_1 \colon D \to \mathcal{M}(B)$ is an infinite repeat of a sufficiently general non-degenerate weakly Ψ_A-Ψ_B–residually nuclear C^*-morphism from D in $\mathcal{M}(B)$ (The existence of such H_1 for *exact* A follows later from results in Chapter 12).

The unitary homotopy between $H_0 \oplus \psi$ and H_0 comes in the residually nuclear case from Theorem 5.9.3 in the same way as Theorem 5.6.2(ii) has been used in the proof.

`To-do-list: corollaries for chapter 9:`

LEMMA 8.4.2. *There are natural isomorphisms*

$$\mathrm{Ext}\big(\mathcal{C} \otimes \mathrm{CP}(\mathbb{C}, \mathrm{C}_0(\mathbb{R}))\,;\, D, B \otimes C_0(\mathbb{R})\big) \;\cong\; \mathrm{KK}(\mathcal{C};\, D, B)\,.$$

The isomorphisms are compatible with respect to scaling of $\mathbb{R}$.

The classes in $\mathrm{KK}(\mathcal{C}\,;\; A, B)$ are invariant under homotopy.

There are natural isomorphisms

$$\mathrm{Ext}_{\mathrm{nuc}}(X;\, D, SB) \cong \mathrm{KK}_{\mathrm{nuc}}(X;\, D, B)\,.$$

`Chp:9: By generalized Cor.8.3.3(iii) or Lem. 8.4.2:`

Suppose that ???????

For a C^*-morphism h from D to B with $h \in \mathcal{C}$ the mapping cone construction defines an element $\alpha[h] = [C_h]$ of $\mathrm{Ext}(\mathcal{C} \otimes \mathrm{CP}(\mathbb{C}, \mathrm{C}_0(\mathbb{R}));\, D, SB)$ which is mapped to the element $[h - 0] \in \mathrm{KK}_{\mathrm{nuc}}(X;\, D, B)$ under the natural isomorphism from $\mathrm{Ext}(\mathcal{C} \otimes \mathrm{CP}(\mathbb{C}, \mathrm{C}_0(\mathbb{R}));\, D, SB)$ onto $\mathrm{KK}(\mathcal{C};\, D, B)$.

`next lem:8.4new used in chp:9`

LEMMA 8.4.3. *, For every homomorphism $k \colon D \to E_{\mathbb{R}}$ that is dominated by H_0, there exists a unitary $u \in E_{\mathbb{R}}$ such that $u^*(k \oplus H_0)(a)u - H_0(a) \in J$ for each $a \in D$.*

`next mentioned in chp:1`

There is a natural group homomorphism for tensor products:

$$\mathrm{KK}(X;\, A, B) \times \mathrm{KK}(C, D) \to \mathrm{KK}(X;\, A \otimes C, B \otimes D)\,,$$

where the action is given, e.g. on $A \otimes C$, by

$$Z \in \mathbb{O}(X) \mapsto \Psi_A(Z) \otimes C \in \mathcal{I}(A \otimes C)\,.$$

Is it the same as

$$\mathrm{KK}(\mathcal{C};\, A, B) \times \mathrm{KK}(C, D) \to \mathrm{KK}(\mathcal{C} \otimes \mathrm{CP}(C, D);\, A \otimes C, B \otimes D)\,?$$

`my view on split extensions:`

REMARK 8.4.4. Suppose that

$$0 \longrightarrow B \longrightarrow C \longrightarrow A \longrightarrow 0$$

is a short exact sequence of graded C^*-algebras, and that $\mathcal{C}_1 \subseteq \mathrm{CP}(A, C)$,

?????

??

We define a map from the locally compact subspaces Y of $\mathbb{R}^2$ into the groups by

$$F(Y) := G(H_Y\,;\, D, E_Y\,) \cong \mathrm{Ext}(\mathcal{C}(Y);\, A, B \otimes \mathrm{C}_0(Y)) \cong \mathrm{KK}(\mathcal{C}(Y), A, SB \otimes \mathrm{C}_0(Y))\,.$$

Then $F(\mathbb{R}_+) = 0$ because $\mathrm{KK}(\mathcal{C};\, \cdot, \cdot)$ is homotopy invariant and the identity map of $B \otimes \mathrm{C}_0(\mathbb{R}_+)$ is homotopic to 0.

PROPOSITION 8.4.5. *With the above notation holds that*

$$\mathrm{K}_*(H_{[0,\infty)}(D)' \cap E_{[0,\infty)}) = 0\ ,$$

that there is a natural isomorphism from $F(\mathbb{R})$ onto the kernel of $\mathrm{K}_1(H_0(D)' \cap \mathrm{Q}(B)) \to \mathrm{K}_1(\mathrm{Q}(B)) \cong \mathrm{K}_0(B)$,
and that $[\widehat{\alpha} \circ h] = [h] \in \mathrm{Ext}(\mathcal{C}(\mathbb{R});\, D, B)$ for every $h\colon D \to E_{\mathbb{R}}$ with $[h] \in F(\mathbb{R})$ and every order-preserving homeomorphism α from $\mathbb{R}$ to $\mathbb{R}$ with $\alpha(0) = 0$.

The proof is contained in the further below given more explicit constructions,

`The reduction to Mayer--Vietoris does not work??`

but we give an independent proof, that reduce the proof to an application of the K_*-theory Mayer–Vietoris sequence to the Y-equivariant isomorphism of $F(Y)$ with the kernel of $\mathrm{K}_0(H_Y(D)' \cap E_Y) \to \mathrm{K}_0(E_Y) \cong \mathrm{K}_1(B \otimes \mathrm{C}_0(Y))$, (that we have seen in Chapters 5 and 4).

LEMMA 8.4.6. *Let $\mathcal{L}(L_2(S^1)) \cong \mathcal{M}(\mathbb{K}) \subseteq H(D)' \cap \mathcal{M}(B)$ given by a non-degenerate map from $\mathbb{K}$ into $H(D)' \cap \mathcal{M}(B)$, and let*

$$\mathrm{C}_0(\mathbb{R}) + \mathbb{C} \cdot 1 \cong \mathrm{C}(S^1) \subseteq \mathcal{L}(L_2(S^1))$$

given by multiplication of functions. Then the C^*-morphism

$$H_1 \colon D \otimes \mathrm{C}_0(\mathbb{R}) \;\to\; H(D)' \cap \mathcal{M}(B)$$

with $H_1(a \otimes f) := D(a)f$ satisfies the assumptions of Corollary 5.4.4 **??**. *for the cone $\mathcal{C} \otimes \mathrm{CP}(\mathrm{C}_0(\mathbb{R}), \mathbb{C})$. Thus*

$$\mathrm{Ext}(\mathcal{C}(\mathbb{R}, Y);\, D \otimes \mathrm{C}_0(\mathbb{R}), B \otimes \mathrm{C}_0(Y)) \cong G(\pi_B \circ H_1;\, D \otimes \mathrm{C}_0(\mathbb{R}), E_Y)$$

and is isomorphic to the kernel of

$$\mathrm{K}_0(T) \to \mathrm{K}_0(E_Y) \cong \mathrm{K}_1(B \otimes \mathrm{C}_0(Y))$$

where $T := \pi_B(H_1(D \otimes \mathrm{C}_0(\mathbb{R})))' \cap E_Y$.

There is an epimorphism *from* $\mathrm{Ext}(\mathcal{C}(\mathbb{R}, \mathbb{R}_+)\,;\, D \otimes \mathrm{C}_0(\mathbb{R}), B \otimes \mathrm{C}_0(\mathbb{R}_+))$ *onto the kernel of the group morphism*

$$\mathrm{K}_1(H_{[0,\infty)}(D)' \cap E_{[0,\infty)}) \to \mathrm{K}_1(E_{[0,\infty)}) \cong \mathrm{K}_0(B \otimes \mathrm{C}_0([0,\infty)))\,.$$

PROOF. **??** □

`Alternatively: use explicit` KK`-equivalences in` $\mathbb{E}(\mathbb{C}, \mathrm{C}_0(\mathbb{R})_{(1)})$ `and` $\mathbb{E}(\mathrm{C}_0(\mathbb{R})_{(1)}, \mathbb{C})$

PROOF OF PROPOSITION 8.4.5. : Since there are exact sequence

$$0 \to F(\mathbb{R}_+) \to \mathrm{K}_0(H_{[0,\infty)}(D)' \cap E_{[0,\infty)}) \to \mathrm{K}_1(B \otimes \mathrm{C}_0(\mathbb{R}_+)),$$
$$0 \to F(\mathbb{R}_-) \to \mathrm{K}_0(H_{[0,-\infty)}(D)' \cap E_{[0,-\infty)}) \to \mathrm{K}_1(B \otimes \mathrm{C}_0(\mathbb{R}_-)),$$

the monomorphism $F(Y) := G(H_Y;\, D, E_Y) \to \mathrm{K}_0(H_Y(D)' \cap E_Y)$ and the morphisms $\mathrm{K}_*(H_Y(D)' \cap E_Y) \to \mathrm{K}_*(E_Y)$ and the isomorphisms $\mathrm{K}_0(E_Y) \cong \mathrm{K}_1(B \otimes \mathrm{C}_0(Y))$ behave in a natural way equivariant with respect to homeomorphisms σ of Y, because $\widehat{\sigma} \circ H_Y = H_Y$. If X is a closed subset of Y such that for every $f \in \mathrm{C_b}(Y)_+$ with $f|X \in \mathrm{C}_0(X)$ there exists $g \in \mathrm{C_b}(Y)_+$ with $gf \in \mathrm{C}_0(Y)$ and $gf|X = f|X$, then the natural map $H_Y(D)' \cap E_Y \to H_X(D)' \cap E_X$ is an *epimorphism* (that is induced by the natural epimorphism $E_Y \to E_X$).

The algebra $H_\mathbb{R}(D)' \cap E_\mathbb{R}$ is the pullback of $H_{(-\infty,0])}(D)' \cap E_{(-\infty,0])}$ and $H_{[0,\infty)}(D)' \cap E_{[0,\infty)}$ by its natural morphism *onto* $H_{[0,\infty)}((D)' \cap E_{\{0\}}$. Since $\mathrm{K}_*(\mathrm{C}_0(\mathbb{R}_+, B)) = 0$ and $\mathrm{K}_*(H_{[0,\infty)}(D)' \cap E_{[0,\infty)}) = 0$ (by the first part), we get that $\mathrm{K}_1(\pi_B(H_0(D))' \cap \mathrm{Q^s}(B)) \cong \mathrm{K}_0(H_\mathbb{R}(D)' \cap E_\mathbb{R})$.

The diagram (and thus the isomorphism) is invariant under $\widehat{\sigma}$ if σ is an order preserving homeomorphism of $\mathbb{R}$ and $\sigma(0) = 0$. Then the morphisms of the Mayer–Vietoris sequence are also $\widehat{\sigma}$-equivariant. Since $\mathrm{K}_1(\widehat{\sigma}|\{0\}) = \mathrm{K}_1(\mathrm{id})$ on $\mathrm{K}_1(H_0(D)' \cap E_0)$ it follows $\widehat{\sigma} = \mathrm{id}$ on $\mathrm{K}_0(H_\mathbb{R}(D)' \cap E_\mathbb{R})$

More??? **??**

□

One can check that the kernel of $\mathrm{K}_1(H_0(D)' \cap \mathrm{Q}(B)) \to \mathrm{K}_1(\mathrm{Q}(B)) \cong \mathrm{K}_0(B)$ is nothing else $\mathrm{KK}_{\mathrm{nuc}}(A, B)$ if H_0 corresponds to $\mathrm{CP}_{\mathrm{nuc}}(A, B)$ (and similarly in the residually nuclear case $\mathrm{KK}_{\mathrm{nuc}}(X;\, A, B)$ or in the case of $\mathrm{KK}(\mathcal{C};\, A, B)$ with general non-degenerate m.o.c. cone $\mathcal{C} \subseteq \mathrm{CP}(A, B)$). Notice here that A and B are trivially graded.

`Protocol (until 16.9.2009):`
`Some TO DO list for chp.8, applied in Chapter 11:`

(0.1) In all points (*.*) and (*) below:

We should work with a suitable G-equivariant bi-functor $(A, B) \mapsto \mathcal{C}_{A,B} \subseteq \mathrm{CP}(A, B)$ on suitable categories of G-algebras with G-equivariant morphisms, where G is a Polish group.

(0.2) The only additional requirement for (G, X)-equivariant Kasparov modules is that A and B are graded G algebras. That ϕ, and the gradings are G-equivariant, and that the bi-module is G-modular, and that $(g(F) - F)\phi(A) \in \mathbb{K}(E)$ for all $g \in G$, and $g \to g(F)$ is norm-continuous.

(1) Each element of $\mathrm{KK}^G(X;\, A, B)$ can be represented by a non-degenerate $(G, X)-$ Kasparov A–B-module (E, ϕ, F) (i.e., $\phi(A)E = E$).

(It gives the σ-additivity of $\mathrm{KK}^G(X\, ;\, \cdot\, , B)$???

But it is probably only for a special class of groups G possible, that contains ??????? compact ????? groups (?).

For them, one can reduce all to the stable case and then use the Brown stability or Kasparov trivialization in a G-equivariant manner ????.)

(2) $\mathrm{KK}^G(X;\, \cdot\, , B)$ is half exact on (G, X)-semi-split sequences (and additive on (G, X)-split-exact sequences). Needed (!!!), because of the KK^G–proof in chapter 11.

(3) Desire: Give an explicit module for the KK-equivalence of split sequences.

(4) Morphisms:
If $\psi\colon A \to B$ satisfies $\psi \circ \mathcal{C}_1 \subseteq \mathcal{C}_2$, (that is symbolic $\psi \in \mathcal{C}_2\mathcal{C}_1^{-1} \subseteq \mathrm{CP}(A, B)$), then $\psi_*\colon \mathrm{KK}(\mathcal{C}_1\, ;\, D, A) \to \mathrm{KK}(\mathcal{C}_2\, ;\, D, B)$ is well-defined in the usual way.

If there are G-actions δ, α and β on D,A,B with $\alpha(g) \circ \mathcal{C}_1 \circ \delta(g^{-1}) \subseteq \mathcal{C}_1$ and $\beta(g) \circ \mathcal{C}_2 \circ \delta(g^{-1}) \subseteq \mathcal{C}_2$ for all $g \in G$, and if $\psi \circ \alpha(g) = \beta(g) \circ \psi$, then $\psi_*\colon \mathrm{KK}^G(\mathcal{C}_1\, ;\, D, A) \to \mathrm{KK}^G(\mathcal{C}_2\, ;\, D, B)$ is well-defined.

Suppose that G acts on a T_0-space X and that D, A, B are (G, X)-algebras. If $\psi\colon A \to B$ is compatible with the (G, X)-actions on A and B, then $\psi_*\colon \mathrm{KK}^G(X;\, D, A) \to \mathrm{KK}^G(X;\, D, B)$ *and* $\psi_*\colon {\mathrm{KK}_{\mathrm{nuc}}}^G(X;\, D, A) \to {\mathrm{KK}_{\mathrm{nuc}}}^G(X;\, D, B)$ are well-defined. (This can be deduced from the case of cone-depending KK, by taking $\mathcal{C}_1 := \mathcal{C}(X;\, D, A)$ and $\mathcal{C}_2 := \mathcal{C}(X;\, D, B)$, respectively $\mathcal{C}_1 := \mathcal{C}_{\mathrm{rn}}(X;\, D, A)$ and $\mathcal{C}_2 := \mathcal{C}_{\mathrm{rn}}(X;\, D, B)$.)

Similar (obvious "opposite") sufficient conditions can be given for the existence of $\psi^*\colon \mathrm{KK}^G(\mathcal{C}_4\, ;\, B, E) \to \mathrm{KK}^G(\mathcal{C}_3\, ;\, A, E)\colon$ ψ should be G-equivariant and $\mathcal{C}_4 \circ \psi \subseteq \mathcal{C}_3$

We get that $\psi^*\colon \mathrm{KK}^G(X;\, B, E) \to \mathrm{KK}^G(X;\, A, E)$ is well-defined if ψ is (G, X)-equivariant.

(5) The cones $\mathcal{C}$ needed for Mayer-Vietoris sequence:

(5a) Pull-back of epic morphisms $\varphi_k\colon A_k \to C$:
In the case of the pull-back $P := A_1 \oplus_{\varphi_1, \varphi_2} A_2$ of $\varphi_k\colon A_k \to C$ (with $\varphi_k \circ \mathcal{C}_{D,A_k} \subseteq \mathcal{C}_{D,C}$) one has to take the "pull-back" of the cones $\mathcal{C}_{D,A_k}$ as follows:

Let $\mathcal{C}_{D,P} \subseteq \mathrm{CP}(D,P)$ denote the set of all maps $d \mapsto V_1(d) \oplus V_2(d)$ with $V_1 \in \mathcal{C}_{D,A_1}$, $V_2 \in \mathcal{C}_{D,A_2}$, and $\varphi_1(V_1(d)) = \varphi_2(V_2(d))$ for all $d \in D$.

Notice that $\pi \circ \mathcal{C}_{D,P} \subseteq \mathcal{C}D, C$ for $\pi\colon a_1 \oplus a_2 \in P \to (1/2)(\varphi_1(a_1) + \varphi_2(a_2)) \in C$ and is G-equivariant, because the c.p. map $W\colon a_1 \oplus a_2 \in A_1 \oplus A_2 \mapsto (1/2)(\varphi_1(a_1) + \varphi_2(a_2))$ is G-equivariant and $W \circ (\mathcal{C}_{D,A_1} \oplus \mathcal{C}_{D,A_2}) \subseteq \mathcal{C}_{D,C}$.

The *co-homological case* has to consider given $\mathcal{C}_{A_k,E} \subseteq \mathrm{CP}(A_k, E)$ and $\mathcal{C}_{C,E} \subseteq \mathrm{CP}(C, E)$. The assumptions need the G–invariance of the cones and maps, e.g. $\eta(g) \circ \mathcal{C}_{C,E} \circ \gamma(g^{-1}) \subseteq \mathcal{C}_{C,E}$, etc.

(5b) How to construct the $(G, \mathcal{C})$-lift from lifts of φ_k?

In case that the φ_k are epimorphisms, the required lifts $T_k\colon C \to A_k$ (of φ_k for homology) should satisfy $T_k \circ \mathcal{C}_{D,C} \subseteq \mathcal{C}_{D,A_k}$ (and should be G-equivariant). In the co-homological situation, one has to require that $\mathcal{C}_{A_k,E} \circ T_k \subseteq \mathcal{C}_{C,E}$ etc.

Then $T\colon c \mapsto T_1(c) \oplus T_2(c)$ is a G-equivariant c.p. split of the epimorphism $\pi\colon P \to C$ with $\pi \circ T = \mathrm{id}_C$, and $T \circ \mathcal{C}_{D,C} \subseteq \mathcal{C}_{D,P}$.

(6) Mapping cones, Puppe sequence, Bott periodicity. (The modifications for the $\mathcal{C}$-version!):

$\psi\colon A \to B$ should be $(G, \mathcal{C})$ equivariant (in the relevant sense, depending from the homological or co-homological situation). The mapping cone C_ψ of ψ is the pull-back of $f \in CB = B \otimes \mathrm{C}_0((0,1]) \mapsto f(1) \in B$ and of $\psi\colon A \to B$. $\mathcal{C} =: \mathcal{C}_{D,B} \subseteq \mathrm{CP}(D, B)$ has to be extended to $\mathcal{C}_{D,CB} := \mathcal{C} \otimes \mathrm{CP}(\mathbb{C}, \mathrm{C}_0((0,1])) =: \mathcal{C}(0,1] \subseteq \mathrm{CP}(D, CB)$.

This implies that $\mathcal{C}_{D,C_\psi} \subseteq \mathrm{CP}(D, C_\psi)$ has to be the the set of all those c.p. maps $V_1 \oplus V_2\colon D \to A \oplus CB$ with $V_1 \in \mathcal{C}_{D,A}$, $V_2 \in \mathcal{C}_{D,CB}$ and $\psi(V_1(d)) = V_2(d)(1)$ for all $d \in D$.

In the co-homological situation one has given $\mathcal{C}_{A,E}$ and $\mathcal{C}B, E$ and has to define $\mathcal{C}CB, E \subseteq \mathrm{CP}(CB, E)$ and $\mathcal{C}C_\psi, E \subseteq \mathrm{CP}(C_\psi, E)$: $\mathcal{C}CB, E := \mathcal{C}B, E \otimes \mathrm{CP}(\mathrm{C}_0((0,1]), \mathbb{C})$ $\mathcal{C}C_\psi, E$ as in the above given pull-back construction.

(7) The cones (and conditions in G-equivariant case) needed for the half-exactness on $(G, \mathcal{C})$-semi-split exact sequences.

(On (G, X)-semi-split exact sequences it should be nothing in addition to require.)

Let G a second countable l.c. group, that acts on A and D via $\alpha(g)$ and $\delta(g)$, and let $J \lhd A$ a G-invariant ideal with quotient map $\pi\colon A \to A/J$ and inclusion $\iota\colon J \to A$. The action on J and A/J should be the induced one.

Further, $\mathcal{C}_{D,A} \subseteq \mathrm{CP}(D, A)$, $\mathcal{C}_{D,J} \subseteq \mathrm{CP}(D, J)$, and $\mathcal{C}_{D,A/J} \subseteq \mathrm{CP}(D, A/J)$ are given. We require that $\pi \circ \mathcal{C}_{D,A} \subseteq \mathcal{C}_{D,A/J}$ and $\iota \circ \mathcal{C}_{D,J} \subseteq \mathcal{C}_{D,A}$, moreover, that $\alpha(g)\mathcal{C}_{D,A}\delta(g^{-1}) \subseteq \mathcal{C}_{D,A}$, $\alpha(g)\mathcal{C}_{D,J}\delta(g^{-1}) \subseteq \mathcal{C}_{D,J}$, and $[\alpha](g)\mathcal{C}_{D,A/J}\delta(g^{-1}) \subseteq \mathcal{C}_{D,A/J}$.

DEFINITION 8.4.7. We say that $V\colon A/J \to A$ is a $(G,\mathcal{C})$**-equivariant lift**, if V is completely positive, G-equivariant, and $V \circ \mathcal{C}_{D,A/J} \subseteq \mathcal{C}_{D,A}$. The sequence $0 \to J \to A \to A/J \to 0$ is called **homological** $(G,\mathcal{C})$**-semi-split**, if such V exists.

Similar, one has to require in the *co-homological* case that e.g. $\mathcal{C}_{A,D} \circ V \subseteq \mathcal{C}A/J, D$, etc.

The proof of the 6-term sequences of usual KK-theory applies now. because, the $(G,\mathcal{C})$-analogs of [**73**, lem. 19.5.3, thm. 19.5.5] work.

PROPOSITION 8.4.8. *If the sequence* $0 \to J \to A \to A/J \to 0$ *is* homological $(G,\mathcal{C})$*-semi-split, then the six-term exact sequence of the "homology"* $X \mapsto \mathrm{KK}^G(\mathcal{C}_{D,X}\,;\, D, X)$ *holds (cf.* [**73**, thm. 19.5.7]*).*

If the sequence $0 \to J \to A \to A/J \to 0$ *is* co-homological $(G,\mathcal{C})$*-semi-split, then the six-term exact sequence of the "cohomology"* $X \mapsto \mathrm{KK}^G(\mathcal{C}_{X,D}\,;\, X, D)$ *holds.*

(8) Comments on the applications of $KK^G(\mathcal{C};\,\cdot,\cdot)$ in Chapters 9-12.

(8a) The σ-additivity of $\mathrm{KK}^G(X;\,\cdot\,, D)$ and its consequences:
The σ-additivity immediately follows from the fact that each element can be represented by a *non-degenerate* Kasparov module. One of the consequences is the following lemma:

LEMMA 8.4.9. *Let* B_∞ *denote the inductive limit of a sequence of* (G, X)*-invariant injective morphisms* $\psi_n\colon B_n \to B_{n+1}$*, and suppose that the morphisms* ψ_n *satisfy the following conditions* (i) *and* (ii) *for every* $n \in \mathbb{N}$.

(i) *The element* $[(B_{n+1}, \psi_n, 0)]$ *of* $\mathrm{KK}^G(X;\, B_n, B_{n+1})$ *has an inverses element in* $\mathrm{KK}^G(X;\, B_{n+1}, B_n)$.
(ii) *For every finite subset* $F \subseteq B_n$ *and each* $\varepsilon > 0$*, there are* $m_2 > m_1 \geq n$ *and a* (G, X)*-equivariant c.p. contraction* $V\colon B_{m_2} \to B_{m_1}$ *such that* $\|\psi_n^{m_1}(x) - V(\psi_n^{m_2}(x))\| < \varepsilon$ *for all* $x \in F$.

Then $\psi_1^\infty\colon B_1 \to B_\infty := \mathrm{indlim}(\psi_n\colon B_n \to B_{n+1})$ *defines a* $\mathrm{KK}^G(X;\,\cdot,\cdot)$*–equivalence of* B_1 *and* B_∞*, i.e.,* $\mathrm{KK}(\psi_1^\infty) \in \mathrm{KK}^G(X;\, B_1, B_\infty)$ *admits an inverse in* $\mathrm{KK}^G(X;\, B_\infty, B_1)$.

Notice that (ii) is trivially satisfied for compact G and nuclear B_n (if the action of X on B_n is continuous).

PROOF. The condition (ii) ensures that there is a sequence $n_1 < n_2 < \cdots$ and (G, X)-equivariant completely positive maps $T_k\colon B_\infty \to B_{n_k}$ such that

$$S_k := psi_k^\infty \circ T_k$$

converges point-wise to id_{B_∞}. It follows that the epimorphism from the ((G, X)-contractible) mapping telescope T of the maps $(\psi_1, \psi_2, \ldots)$ onto the inductive limit B_∞ has an (G, X)-equivariant c.p. lift.

Then B_∞ is $\mathrm{KK}^G(X;\cdot,\cdot)$-equivalent to the kernel of $T \to B_\infty$. After realizing that, one is able to apply the standard arguments of cohomology theory to $h(\cdot) := \mathrm{KK}^G(X;\cdot,D)$ (for fixed D), because of homotopy invariance and half-exactness on (G,X)-split-exact sequences. Then one uses that $\mathrm{proj}-\lim^{(1)}(\psi_1^*,\psi_2^*,\ldots) = 0$, and gets that $\psi_1^\infty\colon B_1 \to B_\infty$ satisfies that $(\psi_1^\infty)^*\colon \mathrm{KK}^G(X;B_\infty,D) \to \mathrm{KK}^G(X;B_1,D)$ defines an isomorphism for $\mathrm{KK}^G(X;B_\infty,D)$ onto $\mathrm{KK}^G(X;B_1,D)$ for each separable (G,X)-algebra D.

In particular, there is $y \in \mathrm{KK}^G(X;B_\infty,B_1)$ with $(\psi_1^\infty)^*(y) = [\mathrm{id}_{B_1}]$. Since ψ_1^∞ is (G,X)-equivariant, it defines an element $z := [\psi_1^\infty] := [(B_\infty,\psi_1^\infty,0)]$ of $\mathrm{KK}^G(X;B_1,B_\infty)$ with $z\otimes_{B_\infty} y = (\psi_1^\infty)^*(y) = [\mathrm{id}_{B_1}]$. Then

$$(\psi_1^\infty)^*([\mathrm{id}_{B_\infty}] - (y\otimes_{B_1} z)) = z - (z\otimes_{B_\infty} y)\otimes_{B_1} z = 0\,,$$

hence, $y\otimes_{B_1} z = [\mathrm{id}_{B_\infty}]$ by injectivity of $(\psi_1^\infty)^*$. □

(8b) If A and B are trivially graded, then $[(B,\psi,0)] \in \mathrm{KK}^G(\mathcal{C};A,B)$ corresponds to the element of $\mathrm{Ext}^G(\mathcal{C}\otimes\mathrm{CP}(\mathbb{C},\mathrm{C}_0(\mathbb{R}));A,\mathrm{C}_0(\mathbb{R},B))$ that is defined by the extension of A by $\mathrm{C}_0((0,1),B)$ given by the mapping cone.

(8c) Notice that the mapping cone C_ψ of an (G,X)-equivariant morphism $\psi\colon A\to B$ is in a natural way a (G,X)-algebra (because defined by passage to the cone of B and a pull-back construction), and the lift $a\mapsto a\oplus(a\otimes f_0)\in C_\psi$ is a (G,X)-equivariant. The canonical 6-term exact sequence for the (G,X)-semi-split sequence $0\to SB\to C_\psi\to A\to 0$ has as its connecting maps δ are just the maps $(S\psi)^*\,\mathrm{KK}^G(X;SB,D)\to\mathrm{KK}^G(X,SA,D)$ and $\psi^*\colon \mathrm{KK}^G(X;B,D)\to \mathrm{KK}^G;A,D)$ (for each separable (G,X)-algebra D). Thus, we get:

Lemma 8.4.10. *The (G,X)-algebra C_ψ is $\mathrm{KK}^G(X;\cdot,\cdot)$-trivial, if and only if, $\psi\colon A\to B$ is a $\mathrm{KK}^G(X;\cdot,\cdot)$-equivalence.* □

This has a nice application in chapter 11.

Remark 8.4.11. Suppose that G is a Polish l.c. group, and A is a separable C^*-algebra with two actions α and β of G on A. Let $\mathcal{C} = \mathcal{C}_{in} \subseteq \mathrm{CP}(A,A)$ the cone of approximately inner c.p. maps of A.

If α and β are exterior *equivalent then there is an invertible element in $\mathrm{KK}^G(\mathcal{C};(A,\alpha),(A,\beta))$.*

Here α and β are **exterior equivalent** if there is a strictly continuous map $g\mapsto U(g)$ from G into the the unitary group $\mathcal{U}(\mathcal{M}(A))$, such that $U(gh) = U(g)\alpha(g)(U(h))$, and $\beta(g)(\cdot) = U(g)\alpha(g)(\cdot)U(g^{-1})$ for $g,h\in G$. (Here we extend $\alpha(g)$ naturally to $\mathcal{M}(A)$. It is the same as our notation $\mathcal{M}(\alpha(g))$ in other chapters.)

Proof. The arguments in the *proof* of [**698**, prop. 3.1] apply to our situation, because the cone of approximately inner c.p. maps V is invariant under conjugations, i.e., $\beta(g)\circ V\circ\alpha(g^{-1})$ if α and β are exterior equivalent. □

5. Verifying Condition (DC) of the basic Theorem 4.4.6

The verification of Condition (DC) of Theorem 4.4.6 for our axiomatic picture of $\mathrm{KK}(\mathcal{C}; A, B) \cong \mathrm{Ext}(\mathcal{C}(\mathbb{R}); A, SB)$ is completely contained in the following Proposition 8.5.1. Let us first collect some informations that allow to give a proof at the end of this Section.

In the following we make the overall assumptions that A and B are stable C^*-algebras (real or complex), A is separable, B is σ-unital, and E is any unital C^*-algebra.

We consider in the following Lemmata and in Proposition 8.5.4 also the (trivially graded) real case. Clearly in the complex case the skew-adjoint operators $a^* = -a$ are of the form $a = ib$ with $b^* = b$.

Say/Recall what is here a "non-degenerate" morphism.
Need to check first following facts:

Let A stable and separable, B stable and σ-unital, $CB := \mathrm{C}_0([0, \infty), B)$, $H \colon A \to \mathcal{M}(B)$ a non-degenerate C^*-morphism that is unitarily equivalent to $\delta_\infty \circ H$.

Consider the natural unital injection $\mathcal{M}(B) \subset \mathcal{M}(CB)$ of $\mathcal{M}(B)$ in $\mathcal{M}(CB)$. Then (by Kasparov ...?), $\mathcal{U}(\pi_{CB}(H(A))' \cap (\mathcal{M}(CB)/CB))$ is equal to
$\mathcal{U}_0(\pi_{CB}(H(A))' \cap (\mathcal{M}(CB)/CB))$
. ????

Proposition 8.5.1. *Let A and B stable C^*-algebras, where A is separable and B is σ-unital, and $H \colon A \to \mathcal{M}(B)$ a non-degenerate C^*-morphism in "general position" – in the sense of Definition 3.3.1, i.e., $H(A)B = B$ and H is unitarily homotopic to its infinite repeat $\delta_\infty \circ H$, cf. Definition 5.0.1 and Remark 5.1.1(8).*

Decide ! :
Is it equal to $H(A)B = B$ and that H is approximately unitary equivalent to $\delta_\infty \circ H$ in Norm or strict topology? ([10]).

Let $S, T \in H(A)' \cap \mathcal{M}(B)$ isometries with $SS^* + TT^* = 1$.

Suppose that there exists a strictly continuous map $t \in \mathbb{R} \mapsto U(t) \in \mathcal{M}(B)$ from $(-\infty, +\infty)$ into the unitaries of $\mathcal{M}(B)$ such that

(α) *$[U(t), H(a)] := U(t)H(a) - H(a)U(t) \in B$ for each $a \in A$,*
(β) *the map $\mathbb{R} \ni t \mapsto [U(t), H(a)]$ from $\mathbb{R}$ to B is continuous for each $a \in A$, and*
(γ) *$\lim_{t \to -\infty} \|U(t)H(a) - H(a)U(t)\| = 0$ for each $a \in A$.*

Then there exist strictly continuous maps $t \in \mathbb{R} \mapsto V(t) \in \mathcal{U}(\mathcal{M}(B))$ and $t \in \mathbb{R} \mapsto W(t) \in \mathcal{U}(\mathcal{M}(B))$ that have the following properties for each *$a \in A$:*

(i) *$U(t) \oplus_{S,T} 1 = V(t)W(t)$ for all $t \in \mathbb{R}$,*

[10] Then $\delta_\infty \circ H$ is approximately unitary equivalent to H in $\mathcal{M}(B)$ with respect to the strict topology on $\mathcal{M}(B)$ in sense of Remarks 5.1.1.

(ii) $t \mapsto [V(t), H(a)]$ *is a continuous map from* $\mathbb{R}$ *into* B,
(iii) $\lim_{t\to-\infty} \|[V(t), H(a)]\| = 0$ *and* $\lim_{t\to+\infty} \|[V(t), H(a)]\| = 0$,
(iv) $W(t) = 1$ *for all* $t \leq -1$ *and* $W(t) \in \mathcal{U}(B + \mathbb{C} \cdot 1) \subset \mathcal{U}(\mathcal{M}(B))$ *for all* $t \in \mathbb{R}$,
(v) $t \mapsto [W(t), H(a)] \in B$ *is a continuous map.*

Proposition 8.5.1 says with other words: If $U \in \mathcal{M}(\mathrm{C}_0(\mathbb{R}, B))$ is a unitary with $UH(a) - H(a)U \in \mathrm{C_b}(\mathbb{R}, B)$ and and $\lim_{t\to-\infty} \|U(t)H(a) - H(a)U(t)\| = 0$ for each $a \in A$, then $U \oplus_{S,T} 1$ decomposes as $U \oplus_{S,T} 1 = VW$, $V, W \in \mathcal{U}(\mathcal{M}(\mathrm{C}_0(\mathbb{R}, B)))$ with $W \in 1 + \mathrm{C_b}(\mathbb{R}, B)$ – which implies obviously $WH(a) - H(a)W \in \mathrm{C_b}(\mathbb{R}, B)$ –, with $W(t) = 1$ for $t \leq -1$ and $VH(a) - H(a)V \in \mathrm{C}_0(\mathbb{R}, B)$ for all $a \in A$.

Notice that the assumptions of Proposition the map $t \in \mathbb{R}_+ \to U(t) \in \mathcal{M}(B)$ corresponding to U is only strictly continuous.

We remind first some simple facts and (easy to see) rough estimates concerning skew-adjoint contactions $-c^* = c, c_1, \ldots, c_n \in E$, $\|c\| \leq 1$ in some real or complex unital C^*-algebra E:

(1) $\exp(c) \in \mathcal{U}_0(E)$ if $c^* = -c$.
(If E is complex then $c = ih$ for the self-adjoint element $h = -ic \in E$.)
(2) $\| [\exp(c), T] \| \leq 3 \| [c, T] \|$ for all $T \in E$.
(Use that $\|[c^n, T]\| \leq (n\|c\|^{n-1}) \cdot \|[c, T]\|$, $\|c\| \leq 1$ and $e \leq 3$.)
(3) If $c_1, \ldots, c_n \in E$ are skew-adjoint contraction and $T \in E$, then

$$\| [\exp(c_1) \cdot \exp(c_2) \cdot \ldots \cdot \exp(c_n), T] \| \leq 3n \max \{ \|[c_k, T]\| ; 1 \leq k \leq n \} .$$

(Use part (2) and that $\|\exp(c)\| = 1$ if $c = -c^*$.)

In the following Lemma let B denote a σ-unital (real or complex) C^*-algebra and let $D \subseteq \mathcal{M}(B)$ a (real or complex) separable C^*-subalgebra.

Recall that $\mathcal{M}(B)$ means the multiplier algebra of B and that $\mathcal{M}(B) \subseteq \mathcal{M}(CB)$ unitally by the natural non-degenerate embedding $B \subseteq \mathcal{M}(CB)$, where we define here $CB := \mathrm{C}_0((0, 1], B) \cong \mathrm{C}_0((\alpha, \beta], B)$ for each $\alpha < \beta \in \mathbb{R}$. In this way also $D \subseteq \mathcal{M}(B) \subseteq \mathcal{M}(CB)$ becomes a C^*-subalgebra of $\mathcal{M}(CB)$ by natural identification cf. prove of following Lemma 8.5.2 for details.

Lemma 8.5.2. *Let* B *a* σ*-unital (real or complex)* C^**-algebra,* $D \subseteq \mathcal{M}(B)$ *a separable* C^**-subalgebra of the multiplier algebra of* B, $b_1, \ldots, b_n \in \mathcal{M}(CB)$ skew-adjoint *contractions with the property that* $[b_k, d] \in CB$ *for all* $d \in D$ *and for each* $k = 1, \ldots, n$.

Then, for each given fixed contractions $d_1, \ldots, d_m \in D$ *and* $\varepsilon > 0$*, there exist a positive contraction* $e \in CB$ *and a normal element* $g \in CB$ *such that – with*

$$c_k := (1 - e^2)^{1/2} b_k (1 - e^2)^{1/2}$$

for $k \in \{1, \ldots, n\}$ *– and for* $\ell \in \{1, \ldots, m\}$ *holds:*

(i) $[c_k, d] \in CB$ *for all* $d \in D$,

(ii) $\|[c_k, d_\ell]\| < \varepsilon/(6n+7)$,
(iii) $1+g \in \mathcal{U}_0(\mathbb{C}\cdot 1 + CB)$, *– respectively* $1+g \in \mathcal{U}_0(\mathbb{R}\cdot 1 + CB)$ *–, and*
(iv) $V\cdot(1+g) = \exp(b_1)\cdot\exp(b_2)\cdot\ldots\cdot\exp(b_n)$
for the unitary $V := \exp(c_1)\cdot\exp(c_2)\cdot\ldots\cdot\exp(c_n) \in \mathcal{U}_0(\mathcal{M}(CB))$.

It implies $\|\,[V, d_\ell]\,\| < \varepsilon/2$ *for* $\ell = 1,\ldots,m$, $[V,d] \in CB$ *and* $[g,d], gd, dg \in CB$ *for all* $d \in D$.

There exist $\delta > 0$ *and* $-f^* = f \in CB$ *such that, for* $\ell = 1,\ldots,m$,

$$\|f\| \leq 1\,,\ \exp(-f)(1+g)|(0,\delta] \;=\; 1|(0,\delta] \ \textit{and}\ \|[f,d_\ell]\| < \varepsilon/(3(n+1))\,.$$

It implies that $h =: \exp(-f)(1+g) - 1 \in CB$ *satisfies* $h(t) = 0$ *for* $t \in (0,\delta]$, $V\cdot(1+g) = (V\cdot\exp(f))\cdot(1+h)$ *and*

$$\|\,[V\cdot\exp(f), d_\ell]\,\| < \varepsilon \quad \textit{for}\ \ell = 1,\ldots,m\,.$$

Moreover $1+h = \exp(-f)(1+g) \in \mathcal{U}_0(\mathbb{C}1 + CB)$ *(respectively* $1+h \in \mathcal{U}_0(\mathbb{R}1+CB)$ *in case of a real* C^**-algebra* B*).*

`The later used point is to manage that the`
`product of exponentials and`
`the unitary in` $\mathcal{U}(\mathrm{C}_0((-1,0], B+\mathbb{C}1))$
`becomes equal to 1 -- say at` $(-1,-1/2]$ `if defined on` $(-1,+\infty)$`.`

PROOF. The natural C^*-morphism from B into $\mathcal{M}(CB)$ is non-degenerate, i.e., the span of $B\cdot CB$ is dense in CB. Thus, there is a natural strictly continuous unital *-monomorphism from $\mathcal{M}(B)$ into $\mathcal{M}(CB)$. We identify the elements of $\mathcal{M}(B)$ with there images in $\mathcal{M}(CB)$, i.e., $\mathcal{M}(B) \subset \mathcal{M}(CB)$ in a natural manner. Let $f_0 \in \mathrm{C}_0(0,1]$ the function with $f_0(t) := t$ for $t \in [0,1]$ and let $e_0 \in B_+$ a strictly positive contraction in B. Then $f_0 \otimes e_0 \in CB$ is a strictly positive contraction in CB and the intersection E of CB with the separable C^*-subalgebra $A := C^*(D \cup \{b_1,\ldots,b_n, f_0\otimes e_0\})$ of $\mathcal{M}(CB)$ is a separable C^*-subalgebra of CB and contains the strictly positive element $f_0 \otimes e_0$ of CB.

Thus, the natural inclusion of E in CB defines a unital monomorphism $\phi\colon \mathcal{M}(E) \to \mathcal{M}(CB)$ with the property that $A \subseteq \phi(\mathcal{M}(E)) \subseteq \mathcal{M}(CB)$.

It follows that $C^*(f_0 \otimes e_0)_+ \subseteq CB$ contains a quasi-central approximate unit $0 \leq e_1 \leq e_2 \leq \ldots$ for the elements in $C^*(f_0\otimes e_0)_+$, cf. [**616**, thm. 3.12.14, cor. 3.12.15]. It is important that we can find the e_n with the additional property $e_k e_\ell = e_k$ for $1 < k < \ell$.

This allows to apply the "mirror method". (The new application to the mirrored problem can be done without harming the before done steps.) The result is a decomposition of U into unitaries $U = VW$ with $W \in 1 + J$ and $[V, A] \subseteq \mathrm{C}_0(\mathbb{R}, B)$.

In particular, for each finite subsets $X \subset A$, $Z \subset (A \cap CB)$ and each $\delta > 0$ there exists a positive contraction $e \in CB_+$ with $\|ex - xe\| \,<\, \delta$ and $\|z - ze\| + \|z - ez\| \,<\, \delta$

for $x \in X$ and $z \in Z$. (It suffices to take here $Z := \{f_0 \otimes e_0\}$ and then the $\delta > 0$ sufficiently small.)

?? See for this also Remark 5.1.1(1) and its proof in Section 1 and the Section 3 of Chapter 5 for more details.??

By Proposition 5.3.1, for all $a \geq 0$, every *contraction* x and each $\beta \in [1, \infty)$,

$$\|[x, a^{1/\beta}]\| \leq 3\|[x, a]\|^{1/\beta}.$$

Apply this to $\beta := 2$, $a := 1 - e^2$ and x with $\|x\| \leq 1$ and get

$$\|[x, (1-e^2)^{1/2}]\| \leq 3\|[x, e^2]\|^{1/2} \leq 5\|[x, e]\|^{1/2}.$$

(i): Let $e \in (CB)_+$ a positive contraction. Then $b - (1-e^2)^{1/2} b (1-e^2)^{1/2} \in CB$ for all $b \in \mathcal{M}(CB)$ because $\pi_{CB}(1) = \pi_{CB}((1-e^2)^{1/2})$ for the quotient map $\pi_{CB} \colon \mathcal{M}(CB) \to \mathcal{M}(CB)/CB$.

If we apply π_{CB} to $c := (1-e^2)^{1/2} b (1-e^2)^{1/2} \in \mathcal{M}(CB)$ for $b \in \mathcal{M}(CB)$ with the property $[b, d] \in CB$ for all $d \in D \subseteq \mathcal{M}(CB)$, we get that $\pi_{CB}(c) = \pi_{CB}(b)$ and $\pi_{CB}([c, d]) = \pi_{CB}([b, d])$. Thus $[c, d] \in CB$ for all $d \in D$ if $[b, d] \in CB$ for all $d \in D$.

(ii): $\|[c_k, d_\ell]\| \leq \|[b_k, d_\ell]\| + 2\|[(1-e^2)^{1/2}, d_\ell]\|$ ...

But we have only $[b_k, d_\ell] \in CB$, need that $\|[c_k, d_\ell]\|$ is small.

Since $b_k \in \mathcal{M}(CB)$, $d_\ell \in \mathcal{M}(B) \subseteq \mathcal{M}(CB)$ and $[b_k, d_\ell] \in CB$ for $k = 1, \ldots, n$ $\ell = 1, \ldots, m$ – by assumptions –, we find for given $\delta > 0$ a positive contraction $e \in C * (f_0 \otimes e_0)_+ \subseteq CB$ with $\|[e, b_k]\| < \delta$, $\|[e, d_\ell]\| < \delta$ and $\|(1-e)[b_k, d_\ell]\| + \|[b_k, d_\ell](1-e)\| < \delta$ $f := (1-e^2)^{1/2}$, $1 \leq k \leq n$ and $1 \leq \ell \leq m$.

This ????????????

Let $b := b_k$ and $d := d_\ell$. All are positive contractions.

$(fbfd - dfbf) = fb(fd - df) - (fd - df)bf + f(bd - db)f$ can be estimated by $2\|b\|\|fd - df\| + \|f(bd - db)f\|$. Since $bd - db \in CB$

Let $\gamma := \varepsilon/(6n + 7)$. Since

$$G := C^*(D, b_1, \ldots, b_n) \subseteq \phi(\mathcal{M}(E)) \subseteq \mathcal{M}(CB)$$

is separable we find a quasi-central approximate unit in the positive contractions of CB for the elements of G by [**616**, thm. 3.12.14, cor. 3.12.15], i.e., we find a positive contraction $e \in CB$ with $\|[e, x]\| < \gamma/2$ for $x \in \{d_1, \ldots, d_m, b_1, \ldots, b_n\}$.

and $\|(1-e)[?, ?]\| + \|[?, ?](1-e)\| <$????? (small) for ????

Find contraction $e \in CB_+$ with $\|[(1-e^2)^{1/2} b_k (1-e^2)^{1/2}, d_\ell]\| < \gamma$ ...

(iii,iv): Define g by

$$g := \left(V^{-1} \cdot \exp(b_1) \cdot \exp(b_2) \cdot \ldots \cdot \exp(b_n)\right) - 1$$

for $V := \exp(c_1) \cdot \exp(c_2) \cdot \ldots \cdot \exp(c_n)$.

Since $\pi_{CB}(c_k) = \pi_{CB}(b_k)$ it follows that $\pi_{CB}(V) = \pi_{CB}\big(\exp(b_1)\cdot\exp(b_2)\cdot\ldots\cdot\exp(b_n)\big)$ and therefore $\pi_{CB}\big(V^{-1}\cdot\exp(b_1)\cdot\ldots\cdot\exp(b_n)\big) = \pi_{CB}(1)$, i.e., $g \in CB$.

Clearly $1+g \in \mathcal{U}(\mathbb{C}\cdot 1 + CB)$, respectively $1+g \in \mathcal{U}(\mathbb{R}\cdot 1 + CB)\cap(1+CB)$ in real case. In complex case we have always $\mathcal{U}(\mathbb{C}\cdot 1+CB) = \mathcal{U}_0(\mathbb{C}\cdot 1+CB)$ and in case of real C^*-algebras B holds $\mathcal{U}(\mathbb{R}\cdot 1+CB)\cap(1+CB) \subseteq \mathcal{U}_0(\mathbb{R}\cdot 1+CB)$.

`To be filled in??`

It follows that $\|\,[V, d_\ell]\,\| < \varepsilon/2$ for $\ell = 1,\ldots,m$, $[V,d] \in CB$ and $[g,d], gd, dg \in CB$ for all $d \in D$.

There exist $\delta > 0$ and $-f^* = f \in CB$ such that $\|f\| \leq 1$, $\exp(-f)(1+g)|(0,\delta] = 1|(0,\delta]$ and $\|[f, d_\ell]\| < \varepsilon/(3(n+1))$ for $\ell = 1,\ldots,m$.

It implies that $h =: \exp(-f)(1+g)-1 \in CB$, $h(t) = 0$ for $t \in (0,\delta]$, $V\cdot(1+g) = (V\cdot\exp(f))\cdot(1+h)$ and

$$\|\,[V\cdot\exp(f), d_\ell]\,\| < \varepsilon \quad \text{for } \ell = 1,\ldots,m\,.$$

□

`The following Lemma remains to be checked:`

In the following let A and B denote stable (real or complex) C^*-algebras. We require that A is separable and that B is σ-unital. We fix a a non-degenerate C^*-morphism $H\colon A \to \mathcal{M}(B)$ in general position, i.e., $H(A)B = B$ and H is in $\mathcal{M}(B)$ approximately unitary equivalent to its infinite repeat $\delta_\infty \circ H$.

Lemma 8.5.3. *Let A, B stable C^*-algebras, A separable B σ-unital, $H\colon A \to \mathcal{M}(B)$ non-degenerate faithful and in "general position", i.e., H and $\delta_\infty\circ H$ unitary homotopic in $\mathcal{M}(B)$.*

Given $U \in \mathcal{U}(\mathcal{M}(B[0,2]))$ with $U(t) = 1$ for $t \in [0,1)$ and $b_1,\ldots,b_n \in \mathcal{M}(B[0,2])$, $b_k^* = -b_k$ with $[b_k, H(a)] \in \mathrm{C}_0((1,2],B)$ for $k = 1,\ldots,n$, for all $a \in A$, and such that

$$U(t) = \exp(b_1(t))\cdot\ldots\cdot\exp(b_n(t))W(t)$$

with $W|[0,1] \in 1 + \mathrm{C}([0,1],B)$.

We find modifications b_k' of b_k and $W'(t)$ of $W(t)$ (the latter inside $1+\mathrm{C}([0,1],B)$) such that such that $W'(t) = 1$ for $t \in [0,1/2]$, $W'(1) = W(1)$, $b_k'(1) = b_k(1)$ and

$$U(t) = \exp(b_1'(t))\cdot\ldots\cdot\exp(b_n'(t))\cdot W'(t)$$

on $[0,1]$, and $\lim_{t\to 0} b_k'(t) = 0$ strictly.

Perhaps use an approximately central unit of B? With $b_k'(t) := (1-e(t)^2)^{1/2}b_k(t)(1-e(t)^2)$. Converges strictly to 0.

$$\pi_B(\exp(b_1'(t))\cdot\ldots\cdot\exp(b_n'(t))) = \pi_B(\exp(b_1(t))\cdot\ldots\cdot\exp(b_n(t)))$$

PROPOSITION 8.5.4. *Let A and B stable C^*-algebras (real or complex), where A is separable and B is σ-unital, and let $H\colon A \to \mathcal{M}(B)$ a non-degenerate C^*-morphism "in general position" (i.e., H is approximately unitary equivalent to $\delta_\infty \circ H$).*

in strict or norm topology ???
Compare Chp. 5

Moreover, let $S, T \in H(A)' \cap \mathcal{M}(B)$ isometries with $SS^* + TT^* = 1$.

The then following holds:

If $\alpha < \beta < \gamma \in \mathbb{R}$ and $t \in [\alpha, \gamma] \to u(t) \in \mathcal{U}(\mathcal{M}(B))$ is a strictly continuous map into the unitaries of $\mathcal{M}(B)$ with $u(t) = 1$ for $t \in [\alpha, \beta]$ and $u(t)H(a) - H(a)u(t) \in B$ for each $a \in A$ and $t \in [\alpha, \gamma]$.

Assume moreover that the maps $t \mapsto u(t)H(a) - H(a)u(t) \in B$ is continuous on $[\alpha, \gamma]$ for each $a \in A$ (i.e., $U := \{u(t)\}$ derives $H(A)$ into into $\mathrm{C}([\alpha, \gamma], B)$.

Then for each finite subset $X \subset A$ and every $\varepsilon > 0$ there exist $n \in \mathbb{N}$ and a decomposition $u(t) \oplus_{S,T} 1 = v(t) \cdot w(t)$ into a product of strictly continuous maps $t \in [\alpha, \gamma] \to v(t) \in \mathcal{U}(\mathcal{M}(B))$ and $t \in [\alpha, \gamma] \to w(t) \in \mathcal{U}(\mathcal{M}(B))$ such that $w(t) = 1 = v(t)$ for $t \in [\alpha, (\alpha + \beta)/2]$, $w(t) \in B + \mathbb{C} \cdot 1$ for $t \in [\alpha, \gamma]$

one can only deduce that it $w(t)$ is strictly continuous!!!!

with $t \in [\alpha, \gamma] \to w(t)$ norm-continuous, even with $w(t) \in 1 + B[\alpha, \gamma]$??

and

$$v(t) := \exp(b_1(t)) \cdot \exp(b_2(t)) \cdot \ldots \cdot \exp(b_n(t))$$

for suitable strictly continuous maps $t \mapsto b_k(t) = -b_k(t)^* \in \mathcal{M}(B)$ from $((\alpha + \beta)/2, \gamma]$ with $b_k(t) \in \mathrm{Der}(H(A), B)$ and $\sum_k \|[H(a), b_k(t)]\| < \varepsilon$ for all $a \in X$ and $t \in ((\alpha + \beta)/2, \gamma]$, and the maps

$$t \in ((\alpha + \beta)/2, \gamma] \mapsto [H(a), b_k(t)] \in B$$

are (norm-) continuous and satisfy

$$\lim_{t \to (\alpha+\beta)/2} \|[H(a), b_k(t)]\| = 0\,.$$

PROOF. The problem is:
Given $b_1(t), \ldots, b_n(t)$, with $b_k^* = -b_k \in \mathcal{M}(\mathrm{C}_0((-1/2, 0], B))$
strictly continuous with respect to t $\in$??? and bounded on $(-1/2, 0]$
with
$t \mapsto b_k(t)H(a) - H(a)b_k(t) \in \mathrm{C}_0((-1/2, 0], B)$
and $1 - \exp(b_1) \cdot \ldots \cdot \exp(b_n) \in \mathrm{C}_0((-1/2, 0], B)$.
Can we connect it in a controlled way inside
$[-1, 0]$ and $\mathcal{U}(B + \mathbb{C} \cdot 1)$ with 1 ?? □

Notice that we do not require that $\lim_{t \to (\alpha+\beta)/2} b_k(t) = 0$. Even not strictly.

But ?????

It can happen that distance of $w(\gamma)$ from $\mathbb{C} \cdot 1_{\mathcal{M}(B)}$ is equal to 2.

Remark 8.5.5. It seems that one can show that the number $n \in \mathbb{N}$ in Proposition 8.5.4 has an universal upper bound (clearly *not* depending on ε).

But it could be that ????????

Perhaps one get it by an indirect argument ?

For example one could consider for B the cone over $c_0(B_1, B_2, \ldots)$ from a sequence with $A = \mathbb{K} \otimes (\mathrm{C}(0,1] * \mathrm{C}(0,1])$ of $h_n \colon A \to \mathcal{M}(B_n)$, $\alpha := -1$, $\beta := 0$, $\gamma := 1$, $u_n \colon [-1,1] \to \mathcal{U}(\mathcal{M}(B))$ –

We are now in position to give the Proof of Proposition 8.5.1.

Proof of Proposition 8.5.1. `We can use a ''mirror principle'' and apply induction ...` □

CHAPTER 9

Scale-invariant maps (i+ii of Thm's B,M)

NEEDED???/CHECK???/PROBLEM:
In case A, B, stable and separable, that ???

$$\mathrm{Ext}(\mathcal{C};\, A, B) \cong \ker(\mathcal{U}(\pi_B(H_{\mathcal{C}}(A))' \cap \mathrm{Q}(B)) \to \mathcal{U}(\mathrm{Q}(B)))\,.$$

THIS should apply to $\mathrm{Ext}(\mathcal{C}(0,1]\,;\, A, \mathrm{C}_0((0,1], B)) = 0$ and gives then that each strictly continuous path of unitaries $t \in\to U(t) \in \mathcal{M}(B)$ with

$$\lim_{t\to 0} \|U(t)a - aU(t)\| = 0$$

and $U(t)a - aU(t) \in B$ for all $t \in (0,1]$

`This has NOT been proven somewhere:` is a finite product of exponentials $\exp(h(t))$ with $h(t)^* = -h(t)$ and $\lim_{t\to 0} \|h(t)a - ah(t)\| = 0$ and $h(t)a - ah(t) \in B$.

The number of this exponentials would then have moreover an universal upper bound.

The `injectivity` of

$$\vartheta\colon\ \mathrm{R}(\mathcal{C};\, A, B) \to \mathrm{KK}(\mathcal{C};\, A, B)$$

requires to use that $\mathcal{C} = \mathcal{C}(h_0)$ and we must show that the elements in the kernel of ϑ are homotopic in $\mathrm{R}(\mathcal{C};\, A, B)$ (via boundary maps from $\mathrm{R}(\mathcal{C}[0,1];\, A, B[0,1])$ at $\{0,1\}$ to $\mathrm{R}(\mathcal{C};\, A, B)$) to the class $[h_0]$.

Moreover, one has to show with the method of N.Ch. Phillips that "boundary-homotopic" elements of $\mathrm{SR}(\mathcal{C};\, A, B)$ define the same element of $\mathrm{Gr}(\mathrm{SR}(\mathcal{C};\, A, B))$.

??

In the meantime we rediscovered also our *direct* proof of the injectivity of the natural group homomorphism from $\mathrm{SR}(\mathcal{C};\, A, B)$ onto $\mathrm{Ext}(\mathcal{C};\, A, SB) \cong \mathrm{KK}(\mathcal{C};\, A, B)$ is injective. The proof of the injectivity uses a mirror-principle and triviality of $\mathrm{KK}(\mathcal{C};\, A, \mathcal{C}(\mathbb{R}_-, B))$, which follows from the homotopy invariance of KK via $\mathrm{KK}_c = \mathrm{KK}_{oh} = \mathrm{KK}_h$ (an observations of G. Kasparov).

We prove the parts (i) and (ii) of Theorem B and of Theorem M in this Chapter. We *assume the existence* of the non-degenerate nuclear C^*-morphism $h_0\colon A \to B$ as described in Chapter 1 before Theorem M. The existence of h_0 comes from Theorem A (in the case of Theorem B), and, — if B is separable, stable, strongly purely infinite and contains an Abelian regular C^*-subalgebra —, comes from Corollary 6.3.2.

The general existence of h_0 comes later from Theorem K (in the case of Theorem M). Theorem K will be proven in Chapter 12 with help of Corollary 6.3.2 and Corollary 9.1.7.

In Section 1 we derive also some useful applications of asymptotic maps that are asymptotically scale invariant up to approximate unitary equivalence.

The proof, as given in the second part of this Chapter, is (in conjunction with Theorem 4.4.6) a more detailed reformulation of the proof in the appendix of our preprint from December 1994 (3rd draft), more precisely: We show that the natural morphism from $\mathrm{R}(A, B)$ into $\mathrm{KK}_{\mathrm{nuc}}(A, B)$ (resp. from $\mathrm{R}(X, A, B)$ into $\mathrm{KK}_{\mathrm{nuc}}(X; A, B)$ for $X := \mathrm{Prim}(B)$) is an isomorphism, cf. Corollary 9.4.2. Here we start with the *-monomorphism h_0 described below Theorem A (resp. before Theorem M) which defines the zero element of the R- and $\mathrm{KK}_{\mathrm{nuc}}$-groups and reduce the proofs of the parts (i) and (ii) of Theorems B and M to Theorem 4.4.6. This reduction requires results of Chapters 5 and 7, and Lemma 8.3.2.

Note that the material of Chapter 8 are modifications of well-known results of Kasparov, Skandalis and others, and can also be deduced from textbooks as e.g. [**73**], [**389**], at least in the situation of nuclear C^*-algebras, and only so far as it is needed for Corollary C, if the reader is only interested in the classification result Corollary C.

Then we use the isomorphism $\mathrm{R}(A, B) \cong \mathrm{KK}_{\mathrm{nuc}}(A, B)$ (resp. $\mathrm{R}(X;\, A, B) \cong \mathrm{KK}_{\mathrm{nuc}}(X;\, A, B)$, $\mathrm{R}(\mathcal{C};\, A, B) \cong \mathrm{KK}_{\mathrm{nuc}}(X;\, A, B)$) to conclude with help of Corollary 8.3.4,(ii) (respectively with help of the generalization of Corollary 8.3.4 for $\mathrm{Ext}_{\mathrm{nuc}}(X;\, .,.)$ and $\mathrm{Ext}(\mathcal{C};\, .,.)$) that the elements of $\mathrm{R}(A, B)$ (respectively of $\mathrm{R}(X;\, A, B)$) are invariant under scaling in the sense of the below given Definition 9.1.1. We conclude that every element of $\mathrm{R}(A, B)$ (respectively of $\mathrm{R}(X;\, A, B)$, $\mathrm{R}(\mathcal{C};\, A, B)$) is given by a nuclear (respectively by a morphism $\varphi\colon A \hookrightarrow B$ with $\varphi \in \mathcal{C}$, e.g. for $\mathcal{C} = \mathrm{CP}_{\mathrm{rn}}(X;\, A, B)$). But this proves parts (i) and (ii) of Theorems B and M.

More generally, we show that
*if A is separable, B is σ-unital, A and B are stable, $h_0 = k(\cdot \otimes 1)$ for some non-degenerate *-monomorphism $k\colon A \otimes \mathcal{O}_2 \hookrightarrow B$, and if $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ denotes the point-norm closed matrix operator-convex cone generated by h_0, then the natural morphism*

$$\mathrm{R}(\mathcal{C};\, A, B) \to \mathrm{Ext}(\mathcal{C} \otimes \mathrm{CP}(\mathbb{C}, \mathrm{C}_0(\mathbb{R}));\, A, B \otimes \mathrm{C}_0(\mathbb{R}))$$

is an isomorphism.
The homotopy invariance of $\mathrm{KK}(\mathcal{C};\, A, B)$ and the natural isomorphism

$$\mathrm{Ext}(\mathcal{C} \otimes \mathrm{CP}(\mathbb{C}, \mathrm{C}_0(\mathbb{R}));\, A, B \otimes \mathrm{C}_0(\mathbb{R})) \cong \mathrm{KK}(\mathcal{C};\, A, B)$$

(shown in Chapter 8) then imply that every element of $\mathrm{KK}(\mathcal{C};\, A, B)$ can be represented by a morphism h from A into B that is asymptotically dominated by h_0 (i.e., by $h \in \mathrm{Hom}(A, B)$ with $[h] \in \mathrm{SR}(\mathcal{C};\, A, B)$). Then the definition of $\mathrm{R}(\mathcal{C};\, A, B) = [h_0] + \mathrm{SR}(\mathcal{C};\, A, B) \cong \mathrm{Gr}(\mathrm{SR}(\mathcal{C};\, A, B))$ and the relations in $\mathrm{SR}(\mathcal{C};\, A, B)$ yield that

$[h] = [k]$ in KK($\mathcal{C}$; A, B) if and only if $h \oplus h_0$ and $k \oplus h_0$ are unitarily equivalent. (The latter can be deduced from the identity and isomorphism

$$G(h_0;\, A, \mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B))) = \mathrm{R}(\mathcal{C};\, A, B) \cong KK(\mathcal{C};\, A, B)$$

and the considerations of Chapter 4 on this type of groups.)

1. Scale-invariant elements of SR(X; A, B)

We introduce a notion of generalized invariance under scaling for asymptotic maps:

Consider a topological isomorphism σ from $\mathbb{R}_+$ onto $\mathbb{R}_+$. That is, σ is a bijective continuous function of $\mathbb{R}_+$ onto $\mathbb{R}_+$. Note that $\sigma(0) = 0$ and that σ has to be strictly increasing.

Now let F be a C^*-algebra. The homeomorphism σ induces an automorphism $\widehat{\sigma}$ of $\mathrm{Q}(\mathbb{R}_+, F)$ in a natural way by mapping $\pi(f)$ to $\pi(f \circ \sigma)$, for $f \in \mathrm{C_b}(\mathbb{R}_+, F)$, where $\pi\colon \mathrm{C_b}(\mathbb{R}_+, F) \to \mathrm{Q}(\mathbb{R}_+, F)$ denotes the quotient map. Recall from Chapter 7 that $\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(F))$ is a unital C^*-subalgebra of the multiplier algebra $\mathcal{M}(\mathrm{Q}(\mathbb{R}_+, F))$ of $\mathrm{Q}(\mathbb{R}_+, F)$.

Definition 9.1.1. Let X be a set and $h\colon X \to \mathrm{Q}(\mathbb{R}_+, F)$ a map. The map h will be called **invariant under scaling (up to unitary equivalence)** , if, for every topological isomorphism σ from $\mathbb{R}_+$ onto $\mathbb{R}_+$, $\widehat{\sigma} \circ h$ is unitarily equivalent to h by a unitary in $\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(F)) \subseteq \mathcal{M}(\mathrm{Q}(\mathbb{R}_+, F))$.

We say that h is **approximately scale-invariant** , if, for every topological isomorphism σ from $\mathbb{R}_+$ onto $\mathbb{R}_+$, $\widehat{\sigma} \circ h$ is approximately unitarily equivalent to h by unitaries in $\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(F))$.

An class $[h] \in [\mathrm{Hom}(A, \mathrm{Q}(\mathbb{R}_+, F))]$ will be called **invariant under scaling** if $[h] = [\widehat{\sigma} \circ h]$ for every topological isomorphism σ from $\mathbb{R}_+$ onto $\mathbb{R}_+$ ([1]).

Recall form Chapters 5 and 7 that, for a C^*-algebra F,

$$\mathrm{Q}(\mathbb{R}_+, F) := \mathrm{C_b}(\mathbb{R}_+, F)/\, \mathrm{C_0}(\mathbb{R}_+, F)\,,$$

that $\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(F))$ is in a natural way a C^*-subalgebra of the multiplier algebra $\mathcal{M}(\mathrm{Q}(\mathbb{R}_+.F))$ of $\mathrm{Q}(\mathbb{R}_+, F)$, and that, for every separable subset Y of $\mathrm{Q}(\mathbb{R}_+, F)$ and unitary v in the multiplier algebra of $\mathrm{Q}(\mathbb{R}_+, F)$ there is a unitary $u \in \mathrm{Q}(\mathbb{R}_+, \mathcal{M}(F))$ with $u^*bu = v^*bv$ for every $b \in Y$, *so far as F is stable or is unital*, cf. Proposition 7.4.1. Thus, *one can replace* $\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(F))$ *by* $\mathcal{M}(\mathrm{Q}(\mathbb{R}_+, F))$ *in Definition 9.1.1 if F is unital or F is stable.*

It is obvious from Definition 9.1.1 that, for every set X and every map $k\colon X \to F$ into the "constant" elements of $\mathrm{Q}(\mathbb{R}_+, F)$ and for every unitary $u \in \mathrm{Q}(\mathbb{R}_+, \mathcal{M}(F))$, the map $h(x) := u^*k(x)u$ is, up to unitary equivalence, invariant under scaling. The following Proposition 9.1.2 and Corollary 9.1.3 show that

[1] That means, by our definition of the classes $[\,\cdot\,]$ in Chapters 4 and 7, that $\widehat{\sigma} \circ h$ is unitarily equivalent to h in $\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(F))$, i.e., h is invariant under scaling up to unitary equivalence.

for separable $h(X)$ this is the only example of a map which is scaling invariant up unitary equivalence.

PROPOSITION 9.1.2. *Suppose that X is a compact metric space, F is a σ-unital C^*-algebra, and that $h\colon X \to \mathrm{Q}(\mathbb{R}_+, F)$ is a continuous map.*

If h is approximately scale-invariant, then there exists a continuous map h_1 from X into F, such that h_1 is unitarily equivalent to h by a unitary U in the C^*-subalgebra $\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(F))$, of the multiplier algebra of $\mathrm{Q}(\mathbb{R}_+, F)$.

The following proof shows that we can find the map $h_1\colon X \to F$ and the unitary U such that $U = W + \mathrm{C}_0(\mathbb{R}_+, \mathcal{M}(F))$ with a unitary $W \in \mathrm{C_b}(\mathbb{R}_+, \mathcal{M}(F))$ such that $W(1) = 1_{\mathcal{M}(F)}$. It implies for the above example $h := u^* k(\cdot) u$, that there exists a unitary $W_0 \in \mathcal{M}(F) \subset \mathrm{C_b}(\mathbb{R}_+, \mathcal{M}(F))$ such that $h_1 := W_0^* k(\cdot) W_0$ and $U = W_0^* u$ are as desired.

PROOF. Since $h \in \mathrm{C}(X, \mathrm{Q}(\mathbb{R}_+, F))$ and since $\mathrm{Q}(\mathbb{R}_+, F)$ is a quotient C^*-algebra of $\mathrm{C_b}(\mathbb{R}_+, F)$, there exists $T \in \mathrm{C}(X, \mathrm{C_b}(\mathbb{R}_+, F))$ such that $h(b) = T(b) + \mathrm{C}_0(\mathbb{R}_+, F)$ for every $b \in X$, i.e., $T\colon X \to \mathrm{C_b}(\mathbb{R}_+, F)$ is a topological lift of h.

If σ is a topological isomorphism of $\mathbb{R}_+$, then the bounded continuous function $t \mapsto T(b)(\sigma(t)) \in F$ is a lift of $\widehat{\sigma}(h(b))$ to $\mathrm{C_b}(\mathbb{R}_+, F)$.

Let u be a unitary in $\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(F))$ such that, for all $b \in X$,

$$\|u^* h(b) u - \widehat{\sigma}(h(b))\| < \varepsilon/8\,.$$

There exists a unitary w in $\mathrm{C_b}(\mathbb{R}_+, \mathcal{M}(F))$ such that $u = w + \mathrm{C}_0(\mathbb{R}_+, \mathcal{M}(F))$. w is given by a norm continuous map $w\colon t \in \mathbb{R}_+ \to w(t) \in \mathcal{U}(\mathcal{M}(F))$ ([2]). It follows that

$$\gamma(b,t) := \|T(b)(\sigma(t)) - w(t)^* T(b)(t) w(t)\|$$

satisfies, for every $b \in X$,

$$\lim_{t\to\infty} \gamma(b,t) = \|u^* h(b) u - \widehat{\sigma}(h(b))\| < \varepsilon/8\,.$$

On the other hand, by the triangle inequality, for $t \in \mathbb{R}$ and $a, b \in X$,

$$|\gamma(a,t) - \gamma(b,t)| \,\leq\, 2\|T(a) - T(b)\|$$

(where the last norm comes from $\mathrm{C}(X, \mathrm{C_b}(\mathbb{R}_+, F))$), i.e., $\gamma(b,t)$ is uniformly continuous on the compact space X and, therefore,

$$\lim_{t\to\infty} (\sup_{b\in X} \gamma(b,t)) < \varepsilon/8\,.$$

Let $y \geq 0$. For $x > y$ and $\varepsilon > 0$, consider the set $M(x, \varepsilon)$ of the $s > x$ with the property that there exists a norm continuous map

$$v\colon t \in [x, s] \to v(t) \in \mathcal{M}(F)$$

[2]Note that the choice of w depends from u and thus from σ.

from $[x, s]$ into the unitary group $\mathcal{U}(\mathcal{M}(F))$ of the multiplier algebra of F with $v(x) = 1$ and

$$\|v(t)^* T(b)(t)v(t) - T(b)(x)\| < \varepsilon \tag{1.1}$$

for $b \in X$ and $t \in [x, s]$ ([3]). From the definition of $M(x, \varepsilon)$ we see that $M(x, \varepsilon/2) \subseteq M(x, \varepsilon)$ and $t \in M(x, \varepsilon)$ if $x < t < s$ and $s \in M(x, \varepsilon)$.

We define $m(x, \varepsilon) := \sup M(x, \varepsilon) \in [x, +\infty]$. The real number $2m(x, \varepsilon)$ is not in $M(x, \varepsilon)$ if $m(x, \varepsilon) < \infty$, because $x > 0$.

The properties of $M(x, \varepsilon)$ and

???? what else? **??**

lead to

$$m(x, \varepsilon/2) \leq m(x, \varepsilon)$$

for $\varepsilon > 0$. Moreover, $x < m(x, \varepsilon/2)$ for every $\varepsilon > 0$, because T is (uniformly) continuous.

Intuition says that for every $y \in \mathbb{R}_+$ and every $\varepsilon > 0$ there exists at least one $x > y$ with $m(x, \varepsilon) = \infty$. But we give a very detailed proof of this almost obvious fact:

Let $\varepsilon > 0$ and $y \in \mathbb{R}_+$ be fixed. We show below that the assumption that

$$m(x, \varepsilon) < \infty \quad \text{for every} \quad x > y \tag{1.2}$$

contradicts that h is of approximate scaling invariant.

If $m(x, \varepsilon) < \infty$ for every $x > y$, then we can find a sequence (x_n) in (y, ∞) such that, for every n,

$$n < x_n < m(x_n, \varepsilon/2) < 2m(x_n, \varepsilon) < x_{n+1} < \infty\,. \tag{1.3}$$

This allows us to define a topological isomorphism of $\mathbb{R}_+$ by taking a strictly increasing continuous piecewise linear map $\sigma\colon \mathbb{R}_+ \to \mathbb{R}_+$, satisfying

$$\sigma(x_n) = x_n \qquad \text{and} \qquad \sigma(2m(x_n, \varepsilon)) = x_n + (m(x_n, \varepsilon/2) - x_n)/2 \qquad \text{for every} \quad n\,.$$

As we have seen above, by the assumption of approximate invariance of h under scaling (applied to σ), there exists a norm continuous map $t \mapsto w(t) \in \mathcal{U}(\mathcal{M}(F))$ with

$$\lim_{t\to\infty} \sup_{b\in X} \|T(b)(\sigma(t)) - w(t)^* T(b)(t)w(t)\| \leq \varepsilon/8.$$

Thus there exists x_n in our sequence such that

$$\|w(t)^* T(b)(t)w(t) - T(b)(\sigma(t))\| < \varepsilon/4 \tag{1.4}$$

for $t \geq x_n$ and $b \in X$.

On the other hand, by the definition of $m(x, \varepsilon/2)$, we can find a norm continuous map $t \mapsto z(t) \in \mathcal{U}(\mathcal{M}(F))$ such that $z(x_n) = 1$ and

$$\|z(t)^* T(b)(t)z(t) - T(b)(x_n)\| < \varepsilon/2 \tag{1.5}$$

[3] Note here that v can depend on s and ε.

for $t \in [x_n, x_n + (m(x_n, \varepsilon/2) - x_n)/2]$ and $b \in X$.

Since σ maps $[x_n, 2m(x_n, \varepsilon)]$ onto $[x_n, x_n + (m(x_n, \varepsilon/2) - x_n)/2]$ and since $z(t)$ is unitary, we get from equations (1.4) and (1.5) that, for $t \in [x_n, 2m(x_n, \varepsilon)]$ and $b \in X$,

$$\|w(x_n)T(b)(x_n)w(x_n)^* - T(b)(x_n)\| < \varepsilon/4,$$
$$\|z(\sigma(t))^* w(t)^* T(b)(t) w(t) z(\sigma(t)) - z(\sigma(t))^* T(b)(\sigma(t)) z(\sigma(t))\| < \varepsilon/4,$$
$$\|z(\sigma(t))^* T(b)(\sigma(t)) z(\sigma(t)) - T(b)(x_n)\| < \varepsilon/2 .$$

Let $v(t) := w(t)z(\sigma(t))w(x_n)^*$ for $t \in [x_n, 2m(x_n, \varepsilon)]$. Then the equation $v(x_n) = 1$ and applications of the triangle inequality and of the (isometric) inner automorphisms $w(x_n)(\cdot)w(x_n)^*$ show (together) that

$$\|v(t)^* T(b)(t) v(t) - T(b)(x_n)\| < \varepsilon$$

for every $t \in [x_n, 2m(x_n, \varepsilon)]$ and $b \in X$. It gives $2m(x_n, \varepsilon) \in M(x_n, \varepsilon)$. This leads to the (desired) *contradiction* by inequalities (1.3) because $m(x_n, \varepsilon) < \infty$ (by assumption).

We have seen above that, *for every $y \in \mathbb{R}_+$ and $\varepsilon > 0$, there exist $x > y$ with $m(x, \varepsilon) = \infty$.* Hence, we find a sequence $0 < x_1 < x_2 < \ldots \in \mathbb{R}$ such that $x_{n+1} > \max(x_n, n)$ and $m(x_n, 2^{-n}) = \infty$.

By the definition of $M(x_n, 2^{-n})$ and of $m(x_n, 2^{-n})$ there are norm continuous maps v_n from $[x_n, x_{n+1}]$ into $\mathcal{U}(\mathcal{M}(F))$ such that $v_n(x_n) = 1$ and

$$\|v_n(t)^* T(b)(t) v_n(t) - T(b)(x_n)\| < 2^{-n}$$

for every $t \in [x_n, x_{n+1}]$ and every $b \in X$.

By induction we define a norm continuous map W from $\mathbb{R}_+$ into the unitaries of $\mathcal{M}(F)$ by $W(t) := 1$ for $t \in [0, x_1]$ and $W(t) := v_n(t)V(x_n)$ for $t \in [x_n, x_{n+1}]$.

Since $v_n(x_n) = 1$ and v_n is norm continuous, the map $W : t \mapsto W(t)$ is well-defined and is continuous in norm. Then we have

$$\|W(t)^* T(b)(t) W(t) - W(s)^* T(b)(s) W(s)\| < 2^{(1-n)}$$

for $t, s \in [x_n, x_{n+1}]$ and $b \in X$. Iterated use of the triangle equation gives

$$\|W(t)^* T(b)(t) W(t) - W(s)^* T(b)(s) W(s)\| < 2^{(2-n)} \quad \text{for all } s, t \geq x_n .$$

Thus,

$$h_1(b) := \lim_{t \to \infty} W(t)^* T(b)(t) W(t)$$

exists in F for $b \in X$. If we consider h_1 as a map from X to $F \subseteq \mathrm{Q}(\mathbb{R}_+, F)$ then h_1 is unitarily equivalent to h by the unitary $U = W + \mathrm{C}_0(\mathbb{R}_+, \mathcal{M}(F))$ in $\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(F))$. Hence h_1 is again continuous. □

COROLLARY 9.1.3. *Let D be a separable C^*-algebra, F a stable or a unital C^*-algebra and $h : D \to \mathrm{Q}(\mathbb{R}_+, F)$ a C^*-morphism.*

If h is approximately scale-invariant, then there exists a ("constant") C^*-morphism k from D into $F \subseteq \mathrm{Q}(\mathbb{R}_+, F)$ such that h is unitarily equivalent to k by a unitary in $\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(F))$.

In particular, for separable stable exact A and σ-unital stable B, an element $[h]$ of $\mathrm{SR}(X, A, B)$ is invariant under scaling if, and only if, $[k] = [h]$ for a "constant" C^*-morphism k from A into $B \subseteq \mathrm{Q}(\mathbb{R}_+, B)$.

PROOF. Let $d_1, d_2, \ldots$ be a dense sequence in the unit ball of D and let $X := \{0\} \cup \{2^{-n} d_n : n = 1, 2, \ldots\}$. Then D is the closed span of the compact set X, and the restriction of h to X satisfies the requirements of Proposition 9.1.2.

Thus, there is continuous map $h_1 : X \to F$ and a unitary u in $\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(F))$, which is considered as a C^*-subalgebra of the multiplier algebra of $\mathrm{Q}(\mathbb{R}_+, F)$, such that $u^* h(d) u = h_1(d)$ for $d \in X$.

The map $k : d \in D \mapsto u^* h(d) u$ is a C^*-morphism from D into $\mathrm{Q}(\mathbb{R}_+, F)$ which extends h_1 to a C^*-morphism k from D into $\mathrm{Q}(\mathbb{R}_+, F)$, and k is unitarily equivalent to h by a the unitary u in $\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(F))$.

$k(D) \subseteq F$, because the linear span of X is dense in D and $k|X = h_1$, i.e., k is "constant".

If $D := A$ and $F := B$, then, by Proposition 7.4.1 the various versions of unitary equivalence coincide and we may consider the unitary equivalence by unitaries in $\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(F))$. Then the scale-invariance of $[h]$ means that h is invariant under scaling up to unitary equivalence. Hence h is approximately scale-invariant. □

We get the following useful Corollaries 9.1.4 and 9.1.6, which we apply in Chapters 10 and 12.

COROLLARY 9.1.4. *Suppose that A and B are C^*-algebras, where A is stable and separable. Let $h_0 : A \to B$ be a non-degenerate *-monomorphism.*

*Then h_0 is unitarily homotopic to $h_0 \oplus h_0$, if and only if, there exists a *-monomorphism $k : A \otimes \mathcal{O}_2 \to B$, such that $k_0(a) := k(a \otimes 1)$ is unitarily homotopic to h_0.*

The monomorphism k can be chosen to be non-degenerate, and then $k_0(A)$ commutes with a copy of $\mathcal{O}_2$ which is unitally contained in $\mathcal{M}(B)$.

PROOF. B is stable and σ-unital, because A is stable and separable and h_0 is non-degenerate, i.e., $h_0(A)B$ is dense in B.

Suppose that $k : A \otimes \mathcal{O}_2 \to B$ is such that $k_0(a) := k(a \otimes 1)$ is unitarily homotopic to h_0. Then $k(A \otimes \mathcal{O}_2)$ is a stable C^*-subalgebra that generates B as a closed ideal, because h_0 is non-degenerate. By Corollary 5.5.6(iv), k is unitarily homotopic to a non-degenerate *-monomorphism from $A \otimes \mathcal{O}_2$ into B, because B is stable and σ-unital. Therefore, we can assume that k is non-degenerate.

The extension $\mathcal{M}(k)$ of k to a unital *-monomorphism from $\mathcal{M}(A \otimes \mathcal{O}_2)$ to $\mathcal{M}(B)$ maps $1 \otimes \mathcal{O}_2$ unitally into the commutant of $k_0(A)$. Thus, k_0 is unitarily equivalent to $k_0 \oplus k_0$. It follows that h_0 is unitarily homotopic to $h_0 \oplus h_0$.

Now suppose, that h_0 is unitarily homotopic to $h_0 \oplus h_0$.

By Proposition 7.4.2, there exists, up to unitary equivalence by unitaries in $\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B))$, a unique *-monomorphism $k_1 \colon A \otimes \mathcal{O}_2 \to \mathrm{Q}(\mathbb{R}_+, B)$ with $k_1(a \otimes 1) = h_0(a)$ such that $k_1 \oplus k_1$ is unitarily equivalent to k_1 in $\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B))$.

If we compose k_1 with $\widehat{\sigma}$ for a scaling σ of $\mathbb{R}_+$, then $\widehat{\sigma} k_1$ has the same properties as k_1 with respect to h_0. Thus, $\widehat{\sigma} k_1$ is unitarily equivalent to k_1 by Proposition 7.4.2.

By Corollary 9.1.3, k_1 is unitarily equivalent to a *-monomorphism k from $A \otimes \mathcal{O}_2$ into B by a unitary in $\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B))$. But then $k_0 = k((\cdot) \otimes 1)$ is unitarily equivalent to h_0 in $\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B))$, and this means that h_0 and k_0 are unitarily homotopic. □

REMARK 9.1.5. In view of the following assumptions on asymptotic embeddings of a separable C^*-algebra A it seems to be useful to remember the following basic observations at the beginning of Chapter 3:

Let A a C^*-algebra. Then the following are equivalent:

(i) A is an exact C^*-algebra.
(ii) There exists a faithful nuclear *-representation $\rho \colon A \to \mathcal{L}(\mathcal{H})$ over some Hilbert space $\mathcal{H}$.
(iii) Each C^*-morphism $h \colon A \to B$ into a weakly injective C^*-algebra B is nuclear.
(iv) There exists a nuclear faithful C^*-morphism $h \colon A \to C$ into some C^*-algebra C.
(v) There exists a nuclear completely isometric embedding of A into some C^*-algebra D.

PROOF. The equivalence of (i) and (ii) is discussed in Remarks **??** ????? Section 1 of Chapter 3. The equivalence of (ii)-(v) follow essentially from the Arveson extension theorem [**42**], i.e., that each of the conditions (iii)-(v) implies that the faithful *-representations of A on a Hilbert space $\mathcal{H}$ are nuclear, cf. Chapter 3 for more details. □

COROLLARY 9.1.6. *Suppose that A and B are stable C^*-algebras, where A is separable and exact, and that k is a nuclear *-monomorphism from $A \otimes \mathcal{O}_2$ into* $\mathrm{Q}(\mathbb{R}_+, B)$.

Let $k_0(a) := k(a \otimes 1)$ for $a \in A$.

If $k_0(A) \cap J_1 = k_0(A) \cap J_2$ for all pairs of closed ideals J_1 and J_2 of $\mathrm{Q}(\mathbb{R}_+, B)$ *with $J_1 \cap B = J_2 \cap B$, then there exists a nuclear *-monomorphism h from $A \otimes \mathcal{O}_2$ into B, such that the *-monomorphisms $h_0 := h((\cdot) \otimes 1)$ and k_0 from A into* $\mathrm{Q}(\mathbb{R}_+, B)$ *are unitarily equivalent by a unitary in* $\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B))$.

If, moreover, B is σ-unital, and B is contained in the closed ideal of $\mathrm{Q}(\mathbb{R}_+, B)$ *that is generated by the image of k, then h can be found such that, moreover, h_0 is non-degenerate and unitarily equivalent to $h_0 \oplus h_0$ by a unitary in $\mathcal{M}(B)$.*

PROOF. If σ is a homeomorphism of $\mathbb{R}_+$, $a \in A$, $I \in \mathcal{I}(\mathrm{Q}(\mathbb{R}_+, B))$, then $\widehat{\sigma} k_0(a) \in I$, if and only if, $k_0(a) \in \widehat{\sigma}^{-1}(I)$, if and only if, $k_0(a) \in I$, because $B \cap I = B \cap \widehat{\sigma}^{-1}(I)$.

Thus, k_0 and $k_1 := \widehat{\sigma} \circ k_0$ are nuclear *-monomorphisms, such that k_0 and k_1 extend to C^*-morphisms k and $\widehat{\sigma} k$ from $A \otimes \mathcal{O}_2$ into $\mathrm{Q}(\mathbb{R}_+, B)$, and, for every $I \in \mathcal{I}(\mathrm{Q}(\mathbb{R}_+, B))$,

$$k_0^{-1}(k_0(A) \cap I) = k_1^{-1}(k_1(A) \cap I)\,.$$

By Corollary 7.4.3, this implies that k_0 and k_1 are approximately unitarily equivalent.

Therefore k_0 is approximately scale-invariant. By Corollary 9.1.3, k_0 is unitarily equivalent to a C^*-morphism h_1 from A into B by a unitary in $\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B))$. By Corollary 7.4.3, k_0 and $k_0 \oplus k_0$ are unitarily equivalent in $\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B))$. Thus h_1 is unitarily homotopic to $h_1 \oplus h_1$. Now we can proceed as in the proof of Corollary 9.1.4, and get a *-monomorphism $h\colon A \otimes \mathcal{O}_2 \to B$, such that $h_0 := h((\cdot) \otimes 1)$ is unitarily homotopic to h_1. Thus, h_0 and k_0 are unitarily equivalent in $\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B))$.

It follows that h_0 is a nuclear map, if we consider it as a map from A into $\mathrm{Q}(\mathbb{R}_+, B)$. But B is relatively weakly injective in $\mathrm{Q}(\mathbb{R}_+, B)$, i.e., there is a normal conditional expectation from the second conjugate of $\mathrm{Q}(\mathbb{R}_+, B)$ onto the second conjugate of B ([4]). Thus h_0 is also a nuclear map from A into B.

We use the nuclearity criteria (i) in Remark 3.1.2, to show that h is nuclear if h_0 is nuclear: Let C be a C^*-algebra. Consider the natural C^*-morphism

$$g := \mathrm{id}_C \otimes^{max} h\colon C \otimes^{max} (A \otimes \mathcal{O}_2) \to C \otimes^{max} B\,.$$

The restriction of g to $C \otimes^{max} (A \otimes 1)$ annihilates the kernel of the natural epimorphism from $C \otimes^{max} (A \otimes 1)$ onto $C \otimes (A \otimes 1)$, because h_0 is nuclear. Since, by nuclearity of $\mathcal{O}_2$, on the algebraic tensor product $(C \otimes A) \odot \mathcal{O}_2$ there is a unique C^*-norm, we get that g annihilates the kernel of the natural epimorphism from $C \otimes^{max} (A \otimes \mathcal{O}_2)$ onto $C \otimes (A \otimes \mathcal{O}_2)$. Thus h is nuclear.

Now we suppose, in addition, that the closed ideal I_0 of $\mathrm{Q}(\mathbb{R}_+, B)$, which is generated by $k_0(A)$, contains B, and that B is σ-unital.

Let J denote the closed ideal of B, which is generated by $h_0(A)$. The ideal $\mathrm{Q}(\mathbb{R}_+, J)$ of $\mathrm{Q}(\mathbb{R}_+, B)$ contains $k_0(A)$ and I_0, because $h_0(A)$ and $k_0(A)$ generate the same ideal of $\mathrm{Q}(\mathbb{R}_+, B)$. Since $B \cap \mathrm{Q}(\mathbb{R}_+, J) = J$ and $B \cap I_0 = B$, we get $B = J$. Thus, $h(A \otimes O_2)$ is a stable C^*-subalgebra of B and the closed ideal generated by $h(A \otimes O_2)$ is the σ-unital stable C^*-algebra B. By Corollary 5.5.6(iv), h is unitarily homotopic to a non-degenerate *-monomorphism h' from A to B. The

[4]Use normalizations of suitable c.p. maps $\mathrm{Q}(\mathbb{R}_+, B) \to \ell_\infty(B^{**})/c_0(B^{**}) \to B^{**}$.

non-degenerate *-monomorphism h_0' is again unitary equivalent to k_0 by a unitary in $\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B))$. The image of h_0' commutes element-wise with the unital copy $\mathcal{M}(h')(1_{\mathcal{M}(A)} \otimes \mathcal{O}_2)$ of $\mathcal{O}_2$, if $\mathcal{M}(h')$ is the unital extension of h' to the multiplier algebras. □

We can *rephrase* Corollary 9.1.6 in the language of actions of $\mathrm{Prim}(B)$ on A as follows:

Corollary 9.1.7. *Suppose that A and B are stable separable C^*-algebras, and that $\Psi\colon \mathcal{I}(B) \to \mathcal{I}(A)$ is a lower semi-continuous action of $\mathrm{Prim}(B)$ on A, such that $\Psi(0) = 0$ and $\Psi^{-1}(A) = \{B\}$.*

*If $k\colon A \otimes \mathcal{O}_2 \to \mathrm{Q}(\mathbb{R}_+, B)$ is a nuclear *-monomorphism, such that, for every closed ideal I of $\mathrm{Q}(\mathbb{R}_+, B)$ and for $k_0 := k((\cdot) \otimes 1)$,*

$$k_0(\Psi(I \cap B)) = k_0(A) \cap I,$$

then there exists a non-degenerate nuclear C^*-morphism $h\colon A \otimes \mathcal{O}_2 \to B$, such that $h_0(\Psi(J)) = h_0(A) \cap J$ for every closed ideal J of B, where $h_0(a) := h(a \otimes 1)$.

*The morphism h_0 is unitarily equivalent to $h_0 \oplus h_0$. Every nuclear *-monomorphism $h_1\colon A \to B$ which satisfies $h_1(\Psi(J)) = h_1(A) \cap J$ for $J \in \mathcal{I}(B)$, and is unitarily homotopic to $h_1 \oplus h_1$, is unitarily homotopic to h_0.*

Proof. Since the *-monomorphism $k\colon A \otimes \mathcal{O}_2 \to \mathrm{Q}(\mathbb{R}_+, B)$ is nuclear, the algebra A is exact.

By assumption, the intersection of the image of k_0 with a closed ideal of $\mathrm{Q}(\mathbb{R}_+, B)$ depends only from the intersection of the ideal with B.

The closed ideal I_0 of $\mathrm{Q}(\mathbb{R}_+, B)$ which is generated by the image of $k_0 := k((\cdot)\otimes 1)$ satisfies $k_0(\Psi(B \cap I)) = k_0(A)$. Since $\Psi^{-1}(A) = \{B\}$, we have $B \cap I = B$. Thus Corollary 9.1.6 applies to k. It gives the existence of the desired non-degenerated nuclear h with h_0 unitarily equivalent to $h_0 \oplus h_0$ by a unitary in $\mathcal{M}(B)$.

Since h_0 is unitarily homotopic to k_0, for $a \in A$ and closed ideals I of $\mathrm{Q}(\mathbb{R}_+, B)$, $h_0(a) \in I$ if and only if $k_0(a) \in I$. This applies to the ideals $I := \mathrm{Q}(\mathbb{R}_+, J)$, where $J \in \mathcal{I}(B)$. We have $J = I \cap B$. Thus, $h_0(\Psi(J)) = h_0(A) \cap J$ for $J \in \mathcal{I}(B)$.

If $h_1\colon A \to B$ is a nuclear *-monomorphism, such that h_1 is unitarily homotopic to $h_1 \oplus h_1$, and such that, for $J \in \mathcal{I}(B)$,

$$h_1^{-1}(h_1(A) \cap J) = h_0^{-1}(h_0(A) \cap J),$$

then h_0 and h_1 are unitarily homotopic by Corollary 7.4.3. □

2. Mapping-cone construction defines isomorphism

Let D a stable separable C^*-algebra. We start with any non-degenerate *-monomorphism $k\colon D\otimes\mathcal{O}_2 \to B$, i.e., we suppose that D, k and $\mathcal{C}$ with the following properties (a)–(c) are given:

(a) D is a separable and stable C^*-algebra,
(b) $k\colon D\otimes\mathcal{O}_2\to B$ is a non-degenerate *-monomorphism, and
(c) $\mathcal{C}\subseteq \mathrm{CP}(D,B)$ is the point-norm closed matrix operator-convex cone that is generated by the *-monomorphism $k_0 := k((\cdot)\otimes 1)\in \mathrm{Hom}(A,B)$.

The p.i. algebra $k(A\otimes\mathcal{O}_2)$ is a non-degenerate C^*-subalgebra of B by (b), i.e., $k(A\otimes\mathcal{O}_2)B$ is dense in B and k extends uniquely to a strictly continuous unital monomorphism $\mathcal{M}(k)$ from $\mathcal{M}(A\otimes\mathcal{O}_2)$ into $\mathcal{M}(B)$. It follows that

(d) B is σ-unital and stable, cf. Remark 5.1.1(9),
(e) the morphism $k_0 := k((\cdot)\otimes 1)$ is is unitarily equivalent to $k_0\oplus k_0$ by a unitary in $\mathcal{M}(B)$ by Proposition 4.3.5(iii), because $k_0(A)$ commutes with the unital copy $\mathcal{M}(k)(1_{\mathcal{M}(A)}\otimes\mathcal{O}_2)$ of $\mathcal{O}_2$ in $\mathcal{M}(B)$), and
(f) $k_0\colon D\to B$ is non-degenerate.

We know from Corollary 7.4.19, that

$$\mathrm{SR}(\mathcal{C};\, D,B) = S(k_0;\, D, \mathrm{Q}(\mathbb{R}_+,\mathcal{M}(B)))\,,$$

and that a non-degenerate *-morphism $k_1\in\mathrm{Hom}(A,B)\cap\mathcal{C}$ is necessarily unitarily homotopic to k_0 if k_1 generates $\mathcal{C}$ and if k_1 is unitarily homotopic to $k_1\oplus k_1$. In so far k_0 and $\mathcal{C}$ determine each other uniquely.
We recall some definitions and results of Chapters 5, 7 and 8:

Remark 9.2.1. For locally compact Y, e.g. if Y equals one of $\mathbb{R}$, $\mathbb{R}_+=[0,\infty)$ or $\mathbb{R}_- := (-\infty,0]$, we have defined in Chapter 7 the asymptotic coronas $\mathrm{Q}(Y,B)$:

$$\mathrm{Q}(Y,B) := \mathrm{C_b}(Y,B)/\,\mathrm{C_0}(Y,B).$$

Recall that there is a natural isomorphism

$$\mathrm{Q}(\mathbb{R},B)\cong \mathrm{Q}(\mathbb{R}_-,B)\oplus\mathrm{Q}(\mathbb{R}_+,B),$$

and that $\mathrm{Q}(\mathbb{R},B)$ is an ideal in $E_{\mathbb{R}}=\mathrm{Q}^s(SB)$, where we write

$$SB := \mathrm{C_0}(\mathbb{R},B)\qquad\text{and}\qquad E_{\mathbb{R}} := \mathcal{M}(SB)/SB\cong \mathrm{Q}^s(SB).$$

We denote the canonical epimorphism from $\mathcal{M}(SB)$ onto $E_{\mathbb{R}}$ by π_{SB}.

Thus $\mathrm{Q}(\mathbb{R}_+,B)$ contains B naturally and $\mathrm{Q}(\mathbb{R}_+,B)$ is naturally isomorphic to an ideal of $E_{\mathbb{R}}$. We let J denote the closed ideal of $E_{\mathbb{R}}$ that is naturally isomorphic to $\mathrm{Q}(\mathbb{R}_+,B)$ and let $I_1\colon\, \mathrm{Q}(\mathbb{R}_+,B)\to J$ denote the natural isomorphism from $\mathrm{Q}(\mathbb{R}_+,B)$ onto $J\subseteq E_{\mathbb{R}}$. We define a monomorphism $h_0\colon D\to J$, by

$$h_0 := I_1\circ k_0\,. \tag{2.1}$$

To make I_1 and all related calculations of later identities explicit, we can take the continuous function $\lambda(t):=\min(1,\max(0,t))$ (for $t\in\mathbb{R}$) and build an element $\widetilde{f}(t):=\lambda(t)f(t)$ in $\widetilde{f}\in\mathrm{C_b}(\mathbb{R},B)$ by $\widetilde{f}(t):=\lambda(t)\cdot f(t)$ ($t\in[0,\infty)$) and $\widetilde{f}(t):=0$ for $t<0$, where $f\in\mathrm{C_b}(\mathbb{R}_+,B)$ is a given representative of an element $f+\mathrm{C_0}(\mathbb{R}_+,B)$ in $\mathrm{Q}(\mathbb{R}_+,B)$. Then

$$I_1\bigl(f+\mathrm{C_0}(\mathbb{R}_+,B)\bigr)=\widetilde{f}+\mathrm{C_0}(\mathbb{R},B)\,.$$

All notions of unitary equivalence in $\mathrm{Hom}(D, \mathrm{Q}(\mathbb{R}_+, B))$ coincide with the equivalence induced by unitaries of $E_{\mathbb{R}} := \mathcal{M}(SB)/SB \cong \mathrm{Q}^s(SB)$, or by unitaries coming from $\mathrm{C_b}(\mathbb{R}, \mathcal{M}(B))$, because B is stable, cf. Proposition 7.4.1. Therefore, the inclusion map $I_1\colon \mathrm{Q}(\mathbb{R}_+, B) \hookrightarrow E_{\mathbb{R}} = \mathrm{Q}^s(SB)$ defines a natural semigroup monomorphism ψ from the semigroup $[\mathrm{Hom}(D, \mathrm{Q}(\mathbb{R}_+, B))]$ of classes of unitarily equivalent morphisms in $\mathrm{Hom}(D, \mathrm{Q}(\mathbb{R}_+, B))$ (by unitaries in $\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B)) \subseteq \mathcal{M}(\mathrm{Q}(\mathbb{R}_+, B))$) to $[\mathrm{Hom}(D, E_{\mathbb{R}})]$ those of $\mathrm{Hom}(D, E_{\mathbb{R}})$. Note that *the additive map ψ generalizes the usual mapping cone construction* in a natural way.

The natural inclusions and isomorphism

$$\mathcal{M}(B) \subseteq \mathrm{C_b}(\mathbb{R}, \mathcal{M}(B)) \subseteq \mathrm{C_{b,st}}(\mathbb{R}, \mathcal{M}(B)) \cong \mathcal{M}(\mathrm{C_0}(\mathbb{R}, B))$$

of Lemma 7.4.5 induce natural inclusions

$$\mathcal{M}(B) \subseteq \mathrm{C_b}(\mathbb{R}, \mathcal{M}(B))/\,\mathrm{C_0}(\mathbb{R}, B) \subseteq E_{\mathbb{R}}\,.$$

We denote by I_2 is the unital inclusion map of $\mathcal{M}(B)$ into $E_{\mathbb{R}}$.

We define a *-monomorphism

$$H_0' := \delta_\infty k_0\colon D \to \mathcal{M}(B)\,.$$

Let $H_0 := H_{\mathbb{R}} := I_2 \circ H_0'\colon D \to E_{\mathbb{R}}$. Then H_0 for H_0' is related to $\mathcal{C} := \mathcal{C}(k_0)$ in the sense of Corollary 5.4.4.

Let $\widetilde{\beta}$ be the *-automorphism of $\mathcal{M}(\mathrm{C_0}(\mathbb{R}, B))$ which is defined by $\widetilde{\beta}(f)(t) = f(-t)$ for $f \in \mathrm{C_{b,st}}(\mathbb{R}, \mathcal{M}(B)) \cong \mathcal{M}(\mathrm{C_0}(\mathbb{R}, B))$. $\widetilde{\beta}$ maps $\mathrm{C_0}(\mathbb{R}, B)$ onto $\mathrm{C_0}(\mathbb{R}, B)$ and defines therefore an automorphism β of $E_{\mathbb{R}}$ with $\beta^2 = \mathrm{id}$.

Certainly, $\beta(b) = b$ for $b \in I_2(\mathcal{M}(B)) \subseteq E_{\mathbb{R}}$, and $\beta(\mathrm{Q}(\mathbb{R}_+, B)) = \mathrm{Q}(\mathbb{R}_-, B)$. Thus $\beta(J) \cap J = 0$, $\beta H_0 = H_0$ and $J + \beta(J) = \mathrm{Q}(\mathbb{R}, B) \subseteq E_{\mathbb{R}}$. Furthermore $h_0 + \beta h_0 = I_2 \circ k_0$, because $I_2(b) = I_1(b) + \beta I_1(b)$ for $b \in B$.

Since H_0 dominates h_0, the map ψ induces a semigroup homomorphism

$$\vartheta\colon [h] \in S(h_0;\, D, E_{\mathbb{R}}) \to [h] + [H_0] \in G(H_0;\, D, E_{\mathbb{R}})\,.$$

Then $\vartheta | G(h_0, D, E_{\mathbb{R}})$ is a group homomorphism and $\vartheta([h] + [h_0]) = [h] + [H_0]$ by Proposition 4.4.2(ii).

We have seen in Chapters 5 and 8 that

$$\mathrm{Ext}(\mathcal{C} \otimes \mathrm{CP}(\mathbb{C}, \mathrm{C_0}(\mathbb{R}));\, D, SB) = G(H_0, D, E_{\mathbb{R}})$$

(cf. Corollary 5.9.23) and

$$\mathrm{Ext}(\mathcal{C} \otimes \mathrm{CP}(\mathbb{C}, \mathrm{C_0}(\mathbb{R}));\, D, SB) \cong \mathrm{KK}(\mathcal{C};\, D, B)$$

(cf. Lemma 8.4.2).

The semigroup $S(h_0;\, D, E_{\mathbb{R}})$ is a sub-semi-group of $S(H_0;\, D, E_{\mathbb{R}})$ because H_0 dominates h_0 (almost obviously). Thus, $[h] \mapsto [h \oplus H_0] = [h] + [H_0]$ defines a natural group morphism ϑ from $\mathrm{R}(\mathcal{C};\, D, B) = G(h_0;\, D, E_{\mathbb{R}})$ into $\mathrm{Ext}(\mathcal{C} \otimes \mathrm{CP}(\mathbb{C}, \mathrm{C_0}(\mathbb{R}));\, D, SB) = G(H_0;\, D, E_{\mathbb{R}})$.

By Chapters 4 and 7, we have

$$G(k_0;\, D, Q(\mathbb{R}_+, B)) = \mathrm{R}(\mathcal{C};\, D, B) \cong G(h_0;\, D, E_{\mathbb{R}}) = [h_0] + S(h_0;\, D, E_{\mathbb{R}})\,.$$

Proof of Prop. 9.2.4 and Cor. 9.2.5 requires to prove first homotopy invariance of $\mathrm{R}(\mathcal{C}\,;\, D, B)$,
i.e., that

$$\pi_0, \pi_1 \colon\, \mathrm{R}(\mathcal{C}[0,1]\,;\, D, B[0,1]) \to \mathrm{R}(\mathcal{C}\,;\, D, B)$$

satisfy $\pi_0 = \pi_1$.

Is the homotopy invariance of $\mathrm{R}(\mathcal{C}\,;\, D, B)$ equivalent to the to the injectivity of

$$\mathrm{R}(\mathcal{C}\,;\, D, B) \to \mathrm{KK}(\mathcal{C}\,;\, D, B)\,.$$

???

But there is also a a direct proof of the criteria in Theorem 4.4.6 for the injectivity of $G(h_0;\, D, E_{\mathbb{R}}) \;\to\; G(H_0;\, D, E_{\mathbb{R}})$, given by an inductive decomposition procedure (see below).

Lemma 9.2.2. *Suppose that D and B are stable, D is separable, B is σ-unital, $H\colon D \to \mathcal{M}(B)$ is a non-degenerate C^*-morphism, and a_1, a_2 are self-adjoint generators of D, i.e., $D = C^*(a_1, a_2)$.*

Then there exists exists a constant $\Omega(H) \in \mathbb{N}$ with the following property:

For every unitary $U \in \mathcal{M}\big(\mathrm{C}_0((-\infty, 1], B)\big)$, – given by a strictly continuous map $U\colon (-\infty, 1] \ni t \mapsto U(t) \in \mathcal{U}(B)$ – with $\gamma_{U,k} \in \mathrm{C}_0((-\infty, 1], B)$ for $\gamma_{U,k}(t) := H(a_k)U(t) - U(t)H(a_k)$ and every $\delta > 0$ there exist $n \le \Omega(D, B, H)$ and contractions $T_1, \ldots, T_n \in \mathcal{M}\big(\mathrm{C}_0((-\infty, 1], B)\big)$ with $T_j^* = -T_j$ and a unitary $V \in 1 + \mathrm{C}_0((-\infty, 1], B)$, such that $[T_j, H(a_k)] \in \mathrm{C}_0((-\infty, 1], B)$, $\|[T_j, H(a_k)]\| < \delta$ for $j = 1, \ldots, n$, $k = 1, 2$, and

$$U \oplus_{s_1,s_2} 1 = V \cdot \exp(T_1) \cdot \ldots \cdot \exp(T_n)\,.$$

In particular,

$$\|[V^*(U \oplus 1), H(a_k)]\| \le n \cdot \delta \le \Omega(D, B, H) \cdot \delta\,.$$

Proof. Is not very likely that a proof exist!!!

To be filled in ?? □

Next lemma describes a correction method for paths of unitaries by mirroring the interval $[\alpha, \beta)$ onto $(-\infty, \alpha]$ via the bijective map

$$[\alpha, \beta) \ni t \mapsto \alpha - (t - \alpha)/(\beta - t) \in (-\infty, \alpha]\,.$$

Lemma 9.2.3. *Let D and B stable C^*-algebras, D separable and B σ-unital, $H\colon D \to \mathcal{M}(B)$ a non-degenerate C^*-morphism in general position (i.e., $\delta_\infty \circ H$ unitarily homotopic to H), $0 \le \alpha < \beta$ real numbers, $a_1, a_2 \in D$ self-adjoint contractions,*

$$(-\infty, \beta] \ni t \mapsto U(t) \in \mathcal{U}(\mathcal{M}(B))$$

a strictly continuous map.

Let $\lambda(t) := U(t)H(a) - H(a)U(t)$ *in* $\mathcal{M}(B)$ *for* $t \in (-\infty, \beta]$ *and suppose that* $\lambda \in \mathrm{C}((-\infty, \beta], B)$ *and* $\lim_\infty \|\lambda(t)\| = 0$.

Let $n, m \in \mathbb{N}$ *with* $\max(m, n) \le \Omega(D, B, H)$, *and* $0 < \delta \le \varepsilon$. *Suppose that the following are given (e.g. coming from Lemma 9.2.2):*

(i) $S_1, \ldots, S_m \in \mathrm{C}_{\mathrm{b,st}}((-\infty, \alpha], \mathcal{M}(B))$ *with* $S_j^* = -S_j$, $\|S_j\| \le 1$, $[S_j, a_k] \in \mathrm{C}_0((-\infty, \alpha], B)$, $\|[S_j, H(a_k)]\| < \varepsilon$ *and*

$$V_1^*(U|(-\infty, \alpha]) \in 1 + \mathrm{C}_0(-\infty, \alpha], B)\,,$$

for $V_1 := \exp(S_1) \cdot \ldots \cdot \exp(S_m)$.

(ii) $T_1, \ldots, T_n \in \mathrm{C}_{\mathrm{b,st}}((-\infty, \alpha], \mathcal{M}(B))$ *with* $T_j^* = -T_j$, $\|T_j\| \le 1$, $[T_j, H(a_k)] \in \mathrm{C}_0((-\infty, \beta], B)$, $\|[T_j, H(a_k)]\| < \varepsilon$ *and*

$$V_2^* U \in 1 + \mathrm{C}_0(-\infty, \beta], B)\,,$$

for $V_2 := \exp(T_1) \cdot \ldots \cdot \exp(T_n)$.

Then there exists a unitary in $W \in 1 + \mathrm{C}([\alpha, \beta], B)$ *with* $W(\beta) = 1$, $W(\alpha) = V_2(\alpha)^* V_1(\alpha)$ *and, for* $t \in [\alpha, \beta]$, *?????*

$\|[W(t), H(a_k)]\| \le \|[V_1, H(a_k)]\| + \|[(V_2|(-\infty, \alpha]), H(a_k)]\| \le n\delta + m\varepsilon \le 2\varepsilon\Omega(?????)$.

Then $W(\alpha)^* V_2(\alpha)^* U(\alpha) = V_1(\alpha)^* U(\alpha)$, $V_2(\alpha)W(\alpha) = V_1(\alpha)$, $V_2(\beta)W(\beta) = V_2(\beta)$.

Moreover $V_3(t) := V_1(t)$ *for* $t \in (-\infty, \alpha]$ *and* $V_3(t) := V_2(t)W(t)$ *for* $t \in (\alpha, \beta]$ *is strictly continuous on* $(-\infty, \beta]$, *with* $V_3^* U \in 1 + \mathrm{C}_0((-\infty, \beta], B)$,

$$\|[V_3(t), H(a_k)]\| \le m\varepsilon + 2n\delta \le 2\varepsilon\Omega(D, B, H)$$

and $\|[V_3(\beta), H(a_k)]\| = \|[V_2(\beta), H(a_k)]\| \le n\delta \le \delta\Omega(D, B, H)$.

PROOF. `To be filled in` ?? □

PROPOSITION 9.2.4. *The semigroup homomorphism* ψ *defines a surjective group homomorphism* $\vartheta\colon [h] + [h_0] \mapsto [h] + [H_0]$ *from* $G(h_0; D, E_{\mathbb{R}})$ *onto* $G(H_0; D, E_{\mathbb{R}})$, *if* $H_0\colon D \to E_{\mathbb{R}} := \mathcal{M}(B[\mathbb{R}])/B[\mathbb{R}]$ *is as above defined.*

The epimorphism ϑ *is an* isomorphism *from* $G(h_0; D, E_{\mathbb{R}})$ *onto* $G(H_0; D, E_{\mathbb{R}})$, *if* $Y \mapsto \mathrm{R}(\mathcal{C}[Y]; D, B[Y])$ *(*Y *compact metric space) is homotopy invariant, in the sense that the evaluation maps*

$$\pi_t\colon\ \mathrm{R}\big(\mathcal{C}[Y \times I]; D, B[Y \times I]\big) \to \mathrm{R}\big(\mathcal{C}[Y]; D, B[Y]\big)$$

have the same images for $t \in \{0, 1\} \subset I := [0, 1]$.

Recall that we denote by $\mathcal{C}[\mathbb{R}]$ (or likewise $\mathcal{C}_{\mathbb{R}}$, $S\mathcal{C}$) respectively by the matrix operator convex cone $\mathcal{C} \otimes \mathrm{CP}(\mathbb{C}, \mathrm{C}_0(\mathbb{R}))$, that is the tensor product of $\mathcal{C}$ and $\mathrm{CP}(\mathbb{C}, \mathrm{C}_0(\mathbb{R}))$ inside the *category of m.o.c. cones*, and we urge the reader to remind that the tensor product in the category of m.o.c. cones has not *not* much to do with a completion of some tensorproduct in the ordinary sense, because of the many different "canonical" matrix-cones on tensor products, compare Chapter 3.

Remember that $B[\mathbb{R}]$ (or likewise $B_{\mathbb{R}}$, SB) are other notations for the C^*-algebra $\mathrm{C}_0(\mathbb{R}, B) \cong B \otimes \mathrm{C}_0(\mathbb{R})$. The above listed results of Chapters 5, 7 and 8 immediately yield the following.

It suffices to consider the case $Y :=$ point in Proposition 9.2.4 by replacing B by $B[Y] = \mathrm{C_b}(Y, B)$.

Corollary 9.2.5. *The semigroup homomorphism ψ induces a natural group epimorphism ϑ of $\mathrm{R}(\mathcal{C};\, D, B)$ onto $\mathrm{Ext}(\mathcal{C}[\mathbb{R}];\, D, B[\mathbb{R}]) \cong \mathrm{KK}(\mathcal{C};\, D, B)$. The epimorphism ϑ is an isomorphism if the evaluation maps*

$$\pi_0, \pi_1 \colon\ \mathrm{R}(\mathcal{C}[0,1];\, D, B[0,1]) \to \mathrm{R}(\mathcal{C};\, D, B)$$

have the same image. □

We need several elementary observations for the proofs of Proposition 9.2.4 and Corollary 9.2.5, e.g.

Lemma 9.2.6. *Suppose that D is a stable and σ-unital C^*-algebra and that k is a non-degenerate *-monomorphism from $D \otimes \mathcal{O}_2$ into B.*

Let $r_1, r_2, \ldots$ a sequence of isometries in $\mathcal{M}(B)$ such that $\sum r_n (r_n)^*$ converges strictly to 1, and let $\delta_\infty := \sum r_n(\cdot)(r_n)^*$ the corresponding infinite repeat endomorphism of $\mathcal{M}(B)$. Then:

- (i) *There exists a unital *-morphism $\epsilon \colon \mathcal{M}(\mathcal{O}_2 \otimes \mathbb{K}) \hookrightarrow \mathcal{M}(B)$ such that*
  - (0) *ϵ is a strictly continuous monomorphism,*
  - (1) *$\epsilon(\mathcal{M}(\mathcal{O}_2 \otimes \mathbb{K}))$ commutes element-wise with $\delta_\infty(k(D \otimes 1))$,*
  - (2) *$\epsilon(\mathcal{O}_2 \otimes 1_{\mathcal{M}(\mathbb{K})})$ commutes element-wise with $k(D \otimes 1)$, and*
  - (3) *$r_1 r_1^* = \epsilon(1_{\mathcal{O}_2} \otimes p_{11})$, and*
  - (4) *$\delta_\infty(k(D \otimes 1)) \cdot \epsilon(\mathcal{O}_2 \otimes \mathbb{K}) \subseteq B$.*
- (ii) *If $\epsilon \colon \mathcal{M}(\mathcal{O}_2 \otimes \mathbb{K}) \to \mathcal{M}(B)$ is any unital *-morphism that has the properties (0)–(4) of Part (i), then*

$$d \otimes f \mapsto \delta_\infty(k(d \otimes 1))\epsilon(f \otimes p_{11})$$

  *extends to a *-monomorphism $k_1 \colon D \otimes \mathcal{O}_2 \to B$, such that $d \in D \mapsto k_1(d \otimes 1)$ is unitarily homotopic to $d \in D \mapsto k(d \otimes 1)$.*
- (iii) *$\epsilon(\mathcal{O}_2 \otimes \mathbb{K})B$ is dense in B, and there exists an isometry $t_0' \in \epsilon(\mathcal{M}(\mathcal{O}_2 \otimes \mathbb{K}))$ such that $t_0' t_0'^* = 1 - r_1 r_1^*$.*

Proof. (i): First we consider the case $B = D \otimes \mathcal{O}_2$ and $k := \mathrm{id}$.

Let $\lambda \colon \mathbb{K} \otimes \mathbb{K} \to \mathbb{K}$ be an isomorphism. Then there exist sequences (I_n), (s_n) of isometries in $\mathcal{M}(\mathbb{K})$, such that $\sum I_n I_n^*$ and $\sum s_n s_n^*$ strictly converge to 1, $\lambda(a \otimes p_{nn}) = I_n a I_n^*$ and $\lambda(p_{nn} \otimes a) = s_n a s_n^*$ for $a \in \mathbb{K}$.

In particular $\mathcal{M}(\lambda)(1 \otimes p_{11}) = I_n I_n^*$.

Then the infinite repeats $\delta^{(1)} := \sum I_n(\cdot)I_n^*$ and $\delta^{(2)} := \sum s_n(\cdot)s_n^*$ have element-wise commuting images and $\delta^{(1)}(a)\delta^{(2)}(b) = \lambda(a \otimes b)$ for $a, b \in \mathbb{K}$. Indeed, $\delta^{(1)} = \mathcal{M}(\lambda)((\cdot) \otimes 1)$ and $\delta^{(2)} = \mathcal{M}(\lambda)(1 \otimes (\cdot))$.

Let $r'_n := 1 \otimes I_n \otimes 1$, $s'_n := 1 \otimes s_n \otimes 1$, and $\epsilon'(f) := \sum s'_n(1 \otimes \mathcal{M}(\kappa)(f))s'_n$ for $f \in \mathcal{M}(\mathcal{O}_2 \otimes \mathbb{K})$, where κ denotes here the flip-isomorphism from $\mathcal{O}_2 \otimes \mathbb{K}$ onto $\mathbb{K} \otimes \mathcal{O}_2$. Then ϵ' has the quoted properties with respect to $r'_1, r'_2, \ldots$ and id (in place of $\epsilon, r_1, r_2, \ldots, k$):

For $a \in A$ and $b \in \mathbb{K}$, where $D := A \otimes \mathbb{K}$

`Is` A `sufficiently well-defined? ??`

let ??????

$$\delta_\infty(a \otimes b \otimes 1) = a \otimes \delta^{(1)}(b) \otimes 1,$$

and, for $e \in \mathbb{K}$ and $f \in \mathcal{O}_2$,

$$\epsilon'(e \otimes f) = 1 \otimes \delta^{(2)}(e) \otimes f.$$

In particular,

$$\epsilon'(1 \otimes p_{11}) = 1 \otimes \mathcal{M}(\lambda)(1 \otimes p_{11}) \otimes 1 = r'_1(r'_1)^* .$$

$D \otimes 1$ and $\epsilon'(\mathcal{O}_2 \otimes 1)$ commute, because, for $a \in A$, $b, c \in \mathbb{K}$ and $f \in \mathcal{O}_2$,

$$(a \otimes \lambda(b \otimes c)) \cdot \epsilon'(f \otimes 1) = a \otimes \lambda(b \otimes c) \otimes f .$$

In the *general case*, let $\mathcal{M}(k) \colon \mathcal{M}(D \otimes \mathcal{O}_2) \hookrightarrow \mathcal{M}(B)$ the strictly continuous unital extension of k. By Lemma 5.1.2(i) there is a unitary $u \in \mathcal{M}(B)$ such that $r_n = u\mathcal{M}(k)(r'_n)$. Let $\epsilon := u\mathcal{M}(k)(\epsilon'(\cdot))u^*$, then ϵ satisfies (0)-(4).

(ii): By the properties listed in (i), there is a C^*-morphism g from the algebraic tensor product $D \odot \mathcal{O}_2$ into B such that, for $d \in D$, $f \in \mathcal{O}_2$,

$$g(d \otimes f) = \delta_\infty(k(d \otimes 1))\epsilon(f \otimes p_{11}) ,$$

moreover g extends to a C^*-morphism k_1 from $D \otimes \mathcal{O}_2$ into B, because $\mathcal{O}_2$ is nuclear and simple.

Let $k_2 := k_1((\cdot) \otimes 1)$ and $k_0 := k((\cdot) \otimes 1)$. Since $r_1(r_1)^* = \epsilon(1 \otimes p_{11})$, $k_2 = r_1 k_0(\cdot) r_1^*$. Thus $k_0 = r_1^* k_2(\cdot) r_1$. By Corollary 7.4.4, k_2 and k_0 are unitarily homotopic, because B is stable, D is separable and $r_1 \in \mathcal{M}(B)$.

(iii): $\epsilon(\mathcal{O}_2 \otimes \mathbb{K})B$ is dense in B, because ϵ is strictly continuous and unital.

By (i), $\epsilon(1 \otimes (1 - p_{11})) = 1 - r_1 r_1^*$.

Let T_0 an isometry in $\mathcal{M}(\mathbb{K}) \cong \mathcal{L}(H)$ with $T_0(T_0)^* = 1 - p_{11}$, and let $t'_0 := \epsilon(1 \otimes T_0)$. Then t'_0 is an isometry in $\epsilon(\mathcal{M}(\mathcal{O}_2 \otimes \mathbb{K}))$ such that $t'_0 t'^*_0 = 1 - r_1 r_1^*$. □

Proof of Proposition 9.2.4. We use the notations and observations of Remark 9.2.1 and reduce the prove to Theorem 4.4.6. It means, that we are going to find $F \subseteq H_0(D)' \cap E_{\mathbb{R}}$ and elements s, t, p_0, s_0, t_0, u_1 in $E_{\mathbb{R}}$, such that the above defined D, $E_{\mathbb{R}}$, J, h_0, H_0, β, together with with the below defined F, s, t, p_0, s_0, t_0 and u_1 satisfy the assumptions (i)–(vi) of Theorem 4.4.6. Then Theorem 4.4.6 implies that the generalized mapping cone construction $\psi\colon S(h_0;\, E, E_{\mathbb{R}}) \to G(H_0;\, D, E_{\mathbb{R}})$ defines a group *epimorphism* ϑ from $G(h_0;\, D, E_{\mathbb{R}})$ onto $G(H_0;\, D, E_{\mathbb{R}})$. It becomes an *isomorphism* if we later can show in addition that that $\Gamma(H_0(D), J, E) = 0$.

We are now going to define the missing ingredients for this list. Parallel, we check that the conditions (i)-(vi) of Theorem 4.4.6 are fulfilled for them:

Let $r_1, r_2, \ldots$ be a sequence of isometries in $\mathcal{M}(B)$, such that $\sum r_n(r_n)^* = 1$, and let $\epsilon\colon \mathcal{M}(\mathcal{O}_2 \otimes \mathbb{K}) \to \mathcal{M}(B)$ the strictly continuous unital *-monomorphism that satisfies (0)-(4) of Lemma 9.2.6(i) with respect to $k\colon D \otimes \mathcal{O}_2 \to B$ and $(r_1, r_2, \ldots)$.

By Lemma 9.2.6(iii), there is an isometry t'_0 in $\epsilon(\mathcal{M}(\mathcal{O}_2 \otimes \mathbb{K}))$, such that $t'_0(t'_0) = 1 - r_1(r_1)^*$. Thus t'_0 commutes element-wise with $H'_0(D)$.

Therefore $\delta_\infty(k_0(D))$ and $k_0(D)$ both commute element-wise with the unital copy $\eta(\mathcal{O}_2) := \epsilon(\mathcal{O}_2 \otimes 1)$ of $\mathcal{O}_2$ in $\mathcal{M}(B)$, where

$$\eta(\cdot) := \epsilon((\cdot) \otimes 1_{\mathcal{M}(\mathbb{K})})\,.$$

Let s_1, s_2 generators of $\mathcal{O}_2$ and let $s := I_2(\eta(s_1))$, $t := I_2(\eta(s_2))$. Then both are isometries in $I_2(\mathcal{M}(B)) \subseteq E_{\mathbb{R}}$ and generate a unital copy of $\mathcal{O}_2$. Since β fixes the elements of $I_2(\mathcal{M}(B))$, we have $\beta(s) = s$ and $\beta(t) = t$.

By Lemma 9.2.6(i), $\eta(\mathcal{O}_2) \subseteq H'_0(D)' \cap k_0(D)'$. If we apply I_2, we get that s and t are in $H_0(D)' \cap (h_0 + \beta h_0)(D)' \cap E_{\mathbb{R}}$.

Recall that $k_0\colon D \to B$ is non-degenerate.

By Lemma 7.4.17, there exists a contraction $g_1 \in \mathrm{C_b}(\mathbb{R}, \epsilon(1 \otimes \mathbb{K}))_+$ such that $g_1(x) = 0$ for $x \leq 0$ and $\lim_{x\to+\infty} g_1(x)k_0(a) = k_0(a)$ for every $a \in D$, because $k_0(D)$ is separable. Let $g := g_1 + SB \in E_{\mathbb{R}}$. Then $(h_0 + \beta h_0)(a)g = h_0(a)$. The positive contraction g commutes with s and t, because $\epsilon(1 \otimes \mathbb{K})$ commutes with $\epsilon(\mathcal{O}_2 \otimes 1_{\mathcal{M}(\mathbb{K})})$. Thus s and t also commute element-wise with $h_0(D)$.

Commutation of s, t with $h_0(D)$
follows also from commutation of s, t with
$(h_0 + \beta h_0)(D)$ and $J \cap \beta J = 0$. ??

Hence, *$s, t \in E_{\mathbb{R}}$ satisfy condition (i) of Theorem 4.4.6.*

Our non-degenerate *-monomorphism $H_0\colon D \to E_{\mathbb{R}}$ satisfies $\mathrm{Ext}(\mathcal{C} \otimes \mathrm{CP}(\mathbb{C}, \mathrm{C}_0(\mathbb{R}));\, D, SB) = G(H_0, D, E_{\mathbb{R}})$ by Corollary 5.9.22(i), as it was explained above.

Therefore, by Lemma 8.4.3, for every homomorphism $k\colon D \to E_{\mathbb{R}}$ that is dominated by H_0, there exists a unitary $u \in E_{\mathbb{R}}$ such that $u^*(k \oplus H_0)(a)u - H_0(a) \in J$ for each $a \in D$.
Thus *condition (ii) of Theorem 4.4.6 is valid.*

Now we want to show that conditions (iii), (iv) and (v) of Theorem 4.4.6 are satisfied:
For $P := \epsilon(\mathcal{O}_2 \otimes \mathbb{K}) \subseteq \mathcal{M}(B)$ with $\epsilon\colon \mathcal{O}_2 \otimes \mathbb{K} \to \mathcal{M}(B)$ we have that $P \cong \mathcal{O}_2 \otimes \mathbb{K}$, and that $P \cdot B$ is dense in B (by Lemma 9.2.6). Moreover $P \cap B = \{0\}$ because

P is simple and P is not contained in B by condition (3) of Lemma 9.2.6(i). Let $F_1 := \mathrm{C_b}(\mathbb{R}, P) \subseteq \mathrm{C_{b,st}}(\mathbb{R}, \mathcal{M}(B)) \cong \mathcal{M}(SB)$. Certainly $\widetilde{\beta}(F_1) \subseteq F_1$, and $F_1 \cap \mathrm{C_0}(\mathbb{R}, B) = \{0\}$, because $\epsilon(g(t)) = f(t)$ for $g(t) \in \mathcal{O}_2 \otimes \mathbb{K}$ and because $f(t) \in B$ implies $f(t) = 0$. Therefore $F := \pi_{SB}(F_1) \subseteq E_{\mathbb{R}}$ is a C^*-subalgebra of $E_{\mathbb{R}}$ that is isomorphic to $\mathrm{C_b}(\mathbb{R}, \mathcal{O}_2 \otimes \mathbb{K})$ and satisfies $\beta(F) = F$. Since $H_0'(D)P \subseteq B$, we get $F_1 H_0'(D) \subseteq \mathrm{C_b}(\mathbb{R}, B)$ and $F H_0(D) \subseteq J + \beta J$.

By Proposition 7.4.18, for every projection $q \in F_1$, and every element $f_1 \in \mathrm{C_b}(\mathbb{R}, B)$ there exists a projection p in F_1 such that $p f_1 p - f_1 \in \mathrm{C_0}(\mathbb{R}, B)$, $q \leq p$ and $q \neq p$.

If we apply π_{SB}, we get that *condition (iii) of Theorem 4.4.6 is satisfied.*

By Lemma 9.2.6(iii), there are isometries r_1, t_0' in $\mathcal{M}(B)$ such that $t_0'(t_0')^* = 1 - p_0'$, $r_1(r_1)^* = p_0' \in P$, $r_1^* H_0'(\cdot) r_1 = k_0$, and $t_0' \in \epsilon(\mathcal{M}(\mathcal{O}_2 \otimes \mathbb{K}))$ commutes with the elements of $H_0'(D)$. If considered as elements of $\mathcal{M}(SB)$ they are fixed by $\widetilde{\beta}$. Let $s_0 := I_2(r_1)$, $t_0 := I_2(t_0')$ and $p_0 := I_2(p_0')$ the corresponding elements in $E_{\mathbb{R}}$. Then s_0 and t_0 are fixed by β, $p_0 = s_0 s_0^* \in F$, and t_0 commutes with the elements of $H_0(D) = I_2(H_0'(D))$. Since $r_1^* H_0'(\cdot) r_1 = k_0$, we get $s_0^* H_0(\cdot) s_0 = I_2 k_0 = h_0 + \beta h_0$. Thus, *condition (iv) of Theorem 4.4.6 is satisfied.*

By [**172**] any two nonzero projections in $\mathcal{O}_2 \otimes \mathbb{K}$ are unitarily equivalent by a unitary in the *-semigroup $1 + \mathcal{O}_2 \otimes \mathbb{K}$ in $\mathcal{M}(\mathcal{O}_2 \otimes \mathbb{K})$. Therefore, *condition (v) of Theorem 4.4.6 is satisfied* by Lemma 7.4.13, because p_0 is a nonzero projection of F and F is isomorphic to $\mathrm{C_b}(\mathbb{R}, \mathcal{O}_2 \otimes \mathbb{K})$.

BEGIN (Old vi)

```
The old assumption (OLD vi) has been
proven in new Lemma 4.4.7
from the other assumptions (i)-(v) and (OLD vii).
Thus (OLD vi) is superfluous and Part (OLD vii)
is now the new Part (vi).
```

Check of condition (OLD vi) of Theorem 4.4.6:
Let $h\colon D \to J$. Suppose that H_0 dominates $h + \beta h_0$, i.e., there exists an isometry $T \in E_{\mathbb{R}}$ with $T^* H_0(\cdot) T = h + \beta h_0$. By Lemma 7.4.22(i), there exists a contraction $y \in (J + \beta(J))_+ = \mathrm{Q}(\mathbb{R}, B)_+$ such that $y(h + \beta h_0)(\cdot) y = h$. It follows that $h = y T^* H_0(\cdot) T y$ is dominated by H_0. Since $z := Ty$ is a contraction in the ideal $\mathrm{Q}(\mathbb{R}, B)$ of $E_{\mathbb{R}} = \mathcal{M}(\mathrm{C_0}(\mathbb{R}, B)) / \mathrm{C_0}(\mathbb{R}, B))$ and, since

$$H_0(D) \subseteq \pi_{SB}(\mathcal{M}(B)) \subseteq \pi_{SB}(\mathrm{Q}(\mathbb{R}, \mathcal{M}(B))) \subseteq E_{\mathbb{R}},$$

by the natural embeddings

$$\mathcal{M}(B) \subseteq \mathrm{C_b}(\mathbb{R}, \mathcal{M}(B)) \subseteq \mathrm{C_{b,st}}(\mathbb{R}, \mathcal{M}(B)) = \mathcal{M}(\mathrm{C_0}(\mathbb{R}, B)),$$

there is a contraction $w \in \mathrm{C_b}(\mathbb{R}, B)$ with $w + \mathrm{C_0}(\mathbb{R}, B)) = z$

$$h = w^*(\delta_\infty \circ k_0)(\cdot) w + \mathrm{C_0}(\mathbb{R}, B).$$

By 7.4.22(iv), there is a contraction $v \in \mathrm{C_b}(\mathbb{R}, B)$ with $v(t) = 0$ for $t < 0$ and $v^* k_0(\cdot) v + \mathrm{C}_0(\mathbb{R}, B) = h$. Thus, $d^* h_0(\cdot) d = d^*(h_0 + \beta h_0)(\cdot) d = h$ for the contraction $d := v + \mathrm{C}_0(\mathbb{R}, B) \in J \cong \mathrm{Q}(\mathbb{R}_+, B)$. Since B is stable and $h_0(D)$ is separable, there is an isometry $S \in \mathrm{C_b}(\mathbb{R}, M(B)) \subseteq \mathcal{M}(\mathrm{C}_0(\mathbb{R}, B))$ such that $s := S + \mathrm{C}_0(\mathbb{R}, B) \in E_{\mathbb{R}}$ satisfies $s^* h_0(\cdot) s = d^* h_0(\cdot) d = h$ (cf. Lemma 7.4.22(v)). Thus *assumption (OLD vi) of Theorem 4.4.6 is satisfied.*

END (OLD vi)

`Check again assumption (vi) ?? ??`

Now we verify assumption (vi) of Theorem 4.4.6:

First we define a continuous map $\xi \in \mathbb{R} \to v(\xi)$ into the unitaries of $O_2 = C^*(s_1, s_2)$ for $\xi \in [0, 1]$ by

$$v(\xi) := \xi(s_1 s_1^* + s_2 s_2^*) + (1 - \xi^2)^{1/2}(s_2 s_1^* - s_1 s_2^*)\,,$$

and by $v(\xi) := 1$ for $\xi \geq 1$, $v(\xi) := v(0) = s_2 s_1^* - s_1 s_2^*$ for $\xi \leq 0$.

Let $w(\xi) := \eta(v(\xi))$, then $w \in \mathrm{C_b}(\mathbb{R}, \eta(\mathcal{O}_2))$ is a unitary in $\mathrm{C_{b,st}}(\mathbb{R}, \mathcal{M}(B)) \cong \mathcal{M}(SB)$. Finally, let $u_1 := w + SB = \pi_{SB}(w)$. Then $u_1 \in J' \cap E_{\mathbb{R}}$, because every $a \in J \cong \mathrm{Q}(\mathbb{R}_+, B \otimes \mathbb{K})$ has a representative $b \in \mathrm{C_b}(\mathbb{R}, B)$ with $b(\xi) = 0$ for $\xi \leq 1$, and, for those b, $wb = b = bw$.

Since β fixes $C^*(s, t) = I_2(\eta(\mathcal{O}_2)) \subseteq I_2(\mathcal{M}(B))$ and s, t commutes element-wise with $h_0(D)$, we get that s and t commute element-wise with $\beta h_0(D)$. The elements of βJ can be represented by elements b in $\mathrm{C_b}(\mathbb{R}, B)$ such that $b(\xi) = 0$ for $\xi \geq 0$. We get $wb = \eta(s_2 s_1^* - s_1 s_2^*) b$ and $bw = b\eta(s_2 s_1^* - s_1 s_2^*)$. It implies that the equation

$$u_1 \beta h_0(\cdot) s s^* = t t^* \beta h_0(\cdot) u_1$$

is equivalent to

$$(ts^* - st^*) s s^* \beta h_0(\cdot) = \beta h_0(\cdot) t t^* (ts^* - st^*)\,,$$

i.e., is equivalent to the above shown element-wise commutation of ts^* with $\beta h_0(D)$.

Therefore *condition (vi)* of Theorem 4.4.6 is *satisfied.*

Now we have seen that all conditions of Theorem 4.4.6 are satisfied by D, $E_{\mathbb{R}}$, H_0, h_0, J and β. Therefore

$$\vartheta \colon [k \oplus h_0] \to [k \oplus H_0]$$

is a group epimorphism from $G(h_0;\, D, \mathrm{Q}^s(SB)) \cong \mathrm{R}(\mathcal{C};\, D, B)$ onto

$$G(H_0;\, D, \mathrm{Q}^s(SB)) = \mathrm{Ext}(\mathcal{C} \otimes \mathrm{CP}(\mathbb{C}, \mathrm{C}_0(\mathbb{R}));\, D, SB) \cong \mathrm{KK}(\mathcal{C};\, D, B)\,.$$

□

The following Corollary 9.2.7 and its proof uses the notations and conventions of Remark 9.2.1.

COROLLARY 9.2.7. *Suppose that B and D are stable (and trivially graded), D is separable, B σ-unital, and that $h_0\colon D \to B$ is non-degenerate with $[h_0 \oplus h_0] = [h_0]$. Let $\mathcal{C} := \mathcal{C}(h_0)$ and define* $\mathrm{Hom}(\mathcal{C};\, D, B) := \mathrm{Hom}(D, B) \cap \mathcal{C}$ *. Then:*

(i) $S(h_0\,;\, D, \mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B))) = \mathrm{SR}(\mathcal{C};\, D, B)$.
If $[k] \in S(h_0\,;\, D, \mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B)))$ *then* $h := k \oplus h_0$ *is in* $[h_0] + \mathrm{SR}(\mathcal{C};\, D, B) \cong \mathrm{R}(\mathcal{C};\, D, B)$, *and* $[\widehat{\sigma} \circ h] = [h]$ *in* $\mathrm{SR}(\mathcal{C};\, D, B)$, *for every homeomorphism σ of $\mathbb{R}_+$,*
i.e., h is invariant under scaling *up to unitary equivalence.*

(ii) *The difference construction* $[h - 0] := [(B, h, 0)] \in \mathrm{KK}(\mathcal{C};\, D, B)$ *for* $h \in \mathrm{Hom}(\mathcal{C};\, D, B)$ *defines a semigroup* epi*morphism*

$$\alpha\colon [\mathrm{Hom}(\mathcal{C};\, D, B)] \to \mathrm{KK}(\mathcal{C};\, D, B)$$

from the "constant" sub-semigroup $[\mathrm{Hom}(\mathcal{C}\,;\, D, B)]$ *of* $\mathrm{R}(\mathcal{C}\,;\, D, B)$ onto $\mathrm{KK}(\mathcal{C}; D, B)$.
Elements $[h_1], [h_2] \in [\mathrm{Hom}(\mathcal{C};\, D, B)]$ *define the same element* $[h_1 - 0] = [h_2 - 0]$ *of* $\mathrm{KK}(\mathcal{C};\, D, B)$*, if and only if, $h_1 \oplus h_0$ and $h_2 \oplus h_0$ are unitarily homotopic (cf. Definition 5.0.1).*

`Next example OK ???`
`More information ? ??`

Note that, in "contrast" to Corollary 9.2.7, the natural group homomorphism $G(h_0\,;\, D, B) \to G(h_0\,;\, D, \mathrm{Q}(\mathbb{R}_+, B))$ is neither surjective nor injective in general, e.g. for $D = \mathcal{O}_2 \otimes \mathbb{K}$, $B = \mathcal{O}_2 \otimes \mathcal{O}_2 \otimes \mathbb{K}$ and $h_0(\cdot) := 1 \otimes (\cdot)$.

`Not clear, e.g.:`
`Then` $G(h_0\,;\, D, \mathrm{Q}(\mathbb{R}_+, B))$ `contains only one element ?`
`What about this` $G(h_0\,;\, D, B)$`?`

PROOF. The homotopy invariance of $\mathrm{R}(\mathcal{C};\, D, B)$ follows from different more involved considerations ??

(i): Let $E_{\mathbb{R}} := \mathcal{M}(SB)/SB \cong \mathrm{Q}^s(SB)$, let $I_1\colon \mathrm{Q}(\mathbb{R}_+, B) \cong J \hookrightarrow E_{\mathbb{R}}$ be the natural inclusion, and let $I_2\colon \mathcal{M}(B) \to E_{\mathbb{R}}$ denotes the natural unital monomorphism induced by $\mathcal{M}(B) \subseteq \mathrm{C}_{\mathrm{b,st}}(\mathbb{R}, \mathcal{M}(B)) = \mathcal{M}(SB)$.

By Proposition 7.4.21(i), a morphism $k \in \mathrm{Hom}(D, \mathrm{Q}(\mathbb{R}_+, B))$ has unitary equivalence class $[I_1 \circ k]$ in $S(h_0\,;\, D, E_{\mathbb{R}})$, if an only if $[k] \in \mathrm{SR}(\mathcal{C};\, D, B)$. (The unitary equivalence classes coincide, i.e., $[k] = [k']$ in $[\mathrm{Hom}(D, \mathrm{Q}(\mathbb{R}_+, B))]$ if and only if $[I_1 \circ k] = [I_1 \circ k']$ in $[\mathrm{Hom}(D, E_{\mathbb{R}})]$, cf. Lemma 7.4.20.)

The class $[h] = [(I_1 \circ k) \oplus h_0] = [(I_1 \circ k)] + [h_0]$ is in $G(h_0;\, D, E_{\mathbb{R}}) = [h_0] + S(h_0\,;\, D, E_{\mathbb{R}}) \cong \mathrm{R}(\mathcal{C};\, D, B)$, by Proposition 7.4.21(ii) (and by Proposition 4.4.3).

If σ is a topological isomorphism of $\mathbb{R}_+$ then $\sigma(0) = 0$ and therefore σ extends naturally to an orientation preserving topological isomorphism of $\mathbb{R}$ by letting $\sigma(t) = t$ for $t \in \mathbb{R}_-$. We denote this extension again by σ. It induces in a natural way an automorphism $\widehat{\sigma}$ of $E_{\mathbb{R}} = \mathcal{M}(SB)/(SB)$ such that its restriction to $J \cong \mathrm{Q}(\mathbb{R}_+, B)$ is just the above considered induced automorphism of $\mathrm{Q}(\mathbb{R}_+, B)$, which we also denote by $\widehat{\sigma}$, because all is naturally related by the natural inclusion and restriction maps.

The generalized mapping cone construction $k \mapsto I_1 \circ k$ satisfies $\widehat{\sigma} \circ (I_1 \circ k) = I_1 \circ (\widehat{\sigma} \circ k)$.

On the other hand the isomorphism ϑ of Proposition 9.2.4 satisfies, by definition of ϑ,

$$\vartheta([\widehat{\sigma} \circ (k \oplus h_0)]) = [I_1 \circ (\widehat{\sigma} \circ (k \oplus h_0))] + [H_0] = [\widehat{\sigma} \circ (I_1 \circ (k \oplus h_0))] + [H_0]\,.$$

On the other hand $\widehat{\sigma} \circ H_0 = H_0$ and $\widehat{\sigma} \circ (H \oplus H_0) = (\widehat{\sigma} \circ H) \oplus H_0$, because $\widehat{\sigma}$ fixes $I_2(\mathcal{M}(B))$, $H_0(D)$ is in $I_2(\mathcal{M}(B))$ and $\oplus = \oplus_{s,t}$ (up to unitary equivalence) with canonical generators s, t of $\mathcal{O}_2$ in $I_2(\mathcal{M}(B))$. Thus

$$[\widehat{\sigma} \circ (I_1 \circ (k \oplus h_0))] + [H_0] = [\widehat{\sigma} \circ ((I_1 \circ (k \oplus h_0)) \oplus H_0)]\,.$$

Since $[I_1 \circ (k \oplus h_0)] + [H_0] \in G(H_0;\, D, E_{\mathbb{R}})$, we get from Corollary 8.3.4(ii) that

$$[\widehat{\sigma} \circ (I_1 \circ (k \oplus h_0) \oplus H_0)] = [I_1 \circ (k \oplus h_0) \oplus H_0] = \vartheta([k \oplus h_0]).$$

Since $[k \oplus h_0]$ is in $\mathrm{R}(\mathcal{C};\, D, B)$ and ϑ is faithful on $\mathrm{R}(\mathcal{C};\, D, B)$ by Proposition 9.2.4, this shows the invariance of $[k \oplus h_0]$ under scaling:

$$[k \oplus h_0] = [\widehat{\sigma} \circ (k \oplus h_0)].$$

By Corollary 7.4.19(i),

$$S(h_0;\, D, \mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B))) = \mathrm{SR}(\mathcal{C};\, D, B)\,.$$

The Definition of $S(h_0;\, D, \mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B)))$ yields that $h = k \oplus h_0$ is scaling invariant up to unitary equivalence (by unitaries in $\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B))$. By Corollary 7.4.19(iii),

$$\mathrm{R}(\mathcal{C};\, D, B) \cong \mathrm{SR}(\mathcal{C};\, D, B) + [h_0] \subseteq \mathrm{SR}(\mathcal{C};\, D, B)\,.$$

(ii): Since h_0 is unitarily equivalent to $h_0 \oplus h_0$ we get from Lemma 7.4.24 that

$$\mathrm{Hom}(D, B) \cap \mathcal{C} = \{h \in \mathrm{Hom}(A, B)\,;\ [h] \in \mathrm{SR}(\mathcal{C};\, D, B)\,\}\,.$$

By part (i) and by Corollary 9.1.3, for every $[h] \in G(h_0;\, D, \mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B))) \cong \mathrm{R}(\mathcal{C};\, D, B)$, there exists a unitary $u \in \mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B))$ and a *-morphism $k\colon D \to B$ such that $u^* k(\cdot) u = h$. It follows that $k \in \mathrm{R}(\mathcal{C};\, D, B)$ and $[k \oplus h_0] = [k] + [h_0] = [h] + [h_0] = [h]$. Thus, $k \oplus h_0$ is unitarily homotopic to k, and $k \in \mathrm{Hom}(\mathcal{C};\, D, B)$. We can replace k by $k \oplus h_0$, and may assume that k is a monomorphism that dominates h_0 (in $\mathcal{M}(B)$ itself). It follows that $k \in \mathrm{Hom}(\mathcal{C};\, D, B) \to [k] \in \mathrm{R}(\mathcal{C};\, D, B)$ is surjective.

Morphisms $h_1, h_2 \in \mathrm{Hom}(\mathcal{C};\, D, B)$ define the same element $[h_1] = [h_2]$ in $\mathrm{R}(\mathcal{C};\, D, B)$ if and only if $h_1 \oplus h_0$ and $h_2 \oplus h_0$ are unitarily homotopic by definition of $\mathrm{R}(\mathcal{C};\, D, B) = G(h_0;\, D, \mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B)))$.

It remains to check that the isomorphism $\mathrm{R}(\mathcal{C};\, D, B) \cong \mathrm{KK}(\mathcal{C};\, D, B)$ given by Proposition 9.2.4 and of Corollary 9.2.5 maps $[h] \in \mathrm{R}(\mathcal{C};\, D, B)$ to the difference construction $[h - 0] \in \mathrm{KK}(\mathcal{C};\, D, B)$ if $h \in \mathrm{Hom}(\mathcal{C};\, D, B)$.

Let $\mathcal{C}(\mathbb{R}) := \mathcal{C} \otimes \mathrm{CP}(\mathbb{C}, \mathrm{C}_0(\mathbb{R}))$. By Corollary 5.9.23 and Corollary 8.3.3 there are natural isomorphisms

$$\mathrm{Ext}(\mathcal{C}(\mathbb{R});\, D, SB) \cong G(H_0;\, D, E_{\mathbb{R}})\,,$$

and

$$\mathrm{Ext}(\mathcal{C}(\mathbb{R});\, D, SB) \cong \mathrm{KK}(\mathcal{C};\, D, B)$$

that sends $[H_0]$ to zero and the mapping cones $C_h \in \mathrm{SExt}(\mathcal{C}(\mathbb{R});\, A, SB)$ (corresponding to the Busby invariant $[I_1 \circ h] \in S(H_0;\, D, E_{\mathbb{R}})$) of a morphism $h \in \mathrm{Hom}(\mathcal{C};\, D, B) = \mathrm{Hom}(D, B) \cap \mathcal{C}$ to the difference construction $[h-0] = [(B, h, 0)] \in \mathrm{KK}(\mathcal{C};\, D, B)$.

If we combine this isomorphism with the isomorphism $[h] \mapsto [h] \oplus [H_0]$ from $\mathrm{R}(\mathcal{C};\, D, B) \cong G(h_0;\, D, \mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B)))$ onto $G(H_0;\, D, E_{\mathbb{R}}) \cong \mathrm{Ext}(\mathcal{C}(\mathbb{R});\, D, SB)$, then we get an *epimorphism* α from the Abelian semigroup $[\mathrm{Hom}(\mathcal{C};\, D, B)] \subseteq [\mathrm{Hom}(D, B)]$ of unitary equivalence classes [h] of morphisms $h \in \mathrm{Hom}(\mathcal{C};\, D, B)$ *onto* $\mathrm{KK}(\mathcal{C};\, D, B)$.

The construction of α shows (by inspection of the values of the composed maps) that $\alpha([h]) = [(B, h, 0)] =: [h - 0] \in \mathrm{KK}(\mathcal{C};\, D, B)$. Since the last two morphisms of the compositions

$$[\mathrm{Hom}(\mathcal{C};\, D, B)] \to \mathrm{R}(\mathcal{C};\, D, B) \to \mathrm{Ext}(\mathcal{C}(\mathbb{R});\, D, B) \to \mathrm{KK}(\mathcal{C};\, D, B)$$

are isomorphisms, we get that $[h_1 - 0] = [h_2 - 0]$ in $\mathrm{KK}(\mathcal{C};\, D, B)$ if and only if h_1 and h_1 have the same class in $G(h_0;\, D, \mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B)))$. The latter means that $h_1 \oplus h_0$ and $h_2 \oplus h_0$ are unitarily homotopic. □

3. Unsuspended stable E-theory versus Ext-groups

We consider the case where A is separable and stable, i.e., that $D := A \otimes \mathbb{K} \cong A$, that B is σ-unital and stable and that $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ is a countably generated point-norm closed m.o.c. cone. Moreover, we assume that $\mathcal{C}$ is "faithful" and "non-degenerate" in the sense that if $a \in A_+$ $V(a) = 0$ for all $V \in \mathcal{C}$ implies $a = 0$, and that $\{V(a)\,;\ V \in \mathcal{C}, a \in A\}$ generates B as a closed two sided ideal.

[With other words: There does not exist closed ideals $I \neq \{0\}$ of A or $J \neq B$ of B such that $V(I) = \{0\}$ or $V(A) \subseteq J$ for all $V \in \mathcal{C}$. We exclude this, because otherwise we can in the below considerations A replace by A/I and B by J.]

Recall that in case where A is amenable and B is separable, the m.o.c. cone $\mathcal{C}$ is the same as the m.o.c. cone of all $\Psi_{\mathcal{C}}$-equivariant nuclear c.p.-maps from A to B, where $\Psi_{\mathcal{C}}$ is the lower semi-continuous action of $\mathrm{Prim}(B)$ on A defined by $\mathcal{C}$.

Respectively, $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ is the m.o.c. cone of all Ψ-equivariant c.p.-maps for a given non-degenerate action $\Psi\colon \mathbb{O}(\mathrm{Prim}(B)) \to \mathcal{I}(A)$ of $\mathrm{Prim}(B)$ on A that is lower semi-continuous.

More specially we can take – in the situation where A is exact and the action Ψ is lower s.c. and monotone upper s.c. – the m.o.c. cone $\mathcal{C} \subseteq \mathrm{CP}_{\mathrm{nuc}}(A, B)$ of all

Ψ-equivariant nuclear c.p.-maps $V \colon A \to B$. The exactness of A yields that those V are automatically Ψ-residual nuclear.

This equivalences show that working with an m.o.c. cone $\mathcal{C}$ covers all possible cases of "ideal-equivariant" KK- and Ext-groups.

What is optimal notation?
h, H, H_0 or H_0? Mostly used?
Unify all notation?
What about $h_0 \colon A \to B$ if $\mathcal{C} := \mathcal{C}(h_0)$?

Recall that there is a universal non-degenerate *-monomorphism $H \colon A \to \mathcal{M}(B)$ in "general position", i.e., H is unitarily equivalent to its infinite repeat, that is in 1-1-correspondence to $\mathcal{C}$, cf. Chapters 3 and 5 Precise Refs ?? in Chapters 3 and 5.

Let $H_1 := \pi_B \circ H \colon\ A \to \mathrm{Q}(B) := \mathcal{M}(B)/B$.

Basic observations:

Let A, B, $\mathcal{C}$, $H \colon A \to \mathcal{M}(B)$, $H_1 := \pi_B \circ H$, as above.

Partly obvious generalizations of work of G. Kasparov, Connes/Higson and J. Cuntz proves homotopy invariance of $\mathrm{KK}(\mathcal{C};\, A, \cdot)$, that

$$\mathrm{KK}(\mathcal{C}_{(1)}\,;\, A, B_{(1)}) \cong \mathrm{Ext}(\mathcal{C}\,;\, A, B)$$

and that

$$\mathrm{KK}(\mathcal{C};\, A, B) = \mathrm{Ext}(\mathcal{C};\, A, SB)\,.$$

Moreover, if the m.o.c. cone $\mathcal{C} \subset \mathrm{CP}(A, B)$ is countably generated and non-degenerate, this results allow to give the following "reduction" to a description by "ordinary" K_*-theory (using also a result of Cuntz and Higson):

(1)

$$\mathrm{KK}\big(\mathcal{C}(-\infty, 1]\,;\ A, \mathrm{C}_0((-\infty, 1], B)\big) = 0\,.$$

(2)

$$\mathrm{KK}(\mathcal{C};\, A, B) \ \cong\ \ \text{kernel of}\ \ \mathrm{K}_1(H_1(A)' \cap \mathrm{Q}^s(B)) \to \mathrm{K}_1(\mathrm{Q}^s(B)) = \mathrm{K}_0(B)\,.$$

(3) $\mathrm{Q}^s(B)$ is K_1-bijective.

(4) Homotopy invariance of KK: Each evaluation map

$$B[0,1] = \mathrm{C}([0,1], B) \ni f \mapsto f(t) \in B$$

defines the same natural isomorphism

$$\mathrm{KK}(\mathcal{C}[0,1]\ \ A, B[0,1]) \cong \mathrm{KK}(\mathcal{C}\,;\ A, B)\,.$$

(5) In particular, with $CB := \mathrm{C}_0((0,1], B)$,

$$\mathrm{KK}(\mathcal{C}(0,1];\, A, CB) = 0\,.$$

We need the following natural isomorphisms and descriptions of $\mathrm{KK}(\mathcal{C}\,;\, A, B)$ and and of representatives of its zero elements:

PROPOSITION 9.3.1. *Suppose that A is separable and stable, B is σ-unital and stable, and if the m.o.c. cone $\mathcal{C} \subseteq \mathrm{CP}(A,B)$ is non-degenerate and countably generated, and let then*

$$\mathrm{KK}(\mathcal{C}\,;\,A,B) \;\cong\; \textit{kernel of}\;\; \mathrm{K}_1(H(A)' \cap \mathrm{Q}(B)) \to \mathrm{K}_1(\mathrm{Q}(B))\,,$$

and

$$\mathrm{Ext}(\mathcal{C}\,;\,A,B) \;\cong\; \textit{kernel of}\;\; \mathrm{K}_0(H(A)' \cap \mathrm{Q}(B)) \to \mathrm{K}_0(\mathrm{Q}(B))\,.$$

(i) *The kernel of $\mathrm{K}_1(H_1(A)' \cap \mathrm{Q}(B)) \to \mathrm{K}_1(\mathrm{Q}(B))$ is the image of the map*

$$u \mapsto [\pi_B(u)] \in \mathrm{K}_1(H_1(A)' \cap \mathrm{Q}(B))$$

where $u \in \mathcal{M}(B)$ is in the group of those unitary elements of $\mathcal{M}(B)$ that satisfy $uh(a) - h(a)u \in B$ for all $a \in A$.

(ii) *The defining equivalence relation $u_1 \sim u_2$ – given by $[\pi_B(u_1)] = [\pi_B(u_2)]$ in $\mathrm{K}_1(H(A)' \cap \mathrm{Q}(B))$ – can be equivalently expressed by the property that there exist $T_k \in \mathcal{M}(B)$ $(k = 1, \ldots, n)$ with $T_k^* = -T_k$ and $T_k h(a) - h(a)T_k \in B$, for $a \in A$, $k \in \{1, \ldots, n\}$, such that*

$$(u_1^* u_2) \oplus_{s,t} 1 = \exp(iT_1) \cdot \ldots \cdot \exp(iT_n)\,.$$

Here $s, t \in h(A)' \cap \mathcal{M}(B)$ are isometries with $ss^* + tt^* = 1$.

THIS formulation of Parts (i) and (ii) use the K_1-bijectivity of $\mathrm{Q}^s(B)$ for stable σ-unital B.
See Parts (c) and (iii) of Proposition 4.2.15.
It implies that all unitaries $v \in \mathrm{Q}^s(B)$ with $[v] = 0$ in $\mathrm{K}_1(\mathrm{Q}^s(B))$ are products of exponentials. Thus, there is a unitary $u \in \mathcal{M}(B)$ with $\pi(u) = v$ if and only if $[v] = 0$ in $\mathrm{K}_1(\mathrm{Q}^s(B))$.

PROOF. The formulas for $\mathrm{KK}(\mathcal{C}\,;\,A,B)$ and $\mathrm{Ext}(\mathcal{C}\,;\,A,B)$ have been mentioned/proven somewhere above!

(i): The unit 1 of the C^*-algebra $H_1(A)' \cap \mathrm{Q}(B)$ is properly infinite.

Thus, each element z of $\mathrm{K}_1(H_1(A)' \cap \mathrm{Q}(B))$ has a representative $[v] = z$ by a unitary in $v \in H(A)' \cap \mathrm{Q}(B)$. and $v \oplus 1$ defines the same class in $\mathrm{K}_1(H(A)' \cap \mathrm{Q}(B))$ as v.

If $v = \pi_B(u) \in H(A)' \cap \mathrm{Q}(B)$ for some unitary in $u \in \mathcal{M}(B)$ then $[v] = 0$ in $\mathrm{K}_1(\mathrm{Q}(B))$ because $\mathrm{K}_1(\mathcal{M}(B)) = 0$ by stability of B. Clearly, $[u, h(a)] \in B$ for all $a \in A$ if and only if $\pi_B(u) \in H(A)' \cap \mathrm{Q}(B)$.

Conversely, if v is unitary in $\mathrm{Q}(B)$ and $[v] = 0$ in $\mathrm{K}_1(\mathrm{Q}(B))$, then $v \oplus 1 \in \mathcal{U}_0(\mathrm{Q}(B))$.

If $[u \oplus 1] = 0$ in $\mathrm{K}_1(\mathrm{Q}(B))$, then $u \oplus 1$ is a product of exponentials $\exp(X_1) \cdot \ldots \cdot \exp(X_m)$ with $X_\ell^* = -X_\ell$ and $X_\ell \in \mathrm{Q}(B)$, cf. Lemma 4.2.6(v,2). And this implies that there exists a unitary $u \in \mathcal{M}(B)$ with $\pi_B(u) = v \oplus 1$.

(ii): If $[u] = 0$ in $\mathrm{K}_1(H(A)' \cap \mathrm{Q}(B))$, then – moreover – there exists $Y_1, \ldots, Y_n \in H(A)' \cap \mathrm{Q}(B)$ with $Y_k^* = -Y_k$ such that $u \oplus 1 = \exp(Y_1) \cdot \ldots \cdot \exp(Y_n)$. See Lemma 4.2.6(v,2).

Given any finite subset M of A and $\varepsilon > 0$ then there exist $T_k \in \mathcal{M}(B)$ ($k = 1, \ldots, n$) with $\pi_B(T_k) = Y_k$ and $T_k^* = -T_k$ and $[T_k, h(a)] \in B$ for all $a \in A$ and $\|[T_k, h(a)]\| < \varepsilon$ for all $a \in M$. The latter property can be obtained by lifting the Y_k to $S_k \in \mathcal{M}(B)$ with $S_k^* = -S_k$ and $\pi_B(S_k) = Y_k$ and then one defines $T_k := (1-e)S_k(1-e)$ for a suitable positive contraction $e \in B_+$ in a approximate unit of B that is quasi-central for $h(A) \subseteq \mathcal{M}(B)$. □

The following conjecture

CONJECTURE 9.3.2. *The "logarithmic length" of the unitary* $\pi_{CB}((u_1^* u_2) \oplus_{s,t} 1)$ *with unitaries of* $u_1, u_2 \in \mathcal{M}(CB)$ *such that* $[u_1, h(a)] - [u_2, h(a)] \in CB$ *is bounded by a universal constant, where above considered* B *is replaced here by* $CB := \mathrm{C}_0\big((-\infty, 1], B\big)$.

One can correct this by passing to $u_k \oplus 1$ ($k = 1, 2$) in $\mathcal{U}(\pi_B^{-1}(H(A)' \cap \mathrm{Q}(B)))$.

This is possible, because A is separable and stable, B is σ-unital and stable, and $h \approx_u \delta_\infty h$ for $h \colon A \to \mathcal{M}(B)$ with $H = \pi_B \circ h$, the map

$$u \oplus 1 \mapsto \pi_B(u \oplus 1) \in \mathcal{U}(H(A)' \cap \mathrm{Q}(B)) \to \mathrm{K}_1$$

is surjective map onto the kernel of

$$\mathrm{K}_1(H(A)' \cap \mathrm{Q}(B)) \to \mathrm{K}_1(\mathrm{Q}(B))\,.$$

LEMMA 9.3.3. *An unitary* $u \in \mathcal{M}(B)$ *represents the zero element of* $\mathrm{KK}(\mathcal{C}\,; A, B)$*, if and only if,* $\pi_B(u)$ *represents the zero of* $\mathrm{K}_1(H(A)' \cap \mathrm{Q}(B))$*, if and only if, there exist elements* $T_1, \ldots, T_n \in \mathcal{M}(B)$ *such that* $T_j^* = -T_j$*,*

$$\exp(T_1) \cdot \ldots \cdot \exp(T_n) - (u \oplus 1) \in B$$

and $T_k h(a) - h(a) T_k \in B$ *for all* $a \in A$ *and* $k = 1, \ldots, n$.

Given $\varepsilon > 0$ *and a finite subset* $M \subset A$*, then the* T_k *in this relations can be chosen such that moreover* $\|T_k h(a) - h(a) T_k\| < \varepsilon$ *for* $a \in M$.

Here is the same problem with the possibly missing K_1-injectivity of $H(A)' \cap \mathrm{Q}(B)$ if one hopes to replace $u \oplus 1$ by u itself in this relations.

Is $H(A)' \cap \mathrm{Q}(B)$ K_1-injective if A or B is $\mathcal{O}_\infty$-absorbing?

Is it equivalent to the question about K_1-injectivity of all properly infinite unital E?

The answer is positive if B is s.p.i. and H is nuclear.

Let $B[0,1] := \mathrm{C}([0,1], B) \cong B \otimes \mathrm{C}([0,1])$. Define $\mathcal{C}[0,1] \subseteq \mathrm{CP}(A, B[0,1])$ as the set of c.p. maps $V \colon A \to B[0,1]$ with $V(\cdot)(t) \in \mathcal{C}$ for each $t \in [0,1]$. The corresponding realization of $\mathcal{C}[0,1]$ is induced by the natural embedding $\eta\colon b \mapsto b \otimes 1 \in B[0,1]$ of B into $B[0,1]$ in the sense that $\mathcal{M}(\eta) \circ h\colon A \to \mathcal{M}(B[0,1])$ is the corresponding universal *-monomorphism from A into $\mathcal{M}(B[0,1])$ that defines $\mathcal{C}[0,1]$.

Thus, the kernel of

$$\mathrm{K}_1((\pi_{B[0,1]} \circ \mathcal{M}(\eta) \circ h)(A)' \cap Q(B[0,1])) \to \mathrm{K}_1(Q(B[0,1]))$$

is naturally isomorphic to $\mathrm{KK}(\mathcal{C}[0,1]\,;\, A, B[0,1])$.

A natural generalization of Kasparov's result of homotopy invariance of KK- and Ext-groups is the following:
For (given fixed) $t \in [0,1]$, the evaluation map $f \in B[0,1] \mapsto f(t) \in B$ defines a natural *isomorphism* from $\mathrm{KK}(\mathcal{C}[0,1]\,;\, A, B[0,1])$ onto $\mathrm{KK}(\mathcal{C}\,;\, A, B)$. ("Homotopy invariance" of $\mathrm{KK}(\mathcal{C}\,;\, A, B)$.)

On the set of "representing" unitaries $u \in \mathcal{M}(B)$, respectively of $\{u(t)\} = U \in \mathcal{M}(B[0,1])$ (with $t \mapsto u(t) \in \mathcal{M}(B)$ strictly continuous), this isomorphism corresponds to the evaluation map $U = \{u(t)\} \mapsto u(t) \in \mathcal{M}(B)$.

Consequently:

Corollary 9.3.4. *Suppose that A and B are stable, A separable and B σ-unital, $\mathcal{C} \subseteq \mathrm{CP}(A,B)$ a countably generated non-degenerate m.o.c. cone.*

Let $a_0 \in A$ such that $A = C^*(a_0)$ and let $h\colon A \to \mathcal{M}(B)$ a non-degenerate C^*-monomorphism that is unitary homotopic to is infinite repeat $\delta_\infty \circ h$, satisfies $V_b := \langle h(\cdot)b, b\rangle \in \mathcal{C}$ for all $b \in B$ and that $\mathcal{C}$ is generated by $\{V_b\,;\; b \in B\}$.

Let $B[0,1] := \mathrm{C}([0,1], B)$ and $\eta\colon \mathcal{M}(B) \to \mathrm{C}_{\mathrm{b,st}}([0,1], \mathcal{M}(B)) \cong \mathcal{M}(B[0,1])$ the natural embedding.

If $U \in \mathcal{M}(B[0,1])$ is a representing unitary for an element of

$$\mathrm{KK}(\mathcal{C}[0,1]\,;\, A, B[0,1])\,,$$

i.e., and if $U(0) \oplus 1$ can be written modulo B as finite product of $\exp(T_k)$, $k = 1, \ldots, n$, with $-T_k^* = T_k \in \mathcal{M}(B[0,1])$ and $T_k h(a) - h(a)T_k \in B[0,1]$ for $a \in A$, $k = 1, \ldots, n$, then $U \oplus 1$ can be written modulo $B[0,1]$ as a finite product of $\exp(S_\ell)$, $\ell = 1, \ldots, m$, $-S_\ell^* = S_\ell \in \mathcal{M}(B[0,1])$ and $S_\ell(\mathcal{M}(\eta) \circ h)(a) - (\mathcal{M}(\eta) \circ h)(a) S_\ell \in B[0,1]$ for $a \in A$, i.e.,

$$-S_\ell^* = S_\ell \in \mathrm{Der}(\mathcal{M}(\eta)(h(A)), B[0,1]) \subseteq \mathcal{M}(B[0,1])$$

and `Commutator norms ????`

??????????????????????????

Here $\mathcal{M}(\eta)\colon \mathcal{M}(B) \to \mathcal{M}(B[0,1])$ is the natural inclusion map.

Proof. `To be filled in` ?? ?? □

COROLLARY 9.3.5. *Let* A, B, $\mathcal{C} \subseteq \mathrm{CP}(A,B)$ *and* $h\colon A \to \mathcal{M}(B)$ *as above,* $\mathcal{M}(\eta)\colon \mathcal{M}(B) \to \mathrm{C}_{\mathrm{b,st}}((-\infty,1],\mathcal{M}(B)) \cong \mathcal{M}(\mathrm{C}_0((-\infty,1],B))$ *the natural monomorphism.*

Let $u \in \mathcal{M}(\mathrm{C}_0((-\infty,1],B))$ *a unitary given by the strictly continuous map* $(-\infty,1] \ni t \mapsto u(t) \in \mathcal{U}(\mathcal{M}(B))$ *from* $(-\infty,1]$ *into the unitaries in* $\mathcal{M}(B)$.

Suppose that $[u(t),h(a)] \in B$ *for all* $a \in A$ *and* $t \in (-\infty,1]$ *and that* $t \mapsto [u(t),h(a)]$ *is continuous, and*

$$\lim_{t\to-\infty} \|[u(t),h(a)]\| = 0 \quad \forall\, a \in A\,,$$

i.e., $[u,h(A)] \subseteq \mathrm{C}_0((-\infty,1],B)$.

Then there exist $S_1,\ldots,S_n \in \mathcal{M}(\mathrm{C}_0((-\infty,1],B))$ *with* $S_k^* = -S_k$, $[s_k,h(a)] \in B$ *for all* $a \in A$ *and*

$$U = \exp(S_1)\cdot\ldots\cdot\exp(S_n)\cdot W$$

for some $W \in \mathcal{U}(\mathrm{C}_0((-\infty,1],B)+\mathbb{C}\cdot 1)$ *with* $1 - W \in \mathrm{C}_0((-\infty,1],B)$.

Such W *is a product of exponentials* $W = \exp(T_1)\cdot\ldots\cdot\exp(T_\ell)$ *with* $T_j = -T_j^* \in \mathrm{C}_0((-\infty,1],B)$.

In particular, $W(t) \in \mathcal{U}_0(B+\mathbb{C}\cdot 1)\cap(1+B)$ *for each* $t \in (-\infty,1]$.

QUESTION 9.3.6. Suppose that $T_1,\ldots,T_m \in \mathrm{Der}(h(A),B) \subseteq \mathcal{M}(B)$ and

$$S_1,\ldots,S_n \in \mathrm{Der}(h(A),B[0,1]) \subseteq \mathcal{M}(B[0,1])$$

with $T_j^* = -T_j$, $S_k^* = -S_k$, $V_1,V_2 \in U_0(B+\mathbb{C}\cdot 1)\cap(1+B)$ and $a \in A$ are given with

$$\exp(T_m)\cdot\ldots\cdot\exp(T_1)V_1 = W(0)V_2\,,$$

for $W(t) := \exp(S_1(t))\cdot\ldots\cdot\exp(S_n(t))$.

Does there exist for each $\gamma > 0$ and $\varepsilon \in (0,\gamma)$ a unitary

$$U \in \mathcal{U}_0(B[0,1]+\mathbb{C}\cdot 1)\cap(1+B[0,1])$$

with $U(0) = 1$,

$$\|[W(t)V_2U(t),h(a)]\| \le \gamma + \|[W(0)V_2,h(a)]\|$$

for $t \in [0,1]$ and

$$\|[W(1)V_2U(1),h(a)]\| \le \varepsilon \quad ?$$

LEMMA 9.3.7. *Suppose that* M *is a* C^**-algebra,* $B \subseteq M$ *a closed ideal,* $X = \{a_1,\ldots,a_n\} \subseteq M$ *a finite subset, and let*

$$\nu(a;\, S_1,\ldots,S_n) := \exp(S_1)\cdot\ldots\cdot\exp(S_n)a - a\exp(S_1)\cdot\ldots\cdot\exp(S_n)$$

for $a, S_1,\ldots,S_n \in M$, *with* $S_k = -S_k^*$.

Suppose that $T_1,\ldots,T_n \in M$ *satisfy* $T_k = -T_k^*$ *and* $T_ka - aT_k \in B$ *for all* $a \in X$ *and* $k = 1,\ldots,n$.

Then for each $\varepsilon > 0$ there exists a positive contraction $b = b(\varepsilon) \in B_+$ such that

$$\big\| \nu\big(a;\, (1-b)T_1(1-b), \dots, (1-b)T_n(1-b)\big)\big\| \leq \varepsilon \quad \forall\, a \in X\,.$$

`But the QUESTION is ???:`
`Let` $B := \mathrm{C}([0,1], C)$, `with` C σ`-unital and stable,`
$T_1, \dots, T_n \in \mathcal{M}(B)$ `self-adjoint contractions`
`with` $T_k h(a) - h(a)T_k \in B$ `for all` $a \in A$ `and` $k = 1, \dots, n$`, and, in addition,`

$$\exp(T_1(0)) \cdot \ldots \cdot \exp(T_n(0)) = 1\,.$$

`Can we find the` $b \in B_+$ `in this case such that` $b = \{c(t)\}$ `satisfies`
`in addition the following inequality ?`

$$\|1 - \exp\big(i(1-c(0))T_1(0)(1-c(0))\big) \cdot \ldots \cdot \exp\big(i(1-c(0))T_1(0)(1-c(0))\big)\| < \varepsilon\,.$$

Proof. Without loss of generality, one can suppose that M is separable and $a \neq 0$, because we can replace M and B in the proof by by $C^*(X \cup \{T_1, \dots, T_n\})$ and B by $B \cap C^*(X \cup \{T_1, \dots, T_n\})$. Then B contains a strictly positive contraction $e \in B_+$. If we define by functional calculus elements $f(e) \in B_+$ with $f \in \mathrm{C}[0,1]_+$, $\|f\| \leq 1$ and $f([0,\delta]) = 0$ for some $\delta \in (0,1)$, then we can select from this family of positive contractions a commutative approximate unit $e_1, e_2, \dots$ of B that is an approximately central sequence for M and satisfies $e_{m+1}e_m = e_m$. It implies $(1-e_m)(1-e_{m+k})^\ell = (1-e_{m+k})^\ell$ for $k, \ell \geq 1$.

Given $\varepsilon > 0$ we let $\gamma := \max(\|T_1\|, \dots, \|T_n\|)$ and

$$\delta := \varepsilon / n(1+2\gamma) \cdot \exp(\gamma)\,.$$

Since $[a, T_k] := aT_k - T_k a \in B$ for $a \in X$, and since (e_m) is an approximate unit of B that is approximately central for the elements of M, there exists $m_0 \in \mathbb{N}$ with $\|e_m a - a e_m\| < \delta$ and $\|[a, T_k](1-e_m)\| < \delta$ for all $m \geq m_0$ and $a \in X$.

Recall that $[a, x] := ax - xa$ satisfies the Leibnitz rule $[a, xy] = [a, x]y + x[a, y]$.

We obtain with this rule that

$$\|[a, (1-e_m)T_k(1-e_m)]\| \leq \|[a, T_k](1-e_m)\| + 2\|[a, e_m]\|\|T_k\| < \delta \cdot (1 + 2\|T_k\|)\,.$$

It follows that

$$\|[a, x_1 \cdot \ldots \cdot x_n]\| \leq \gamma^{n-1}(\|[a, x_1]\| + \ldots + \|a, x_n\|)$$

for $\gamma = \max\{\|x_1\|, \dots, \|x_n\|\}$, and, for self-adjoint $S, S_1, \dots, S_n \in M_{s.a.}$ that

$$\big\|\nu(a;\, S_1, \dots, S_n)\big\| \leq \sum_{k=1}^{n} \|[a, \exp(iS_k)]\|\,.$$

Moreover, $\|[a, \exp(iS)]\| \leq \|[a, S]\| \cdot (\exp \|S\|)$.

With $\gamma := \max\{\|S_1\|, \ldots, \|S_n\|\}$ and $S_k \in M_{s.a.}$, we get

$$\big\|\nu(a;\, S_1, \ldots, S_n)\big\| \leq \exp(\gamma) \cdot \sum_{k=1}^{n} \|[a, S_k]\| \,.$$

If $T_k \in M_{s.a.}$ with $T_k a - aT_k \in B$ for all $a \in X$ then we can find $m_0 \in \mathbb{N}$ such that $\|[a, (1-e_m)T_k(1-e_m)]\| < \delta \cdot (1+2\gamma)$ for all $m \geq m_0$. Thus, for $m \geq m_0$,

$$\big\|\nu(a;\, (1-e_m)T_1(1-e_m), \ldots, (1-e_m)T_n(1-e_m))\big\| < n\delta \cdot (1+2\gamma) \cdot \exp(\gamma) = \varepsilon \,.$$

□

We denote by $\xi\colon \mathcal{M}(B) \to \mathcal{M}(\mathrm{C}_0(\mathbb{R}, B))$ the natural unital embedding given by the strictly continuous extension of

$$B \ni b \to 1 \otimes b \in \mathrm{C_b}(\mathbb{R}, B) \subseteq \mathcal{M}(\mathrm{C}_0(\mathbb{R}, B)) \,.$$

The next proposition is the base for the final proof the injectivity of

$$\mathrm{R}(\mathcal{C};\, A, B) = G(h_0, A, E) \to G(H_0, A, E) = \mathrm{KK}(\mathcal{C};\, A, B) \,.$$

Proposition 9.3.8. *Suppose that A and B are stable C^*-algebra, A is separable and B is σ-unital, and let $h\colon A \to \mathcal{M}(B)$ a non-degenerate C^*-morphism such that $\delta_\infty \circ h$ is unitary equivalent to h. Denote by $\xi\colon \mathcal{M}(B) \hookrightarrow \mathrm{C_{b,st}}(\mathbb{R}, \mathcal{M}(B))$ the natural inclusion.*

If $U \in \mathcal{M}(\mathrm{C}_0(\mathbb{R}, B)) \cong \mathrm{C_{b,st}}(\mathbb{R}, \mathcal{M}(B))$ a unitary such that, for all $t \in \mathbb{R}$,

$$U(t)h(a) - h(a)U(t) \in B$$

and

$$\lim_{t\to-\infty} \|U(t)h(a) - h(a)U(t)\| = 0$$

for each $a \in A$, i.e.,

$$U \cdot (\xi \circ h)(a) - (\xi \circ h)(a) \cdot U \in J_{-\infty}$$

for $J_{-\infty} := \{c \in \mathrm{C_b}(\mathbb{R}, B)\,;\ \lim_{t\to-\infty} c(t) = 0\,\}$.

Then there exist unitaries $V, W \in \mathcal{M}(\mathrm{C}_0(\mathbb{R}, B))$ such that $U \oplus 1 = VW$,

$$W(\xi \circ h)(a) - (\xi \circ h)(a)W \in \mathrm{C}_0(\mathbb{R}, B) \quad \forall\, a \in A \,,$$

$V \in 1 + \mathrm{C_b}(\mathbb{R}, B)$ and $V(t) = 1$ for $t \leq -1$.

Proof. Let $a_0 \in A$ a contraction that generates A as C^*-algebra.

First we define $W_0 \in \mathcal{M}(SB)$ by $W_0(t) := W(t)$ for $t \leq 0$ and $W_0(t) := W(-t)$ for $t > 0$. Then $W_0(t)h(a) - h(a)W_0(t) \in B$ for each $t \in \mathbb{R}$ and $a \in A$ and $U_0(t) := W_0(t)^*U(t)$ satisfies $U_0(t) = 1$ for $t \leq 0$ and $[U_0(t), h(a)] \in B$ for all $t \geq 0$.

It follows that, for each (positive) $n \in \mathbb{N}$, there exists a decomposition of $U_n := U_0|(-\infty, 2n]$ of the form $U_n = V_n \cdot W_n$ where $W_n := \exp(T_{n,1}) \cdot \ldots \cdot \exp(T_{n,k_n})$ with $-T_{n,\ell}^* = T_{n,\ell} \in \mathcal{M}(\mathrm{C}_0(-\infty, 2n])$ $[T_{n,\ell}(t), h(a)] \in B$, $V_n(t) \in B+1$, $\lim_{t\to-1} V_n(t) = 1$, $\|[T_{n,\ell}(t), h(a_0)]\| < 4^{-n}$

Connect then by going back to -1 by both decompositions for U_n and U_{n+1} and by shifting and rescaling the "mirrors" at -1.

It gives a path in $[2n, 2n+2]$ of elements in $\mathcal{U}(B + \mathbb{C} \cdot 1)$ that corrects W_n on $[2n, 2n+1]$ in controlled way.

□

We could use the above mentioned results on intervals $[n, n+1]$ (instead of $[0,1]$) for a proof if we can find at the end-points a "fitting-together" procedure for the above described approximate decomposition. Or if we can find similar approximate decompositions with help of approximately central units in the ideal $\mathrm{C_b}([n,\infty), B)$ of $\mathcal{M}(\mathrm{C_0}([n,\infty), B))$. (But suitable combined).

It has to do with the question if unsuspended m.o.c. cone-related E-theory for strongly purely infinite separable C^*-algebras is homotopy-invariant, i.e., if for the Rørdam groups $\mathrm{R}(\mathcal{C};\, A, B)$ two asymptotic homomorphisms $h(0), h(1) \colon A \to \mathrm{Q}(\mathbb{R}_+, B)$ are asymptotically stably unitary equivalent in $\mathrm{C_b}(\mathbb{R}_+, \mathcal{M}(B))/\,\mathrm{C_0}(\mathbb{R}_+, B)$ if they are homotopic, i.e., are boundaries of $h \colon A \to \mathrm{Q}(\mathbb{R}_+, \mathrm{C}([0,1], B)$ with $[h] \in \mathrm{R}(\mathcal{C};\, A, B[0,1])$. One can directly prove this kind of homotopy invariance for the Rørdam groups $\mathrm{R}(\mathcal{C};\, A, B)$.

We discuss now the natural relation of this homotopy invariance and the decomposition condition (DC) of Theorem 4.4.6.

Suppose that A and B are stable, A is separable and B is σ-unital. Let $h_0 \colon A \to B$ a non-degenerate *-monomorphism such that h_0 extends to a *-monomorphism $k_0 \colon A \otimes \mathcal{O}_2 \to B$ with $h_0 = k_0((\cdot) \otimes 1)$.

Let $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ the corresponding m.o.c. cone. $H := \delta_\infty \circ h_0 \colon A \to \mathcal{M}(B)$ denote the infinite repeat of h_0. Consider $\mathcal{M}(B)$ naturally as a unital C^*-subalgebra of constant elements of $\mathcal{M}(\mathrm{C_0}(\mathbb{R}, B)) \cong \mathrm{C_{b,st}}(\mathbb{R}, \mathcal{M}(B))$. Let consider also $\mathrm{C_b}(\mathbb{R}, B)$ as an ideal of $\mathcal{M}(\mathrm{C_0}(\mathbb{R}, B))$.

There exists a *-monomorphism $k_1 \colon \mathcal{O}_2 \otimes \mathbb{K} \to H(A)' \cap \mathcal{M}(B)$ such that $k_1(\mathcal{O}_2 \otimes \mathbb{K})B = B$, such that $H(a)k_1(c) \in B$ for all $a \in A$ and $c \in k_1(\mathcal{O}_2 \otimes \mathbb{K})$, and that $p_0 := k_1(1 \otimes p_{11})$ is a full in $\mathcal{M}(B)$ and $1 - p_0$ is a full and properly infinite projection in $H(A)' \cap \mathcal{M}(B)$. Since p_0 is properly infinite in $k_1(\mathcal{O}_2 \otimes \mathbb{K})$ with $[p_0] = 0 \in \mathrm{K_0}(k_1(\mathcal{O}_2 \otimes \mathbb{K}))$, there exists an isometry in $s_0 \in M(B)$ with $s_0 s_0^* = p_0$ and an isometry $t_0 \in H(A)' \cap \mathcal{M}(B)$ with $t_0 t_0^* = 1 - p_0$.

Let F denote the image of $\mathrm{C_b}(\mathbb{R}, \mathcal{O}_2 \otimes \mathbb{K}) \supset \mathcal{O}_2 \otimes \mathbb{K}$. We consider F naturally as a non-degenerate C^*-subalgebra of $\mathrm{C_{b,st}}(\mathbb{R}, \mathcal{M}(B)) \cong \mathcal{M}(\mathrm{C_0}(\mathbb{R}, B))$ using the *-monomorphism $f \mapsto \{k_1(f(t))\} \in \mathrm{C_{b,st}}(\mathbb{R}, \mathcal{M}(B))$. Then $p_0 \in F$, $1 - p_0 \in 1 + F$. It is easy to see that each non-zero projection $p \in F$ is equivalent to p_0 by a unitary $u \in 1 + F$, because this is true for $\mathrm{C}([0,1], \mathcal{O}_2 \otimes \mathbb{K})$ (in place of F).

Remarks 9.3.9. For each positive element $g \in \mathrm{C_b}(\mathbb{R}, B)$ there is a projection $p \in F$ with $g - pg \in \mathrm{C_0}(\mathbb{R}, B)$, $p \geq p_0$.

$F \subseteq H(A)' \cap \mathcal{M}(\mathrm{C_0}(\mathbb{R}, B))$.

If $V = \{V(t)\} \in \mathcal{M}(\mathrm{C}_0(\mathbb{R},B)) \cong \mathrm{C}_{\mathrm{b,st}}(\mathbb{R},\mathcal{M}(B))$ is a unitary with $\lim_{t\to-\infty}\|V(t)H(a) - H(a)V(t)\| = 0$ and $VH(a) - H(a)V \in \mathrm{C}_{\mathrm{b}}(\mathbb{R},B)$ for all $a \in A$ (i.e., $V(t)H(a) - H(a)V(t) \in B$ for all $t \in \mathbb{R}$ and $a \in A$). Then $W \in \mathcal{M}(\mathrm{C}_0(\mathbb{R},B))$ with $W(t) := V(t)^*$ for $t \leq 0$ and $W(t) := V(-t)^*$ for $t \geq 0$ is a unitary that satisfies $WH(a) - H(a)W \in \mathrm{C}_0(\mathbb{R},B)$ for all $a \in A$. If $U := VW$ then $U(t) = 1$ for $t \leq 0$ and $UH(a) - H(a)U \in \mathrm{C}_{\mathrm{b}}(\mathbb{R},B)$ for all $a \in A$.

Let $U \in \mathcal{M}(\mathrm{C}_0(\mathbb{R},B))$ a unitary with $U(t) = 1$ for $t \leq 1$ and $UH(a)-H(a)U \in \mathrm{C}_{\mathrm{b}}(\mathbb{R},B)$ for all $a \in A$. Define $U_e(t,s) := U(t - s^{-1} + 1)$ for $t \in \mathbb{R}$ and $s \in (0,1]$ and $U_e(t,0) := 1$ for all $t \in \mathbb{R}$. Then U_e is a unitary in

$$\mathcal{M}(\mathrm{C}_0(\mathbb{R}\times[0,1],B)) \cong \mathrm{C}_{\mathrm{b,st}}(\mathbb{R}\times[0,1],\mathcal{M}(B))$$

with $U_e(t,s) = 1$ if $t \leq 1$ and $U_eH(a) - H(a)U_e \in \mathrm{C}_{\mathrm{b}}(\mathbb{R}\times[0,1],B)$ for all $a \in A$.

Notice $\mathrm{C}_{\mathrm{b}}(\mathbb{R},\mathrm{C}([0,1],B)) \cong \mathrm{C}_{\mathrm{b}}(\mathbb{R}\times[0,1],B)$. Same for C_0 in place of C_{b}, and for $(\mathrm{C}_{\mathrm{b,st}},\mathcal{M}(\mathrm{C}([0,1],B)),\mathcal{M}(B))$ in place of $(\mathrm{C}_{\mathrm{b}},\mathrm{C}([0,1],B),B)$.

For each $s \in [0,1]$ define the unitary $U_s(t) := U_e(t,s)$. The U_s are unitaries in $\mathcal{M}(\mathrm{C}_0(\mathbb{R},B))$ that satisfy $U_0 = 1$ and $U_s(t) = 1$ for $t \leq s^{-1} - 1$ if $s \in (0,1]$. In particular, $U_s(t) = 1$ for all $t \leq 0$ and $s \in [0,1]$.

There exists a projection $p \in F$ such that

$$(1-p)(U_eH(a) - H(a)U_e) \in \mathrm{C}_0(\mathbb{R}\times[0,1],B) \quad \text{for all } a \in A\,.$$

Let $v \in 1 + F$ a unitary with $vpv^* = p_0$. Then

$$(1-p_0)(vU_sH(a) - H(a)vU_s) \in \mathrm{C}_0(\mathbb{R},B)$$

for all $a \in A$.

The projections $(1-p_0)$ and p_0 commute with $H(a)$ and commute modulo $\mathrm{C}_0(\mathbb{R},B)$ with $(vU_s)H(a)(vU_s)^*$ for each $a \in A$. We define for $s \in [0,1]$ the completely positive map $T_s\colon A \to \mathrm{C}_{\mathrm{b}}(\mathbb{R},B)$ by

$$T_s(a) := p_0(vU_s)H(a)(vU_s)^*p_0 \quad \text{for } a \in A$$

Then

$$T_s(a) - p_0(vU_s)H(a)(vU_s)^* \in \mathrm{C}_0(\mathbb{R},B)$$

and

$$T_s(a^*a) - T_s(a)^*T_s(a) \in \mathrm{C}_0(\mathbb{R},B)\,.$$

Recall that $T_s(a)(t) = p_0v(t)U(s,t)H(a)(v(t)U(s,t))^*p_0$ for $(t,s) \in (-\infty,\infty)\times[0,1]$. In particular, $T_0(a) = p_0H(a)$, because $U(0,t) = 1$ and $v(t)$ commutes with $H(a)$. For $t \in \mathbb{R}$ holds $T_1(a)(t) = p_0v(t)U(t)H(a)U(t)^*v(t)^*p_0$ where $U := \{U(t)\}$ is the above considered unitary $U \in \mathcal{M}(\mathrm{C}_0(\mathbb{R},B))$ with $U(t) = 1$ for $t \leq 0$.

The restriction to $(t,s) \in [0,\infty)\times[0,1]$ of T_s defines a homotopy in $\mathrm{SR}(\mathcal{C};\, A,B)$ from $T_0 = p_0H(\cdot)$ to $T_1(\cdot)|[0,\infty)$.

It holds $T_s(a)(t) = p_0H(a)$ for all $t \leq 0$ and $a \in A$, and $a \in A \mapsto T_s(a) \in \mathrm{C}_{\mathrm{b}}(\mathbb{R},B)$ is a c.p. contraction, with $T_s(a^*a) - T_s(a)^*T_s(a) \in \mathrm{C}_0(\mathbb{R},B)$ for $a \in A$.

PROOF. to be filled in ?? □

PROPOSITION 9.3.10. *Let* $U = \{U(t)\} \in \mathrm{C_{b,st}}(\mathbb{R}, B) = \mathcal{M}(\mathrm{C_0}(\mathbb{R}, B))$ *and* $v = \{v(t)\} \in 1 + F \in H(A)' \cap \mathcal{M}(\mathrm{C_0}(\mathbb{R}, B))$ *the above considered unitary operators.*

Then $(1-p_0)(vU)H(a)(vU)^* - (1-p_0)H(a) \in \mathrm{C_0}(\mathbb{R}, A)$, $p_0(vU)H(a)(vU)^*p_0 \in \mathrm{C_b}(\mathbb{R}, A)$ *and* $p_0(vU)H(a)(vU)^*(1-p_0) \in \mathrm{C_0}(\mathbb{R}, A)$ *for* $a \in A$.

Let $k(a) := s_0^* p_0(vU)H(a)(vU)^* p_0 s_0$ *and* $h_0(a) := s_0^* p_0 H(a) s_0$ *for* $a \in A$.

Suppose that there exists a unitary $V \in \mathrm{C_{b,st}}(\mathbb{R}, \mathcal{M}(B))$ *such that*

$$V^* h_0(a) V - k(a) \oplus_{s_0,t_0} h_0(a) \in \mathrm{C_0}(\mathbb{R}, B) \quad \textit{for all} \;\; a \in A\,.$$

Then $U = U_1 U_2$ *for suitable unitary operators* $U_1, U_2 \in \mathcal{M}(\mathrm{C_0}(\mathbb{R}, B))$ *with*

$$H(a)(U_1 - 1),\, U_2 H(a) - H(a) U_2 \;\in \mathrm{C_0}(\mathbb{R}, B) \quad \textit{for all} \;\; a \in A\,.$$

PROOF. We consider first the special case where the c.p. map $k\colon A \to \mathrm{C_b}(\mathbb{R}, B)$ given by

$$k(a)(t) := \; s_0^*(v(t)U(t))H(a)(v(t)U(t))^* s_0$$

is itself unitary equivalent modulo $\mathrm{C_0}(\mathbb{R}, B)$ to h_0, i.e., we suppose in this special case that there exists a unitary $W = \{W(t)\} \in \mathrm{C_{b,st}}(\mathbb{R}, \mathcal{M}(B))$ with

$$W^* h_0(a) W - k(a) \in \mathrm{C_0}(\mathbb{R}, B) \quad \text{for all} \;\; a \in A\,.$$

By definition of $k(\cdot)$ and Cuntz addition $\oplus_{s_0,t_0}$,

$$s_0 k(a) s_0^* + (1-p_0)H(a) = k(a) \oplus_{s_0,t_0} H(a)\,,$$

where t_0 is an isometry in $H(A)' \cap \mathcal{M}(\mathrm{C_0}(\mathbb{R}, B))$ with $t_0 t_0^* = 1 - p_0$, and

$$s_0 k(a) s_0^* = p_0(vU)H(a)(vU)^* p_0\,.$$

Since $(1-p_0)H(a) - (1-p_0)(vU)H(a)(vU)^* \in \mathrm{C_0}(\mathbb{R}, B)$ and

$$p_0 vUH(a)(vU)^* - p_0(vU)H(a)(vU)^* p_0 \in \mathrm{C_0}(\mathbb{R}, B)\,,$$

we get that

$$\big(k(a) \oplus_{s_0,t_0} H(a)\big) - (vU)H(a)(vU)^* \in \mathrm{C_0}(\mathbb{R}, B) \quad \text{for all} \;\; a \in A\,.$$

Let $V_1 := s_0 W s_0^* + (1-p_0)$. Then

$$V_1^*(h_0(a) \oplus_{s_0,t_0} H(a))V_1 - (k(a) \oplus_{s_0,t_0} H(a)) \in \mathrm{C_0}(\mathbb{R}, B) \quad \text{for all} \;\; a \in A\,.$$

Since $h_0(a) \oplus_{s_0,t_0} H(a) = H(a)$ for all $a \in A$, it follows that $V_1^* H(a) V_1 - (vU)H(a)(vU)^* \in \mathrm{C_0}(\mathbb{R}, B)$ for all $a \in A$. Thus, $V_2 := V_1 vU$ commutes with $H(a)$ modulo $\mathrm{C_0}(\mathbb{R}, B)$ for $a \in A$. Notice $U = U_1 U_2$ with $U_1 := v^* V_1^* v$ and $U_2 := v^* V_2$. Since $v \in 1 + F \subseteq H(A)' \cap \mathcal{M}(\mathrm{C_0}(\mathbb{R}, B))$ we get that U_2 satisfies $U_2 H(a) - H(a) U_2 \in \mathrm{C_0}(\mathbb{R}, B)$. The operator $V_1 - 1 = s_0 W s_0 - p_0$ is contained in $p_0 \mathcal{M}(\mathrm{C_0}(\mathbb{R}, B)) p_0$. Since $p_0 H(a) = H(a) p_0 \in B$ for $a \in A$ it follows that $H(A)(V_1 - 1) \subseteq \mathrm{C_b}(\mathbb{R}, B)$. Since v commutes with $H(a)$ and $\mathrm{C_b}(\mathbb{R}, B)$ is an ideal of $\mathcal{M}(\mathrm{C_0}(\mathbb{R}, B))$, we get that $H(A)(U_1 - 1) \subseteq \mathrm{C_b}(\mathbb{R}, B)$.

Now we reduce the general case to the above considered special case:

Recall:

$p_0 := k_1(1 \otimes p_{11}) \in k_1(\mathcal{O}_2 \otimes \mathbb{K}) \supset F$

$k(a) := s_0^* p_0 (vU) H(a) (vU)^* p_0 s_0$

$h_0(a) := s_0^* p_0 H(a) s_0$ for $a \in A$.

It exits unitary $V \in \mathrm{C}_{\mathrm{b,st}}(\mathbb{R}, \mathcal{M}(B))$ with

$$V^* h_0(a) V - k(a) \oplus_{s_0,t_0} h_0(a) \in \mathrm{C}_0(\mathbb{R}, B) \quad \text{for all} \quad a \in A\,.$$

Want to show:

There exists $p_1 \geq p_0$ in and a unitary $W \in p_1 \mathcal{M}(B) p_1 + (1 - p_1)$ such that $WH(a)W^* - (vU)H(a)(vU)^* \in \mathrm{C}_0(A, B)$.

By properties of F, – or directly by simple properties of $\mathcal{O}_2 \otimes \mathbb{K}$ –, there exist unitary $w_1, w_2 \in 1 + F$ such that $w_1^* p_0 w_1 \leq 1 - p_0$ and $w_2^* p_1 w_2 = p_0$ for $p_1 := p_0 + w_1^* p_0 w_1$. Notice

$$w_1 (p_1 - p_0) w_1^* = p_0 \leq w_1 (1 - p_0) w_1^*\,.$$

For $a \in A$ it follows that

$$p_1 (vU) H(a) (vU)^* - (s_0 k(a) s_0^* + (p_1 - p_0) H(a)) = p_0 (vU) H(a) (vU)^* (1 - p_0)$$

is in $\mathrm{C}_0(\mathbb{R}, A)$.

Let $h_1(a) := t_0^* (p_1 - p_0) H(a) t_0 = t_0^* (p_1 - p_0) t_0 H(a)$ and $z := t_0^* w_1^* s_0\,.$

The mapping h_1 is a C^*-morphism because $p_1 - p_0 \leq (1 - p_0) = t_0 t_0^*$ and $p_1 - p_0$ commutes with $H(A)$. Then

$$s_0 k(a) s_0^* + t_0 h_1(a) t_0^* = s_0 k(a) s_0^* + (p_1 - p_0) H(a)\,.$$

We show below that h_1 is unitary equivalent to h_0 modulo $\mathrm{C}_0(\mathbb{R}, B)$.

Let $V_1 \in \mathcal{M}(\mathrm{C}_0(\mathbb{R}, B))$ a unitary with $V_1^* h_0(a) V_1 - h_1(a) \in \mathrm{C}_0(\mathbb{R}, B)$ and let $V_2 := s_0 s_0^* + t_0 V_1 t_0^*$. Then

$$(s_0 k(a) s_0^* + t_0 h_1(a) t_0^*) - V_2^* (s_0 k(a) s_0^* + t_0 h_0(a) t_0^*) V_2 \in \mathrm{C}_0(\mathbb{R}, B)\,.$$

On the other hand, there ?????

It follows that ?????

We have

$$p_1 (vU) H(a) (vU)^* - (s_0 k(a) s_0^* + t_0 h_1(a) t_0^*) \in \mathrm{C}_0(\mathbb{R}, B)$$

Next ????????????

In the same way we get that $p_1 H(a) = s_0 h_0(a) s_0^* + t_0 h_1(a) t_0^*$

$$(s_0 h_0(a) s_0^* + t_0 h_0(a) t_0^*) - V_3^* (s_0 h_0(a) s_0^* + t_0 h_1(a) t_0^*) V_3 \in \mathrm{C}_0(\mathbb{R}, B)\,,$$

and ?????

We want to show that ?????

Recall $h_0(a) = s_0^* p_0 H(a) s_0$.

We get from $t_0 t_0^* = 1 - p_0$ that

$$z^* z = s_0^* w_1 (1 - p_0) w_1^* s_0 = 1\,,$$

and

$$zz^* = t_0^* w_1^* s_0 s_0^* w_1 t_0 = t_0^* w_1^* p_0 w_1 t_0 == t_0^* (p_1 - p_0) t_0\,.$$

Notice that w_1, p_1, p_0, t_0 commute with $H(a)$. Thus $(w_1(p_1 - p_0)t_0)(t_0^*(p_1 - p_0)) = w_1(p_1 - p_0)$ commutes with $H(a)$. Since

$$w_1 t_0 h_1(a) t_0^* w_1^* = s_0^* w_1 (p_1 - p_0) H(a) w_1^* = w_1 (p_1 - p_0) w_1^* H(a)$$

it follows

$$z^* h_1(a) z = s_0^* w_1 (p_1 - p_0) w_1^* H(a) s_0 = s_0^* p_0 H(a) s_0 = h_0(a)\,,$$

and

$$\begin{aligned} zh_0(a)z^* = zs_0^* H(a) s_0 z^* &= t_0^* w_1^* p_0 H(a) w_1 t_0 = \\ t_0^* w_1^* p_0 w_1 H(a) t_0 &= t_0^* (p_1 - p_0) H(a) t_0 = h_1(a)\,. \end{aligned}$$

Since h_1 dominates h_0 and h_0 dominates 0 modulo $\mathrm{C}_0(\mathbb{R}, B)$. It follows that h_1 dominates zero modulo $\mathrm{C}_0(\mathbb{R}, B)$, i.e.,

$$[\pi_{\mathrm{C}_0(\mathbb{R},B)} \circ h_1] + [0] = [\pi_{\mathrm{C}_0(\mathbb{R},B)} \circ h_1]$$

in $\mathcal{M}(\mathrm{C}_0(\mathbb{R}, B))/\mathrm{C}_0(\mathbb{R}, B)$. It follows that there exists isometries $S, T \in \mathcal{M}(\mathrm{C}_0(\mathbb{R}, B))$ with $Sh_1(a) - h_1(a)S \in \mathrm{C}_0(\mathbb{R}, B)$, $SS^* + TT^* = 1$ and $T^* h_1(a) T \in \mathrm{C}_0(\mathbb{R}, B)$.

???????? □

We extend an m.o.c. cone $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ naturally to $\mathcal{C}[Y] \subseteq \mathrm{CP}(A, B[Y])$ by letting $B[Y] := \mathrm{C}_0(Y, B)$ and $V \in \mathrm{CP}(A, B[Y])$ is an element of $\mathcal{C}[Y]$ if and only if there is a point-norm continuous map $y \in Y \mapsto V_y \in \mathcal{C}$ with $y \mapsto \|V_y(a)\|$ is in $\mathrm{C}_0(Y)$, such that $V(a)(y) = V_y(a)$ for $a \in A$.

Corollary 9.3.11. *Suppose that A and B are stable C^*-algebras, A is separable, B is σ-unital, the m.o.c. cone $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ is generated by $h_0 \in \mathcal{C}$, where $h_0(a) := k(a \otimes 1)$ for some a non-degenerate *-monomorphism $k \colon A \otimes \mathcal{O}_2 \to B$.*

Then $\mathrm{R}(\mathcal{C};\, A, B[Y]) \to \mathrm{KK}(\mathcal{C};\, A, B[Y])$ is injective, if and only if, $Y \mapsto \mathrm{R}(\mathcal{C};\, A, B[Y])$ is homotopy invariant on locally compact metric spaces Y, – in the sense that the canonical evaluation group morphisms

$$\mathrm{R}(\mathcal{C};\, A, B[Y \times [0, 1]]) \to \mathrm{R}(\mathcal{C};\, A, B[Y])$$

are isomorphisms for $t \in [0, 1]$.

Proof. `to be filled in` ?? □

4. Proofs of Parts (i) and (ii) of Theorems B and M

Now we carry out the program for the proof of Parts (i) and (ii) of Theorems B and M that we have described in the beginning of this Chapter 9. First we explain why Parts (i) and (ii) of Theorem B are a special cases of Parts (i) and (ii) of Theorem M (from the point of view of our program), and why they are both special cases of Corollary 9.2.7.

Remark 9.4.1. Let A a separable exact C^*-algebra. we use in the remaining part of this section the definition $D := A \otimes \mathbb{K}$. Note that, by Corollary 5.5.6, the *-monomorphism $a \in A \mapsto a \otimes p_{11}$ is is unitarily homotopic to an isomorphism from A onto D, if A is stable.

For notational simplicity we assume that in the sequel B denotes a stable σ-unital C^*-algebra. Then the assumptions of Theorem B can be reformulated as follows: *The C^*-algebra A is unital, separable and exact, and B is a stable C^*-algebra that contains a copy N of $\mathcal{O}_2 \otimes \mathbb{K}$ such that NB is dense in B.*

We modify the definition of the *-monomorphism $h_0 \colon D \to N \subseteq B \otimes \mathbb{K}$ (given in Chapter 1 after Theorem A):

By Theorem A, we find a unital *-monomorphism $h_1 \colon A \otimes \mathcal{O}_2 \to \mathcal{O}_2$. Then we define a unital *-monomorphism $k_1 \colon D \to \mathcal{O}_2 \otimes \mathbb{K}$ by $k_1 := k_1^u \otimes \mathrm{id}_{\mathbb{K}}$, where $k_1^u(a) := h_1(a \otimes 1)$.

Since B contains the non-degenerate copy N of $\mathcal{O}_2 \otimes \mathbb{K}$, the monomorphism k_1 defines a unital nuclear *-monomorphism k_0 from D into B by $k_0 := \vartheta k_1$, where ϑ is an isomorphism from $\mathcal{O}_2 \otimes \mathbb{K}$ onto N.

k_0 is nuclear and non-degenerate, and there is a non-degenerate *-monomorphism k from $D \otimes \mathcal{O}_2$ into $N \subseteq B$ such that $k_0 = k((\cdot) \otimes 1)$. Thus k_0 and $k_0 \oplus k_0$ are unitarily equivalent.

The *-monomorphism k can be defined by $\vartheta(h_1 \otimes id_{\mathbb{K}})\gamma$, where γ means here the natural isomorphism from $(A \otimes \mathbb{K}) \otimes \mathcal{O}_2$ onto $(A \otimes \mathcal{O}_2) \otimes \mathbb{K}$.

Later it follows, as a corollary of Theorem B, that any copy of $\mathcal{O}_2 \otimes \mathbb{K}$ in B, that generates a full hereditary subalgebra of B, could be used in place of our particular fixed copy N of $\mathcal{O}_2 \otimes \mathbb{K}$ in B. Also later the reader can deduce from Corollary 9.4.2 that the above defined k_0 could be replaced in the sequel by any *-monomorphism from $D = A \otimes \mathbb{K}$ into $\mathcal{O}_2 \otimes \mathbb{K}$, because of $\mathrm{R}(D, \mathcal{O}_2 \otimes \mathbb{K}) \cong \mathrm{KK}(A, \mathcal{O}_2) = 0$ and of the absorption result (iii) of Theorem B, proved in Chapter 7, cf. Corollary 7.4.16.

Suppose, now that $N \subseteq B$ is a (non-simple) strongly purely infinite C^*-subalgebra of B with NB dense in B, and that $k \colon D \otimes \mathcal{O}_2 \to N$ is a non-degenerate *nuclear* *-monomorphism. Let $k_0 := k((\cdot) \otimes 1) \in \mathrm{Hom}_{\mathrm{nuc}}(D, B)$. With the definitions and elementary observations of Chapter 1 in hand, the reader can see, that $X := \mathrm{Prim}(N)$ acts on B upper semi-continuously by Ψ_B where $\Psi_B(J)$ is the closed ideal of B generated by the closed ideal J of N. The T_0 space X acts lower semi-continuously on D by Ψ_D, and, moreover, the action Ψ_D is *monotone upper* *semi-continuous*, i.e., satisfies also condition (ii) of Definition 1.2.6. Here $\Psi_D(J)$ for $J \in \mathcal{I}(N)$ is defined by

$$\Psi_D(J) := k_0^{-1}(k_0(D) \cap J).$$

The later in Chapter 12 given proof of Theorem K shows that $k_0 \colon D \to B$ (and $k \colon D \otimes \mathcal{O}_2 \to B$) can be constructed up to unitary homotopy from the actions Ψ_D and Ψ_B of X on D respectively B. In fact, by Corollary 7.4.23 holds $\mathrm{CP}_{\mathrm{rn}}(\Psi) = \mathcal{C}(k_0)$ and

$$\mathrm{SR}(X;\, D, B) = \mathrm{SR}(\mathrm{CP}_{\mathrm{nuc}}(\Psi);\, D, B) = S(k_0;\, D, \mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B))\,.$$

Let $X := \mathrm{Prim}(N)$, and use the natural lattice isomorphism between the open subsets of of X and the closed ideals of N, cf. Section 2. Then $\Psi_D(J) := (k_0)^{-1}(k_0(D) \cap J)$ and $\Psi_B(J) := \Psi_0^{N,B}(J) = \overline{\mathrm{span}(BJB)}$ are actions of X on D and B, respectively. Here Ψ_D is lower semi-continuous and Ψ_B is upper semi-continuous.

We define actions of $\mathcal{I}(N)$ on $E_{\mathbb{R}} = \mathrm{Q}(SB)$ and on $\mathrm{Q}(\mathbb{R}_+, B) \cong J$ by $\Psi_{E_{\mathbb{R}}}(I) := \pi_{SB}(\mathcal{M}(SB, S\Psi_B(I)))$, $\Psi_{\mathrm{Q}(\mathbb{R}_+,B)}(I) := \mathrm{Q}(\mathbb{R}_+, \Psi_B(I)) = \Psi_{E_{\mathbb{R}}}(I) \cap J$ for $I \in \mathcal{I}(N)$.

Def.of action OK? ??

From the exactness of D it follows that h is Ψ-residually nuclear, if and only if, h is nuclear and is Ψ-residually equivariant (cf. Chapter 3).

Thus H_0 is *nuclear* and has a lift $H_0' := \delta_\infty \circ k_0$ which maps D into the multiplier algebra

$$\mathcal{M}(N) \subseteq \mathcal{M}(B) \subseteq \mathrm{C}_{\mathrm{b,st}}(\mathbb{R}, \mathcal{M}(B)) = \mathcal{M}(\mathrm{C}_0(\mathbb{R}, B))$$

of the purely infinite C^*-algebra $N \subseteq B$, but $H_0'(D)$ intersects N exactly in zero.

Therefore, by Corollary 5.9.23,

$$\mathrm{Ext}_{\mathrm{nuc}}(X;\, D, SB) = G(H_0;\, D, E_{\mathbb{R}}).$$

If D is exact, we have moreover $G(H_0, D, E_{\mathbb{R}}) = [H_0] + [\mathrm{Hom}_{\mathrm{nuc}}(X;\, D, E_{\mathbb{R}})]$, but we don't need this (for the proofs in section 9.2).

In Chapters 5 and 8 we have seen that there are natural isomorphisms

$$\mathrm{Ext}_{\mathrm{nuc}}(X;\, D, SB) \cong \mathrm{KK}_{\mathrm{nuc}}(X;\, D, B)\,.$$

Since $h_0 \colon D \to E_{\mathbb{R}}$ is dominated by H_0, every element in $S(h_0\,;\, D, E_{\mathbb{R}})$ is the unitary equivalence class $[h]$ with nuclear h and defines an element of $\mathrm{Ext}_{\mathrm{nuc}}(X;\, D, SB)$ by the unitary equivalence class $[h \oplus H_0]$, cf. Corollary 5.9.22(??).

By Proposition 7.4.15, $S(h_0\,;\, D, E_{\mathbb{R}})$ is nothing else the semigroup of unitary equivalence classes Ψ-residually nuclear C^*-morphisms h from D into $\mathrm{Q}(\mathbb{R}_+, B)$, where $\Psi_A(J)$ and $\Psi_{\mathrm{Q}(\mathbb{R}_+,B)}$ are defined as above.

In Chapter 7 we have seen that

$$\mathrm{R}(X;\, D, B) = G(h_0;\, D, E_{\mathbb{R}}) = [h_0] + [\mathrm{Hom}_{\mathrm{nuc}}(X;\, D, J)]\,.$$

(If h_0 resp. k exists.)

COROLLARY 9.4.2. *If D is exact and $k\colon D\otimes\mathcal{O}_2\to B$ is a non-degenerate nuclear *-morphism that induces the above considered action of $X := \mathrm{Prim}(B)$ on D, then ψ induces an isomorphism α of $\mathrm{R}(X;\, D, B)$ onto $\mathrm{Ext}_{\mathrm{nuc}}(X;\, D, SB)\cong \mathrm{KK}_{\mathrm{nuc}}(X;\, D, B)$.*

PROOF. `to be filled in` ?? □

Following Lemma uses above conventions and explanations in Remark 9.4.1.

LEMMA 9.4.3. *If A is exact and h_0 is nuclear, let Ψ_A denote the action of $\mathrm{Prim}(B)$ induced by h_0.*

For every nuclear Ψ-residually equivariant C^*-morphism $k\colon D\to \mathrm{Q}(\mathbb{R}_+, B)$, i.e., for $[k]\in \mathrm{SR}(X;\, D, B)$, the morphism $h := k\oplus h_0$ defines an element $[h]$ in $\mathrm{R}(X;\, D, B)$ that is approximately scale-invariant.

PROOF. Use Corollary 9.2.7 with $\mathcal{C} := \mathcal{C}(h_0) = \mathcal{C}_{\mathrm{rn}}(X; D, B)$.

`Give new proof based on Corollary 9.2.7` ??

Let $E_{\mathbb{R}} := \mathrm{Q}^s(SB)$. By Proposition 7.4.15(??), **??** for separable stable and exact D, $k\in \mathrm{Hom}(X;\, D, \mathrm{Q}(\mathbb{R}_+, B))$ has unitary equivalence class $[k]$ in $S(h_0\,;\, D, E_{\mathbb{R}})$, if an only if k is nuclear.

$[h] = [k\oplus h_0] = [k] + [h_0]$ is in $\mathrm{R}(X;\, D, B)$, because $\mathrm{R}(X;\, D, B) = [h_0] + S(h_0\,;\, D, E_{\mathbb{R}})$ by Proposition 7.4.15(??) and Proposition 4.4.3.

If σ is a topological isomorphism of $\mathbb{R}_+$ then $\sigma(0) = 0$ and therefore σ extends naturally to an orientation preserving topological isomorphism of $\mathbb{R}$ by letting $\sigma(t) = t$ for $t\in\mathbb{R}_-$. We denote this extension again by σ. It induces in a natural way an automorphism $\widehat{\sigma}$ of $\mathrm{Q}^s(SB)$ such that its restriction to $J\cong \mathrm{Q}(\mathbb{R}_+, B)$ is just the above considered induced automorphism of $\mathrm{Q}(\mathbb{R}_+, B)$, which we also denote by $\widehat{\sigma}$, because all is trivially related by restriction maps.

Let $I_1\colon\ \mathrm{Q}(\mathbb{R}_+, B)\cong J\hookrightarrow \mathrm{Q}^s(SB)$ the natural inclusion. Then for the generalized mapping cone construction $k\mapsto I_1\circ k$ we have, obviously, $\widehat{\sigma}\circ(I_1\circ k) = I_1\circ(\widehat{\sigma}\circ k)$.

On the other hand the isomorphism α of Proposition 9.2.4 satisfies, by definition of α,

$$\alpha([\widehat{\sigma}\circ(k\oplus h_0)]) = [I_1\circ(\widehat{\sigma}\circ(k\oplus h_0))] = [\widehat{\sigma}\circ(I_1\circ(k\oplus h_0))].$$

By Corollary 8.3.4(ii), we have

$$[\widehat{\sigma}\circ(I_1\circ(k\oplus h_0))] = [I_1\circ(k\oplus h_0)] = \alpha([k\oplus h_0]).$$

Since $[k\oplus h_0]$ is in $\mathrm{R}(X;\, D, B)$ and α is faithful on $\mathrm{R}(X;\, D, B)$ by Proposition 9.2.4, this shows the invariance of $[k\oplus h_0]$ under scaling:

$$[k\oplus h_0] = [\widehat{\sigma}\circ(k\oplus h_0)]\,.$$

□

Proof of (i) and (ii) of Theorems B and M.. Give new proof based on Corollary 9.2.7!!! ??

In case of Theorem B we pass to the stabilizations $D := A \otimes \mathbb{K}$ and replace B by $B \otimes \mathbb{K}$.

In the case of Theorem M we assume the existence of h_0 (i.e., we prove (i) and (ii) modulo the result of Theorem K, see our above made conventions).

By Corollary 9.4.2, the natural map $h \mapsto I_1 \circ h$ from $\mathrm{Hom}_{\mathrm{nuc}}(X;\, D, \mathrm{Q}(\mathbb{R}_+, B))$ into $\mathrm{Hom}_{\mathrm{nuc}}(X;\, D, \mathrm{Q}^s(SB))$ defines an isomorphism

$$\alpha\colon\ \mathrm{R}(X;\, D, B) \xrightarrow{\sim} \mathrm{Ext}_{\mathrm{nuc}}(X;\, D, SB) \cong \mathrm{KK}_{\mathrm{nuc}}(X;\, D, B).$$

By Corollary 8.3.3(iii), for a nuclear C^*-morphism h from D to B the mapping cone construction defines an element $\alpha[h] = [C_h]$ of $\mathrm{Ext}_{\mathrm{nuc}}(X;\, D, SB)$ which is mapped to the element $[h - 0] \in \mathrm{KK}_{\mathrm{nuc}}(X;\, D, B)$ under the natural isomorphism from $\mathrm{Ext}_{\mathrm{nuc}}(X;\, D, SB)$ onto $\mathrm{KK}_{\mathrm{nuc}}(X;\, D, B)$.

Thus the relations considered in Theorems B(ii) and M(ii) are just the relations which are induced by the semigroup homomorphism from the unitary equivalence classes of elements of $\mathrm{Hom}_{\mathrm{nuc}}(X;\, D, B)$ into $\mathrm{R}(X;\, D, B)$. I.e., if h and k are in $\mathrm{Hom}_{\mathrm{nuc}}(X;\, D, B)$ then $[h - 0] = [k - 0] \in \mathrm{KK}_{\mathrm{nuc}}(X;\, D, B)$ if and only if they define the same element of $\mathrm{R}(X;\, D, B)$. But this means that there is a strongly continuous map $t \mapsto U(t)$ from $\mathbb{R}_+$ into the unitary group of $\mathcal{M}(B)$ such that $h \oplus h_0 = \lim_{t\to\infty} U(t)^*(k \oplus h_0)U(t)$. This proves the second part of Theorems B and M.

To complete the proof of the first part of Theorem B, we have to show that every element of $\mathrm{R}(X;\, D, B)$ can be represented by a Ψ-residually nuclear C^*-morphism $h\colon D \to B$. But this follows from Lemma 9.4.3 and Corollary 9.1.3, because $\mathrm{R}(X;\, D, B) = \mathrm{SR}(X;\, D, B) + [h_0] \subseteq \mathrm{SR}(X;\, D, B)$ and $[h_0]$ is the neutral element of $\mathrm{R}(X;\, D, B)$, cf. Chapter 4. □

Remark 9.4.4. Let us shortly mention alternative approaches as e.g. by N. C. Phillips [**627**] in the case where X is a point:
If one finds another way to show the homotopy invariance of $\mathrm{R}(A, B)$ with respect to the second variable B, then one can directly apply Corollary 9.1.3. And one gets that the representatives of $\mathrm{R}(A, B)$ can be chosen as nuclear C^*-morphisms from $A \otimes \mathbb{K}$ into $B \otimes \mathbb{K}$. Then it follows that there is a composition that replaces the Kasparov products. But then it still remains to show that the natural morphism from $\mathrm{R}(A, B)$ to $\mathrm{KK}_{\mathrm{nuc}}(A, B) \cong E_{\mathrm{nuc}}(A, B)$ is both faithful and surjective ([5]). The zero functor satisfies all requirements of category theory descriptions of Kasparov or E-theory type functors, *except of the universality.* A less trivial example, which is also a two-sided ideal of KK-theory (and even of E-theory) is the subgroup of the elements of $\mathrm{KK}_{\mathrm{nuc}}(A, B)$ that factorize through a commutative C^*-algebra (it is a

[5] In principle, it could happen that h_0 is – up to asymptotic unitary homotopy – the only element of $\mathrm{R}(A, B)$.

group by Bott periodicity). Therefore, formal category theoretic (algebraic) arguments that prove the coincidence of $\mathrm{R}(A, B)$ and $\mathrm{KK}_{\mathrm{nuc}}(A, B)$ *without assuming UCT* for A or B require some care.

The *-epimorphism $b \mapsto b(t)$, for $b \in \mathrm{C}([0,1], B)$, extends naturally to a *-epimorphism $\pi_t \colon \mathrm{C_b}(\mathbb{R}_+ \times [0,1], B) \to \mathrm{C_b}(\mathbb{R}_+, B)$ by

$$\pi_t((b_s)_{s\in\mathbb{R}_+}) := (b_s(t))_{s\in\mathbb{R}_+} .$$

The π_t define evaluation semi-group morphisms

$$(\pi_t)_* \colon \mathrm{SR}(\mathcal{C}[0,1];\, A, B[0,1]) \to \mathrm{SR}(\mathcal{C};\, A, B)$$

that naturally define group morphisms

$$(\pi_t)_* \colon \mathrm{R}(\mathcal{C}[0,1];\, A, B[0,1]) \to \mathrm{R}(\mathcal{C};\, A, B) .$$

CHAPTER 10

Unitarily homotopic algebras and Theorem B(iv)

We give in this chapter the proof of part (iv) of Theorem B and obtain related results. This finishes the proof of Theorem B, because parts (iii), (i)+(ii) have been shown in Chapters 7 and 9 respectively.

We consider here also *non-simple* σ-unital C^*-algebras.

1. Unitary homotopies and Proof of Theorem B(iv)

We recall that two morphisms $\varphi, \psi \colon A \to B$ are **unitarily homotopic** if there is a norm-continuous map $t \in \mathbb{R}_+ \mapsto U(t) \in \mathcal{M}(B)$ into the unitary operators in the multiplier algebra $\mathcal{M}(B)$ of B such that $\varphi(a) = \lim_{t\to\infty} U(t)^*\psi(a)U(t)$ for all $a \in A$, cf. Definition 5.0.1 ([1]).

We say that *-homomorphism $\varphi \colon A \to B$ *defines* a **unitary homotopy** between A and B, if there exists a *-homomorphism $\psi \colon B \to A$ such that $\psi \circ \varphi$ is unitarily homotopic to id_A and $\varphi \circ \psi$ is unitarily homotopic to id_B.

A simple calculation shows that unitarily homotopic morphisms have the same kernel. Therefore, *a unitary homotopy $\varphi \colon A \to B$ always is a monomorphism.*

If $\varphi \colon A \to B$ is a unitary homotopy and $\psi \colon B \to A$ is a *-homomorphism as in the above definition, then ψ defines again a unitary homotopy between A and B.

In the following we denote by $\overline{BXB}$ the closed ideal of B which is generated by a subset X of the multiplier algebra $\mathcal{M}(B)$ of B, i.e., $\overline{BXB}$ means the *closure of the linear span* of BXB.

A unitary homotopy $\varphi \colon A \to B$ always satisfies that $\varphi(A)$ is not contained in a non-trivial closed ideal of B, i.e. $\overline{B\varphi(A)B} = B$:

PROOF. $J := \overline{B\varphi(A)B}$ is a closed ideal of B and $\varphi\psi(B) \subset \varphi(A) \subset J$. Since $\varphi\psi$ is unitarily homotopic to id_B, this implies that every element of B is approximately unitarily equivalent to an element of the ideal J. Thus $B = J$. □

[1]It suffices to suppose that $t \mapsto U(t) \in$ is strongly continuous. Then we say that φ and ψ are "weakly unitarily homotopic". Since the unitary operators are a topological group with strict topology (and strong and strict topology coincides on the unitaries), the "weakly unitary homotopy" of maps φ and ψ is an equivalence relation. If A and B are σ-unital and B is stable then weakly unitarily homotopic φ and ψ are unitarily homotopic (by an other norm-contiuous path $t \mapsto \widetilde{U}(t)$), cf. Corollary 7.1.5.

A similar argument shows that B *and* φ *must be unital (resp.* B *is* σ*-unital) if* A *is unital (resp. is* σ*-unital) and* $\varphi\colon A \to B$ *is a unitary homotopy.*

In order to prove Theorem B(iv), we use the following observations (I)-(III):

(I) *Suppose that* A *and* B *are* σ*-unital and stable, and* $h\colon A \to B$ *is a monomorphism, such that* $\overline{Bh(A)B} = B$.
Then h *is unitarily homotopic to a monomorphism* $k\colon A \to B$ *with* $k(A)B = B$ ([2]).

(II) *If* $h_1\colon A \to B$ *and* $h_2\colon B \to C$ *are unitarily homotopic to* $k_1\colon A \to B$ *respectively* $k_2\colon B \to C$*, and if* $k_2(B)C$ *is dense in* C*, then* $h_2 \circ h_1$ *is unitarily homotopic to* $k_2 \circ k_1$.

(III) *Suppose that* A *and* B *are separable, that* $\varphi\colon A \to B$ *defines an unitary homotopy of* A *and* B*, and that* $\varphi(A)$ *contains a strictly positive element of* B*. Then* φ *is unitarily homotopic to an isomorphism* χ *from* A *onto* B.

Observation (I) is a special case of Corollary 7.4.6. The observations (I), (II) and (III) together imply that unitarily homotopic separable C^*-algebras are isomorphic if they are σ-unital and stable or if they are unital, i.e., (I), (II) and (III) imply Theorem B(iv).

Proof of the implication { (I),(II),(III) } $\Rightarrow$ (iv) of Theorem B:. Let $\varphi\colon A \to B$ a unitary homotopy and $\psi\colon B \to A$ a *-homomorphism such that $\varphi \circ \psi$ is unitarily homotopic to id_B and $\psi \circ \varphi$ is unitarily homotopic to id_A. Above we have shown that φ and ψ must be monomorphisms such that $B\varphi(A)B$ is dense in B and $A\psi(B)A$ is dense in A. By (I) there exists monomorphisms $\varphi_1\colon A \to B$ and $\psi_1\colon B \to A$ which are unitarily homotopic to φ and ψ respectively, such that $\varphi_1(A)B$ and $\psi_1(B)A$ are dense in B and A respectively.

By (II), the φ_1 and ψ_1 again define a unitary homotopy between A and B.

Now (III) applies, and we get an isomorphism χ from A onto B such that χ is unitarily homotopic to φ_1. But then χ is unitarily homotopic to φ by (II).

We have that B, φ and ψ are unital if A unital. Thus (III) applies to φ in the unital case. □

Proof of (II): . The definition of unitary homotopy shows immediately that k_2h_1 is unitarily homotopic to h_2h_1. Since $k_2(B)C$ is dense in C there is a unital strictly continuous *-homomorphism ψ from the multiplier algebra $\mathcal{M}(B)$ of B into the multiplier algebra $\mathcal{M}(C)$ of C such that $\psi|B = k_2$. If $t \in \mathbb{R}_+ \mapsto u(t) \in \mathcal{M}(B)$ is a strictly continuous map into the unitaries of $\mathcal{M}(B)$ such that $\lim \|u(t)^*h_1(a)u(t) - k_1(a)\| = 0$ for $a \in A$, then $t \in \mathbb{R}_+ \to v(t) := \psi(u(t)) \in \mathcal{M}(C)$ is strictly continuous and $\lim \|v(t)^*k_2(h_1(a))v(t) - k_2(k_1(a))\| = 0$ for $a \in A$. Thus k_2h_1 and k_2k_1 are

[2] The norm-continuous path $t \in \mathbb{R}_+ \mapsto U(t) \in \mathcal{M}(B)$ with $\lim_{t\to\infty} \|k(a) - U(t)^*h(a)U(t)\| = 0$ (for all $a \in A$) can be taken in the unitization $\widetilde{B} = B + \mathbb{C}\cdot 1 \subset \mathcal{M}(B)$.

unitarily homotopic. Since unitary homotopy is an equivalence relation, k_2k_1 is unitarily homotopic to h_2h_1. □

2. Proof of property (III)

This Section is concerned with the proof of (III), that finishes the proof of Theorem B. The proof of (III) is given above Corollary 10.3.1. Then we get some other Corollaries of our technical Proposition 10.2.1.

We start with a very general Proposition 10.2.1 that is not exactly stated in [**438**] as here, but is proved in [**438**], cf. proofs of [**438**, cor. 2.4(II), prop. 2.3].

Let $X_n \subset Y$ be a sequence of Banach spaces and closed subspaces, and let $V_n \colon X_n \to X_{n+1}$ be a sequence of contractions. Then the inductive limit $\operatorname{indlim}(V_n \colon X_n \to X_{n+1})$ is well-defined and naturally contained in $\ell_\infty(Y)/c_0(Y)$ (or in a norm ultrapower Y_ω) as a closed subspace. By

$$V_n^\infty \colon X_n \to \operatorname{indlim}(V_n \colon X_n \to X_{n+1})$$

we denote the natural contractions which are given in the definition of inductive limits by universal diagrams (and satisfy $V_{n+1}^\infty \circ V_n = V_n^\infty$). See [**438**, sec. 2] for definitions and explicit formulas (in the case of operator systems).

In the following Proposition 10.2.1 let X be a separable Banach space and Y a closed subspace of X, $\mathcal{S} \subset \mathcal{L}(X)$ a semigroup of linear contractions on X, G be a topological *semigroup* $\pi \colon G \to \mathcal{S}$ a strongly continuous semigroup epimorphism.

To simplify notation we write V, V_n, $V(t)$ and $V_n(t)$ instead of $\pi(g)$, $\pi(g_n)$, $\pi(g(t))$, $\pi(g_n(t))$ etc.

Proposition 10.2.1. *Let X, Y, $\mathcal{S}$, G and π be as above.*

(i) *Assume that for every finite dimensional subspace Z_1 of X and for every finite dimensional subspace Z_2 of Y and every $\varepsilon > 0$ there exist $V \in \mathcal{S}$ with*

$$\|z - Vz\| \le \varepsilon \|z\| \quad \forall z \in Z_2 \quad \text{and} \quad \operatorname{dist}(Vz, Y) \le \varepsilon \|z\| \quad \forall z \in Z_1.$$

Then there exist a sequence $V_1, V_2, \ldots$ in $\mathcal{S}$ and an isometric isomorphism

$$\varphi \colon Y \xrightarrow{\sim} \operatorname{indlim}(V_n \colon X \to X)$$

from Y onto $\operatorname{indlim}(V_n \colon X \to X)$*, such that, for $y \in Y$,*

$$\varphi(y) = \lim_{n\to\infty} V_n^\infty(y)\,.$$

If, moreover, G is a group and $\pi(1_G) = \mathrm{id}_X$, then $(V_1^\infty)^{-1}$ is an isometric isomorphism from $\operatorname{indlim}(V_n \colon X \to X)$ *onto X and there is a sequence (of isometries) $T_n \in \mathcal{S}$ such that, for $y \in Y$,*

$$(V_1^\infty)^{-1}(\varphi(y)) = \lim_{n\to\infty} T_n(y).$$

$(V_1^\infty)^{-1} \circ \varphi$ is an isomorphism from Y onto X.

(ii) *Suppose that, moreover,* $\mathrm{id}_X \in \mathcal{S}$, *G is unital,* $\pi(1_G) = \mathrm{id}_X$, *and for every pair of subspaces* $Z_1 \subset X$, $Z_2 \subset Y$ *of finite dimension and for every* $\varepsilon > 0$, *there exists a continuous map* $s \in [0,1] \mapsto g(s) \in G$ *with* $g(0) = 1_G$, *such that, with* $V(s) := \pi(g(s))$, *for all* $s \in [0,1]$,

$$\|z - V(s)z\| \leq \varepsilon \|z\| \quad \forall z \in Z_2 \quad \textit{and} \quad \mathrm{dist}(V(s)z, Y) \leq \varepsilon \|z\| \quad \forall z \in Z_1 .$$

Then, for every dense sequence $y_1, y_2, \ldots \in Y$ *the sequence* $V_1, V_2, \ldots \in \mathcal{S}$ *in (i) and the sequence* $g_1, g_2, \cdots \in G$ *for which* $\pi(g_n) = V_n$ *in (i) can be selected such that moreover for every* $n \in \mathbb{N}$ *there is a continuous map* $t \in [0,1] \mapsto g_n(t) \in G$ *with* $\|V_n(t)y_k - y_k\| < 2^{-n}$ *for every* $k \leq n$, $g_n(0) = 1_G$, $V_n(1) = V_n$, $V_0(t) \equiv 1$.

Furthermore, $W(t) := V_{n+1}^{\infty} \circ V_n(n+1-t)$ *(for* $n \leq t \leq n+1$*) has the property that*

$$t \in \mathbb{R}_+ \mapsto W(t)y \in \mathrm{indlim}(V_n \colon X \to X)$$

is continuous with $W(0) = V_1^{\infty}$, *and*

$$\lim_{t \to \infty} W(t)y = \varphi(y) .$$

If, moreover, G is a group and $\pi(1_G) = \mathrm{id}_X$, *then* $(V_1^{\infty})^{-1}$ *is an isometric isomorphism from* $\mathrm{indlim}(V_n \colon X \to X)$ *onto X.*

The map $t \in \mathbb{R}_+ \mapsto g(t) \in G$, *which is defined by*

$$g(t) := g_1^{-1} \cdot \ldots \cdot g_n^{-1} g_{n+1}(t-n)^{-1} \quad \textit{for} \;\; n \leq t \leq n+1 ,$$

is continuous and satisfies $\pi(g(t)) = (V_1^{\infty})^{-1} W(t)$.

The inclusion map $Y \hookrightarrow X$ *is homotopic to the isometric isomorphism* $(V_1^{\infty})^{-1} \circ \varphi$ *from Y onto X by the strongly continuous map* $t \in \mathbb{R}_+ \mapsto V(t) := \pi(g(t))$.

Proof. (i): The proof [**438**, cor. 2.4(II)] can be used here (word by word in the same way), but the inductive existence proof of the $V_n \in \mathcal{S}$ with the desired properties does not need in the induction step a Hahn-Banach separation argument, as in [**438**], the existence is just our assumption in (i) that $\mathcal{S}$ is a semigroup and has (!) the the needed approximation property.

If G is a group and $\pi(1_G) = \mathrm{id}_X$, then the V_n are isometries from X onto X and thus V_1^{∞} is an isometric isomorphism from X onto $\mathrm{indlim}(V_n \colon X \to X)$. The desired T_n can be found as iterates (products) of the V_n.

(ii): It is in principle the same proof as of [**438**, cor. 2.4(II)], but one has to construct the finite-dimensional filtrations $X_n \subset X$, $Y_n \subset Y$ and the $V_n = V_n(1)$ in [**438**, prop. 2.3] such that the ball of $V(t)V_m^n(X_n)$ is 8^{-n}-contained in X_{n+1} for $t \in [0,1]$ and $V_n(t) := \pi(g_n(t))$ with $g_n(0) = 1$, $V(1) = V_n$. That can be done by our assumptions in (ii).

Now assume that moreover G is a group and $\pi(1) = \mathrm{id}_X$. Than V_1^{∞} is an isometric isomorphism as one can easily see from the natural model for indlim in

$l_\infty(X)/c_0(X)$, cf. e.g. beginning of [**438**, sec. 2]. The rest can be verified by straight forward calculations. □

Note that on the unitary operators in $\mathcal{M}(B)$ the strong and the strict topology coincide. We get the applications of Proposition 10.2.1 if we considered $\mathcal{M}(B)$ as a closed subalgebra $\{T \in \mathcal{L}(B) \colon \exists (S \in \mathcal{L}(B)), (Sb)^*a = b^*Ta, \forall a, b \in B\}$ of the bounded operators $\mathcal{L}(B)$ on B. The strict topology is the *-strong topology on $\mathcal{L}(B)$ given by the seminorms $T \mapsto \|T(b)\| + \|T(b^*)\|$, $b \in B$.

The natural group epimorphism $u \in \mathcal{M}(B) \mapsto \iota_u \in \mathrm{Int}(B) \subset \mathcal{L}(B)$, with $\iota_u(a) := uau^*$ for $a \in B$, is continuous with respect to the strong topologies (on both sides).

Corollary 10.2.2. *Let $\varphi \colon A \to B$ be a *-homomorphism and suppose that A and B are separable. Then φ is unitarily homotopic to an isomorphism ψ from A onto B, if and only if, φ satisfies the following property (δ):*

φ is a monomorphism and, for every $\varepsilon > 0$, $a_1, \ldots, a_n \in A$, $b_1, \ldots, b_m \in B$ there exist a strongly continuous map $t \in [0,1] \mapsto v(t) \in \mathcal{M}(B)$ from $[0,1]$ into the unitary operators in $\mathcal{M}(B)$ such that

(i) *$v(0) = 1$,*
(ii) *$\|[v(t), \varphi(a_i)]\| < \varepsilon$ for $i = 1, \ldots, n$, $t \in [0,1]$,*
(iii) *$dist(v(1)^* b_j v(1), \varphi(A)) < \varepsilon$ for $j = 1, \ldots, m$.*

Proof. Assume $\varphi \colon A \to B$ satisfies the property (δ), then with $X := B$, $Y := \varphi(A)$, $G = U(\mathcal{M}(B)) :=$ unitary group of $\mathcal{M}(B)$ with strict topology, $\pi(u) := \iota_u$ and $\mathcal{S} := \{\iota_u \colon u \in U(\mathcal{M}(B))\}$ the assumptions of Proposition 10.2.1(ii) are satisfied. Thus the inclusion map $\varphi(A) \hookrightarrow B$ is unitarily homotopic to an isomorphism from $\varphi(A)$ onto B.

Since φ is a monomorphism, it follows that φ is unitarily homotopic to an isomorphism from A onto B.

Conversely, suppose that φ is unitarily homotopic to an isomorphism ψ from A onto B. Along a unitary homotopy the norm of an element remains constant. Thus φ is a monomorphism.

Let $t \in \mathbb{R}_+ \mapsto u(t) \in \mathcal{M}(B)$ be the strongly continuous map into the unitaries corresponding to the unitary homotopy. Then there exists a t_0 such that, for every $t \geq t_0$,

$$\|\varphi(a_i) - u(t)\psi(a_i)u(t)^*\| < \varepsilon/2.$$

Let $f_j := \psi^{-1}(u(t_0)^* b_j u(t_0)) \in A$.

We find $t_1 > t_0$ with $\|\varphi(f_j) - u(t)\psi(f_j)u(t)^*\| < \varepsilon$ for every $t \geq t_1$.

Let $s(t) := t_0 + t(t_1 - t_0)$ and $v(t) := u(t_0)u(s(t))^*$ for $t \in [0,1]$.

Then $v(0) = 1$, $v(t)$ is unitary, $t \mapsto v(t)$ is strongly continuous and, by the triangle inequality, for $t \in [0,1]$, $\|v(t)^*\varphi(a_i)v(t) - \varphi(a_i)\| < \varepsilon$.

Furthermore, $\mathrm{dist}(v(1)^*b_jv(1),\varphi(A)) \leq \|v(1)^*b_jv(1) - \varphi(f_j)\| \leq \varepsilon$, because $v(1)^*b_jv(1) = u(t_1)\psi(f_j)u(t_1)^*$. □

Corollary 10.2.3. *Suppose that $\varphi_n\colon A_n \to A_{n+1}$, $n = 1, 2, \ldots$, are *-homomorphisms, where A_n is separable, $\varphi_n(A_n)$ contains a strictly positive element of A_{n+1}, and there exists an isomorphism ψ_n from A_n onto A_{n+1} such that ψ_n is unitarily homotopic to φ_n.*

Then $\varphi_1^\infty\colon A_1 \to \mathrm{indlim}(\varphi_n\colon A_n \to A_{n+1})$ is unitarily homotopic to an isomorphism from A_1 onto $\mathrm{indlim}(\varphi_n\colon A_n \to A_{n+1})$.

Proof. We have to check the criteria (δ) of Corollary 10.2.2. By Corollary 10.2.2 every φ_n is a monomorphism.

$\bigcup \varphi_n^\infty(A_n)$ is dense in $B := \mathrm{indlim}(\varphi_n\colon A_n \to A_{n+1})$.

The assumptions imply that $\varphi_n^\infty(A_n)$ contains, for every n, a strictly positive element of B, because $\varphi_n(A_n)A_{n+1}$ is dense in A_{n+1}, and then by induction:

$$\overline{\varphi_{n+k} \circ \ldots \circ \varphi_n(A_n)A_{n+k+1}} = A_{n+k+1}, \qquad \overline{\varphi_n^\infty(A_n)B} = B\,.$$

Thus $\mathcal{M}(\varphi_n^\infty(A_n)) \cong \mathcal{M}(A_n)$ is unitally contained in $\mathcal{M}(B)$ and the strict topology on $\mathcal{M}(\varphi_n^\infty(A_n))$ is the same as the topology which is induced by the strict topology of $\mathcal{M}(B)$. Therefore it suffices to check that $\varphi_1^\infty\colon A_1 \to \varphi_n^\infty(A_n)$ satisfies the criteria (δ) of Corollary 10.2.2. But this follows from Corollary 10.2.2 and the following observation:

By induction and (II), $(\varphi_n^\infty)^{-1} \circ \varphi_1^\infty = \varphi_{n-1} \circ \ldots \circ \varphi_1$ is unitarily homotopic to the isomorphism $\psi_{n-1} \circ \cdots \circ \psi_1$ from A_1 onto A_n, where $\psi_k\colon A_k \to A_{k+1}$ are isomorphisms which are unitarily homotopic to $\varphi_k\colon A_k \to A_{k+1}$ ($k = 1, \ldots, n-1$). □

Now we are ready for the proof of the above statement (III), and *finish here the proof of Theorem B*:

check next proof again!!

Proof of (III). Suppose that A and B are separable.

Let $h\colon A \to B$ and $k\colon B \to A$ monomorphisms, such that $\overline{h(A)B} = B$ and $\overline{k(B)A} = A$, i.e., $h(A)$ contains a strictly positive element of B, and $h(B)$ contains a strictly positive element of A. It follows

$$\overline{hk(B)B} = \overline{hk(B)h(A)B} = \overline{h(k(B)A)B} = \overline{h(A)B} = B.$$

In the same way $\overline{kh(A)A} = A$. If, moreover, kh is unitarily homotopic to id_A, then, by Corollary 10.2.3, there exists an isomorphism α from A onto the inductive limit A_∞ of the sequence of morphisms $\chi_n\colon A \to A$ with $\chi_n := kh$, such that α is unitarily homotopic to $\chi_1^\infty\colon A \to A_\infty$.

If hk is unitarily homotopic to id_B, then there exists an isomorphism β from B onto the inductive limit B_∞ of $\psi_n \colon B \to B$ with $\psi_n := hk$, such that β is unitarily homotopic to $\psi_1^\infty \colon B \to B_\infty$.

If we consider the natural inclusions

$$A_\infty \subset l_\infty(A)/c_0(A), \qquad B_\infty \subset l_\infty(B)/c_0(B),$$

we see, that

$$(a_1, a_2, \dots) \mapsto (h(a_1), h(a_2), \dots) \qquad \text{and} \qquad (b_1, b_2, \dots) \mapsto (k(b_1), k(b_2), \dots)$$

define (modulo zero-sequences) monomorphisms μ from A_∞ into B_∞ and ν from B_∞ into A_∞ such that with $\nu\mu = id$ and $\mu\nu = id$. Therefore, μ is an isomorphism.

Thus $\varphi := \beta^{-1} \circ \mu \circ \alpha : A \to B$ is an isomorphism from A onto B. A simple calculation shows that $\mu \circ \chi_1^\infty = \psi_1^\infty \circ h$.

$\beta^{-1} \circ \mu \circ \alpha$ is unitarily homotopic to $\beta^{-1} \circ \mu \circ \chi_1^\infty = \beta^{-1} \circ \psi_1^\infty \circ h$.

Since ψ_1^∞ is unitarily homotopic to β, we get that $\psi_1^\infty \circ h$ is unitarily homotopic to $\beta \circ h$.

Thus $\varphi = \beta^{-1} \circ \mu \circ \alpha$ is unitarily homotopic to h. □

3. Some corollaries

We add some related corollaries of the first part of Proposition 10.2.1, which can be proved by almost the same arguments as above.

COROLLARY 10.3.1. *Let $\varphi \colon A \to B$ be a *-homomorphism, where A and B are separable. Then the following are equivalent:*

(i) *φ is approximately unitarily equivalent to an isomorphism ψ from A onto B.*
(ii) *φ is a monomorphism and for every $\varepsilon > 0$, $a_1, \dots, a_n \in A$, $b_1, \dots, b_m \in B$ there exists a unitary $v \in \mathcal{M}(B)$ with $\|v^*\varphi(a_i)v - \varphi(a_i)\| < \varepsilon$ for $i = 1, \dots, n$ and $\operatorname{dist}(v^*b_jv, \varphi(A)) < \varepsilon$ for $j = 1, \dots, m$.*
(iii) *φ is a monomorphism, and in the relative commutant $\varphi(A)' \cap \mathcal{M}(B)_\omega$ of $\varphi(A)$ in the ultrapower of $\mathcal{M}(B)$ there exists, for every finite sequence $b_1, \dots, b_m \in B$ and every $\varepsilon > 0$, a unitary $v \in \varphi(A)' \cap \mathcal{M}(B)_\omega$ such that v^*b_jv has distance $< \varepsilon$ from $\varphi_\omega(A_\omega)$ for $j = 1, \dots, m$.*

REMARK 10.3.2. Part (iii) of Corollary 10.3.1 is just an equivalent formulation of (ii) in the more rigorous language of ultrapowers. There is a more elegant and far reaching version in the ultrapower context.

One concludes Corollary 10.3.1 from Proposition 10.2.1(i) essentially in the same way as we have deduced Corollary 10.2.2 from Proposition 10.2.1(ii). And one can use the same arguments for the implications "Corollary 10.3.1 ⇒ Corollary 10.3.3 ⇒ Corollary 10.3.4" below as for the implications "Corollary 10.2.2 ⇒ Corollary 10.2.3 ⇒ (III)" above.

Corollaries 10.3.4 and 10.3.5 overlap with (partly not published) results of Elliott.

Corollary 10.3.3. *Suppose that, for $n = 1, 2, \ldots$, A_n is separable, $\varphi_n \colon A_n \to A_{n+1}$ are *-homomorphisms, $\varphi_n(A_n)$ contains a strictly positive element of A_{n+1} and φ_n is approximately unitarily equivalent to an isomorphism from A_n onto A_{n+1}.*

Then $\varphi_1^\infty \colon A_1 \to \operatorname{indlim}(\varphi_n \colon A_n \to A_{n+1})$ is approximately unitarily equivalent to an isomorphism from A_1 onto $\operatorname{indlim}(\varphi_n \colon A_n \to A_{n+1})$.

Corollary 10.3.4. *If A and B are separable C^*-algebras, $h \colon A \to B$ and $k \colon B \to A$ are C^*-algebra morphisms such that $\overline{h(A)B} = B$, $\overline{k(B)A} = A$, kh and hk are approximately unitarily equivalent to id_A and id_B respectively, then h is approximately unitarily equivalent to an isomorphism from A onto B.*

Corollary 10.3.5. *Suppose that A is a separable C^*-algebra, which is stable or unital and that B is a separable unital C^*-subalgebra of the multiplier algebra $\mathcal{M}(A_\omega)$ of A_ω, such that B commutes element-wise with A, and such that $b \in B \mapsto b \otimes 1 \in B \otimes B$ and $b \in B \mapsto 1 \otimes b \in B \otimes B$ are approximately unitarily equivalent (to each other in $B \otimes B$), then*

(i) *B is simple and nuclear.*
(ii) *$A \cong A \otimes B \otimes B \otimes \ldots$ with an isomorphism $\psi \colon A \to A \otimes B \otimes B \otimes \ldots$ which is approximately unitarily equivalent to $a \in A \mapsto a \otimes 1 \otimes 1 \otimes \ldots$*

Proof. (i): Let J be a closed ideal of B and $J \neq B$, ν a pure state of B with $\nu(J) = 0$. Since B is separable, we find a sequence of unitaries $u_n \in B \otimes B$ and 2^{-n}-approximations a_n of u_n in the algebraic tensor product $B \odot B$, such that $b \otimes 1 = \lim_{n\to\infty} u_n^*(1 \otimes b)u_n$. Thus $b = \lim(\mathrm{id} \otimes \nu)(a_n^*(1 \otimes b)a_n)$ for every $b \in B$. The right hand side is a sequence of completely positive finite rank maps with kernels which contain J. Thus $J = 0$ and B is nuclear. Every closed ideal of B is trivial, i.e. B is simple.

(ii): Since B is nuclear and simple, there is a copy of $A \otimes (B \otimes B) \cong (A \otimes B) \otimes B$ in the ultrapower $(A \otimes B)_\omega$ of $A \otimes B$, such that $A \otimes 1 \otimes B$ corresponds naturally to the canonical embedding of $A \otimes B$ in $(A \otimes B)_\omega$ by constant sequences, and $A \otimes B \otimes 1$ is in $C^*(A \cdot (A' \cap \mathcal{M}(A_\omega))) \subset A_\omega \subset (A \otimes B)_\omega$, where A_ω is naturally identified with $(A \otimes 1_B)_\omega$.

Let $v \in \mathcal{M}(A \otimes B)_\omega$ denote the unitary, which is represented by $1_{\mathcal{M}(A)} \otimes u_n$, where u_n is as in part (i). We see that the criteria (iii) of Corollary 10.3.1 is satisfied for $\varphi \colon a \in A \mapsto a \otimes 1_B \in A \otimes B$. Thus φ is approximately unitarily equivalent to to an isomorphism ψ_1 from A onto $A \otimes B$.

It follows by induction that $\varphi_n \colon A_n \to A_{n+1}$ is approximately unitarily equivalent to an isomorphism from A_n onto A_{n+1}, where inductively $A_1 = A$, $A_{n+1} = A_n \otimes B$ and $\varphi_n(a) = a \otimes 1_B$ for $a \in A_n$. But then Corollary 10.3.3 gives that the monomorphism $a \mapsto a \otimes 1_B \otimes 1_B \otimes \ldots$ from A into $A \otimes B \otimes B \otimes \ldots =$

indlim($\varphi_n\colon A_n \to A_{n+1}$) is approximately unitarily equivalent to an isomorphism from A onto $A \otimes B \otimes B \otimes \ldots$. □

Remark 10.3.6. Since we have finished the proof of Theorem B with the above given proof of (III), now we can use the results A-F and H as stated in Chapter 1.

One easily sees from Theorem B(ii)+(iii) and Corollaries C(ii) and F that $B = \mathcal{O}_2$ and $B = \mathcal{O}_\infty$ satisfy the requirements of Corollary 10.3.5. Therefore, also Corollary G now follows from Corollary F and Corollary 10.3.5, if we do not use the original paper [**678**].

We recall from Definition 3.10.1 that a *-homomorphism $h_1\colon A \to B$ *approximately dominates* a completely positive contraction $h_2\colon A \to B$, if and only if, there exists a sequence of contractions $d_n \in B$ such that $\lim \|h_2(a) - d_n^* h_1(a) d_n\| = 0$ for $a \in A$. Clearly, we can choose the d_n's as isometries if A, B, h_1 and h_2 are unital.

If A and B are stable and σ-unital, then, by Proposition 7.4.7, we find isometries $t_n \in \mathcal{M}(B)$ such that $\lim \|h_2(a) - t_n^* h_1(a) t_n\| = 0$ for $a \in A$.

Corollary 10.3.7. *Suppose that A is a separable C*-algebra which is stable or is unital and contains a copy of $\mathcal{O}_2$ unitally.*

If id_A approximately dominates $\mathrm{id}_A \oplus \mathrm{id}_A$, then $A \cong \mathcal{O}_\infty \otimes A$.

If id_A is approximately unitarily equivalent to $\mathrm{id}_A \oplus \mathrm{id}_A$ by a sequence of unitaries in the multiplier algebra of A, then $A \cong \mathcal{O}_\infty \otimes A \cong \mathcal{O}_2 \otimes A$.

Proof. By the above Remark 10.3.6, the assumptions mean that there is an isometry $T \in \mathcal{M}(A)_\omega$ such that $T^*aT = sas^* + tat^*$ for $a \in A$ and suitable canonical generators of $\mathcal{O}_2 \subset \mathcal{M}(A)$. It follows that $t_1 := Tt$ and $s_1 := Ts$ are isometries in $\mathcal{M}(A)_\omega$ such that $t_1^* s_1 = 0$ and the elements t_1 and s_1 commute elementwise with $A \subseteq A_\omega$. $C^*(s_1, t_1)$ contains a copy of $B := \mathcal{O}_\infty$ unitally.

The natural unital *-homomorphism from $\mathcal{M}(A)_\omega$ into $\mathcal{M}(A_\omega)$ fixes $A \subset A_\omega$ and maps, therefore, B unitally and, by simplicity of B, faithfully into $A' \cap \mathcal{M}(A_\omega)$. By Corollary 10.3.5 and Remark 10.3.6, $A \cong \mathcal{O}_\infty \otimes A$.

If id_A is approximately unitarily equivalent to $\mathrm{id}_A \oplus \mathrm{id}_A$, then the above considered T is unitary and $t_1 t_1^* + s_1 s_1^* = 1$, i.e., $C^*(s_1, t_1)$ is naturally isomorphic to $\mathcal{O}_2$. By Corollary 10.3.5 and Remark 10.3.6, $A \cong \mathcal{O}_2 \otimes A$. □

Corollary 10.3.8. *Suppose that A is a separable nuclear C*-algebra. Then A satisfies the WvN-property of Definition 1.2.3, if and only if, $A \otimes \mathbb{K} \cong A \otimes \mathbb{K} \otimes \mathcal{O}_\infty$.*

Proof. We may suppose that A is stable, because A satisfies the WvN-property if and only if $A \otimes \mathbb{K}$ satisfies the WvN-property, as one can see immediately from Definition 1.2.3.

Since $\mathcal{O}_\infty \cong \mathcal{O}_\infty \otimes \mathcal{O}_\infty \otimes \ldots$, we get from Proposition 3.10.15 that A is strongly p.i. and has the WvN-property if $A \cong A \otimes \mathcal{O}_\infty$.

If A is nuclear, then $\mathrm{id} \oplus \mathrm{id}$ is residually nuclear. Thus, if A satisfies the WvN-property, then $\mathrm{id} \oplus \mathrm{id}$ is approximately dominated by id. Hence, $A \cong A \otimes \mathcal{O}_\infty$ by Corollary 10.3.7. □

`Revise next. Give ref.`

REMARK 10.3.9. In the paper with M. Rørdam [**463**] we show that all strongly purely infinite C^*-algebras have the WvN-property.

```
Mention the corrections that have to be done
in the paper with Rørdam [463]
(as in Info for Ando)!!!
```

It is an open question if every purely infinite separable nuclear C^*-algebra has the WvN-property.

`Mention here:`

"regular Abelian C^*-subalgebra"

implies

"Abelian factorization",

implies existence of

"ideal-separating residually nuclear map"

(= "residually nuclear separation")

The progress is partly mentioned in Chp. 12.

COROLLARY 10.3.10. *Suppose that A and B are stable separable nuclear C^*-algebras, and that $h\colon A \to B$, $k\colon B \to A$ and $\psi\colon A \otimes \mathcal{O}_2 \to A \otimes \mathcal{O}_2$ are *-monomorphisms.*

(i) *If, for every primitive ideal $J \subset A$,*

$$\psi(J \otimes \mathcal{O}_2) = \psi(A \otimes \mathcal{O}_2) \cap (J \otimes \mathcal{O}_2),$$

then ψ is unitarily homotopic to the identity map of $A \otimes \mathcal{O}_2$.

(ii) *$h \otimes \mathrm{id}_{\mathcal{O}_2}$ is unitarily homotopic to an isomorphism from $A \otimes \mathcal{O}_2$ onto $B \otimes \mathcal{O}_2$ if $kh(J) = kh(A) \cap J$ and $hk(K) = hk(B) \cap K$ for every primitive ideal $J \subset A$ and every primitive ideal $K \subset B$.*

PROOF. (i): By assumption on ψ, ψ and id are both residually nuclear *-monomorphisms and induce on $A \otimes \mathcal{O}_2$ the same action of the primitive ideal space of A. Thus, by Corollary 7.4.3, ψ and id are unitarily homotopic.

(ii): Since A and B are stable, we find by (I) and (II) *-monomorphisms $h_1\colon A \to B$ and $k_1\colon B \to A$, such that h_1 is unitarily homotopic to h, k_1 is unitarily homotopic to k, $h_1(A)B$ is dense in B, $k_1(B)A$ is dense in A, and hk is unitarily homotopic to h_1k_1, kh is unitarily homotopic to k_1h_1. Thus h_1k_1 and k_1h_1 again take the system of closed ideals invariant. This carries over to $h_1k_1 \otimes \mathrm{id}_{\mathcal{O}_2}$ and

$k_1h_1 \otimes \mathrm{id}_{\mathcal{O}_2}$. Thus, part(i) and the above proven (III) imply, that $h_1 \otimes \mathrm{id}_{\mathcal{O}_2}$, and, therefore, $h \otimes \mathrm{id}_{\mathcal{O}_2}$ are unitarily homotopic to an isomorphism. □

We do not know if it is necessary to assume in the following Corollary 10.3.11 that the algebras B_n are stable.

Corollary 10.3.11. *Suppose that (B_n) is a sequence of separable stable C^*-algebras, and that $h_n \colon B_n \to B_{n+1}$ are *-homomorphisms.*

Let $B := \mathrm{indlim}(h_n : B_n \to B_{n+1})$.

If $B_n \cong B_n \otimes \mathcal{O}_\infty$ (resp. $B_n \cong B_n \otimes \mathcal{O}_2$) for $n = 1, 2, \ldots$, then $B \cong B \otimes \mathcal{O}_\infty$ (resp. $B \cong B \otimes \mathcal{O}_2$).

Proof. Let $h_n^\infty \colon B_n \to B$ the natural morphism and let $C_n := h_n^\infty(B_n)$. Since $\mathbb{K}$, $\mathcal{O}_\infty$ and $\mathcal{O}_2$ are simple and nuclear, C_n is stable and $C_n \cong C_n \otimes \mathcal{O}_\infty$ (resp. $C_n \cong C_n \otimes \mathcal{O}_2$).

The union of the stable subalgebras C_n is dense in B. By [**373**], cf. also Corollary 5.5.3, B is stable, i.e. $B \cong B \otimes \mathbb{K}$.

Therefore, we can assume, that $\mathcal{M}(B)$ contains isometries s, t with $ss^* + tt^* = 1$, such that $dC_n + C_n d \subset C_n$ for every $d \in C^*(s,t) \cong \mathcal{O}_2$ and $n \in \mathbb{N}$. Otherwise, we replace B by $B \otimes \mathbb{K}$, C_n by $C_n \otimes \mathbb{K}$, and h_n by $h_n \otimes \mathrm{id}_{\mathbb{K}}$.

By Corollary 10.3.7, $\mathrm{id}_B |C_n$ approximately dominates $(\mathrm{id}_B \oplus \mathrm{id}_B)|C_n$. Therefore, by Corollary 10.3.7, $B \cong B \otimes \mathcal{O}_\infty$.

If $C_n \cong C_n \otimes \mathcal{O}_2$, then, by Corollary 10.3.7, $\mathrm{id}_B |C_n$ is approximately unitarily equivalent to $(\mathrm{id}_B \oplus \mathrm{id}_B)|C_n$ by unitary elements of the multiplier algebra of C_n.

By [**180**], cf. [**816**, chp. 16], the unitary group of $\mathcal{M}(C)$ is contractible if C is σ-unital and stable, cf. our version **??** of a proof. It follows, that the unitary operators of $\mathcal{M}(C)$ can be approximated by unitary operators in the unitization of C in the strict (= strong*) topology.

Therefore, $\mathrm{id}_B |C_n$ is also approximately unitarily equivalent to $(\mathrm{id}_B \oplus \mathrm{id}_B)|C_n$ by unitaries in the unitization of B. Thus, the morphisms id_B and $\mathrm{id}_B \oplus \mathrm{id}_B$ are approximately unitarily equivalent. Thus, by Corollary 10.3.7, $B \cong B \otimes \mathcal{O}_2$. □

Corollary 10.3.12. *The class of separable nuclear C^*-algebras with WvN-property is closed under inductive limits.*

Proof. There is a more general result for inductive limits of strongly p.i. algebras (cf. [**463**]), but here we use Corollary 10.3.7.

Let $h_n : A_n \to A_{n+1}$, $n = 1, 2, \ldots$, a sequence of *-homomorphisms, where A_n is separable, nuclear and has the WvN-property. Let A denote its inductive limit, and let $B := A \otimes \mathbb{K}$.

By Definition 1.2.3, the class of C^*-algebras with WvN-property is closed under stabilization and passage to hereditary C^*-subalgebras, i.e., it suffices to show that B satisfies the WvN-property.

By Corollary 10.3.8, $B_n := A_n \otimes \mathbb{K}$, satisfies $B_n \cong B_n \otimes \mathcal{O}_\infty$ and B is the inductive limit of the sequence $h_n \otimes \mathrm{id}_\mathbb{K} \colon B_n \to B_{n+1}$.

Therefore, by Corollary 10.3.11, $B \cong B \otimes \mathcal{O}_\infty$.

B is separable, stable and nuclear. Thus B has the WvN-property by Corollary 10.3.8. □

CHAPTER 11

PI-SUN algebras represent the nuclear KK-classes

In this Chapter we prove Theorem I of Chapter 1 and some additional results.

There are different methods to construct purely infinite algebras that are $\mathrm{KK}^G(X;\cdot,\cdot)$-equivalent to a given separable (G,X)-algebra, and have simple fibers with respect to the action of X.

(1) inductive limit construction in the case of exact algebras and exact discrete groups, 1a) direct inverses in Ext. 1b) using σ-additivity of KK w.r.t. first variable.

(2) construction of a suitable Toeplitz-Pimsner algebra (such that it is equal to the corresponding Cuntz-Pimsner algebra).

`Citation from Chapter 1, changes to bundle/equvariant case: ??`

In fact, we prove in Chapter 11 a more general result for continuous fields $(A_x)_{x\in X}$ of exact C^*-algebras A_x on a compact Hausdorff space X with the additional property that the algebra $\mathcal{A}$ of continuous sections is exact (which is e.g. the case if all fibers A_x are nuclear or if X is finite):

One has to take again $\mathcal{A}_t := \mathcal{A}\otimes\mathcal{O}_\infty{}^{\mathrm{st}}$ if $\mathcal{A}$ is unital, and define $\mathcal{A}_t$ as the natural unital split extension of

$$\mathrm{C}(X,\mathcal{O}_2)\cong[\mathrm{C}(X)1_{\mathcal{M}(\mathcal{A})}]\otimes\mathcal{O}_2$$

by $\mathcal{A}\otimes\mathcal{O}_\infty{}^{\mathrm{st}}$ if $\mathcal{A}$ is not unital. Then one can use the sub-trivialization theorem of E. Blanchard [**89**] (that can be shown using Theorem A and is a special case of Theorem K), to get a unital $\mathrm{C}(X)$-module *-monomorphism $h_0^u\colon\mathcal{A}_t\to\mathrm{C}(X,\mathcal{O}_2)\subset\mathcal{A}_t$. We define again $h:=\mathrm{id}_{\mathcal{A}_t}\oplus h_0^u$ and let $\mathcal{P}(\mathcal{A}):=\mathrm{indlim}(h\colon\mathcal{A}_t\to\mathcal{A}_t)$. All the operations are consistent with the above defined constructions of $(A_x)_t$ and $P(A_x)$ for the fibers A_x of $(A_x)_{x\in X}$. It is not difficult to see that $(P(A_x))_{x\in X}$ is a continuous field of C^*–algebras, and that $\mathcal{P}(\mathcal{A})$ is the algebra of continuous sections of this field. By construction, $\mathcal{P}(\mathcal{A})$ is exact. Further, the *-monomorphisms $\eta_x\colon A_x\to P(A_x)$ define a $\mathrm{C}(X)$-module monomorphism η from $\mathcal{A}$ into $\mathcal{P}(\mathcal{A})$.

We show in Chapter 11 the more general result:
The monomorphism η defines a $\mathrm{KK}(X;\cdot,\cdot)$-equivalence between $\mathcal{A}$ and $\mathcal{P}(\mathcal{A})$. ([1]).

At the end of Chapter 11 we outline an other construction that leads to $\mathrm{KK}(X;\cdot,\cdot)$-equivalent exact (respectively nuclear) algebras with primitive ideal space isomorphic to X (cf. Theorems 11.4.1 and O):

[1]The $\mathrm{KK}(X;\mathcal{A},\mathcal{B})$ is for compact metric spaces X just the Kasparov functor $\mathcal{R}\,\mathrm{KK}^G(X;.,.)$ for the base space X, G is the trivial group).

One starts with a suitable Hilbert bimodule and builds the corresponding Cuntz–Krieger–Pimsner algebra. The construction has the advantage that G-actions of locally compact groups G on $(A_x)_{x\in X}$ lead in a natural way to G-actions on $(P(A_x)\otimes \mathbb{K})_{x\in X}$ ([2]).

Furthermore, we modify in Chapter 11 the above described construction of $A \Rightarrow P(A)$ in a way that we get (cf. Theorem 11.0.7):

Suppose that A is a unital separable exact C^*-algebra, G is a countable (discrete) exact *group, and that $\alpha\colon G\to \mathrm{Aut}(A)$ is a group-morphism.*

Then there exist a purely infinite exact unital C^*-algebra B, a group-morphism $\beta\colon G\to \mathrm{Aut}(B)$ and a G-equivariant unital monomorphism *$\eta\colon A\to B$ that defines a KK^G-equivalence $[\eta]\in \mathrm{KK}^G(A,B)$.*

It can be managed that $\eta(A)$ is the range $E(B)$ of a $\beta(G)$-equivariant conditional expectation E on B.

If — in addition — A is nuclear, then one can find B, β and E, such that B is nuclear — in addition —.

`some new approach:`

Definition: ????????????

To get some more general and farer going results on KK-equivalent embedding into purely infinite algebras, we have to make some definitions, concerning maps that changes the identity maps not to much in the sense of KK-theory.

Definition 11.0.1. Suppose that D is unital, separable and exact. A unital monomorphism $h\colon D\to E$ will be called **elementary** if there are

(i) a unital *-monomorphism $h_0\colon D\to \mathcal{O}_2$,
(ii) a *-monomorphism $\gamma\colon \mathcal{O}_2\to\mathcal{O}_\infty$, and
(iii) an isometry $T\in\mathcal{O}_\infty$
(iv) an isomorphism $\iota\colon D\otimes\mathcal{O}_2\to E$ such that

$$h(d)=\iota((d\otimes TT^*)+(1\otimes\gamma(h_0(d))))\quad \text{for all}\ \ d\in D\,.$$

We call h **plain** if $E=D\otimes\mathcal{O}_\infty$ and $\iota=\mathrm{id}$.

`More generally:`

Suppose $\mathcal{O}_\infty\subset\mathcal{M}(D)$, $k_0\colon D\otimes\mathcal{O}_2\to D\otimes\mathcal{O}_\infty$, $h_0(d):=k_0(d\otimes 1)$, “sufficiently” degenerate. consider similar sum-construction variants

$h(d):=TdT^*+h_0(d)$ etc.

Consider the cases of bundles, to see what is the right definition.

$h_0\colon D\to \mathrm{C}_0(X,\mathcal{O}_2)$

[2] At least in the case where A_x is is nuclear, because then, by Theorem M(iii), there are $\mathrm{C}(X)$-module isomorphisms of $\mathcal{P}(\mathcal{A})\otimes\mathbb{K}$ onto any other purely infinite stable separable nuclear $\mathrm{C}(X)$-algebra $\mathcal{B}$ (with simple fibers B_x) that is $\mathrm{KK}(X;\cdot,\cdot)$-equivalent to $\mathcal{A}$.

generally:

Some continuous action of a lattice $\mathbb{O}$ on D should be given.

$$k_0 \colon D \otimes \mathcal{O}_2 \to D \otimes \mathcal{O}_\infty$$

universally for that action (if k_0 goes into $D \otimes \mathcal{O}_\infty$???)

Suppose that $D_1 \to D_2 \to \cdots \to D_k$ are given by elementary morphisms $h_n \colon D_n \to D_{n+1}$ and suppose that $D_1 \cong D_1 \otimes \mathcal{O}_\infty$.

By definition there are isomorphisms $\iota_n \colon D_n \otimes \mathcal{O}_\infty \to D_{n+1}$ related to h_n. Consider

$$\lambda_{j,k} := \iota_j \otimes \mathrm{id} \otimes \cdots \otimes \mathrm{id} \colon D_j \otimes \mathcal{O}_\infty \otimes \mathcal{O}_\infty{}^{\otimes(k-j)} \to D_{j+1} \otimes \mathcal{O}_\infty{}^{\otimes(k-j)}$$

$\eta_k := \lambda_k \otimes \cdots \otimes \lambda_1 \colon D_1 \otimes \mathcal{O}_\infty{}^{\otimes k} \to D_{k+1}$.

The system is called homotopy-commutative, if $\eta_k \otimes \mathrm{id}$ is unitarily homotopic to η_{k+1} and if every unitary homotopy on the boundary of a triangle extends to a homotopy in the interior.

`more precise !!!  ???`

Technical Lemma:

LEMMA 11.0.2. *Iterations of elementary morphisms h are elementary.*

Elementary morphisms $h_1, h_2 \colon D \to E$ are unitarily homotopic if

$$\iota_1, \iota_2 \colon D \otimes \mathcal{O}_\infty \to E$$

are unitarily homotopic.

Elementary h is a KK-*equivalence.*

There is a conditional expectation $P_h \colon E \to h(D)$.

Others???

PROPOSITION 11.0.3. *Suppose that D_1 is separable and exact, $h_n \colon D_n \to D_{n+1}$, $n \in \mathbb{N}$, is a sequence of elementary morphisms and $D_1 \cong D_1 \otimes \mathcal{O}_\infty$. Let*

$$P := \mathrm{indlim}(h_n \colon D_n \to D_{n+1})\,.$$

(i) *P is simple, purely infinite, separable, unital and exact (respectively is pi-sun if the D_n are nuclear).*
(ii) *There is an approximately inner conditional expectation $E \colon P \to P$ onto $h_{1,\infty}(D_1)$, $h_{1,\infty}$ is injective.*
(iii) *The unital monomorphism $h_{1,\infty} \colon D_1 \to P$ defines a* KK-*equivalence between D_1 and P, if the ι_n-diagrams (to/for $D_1 \otimes \mathcal{O}_\infty$) are homotopy commutative.*

The idea is, that one considers the m.o.c. cones $\mathcal{C}_{k,\ell} \subset \mathrm{CP}(D_k, D_\ell)$, $\mathcal{C}_{k,\infty} \subset \mathrm{CP}(D_k, P)$ and $\mathcal{C}_{\infty,k} \subset \mathrm{CP}(P, D_k)$ that are generated by the $h_{k,\ell}$, $h_{k,\infty}$ and conditional expectations from P onto $h_{1,k}(D_1) \subseteq D_k$ etc.

The consider (perhaps $\mathcal{C}$ and "action" - equivariant) asymptotic morphisms:

I.e. consider/construct/define a "natural" asymptotic morphism $\phi\colon P \to \mathrm{Q}(\mathbb{R}_+, D_1)$, such that $\mathrm{Q}(\mathbb{R}_+, h_{1,\infty})\colon \mathrm{Q}(\mathbb{R}_+, D_1) \to \mathrm{Q}(\mathbb{R}_+, P)$ has the property that $[\mathrm{Q}(\mathbb{R}_+, h_{1,\infty}) \circ \phi]\colon P \to \mathrm{Q}(\mathbb{R}_+, P)$ is homotopic to $\mathrm{id}_P\colon P \to \mathrm{Q}(\mathbb{R}_+, P)$ and $\phi \circ h_{1,\infty}\colon D_1 \to \mathrm{Q}(\mathbb{R}_+, D_1)$ is homotopic to $\mathrm{id}_{D_1}\colon D_1 \to \mathrm{Q}(\mathbb{R}_+, D_1)$.

But all this inside the given m.o.c. cones.

The proof will be postponed to Section **??**. (Sec. 11.2 ??)

Instead we first deduce from Proposition 11.0.3 the proof of Theorem I, the proof of its $C(X)$-modular generalization Corollary 11.0.5, and the proof of Theorem 11.0.7, that gives a G-equivariant generalization of Theorem I.

Theorem

THEOREM 11.0.4. *Suppose that A is a stable separable C^*-algebra.*

*Let X a T_0 space and $\Psi\colon \mathbb{O}(X) \to \mathcal{I}(A)$ an action of X on A such that there exists a non-degenerate nuclear *-monomorphism $k_0\colon A \otimes \mathcal{O}_2 \to A \otimes \mathcal{O}_\infty$ that is maximal with respect to the Ψ-residually nuclear maps* and reproduces Ψ*, i.e., $J \in \mathcal{I}(A)$ is in the image of Ψ, if and only if, $k_0(J \otimes \mathcal{O}_2) = k_0(A \otimes \mathcal{O}_2) \cap (J \otimes \mathcal{O}_\infty)$.*

????????????????

Let $h_0 := k_0((\cdot) \otimes 1)$ and $h := \mathrm{id} \oplus (h_0 \otimes \mathrm{id})$. Then $P := \mathrm{indlim}(h\colon A \otimes \mathcal{O}_\infty \to A \otimes \mathcal{O}_\infty)$ is exact (respectively nuclear if A is nuclear), strongly purely infinite (more precisely: $P \cong P \otimes \mathcal{O}_\infty$), $\mathrm{Prim}(P) \cong X$, and $\eta\colon a \in A \mapsto h_{1,\infty}(a \otimes 1) \in P$ defines a is a $\mathrm{KK}(X; \cdot, \cdot)$-equivalence $[\eta] \in \mathrm{KK}(X;\, A, P)$.

COROLLARY 11.0.5. *Let X a locally compact Polish space. Suppose that $\mathcal{A}$ is a separable exact $\mathrm{C}_0(X)$-C^*-algebra, such that $x \in X \to \|a_x\|$ is continuous for every $a \in \mathcal{A}$ (i.e., $\mathcal{A}$ is the algebra of continuous sections vanishing at infinity of a continuous field of C^*-algebras A_x). And let $\mathcal{P}(\mathcal{A})$ be defined as above.*

Then $\mathcal{P}(\mathcal{A})$ is a strongly purely infinite exact $\mathrm{C}_0(X)$-C^*-algebra with simple purely infinite fibers $P(A_x)$, and $\mathcal{P}(\mathcal{A}) \cong \mathcal{P}(\mathcal{A}) \otimes \mathcal{O}_\infty$.

The natural map $\eta\colon A \to P(A)$ defines a $\mathrm{KK}(X; \cdot, \cdot)$-equivalence.

LEMMA 11.0.6. *If $D \cong D \otimes \mathcal{O}_\infty$ and if discrete exact G acts on D by $\alpha\colon G \to \mathrm{Aut}(D)$, then there exists a unitary representation $U\colon G \to \mathcal{U}(\mathcal{O}_\infty)$ and an elementary morphism $h\colon D \to D \otimes \mathcal{O}_\infty$ with ι unitarily homotopic to* id*, such that $h \circ \alpha(g) = (\alpha(g) \otimes \mathrm{Ad}(U(g))) \circ h$ for $g \in G$.*

PROOF. Use an unital embedding η of the exact unital algebra $D \rtimes_{r,\alpha} G$ into $\mathcal{O}_2$. One may suppose that $\mathcal{O}_2$ is unitally contained in $(1 - s_1 s_1^*)\mathcal{O}_\infty(1 - s_1 s_1^*)$ for $\mathcal{O}_\infty = C^*(s_1, s_2, \ldots)$. Then $U(g) = \eta(g) + TT^*$ has the property for $T = s_1$. □

THEOREM 11.0.7. *Suppose that A is an separable unital nuclear C^*-algebra, and $\alpha\colon G \to \mathrm{Aut}(A)$ is an action of a countable discrete exact group G on A.*

Then there exist a pi-sun algebra B with an action $\beta\colon G \to \mathrm{Aut}(B)$ of G on B and a G-equivariant unital monomorphism *$\eta\colon A \to B$ that defines a* KK*-equivalence $[\eta] \in \mathrm{KK}(A, B)$.*

In particular, $\mathrm{K}_*(\beta(g))\circ \mathrm{K}_*(\eta) = \mathrm{K}_*(\eta)\circ \mathrm{K}_*(\alpha(g))$ *and* $\mathrm{K}_*(\eta)\colon \mathrm{K}_*(A) \to \mathrm{K}_*(B)$ *is invertible.*

It seems that (B, β) and η can be chosen, such that η defines even a KK^G-equivalence $[\eta] \in \mathrm{KK}^G(A, B)$. (only "seems" ???)

Proof. Let G act on $D_1 := A \otimes \mathcal{O}_2$ by $\alpha_1(g) := \alpha(g) \otimes \mathrm{id}$ for $g \in G$. Clearly the map $k\colon a \to a \otimes 1$ is a G-equivariant monomorphism from A into D_1, and $[k] \in \mathrm{KK}^G(A, D_1)$ is a KK^G-equivalence, in particular $[k] \in \mathrm{KK}(A, D_1)$ is a KK-equivalence. Let $D_n := A \otimes ({\mathcal{O}_\infty}^{\otimes n})$. By Lemma 11.0.6 there exists actions $\alpha_n\colon G \to \mathrm{Aut}(D_n)$ and G-equivariant plain elementary morphisms $h_n\colon D_n \to D_{n+1}$.

Now let $B := \mathrm{indlim}\, D_n$ and $\eta := h_{1,\infty} \circ k$. Since the h_n are G-equivariant, there is a group morphism $\beta\colon G \to \mathrm{Aut}(B)$ with $h_{1,\infty} \circ \alpha_1(g) = \beta(g) \circ h_{1,\infty}$ for $g \in G$. By Proposition 11.0.3, B is pi-sun and the morphism η defines a KK-equivalence $[\eta] \in \mathrm{KK}(A, B)$. □

Remark 11.0.8. We call a group G ***C*-liftable*** if, for every pi-sun algebra B in the UCT-class with finitely generated $\mathrm{K}_*(B)$ and every grading-preserving action $\gamma\colon G \to \mathrm{Aut}(\mathrm{K}_*(B))$ of G on $\mathrm{K}_*(B)$ that fixes the class $[1] \in \mathrm{K}_0(B)$, there exists an action $\beta\colon G \to \mathrm{Aut}(B)$ such that for the natural group morphism $\mu\colon \mathrm{Aut}(B) \to \mathrm{Aut}(\mathrm{K}_*(B))$ holds $\mu \circ \beta(g) = \gamma \circ \mu$.

The Theorem 11.0.7 implies that the problem of the determination of all C^*-liftable groups G is equivalent to the question under which circumstances for a finitely generated Abelian group H and an action $\gamma_0\colon G \to \mathrm{Aut}(H)$ with G-fixed element $x_0 \in H$ there is a unital nuclear C^*-algebra A in the UCT-class and an action $\alpha\colon G \to \mathrm{Aut}(A)$ such that $\mathrm{K}_1(A) = 0$ and there is an isomorphism $\gamma\colon H \to \mathrm{K}_0(A)$

???????????

Then the case $\mathrm{K}_0(A) = 0$ and $\mathrm{K}_1(A) = H$ can then be studied by replacing A by $A \otimes \mathcal{P}_\infty$, where $\mathcal{P}_\infty$ is the unique pi-sun algebra in the UCT class with $\mathrm{K}_0(\mathcal{P}_\infty) = 0$ and $\mathrm{K}_1(\mathcal{P}_\infty) = \mathbb{Z}$ ([3]).

The general case follows from the consideration of $A = A_1 \oplus (A_2 \otimes \mathcal{P}_\infty)$ in Theorem 11.0.7, where $\mathrm{K}_1(A_j) = 0$ for $j = 1, 2$.

It is evident that every free group is in this class of groups.

`It is not clear if` $\mathrm{Aut}(B) \to \mathrm{KK}(B, B)^{-1}$ `is surjective for pi-sun` B `in UCT-class !!! ??` By the natural epimorphisms (???) $\mathrm{Aut}(B) \to \mathrm{KK}(B, B)^{-1} \to \mathrm{Aut}(\mathrm{K}_*(B))$, (given by the UCT and Theorem B).

---

[3]One can easily show that $\mathcal{P}_\infty = {\mathcal{O}_\infty}^{st} \rtimes \mathbb{Z}_2$ for the flip action μ of $\mathbb{Z}_2$ on the standard form ${\mathcal{O}_\infty}^{st} \cong \mathcal{P}_\infty \otimes \mathcal{P}_\infty$ with $\mathrm{K}_0(\mu)(x) = -x$ — it is simply the flip on the tensor product, cf. [**448**, Rem.4.3(2)] and observe that, for the coordinate flip on $\mathbb{R}^2$, the crossed product $\mathrm{C}_0(\mathbb{R}^2) \rtimes \mathbb{Z}_2$ is isomorphic to $\mathrm{C}_0(\mathbb{R}) \otimes C$, with $C := \{f \in \mathrm{C}_0(\mathbb{R}_0, M_2)\,;\ f(0) = \text{diagonal}\}$, i.e., $\mathrm{K}_*(C) = (\mathbb{Z}, 0)$.

Contributions of J. Spielberg [**732**] and (farer going) results of T. Kasura ([**416**], [**417**]) show that in particular all cyclic groups are C^*-liftable.

Begin of old text:

Note that we can construct in the case of exact algebras only KK-equivalences, but not $\mathrm{KK}_{\mathrm{nuc}}$-equivalences because thre is no useful non-elementary criteria for which exact separable A the identity map of A defines a class $[\mathrm{id}_A]$ in $\mathrm{KK}_{\mathrm{nuc}}(A,A)$. (But there is a natural map from $\mathrm{KK}_{\mathrm{nuc}}(A,A)$ onto an ideal of the ring $\mathrm{KK}(A,A)$.)

Recall that ${\mathcal{O}_\infty}^{st} := (1-s_1s_1^*)\mathcal{O}_\infty(1-s_1s_1^*) \subset \mathcal{O}_\infty$. It contains a copy of $\mathcal{O}_2$ unitally.

If A is exact, separable and unital let $A_t := A \otimes {\mathcal{O}_\infty}^{st}$. If A is exact, separable and non-unital, then let A_t denote the unital C^*-subalgebra of $\mathcal{M}(A)\otimes {\mathcal{O}_\infty}^{st}$ given by

$$A_t := A \otimes {\mathcal{O}_\infty}^{st} + 1 \otimes \mathcal{O}_2 \subseteq \mathcal{M}(A) \otimes {\mathcal{O}_\infty}^{st} \,,$$

a split extension of $\mathcal{O}_2$ by $A \otimes {\mathcal{O}_\infty}^{st}$.

One can variate the construction if A is stable to get a stable version of A_t by considering first a copy of $\mathbb{K} \subset \mathcal{M}(A)$ with $\mathbb{K} \cap A = \{0\}$ and $\mathbb{K}\cdot A = A$, existing by Remark 5.1.1(8), and then let $A_t := A \otimes {\mathcal{O}_\infty}^{st} + \mathbb{K}\otimes \mathcal{O}_2$, contained in $\mathcal{M}(A)\otimes {\mathcal{O}_\infty}^{st}$.

Let S, T the generators of $\mathcal{O}_2 = C^*(S,T;\, SS^* + TT^* = 1, S^*S = 1 = T^*T)$.

The algebra A_t is exact because A is exact and ${\mathcal{O}_\infty}^{st}$ and $\mathcal{O}_2$ are nuclear (cf. [**432**]).

To avoid later problems with notations, now we change the notation for A_t: Let $B := A_t$ in the sequel. Note that the exact C*-algebra B is unital and contains $\mathcal{O}_2$ unitally.

Define $h := \mathrm{id}_B \oplus h_0^u$ where the unital monomorphism $h_0^u \colon B \to \mathcal{O}_2 \subset B$ is as described in Chapter 1 before Theorem B. (Respectively, if A is stable, let $h := \mathrm{id}_B \oplus h_0$ for the more general non-degenerate "maximal" ideal-system preserving nuclear map h_0 from $A \otimes \mathcal{O}_\infty$ into $C \subset A \otimes \mathcal{O}_\infty$, where C is a nuclear and stable, $\mathcal{O}_2$ absorbing C^*-subalgebra of $A \otimes \mathcal{O}_2$ with the ideal system of A)

$P(A) := \mathrm{indlim}(h\colon B \to B)$ is purely infinite and simple by the criteria in

check if (iv) or (v) is used Proposition 2.2.5(iv)

for $h_n = h$, $B_n = B$, because for $\varepsilon > 0$, a, b in B_+ with $\|a\| = \|b\| = 1$ we can find an isometry v in $\mathcal{O}_2$ such that $\|1 - v^* h_0(a) v\| < \varepsilon$. Thus

$$\|h(b) - h(b)^{1/2} v^* t^* h(a) t v h(b)^{1/2}\| < \varepsilon \,.$$

Since exactness is closed under inductive limits ([**432**]), $P(A)$ is exact. $P(A)$ is nuclear if moreover A (and hence B) is nuclear.

The ideal system is the same as that from A because h is ideal system preserving.

For a proof of Theorem I it remains to show:

(i) *There is a conditional expectation from the hereditary C^*-subalgebra D of $P(A)$ generated by $A \otimes p$ onto $A \otimes p \cong A$, and*

(ii) *the inclusion map* $A \cong A \otimes p \subset B \cong h_1^\infty(B) \subset P(A)$ *defines a* KK-*equivalence between* A *and* $P(A)$.

The projection $p = s_2 s_2^*$ is in ${\mathcal{O}_\infty}^{st} = (1 - s_1 s_1^*)\mathcal{O}_\infty(1 - s_1 s_1^*) \subset \mathcal{O}_\infty$. $A \cong A \otimes p \to A \otimes {\mathcal{O}_\infty}^{st}$ is a KK-equivalence, because $\mathbb{C}p \to {\mathcal{O}_\infty}^{st}$ defines a KK-equivalence between $\mathbb{C}$ and ${\mathcal{O}_\infty}^{st}$ and because one can tensor KK-equivalences (by nuclear algebras). It can be seen from the the 6-term exact sequences and from $\mathrm{KK}(., \mathcal{O}_2) = \mathrm{KK}(\mathcal{O}_2, .) = 0$ that $A \otimes {\mathcal{O}_\infty}^{st} \to B$ defines a KK-equivalence. Thus $A \cong A \otimes p \to B$ defines a KK-equivalence between A and B. The hereditary subalgebra of B generated by $A \otimes p$ is $A_0 := A \otimes p\mathcal{O}_\infty p \subset A \otimes {\mathcal{O}_\infty}^{st} \subset B$. Thus $A \otimes p$ is the range of a conditional expectation from the hereditary C*-subalgebra A_0 onto $A \otimes p$.

Above we have seen that the proof of Theorem I, (i.e. of (i) and (ii) above) reduces to the proof of the following:

(i*) $h_1^\infty(B)$ *is the range of a conditional expectation on* $P(A)$, *and*
(ii*) $h_{1,\infty}\colon B \to P(A)$ *defines a* KK-*equivalence* $[h_{1,\infty}] \in \mathrm{KK}(B, P(A))$.

We show $(i*)$ by an induction procedure and then use homotopy invariance of unsuspended E-theory $\mathrm{R}(B, P(A))$ and $\mathrm{R}(P(A), B)$ to prove (ii^*). More precisely we construct a unital asymptotic morphism $g\colon P(A) \to \mathrm{C_b}(\mathbb{R}_+, B)$ such that $g \circ h_{1,\infty}$ is homotopic to id_B and $h_{1,\infty} \circ g$ is homotopic to $\mathrm{id}_{P(A)}$. By the homotopy invariance of Rørdam groups it follows that $h_{1,\infty}$ is a KK-equivalence.

Cuntz addition of morphisms is the same as the "direct" sum of morphisms (after stabilization) and thus induces the sum for the corresponding KK-elements:

$[\mathrm{id}_B] + [h_0] = [\mathrm{id}_B \oplus h_0] = [h]$ and $2[h_0] = [h_0 \oplus h_0] = [h_0]$. It follows that $[h_0] = 0$ and $[h] = [\mathrm{id}]$ in $\mathrm{KK}(B, B)$.

Thus it suffices to show that the following statements (α) and (β) are true in order to prove (i*) and (ii*):

(α) *There is a family of conditional expectations* E_n^m *from* $h_m^\infty(B)$ *onto* $h_n^\infty(B)$ *for* $n < m$ *such that* $E_n^{m+k} h_m^\infty = E_n^m h_m^\infty$. *and* $E_n^k E_m^k h_k^\infty = E_n^k h_k^\infty$ *for* $n < m < k$.

They define conditional expectations $E_n\colon P(A) \to h_n^\infty(B) \subset P(A)$ *with* $E_n(P(A)) = h_n^\infty(B)$ *and* $E_n E_m = E_{min(n,m)}$.

(β) *There exists a completely positive unital map* $V\colon P(A) \to \mathrm{C_b}(\mathbb{R}_+, B)$ *such that* $V(b^*b) - V(b)^*V(b) \in \mathrm{C_0}(\mathbb{R}_+, B)$ *for every* $b \in P(A)$, *and* $[(\pi \circ V) \circ h_1^\infty] = [h] \in \mathrm{KK}(B, B)$, $[h_1^\infty \circ (\pi \circ V)] = [\mathrm{id}_{P(A)}] \in \mathrm{KK}(P(A), P(A))$.

The completely positive maps V, $V \circ h_1^\infty$ and $h_1^\infty \circ V$ in statement (β) define elements of $\mathrm{Ext}^{-1}(P(A), SB)$, $\mathrm{Ext}^{-1}(B, SB)$ and $\mathrm{Ext}^{-1}(P(A), SP(A))$ and [.] denote the corresponding elements of $\mathrm{KK}(., .) \cong \mathrm{Ext}^{-1}(., S(.))$.

1. Proof of (α)

We start with the proof of (α). The proof of (β) is conceptional quite simple but requires some preparation.

PROOF OF (α): By induction we find $(s^n)^*h^n(b)s^n = b$ for $b \in B$ and $n = 1, 2, \ldots$:

$$b = s^*(sbs^* + th_0^u(b)t^*)s = s^*h(b)s = s^*(s^n)^*h^n(h(b))(s^n)s = (s^{n+1})^*h^{n+1}(b)s^{n+1}.$$

Let T_n be given by $T_n(b) := h^n((s^n)^*bs^n)$ and $T_0 = \mathrm{id}_B$. Then T_n is a conditional expectation from B onto $h^n(B)$, because $T_n(B) \subset h^n(B)$ and $T_n(b) = b$ for b in $h^n(B)$, because $(s^n)^*h^n(b)s^n = b$.

The conditional expectations T_n satisfy $T_{n+k}h^k = h^kT_n$ and $T_nT_m = T_{\min(n,m)}$:

The first equation follows from $h^{n+k}((s^n)^*(s^k)^*h^k(b)s^ks^n) = h^k(h^n((s^n)^*bs^n))$.

Certainly $T_nT_m = T_m$ if $n \leq m$ if $n \leq m$ and for $m < n$ we have

$$T_nT_m(b) = h^n((s^n)^*h^m((s^m)^*bs^m)s^n) = h^n((s^{n-m})^*(s^m)^*bs^ms^{n-m}) = T_n.$$

Now we define conditional expectations E_n^m ($n < m$) from $h_m^\infty(B)$ onto $h_n^\infty(B) = h_m^\infty(h^{m-n}(B))$ by

$$E_n^m(b) := h_m^\infty T_{m-n}(h_m^\infty)^{-1}(b)$$

for b in $h_m^\infty(B)$, i.e. by $E_n^m h_m^\infty = h_m^\infty T_{m-n}$.

Then $E_n^m h_k^\infty = E_n^k h_k^\infty$ for $n < m$ and $n < k \leq m$ because

$$E_n^m h_k^\infty = E_n^m h_m^\infty h^{m-k} = h_m^\infty T_{m-n} h^{m-k} = h_m^\infty h^{m-k} T_{k-n} = h_k^\infty T_{k-n} = E_n^k h_k^\infty.$$

If $n < m < k$ we have $E_n^k E_m^k = E_n^k$ because

$$E_n^k E_m^k h_k^\infty = E_n^k h_k^\infty T_{k-m} = h_k^\infty T_{k-n} T_{k-m} = h_k^\infty T_{k-n} = E_n^k h_k^\infty.$$

The consistency of the E_n^m implies the existence and uniqueness of conditional expectations $E_n \colon P(A) \to h_n^\infty(B)$ from $P(A)$ onto $h_n^\infty(B)$ such that $E_n h_k^\infty = E_n^m h_k^\infty$ for $n \leq k \leq m$. Then $E_n E_m = E_m$ if $m \leq n$.

Let $n < m < k \in \mathbb{N}$ then

$$E_n E_m h_k^\infty = E_n E_m^k h_k^\infty = E_n^k E_m^k h_k^\infty = E_n^k h_k^\infty = E_n h_k^\infty\,.$$

Thus $E_n(P(A)) = h_n^\infty(B)$, $E_n E_m = E_{min(n,m)}$ and (α) is shown. □

2. Preliminaries for the proof of (β)

We need some observations for the proof of (β). They are based on elementary properties of $\mathcal{O}_2$ and of Proposition 11.2.2 (which is related to Theorem B).

LEMMA 11.2.1. *Let A be a unital C*-algebra, then the unitary group of $A \otimes \mathcal{O}_2$ is simply connected.*

In particular, any continuous map $u \colon \partial([0,1]\times[0,1]) \to U(\mathcal{O}_2)$ from the boundary of the square $[0,1]\times[0,1]$ into the unitaries of $\mathcal{O}_2$ extends to a continuous map from the square into the unitaries of $\mathcal{O}_2$.

PROOF. Let $F := A \otimes \mathcal{O}_2$. We consider $\mathcal{O}_2 \cong 1 \otimes \mathcal{O}_2$ as a unital subalgebra of F with generators $\{s,t\}$ (to simplify notation). The unital endomorphism $\delta(a) = sas^* + tat^* = a \oplus a$, is point-norm homotopic inside the endomorphisms of $\mathcal{O}_2$ to $\mathrm{id}_{\mathcal{O}_2}$, by [**172**, prop.2.2], $\mathcal{O}_2$ is K_1-injective by [**172**, thm.1.9], and $\mathrm{K}_1(\mathcal{O}_2) = 0$ by [**172**, thm.3.8].

Thus, $\mathcal{U}(\mathcal{O}_2) = \mathcal{U}_0(\mathcal{O}_2)$, and it follows that $\mathrm{id}_A \otimes \delta$ is homotopic to id_F and $u \sim_h u \oplus u$ in $\mathcal{U}(F)$.

Notice that $v \oplus 1$ is unitarily equivalent to $1 \oplus v$ by the selfadjoint unitary $U_c := ts^* + st^*$ in $M_2 \subset \mathcal{O}_2$ and $(u_1 \oplus u_2) \oplus u_3$ is unitarily equivalent to $u_1 \oplus (u_2 \oplus u_3)$ by the unitary $U_d \in \mathcal{U}(\mathcal{O}_2) = \mathcal{U}_0(\mathcal{O}_2)$, defined by equation (2.4), see Lemma 4.2.6(o) or Proposition 4.3.2.

Since the unitary group of $\mathcal{O}_2$ is connected by [**172**, thm.1.9, thm.3.8], we get that the unitary $U_d \in \mathcal{O}_2$ defined by equation (2.4) is homotopic to 1 in E. Together we get the following homotopies in the unitary group of F:

$u \sim u \oplus u = (u \oplus 1)(1 \oplus u) \sim u^2 \oplus 1$, and with $v = u^2$

$$1 = (v \oplus 1)(v^* \oplus 1) \sim v \oplus v^* \sim (v \oplus v) \oplus v^* \sim v \oplus (v \oplus v^*) \sim v \oplus 1 = u^2 \oplus 1.$$

Thus $u \sim 1$.

For $T := \partial([0,1]\times[0,1])$ and $D := [0,1]\times[0,1]$ this implies that the epimorphism $\mathrm{C}(D, \mathcal{O}_2) \to \mathrm{C}(T, \mathcal{O}_2)$ maps the unitary group of $\mathrm{C}(D, \mathcal{O}_2)$ onto the unitary group of $\mathrm{C}(T, \mathcal{O}_2) \cong \mathrm{C}(T) \otimes \mathcal{O}_2$. □

The following Proposition 11.2.2 generalizes some aspects of Theorem B.

The unitary equivalence modulo $\mathrm{C}_0(\mathbb{R}_+, \mathrm{C}(X,D))$ implies that k and h define the same element of $\mathrm{Ext}_{\mathrm{nuc}}(A, S\,\mathrm{C}(X,D))$.

Thus $[h] = [k]$ in $\mathrm{KK}_{\mathrm{nuc}}(A, \mathrm{C}(X,D))$.

Parts (i) and (ii) of Proposition 11.2.2 simply mean that $h \oplus h_0^u$, h and k are unitarily homotopic in $\mathrm{C}(X,D)$ if $h(A)$ and $k(A)$ are contained in $\mathrm{C}(X,D) \subset \mathrm{C}_\mathrm{b}(\mathbb{R}_+, \mathrm{C}(X,D))$.

By $\pi_y \colon \mathrm{C}_\mathrm{b}(Y,D) \to D$ we denote the evaluation at the point $y \in Y = \mathbb{R}_+ \times X$.

PROPOSITION 11.2.2. *Suppose that X is a compact space, D is a unital simple purely infinite C*-algebra which contains a copy of $\mathcal{O}_2$ unitally, that A a unital separable exact C*-algebra, and that $h, k \colon A \to \mathrm{C}_\mathrm{b}(\mathbb{R}_+ \times X, D) \cong \mathrm{C}_\mathrm{b}(\mathbb{R}_+, \mathrm{C}(X,D))$ are unital C*-morphisms with the property that, for every $y \in \mathbb{R}_+ \times X$, $\pi_y h$ and $\pi_y k$ are monomorphisms. Then:*

(i) *There is a unitary* $U_0 \in \mathrm{C_b}(\mathbb{R}_+, \mathrm{C}(X,D))$ *such that* $(h \oplus h_0^u)(a) - U_0^* h(a) U_0$ *is in* $\mathrm{C}_0(\mathbb{R}_+, \mathrm{C}(X,D))$ *for every* $a \in A$.

(ii) *If, moreover,* h *and* k *are nuclear and* $[h] = [k]$ *in* $\mathrm{KK_{nuc}}(A, \mathrm{C}(X,D))$, *then there exist a unitary* $U \in \mathrm{C_b}(\mathbb{R}_+, \mathrm{C}(X,D))$ *such that* $h(a) - U^* k(a) U$ *is in* $\mathrm{C}_0(\mathbb{R}_+, \mathrm{C}(X,D))$ *for every* $a \in A$.

(iii) *For* $\varphi \colon A \otimes \mathbb{K} \to \mathrm{C}(X,D) \otimes \mathbb{K}$ *with* $[\varphi(1 \otimes p_{11})] = 0$ *in* $\mathrm{K}_0(\mathrm{C}(X,D))$ *there exits a unital* C^**-morphism* $h \colon A \to \mathrm{C}(X,D)$ *such that* $\pi_y h$ *is a monomorphism for every* $y \in X$ *and* $h \otimes \mathrm{id}_{\mathbb{K}}$ *and* $\varphi \oplus h_0$ *(where* $h_0 = h_0^u \otimes \mathrm{id}_{\mathbb{K}}$*) are unitarily homotopic.* h *is nuclear if* φ *is nuclear. In particular, every* $z \in \mathrm{KK_{nuc}}(A, \mathrm{C}(X,D))$ *with* $[1_A] \otimes_A z = [1_{\mathrm{C}(X,D)}] = 0$ *is of the form* $z = [h]$ *for a nuclear* h *of the type above.*

Proof. Ad(i): Let $\mathrm{Q}(\mathbb{R}_+, \mathrm{C}(X,D)) := \mathrm{C_b}(\mathbb{R}_+, \mathrm{C}(X,D)) / \mathrm{C}_0(\mathbb{R}_+, \mathrm{C}(X,D))$ and let π denotes the quotient map $\pi \colon \mathrm{C_b}(\mathbb{R}_+, \mathrm{C}(X,D)) \to \mathrm{Q}(\mathbb{R}_+, \mathrm{C}(X,D))$.

$\mathrm{C_b}(\mathbb{R}_+ \times X, D) \cong \mathrm{C_b}(\mathbb{R}_+, \mathrm{C}(X,D))$ and $\mathrm{C}_0(\mathbb{R}_+ \times X, D) \cong \mathrm{C}_0(\mathbb{R}_+, \mathrm{C}(X,D))$ by a natural isomorphism.

Consider $\mathrm{C}(X,D)$ as a unital C*-subalgebra of $\mathrm{Q}(\mathbb{R}_+, \mathrm{C}(X,D))$. Then the relative commutant $h_0^u(A)' \cap \mathrm{Q}(\mathbb{R}_+, \mathrm{C}(X,D))$ contains a copy of $\mathcal{O}_2$ unitally (by the definition of h_0^u in Chapter 1 before Theorem B).

Thus by Proposition 4.3.5 it suffices to show that $\pi h \colon A \to \mathrm{Q}(\mathbb{R}_+ \times X, D)$ dominates $h_0^u \colon A \to \mathcal{O}_2 \subset \mathrm{Q}(\mathbb{R}_+ \times X, D)$. But this follows from Corollary 7.4.6, because the lift $h_0^u \colon A \to \mathcal{O}_2 \subset \mathrm{C_b}(\mathbb{R}_+ \times X, D)$ is nuclear and the evaluations $\pi_y h$ at $y \in \mathbb{R}_+ \times X$ of the lift $h \colon A \to \mathrm{C_b}(\mathbb{R}_+ \times X, D)$ of πh are unital monomorphisms.

Ad(ii): By the proof of Theorem B(i) and (ii) in Chapter 9 we have for $h_0 := h_0^u \otimes \mathrm{id}_{\mathbb{K}}$ that the morphisms $h \otimes \mathrm{id}_{\mathbb{K}} \oplus h_0$ and $k \otimes \mathrm{id}_{\mathbb{K}} \oplus h_0$ from $A \otimes \mathbb{K}$ into $\mathrm{C_b}(\mathbb{R}_+, \mathrm{C}(X,D) \otimes \mathbb{K})$ are unitarily equivalent modulo $\mathrm{C}_0(\mathbb{R}_+, \mathrm{C}(X,D)) \otimes \mathbb{K}$ Since $h \otimes \mathrm{id}_{\mathbb{K}} \oplus h_0 = (h \oplus h_0^u) \otimes \mathrm{id}_{\mathbb{K}}$ the argument before Corollary C in Chapter 1 shows that this implies that $h \oplus h_0^u$ and $k \oplus h_0^u$ are unitarily equivalent in $\mathrm{C_b}(\mathbb{R}_+, \mathrm{C}(X,D))$ modulo $\mathrm{C}_0(\mathbb{R}_+, \mathrm{C}(X,D))$. By the assumptions on the $\pi_y h$ and $\pi_y k$ we get from part(i) that moreover h and k are unitarily equivalent in $\mathrm{C_b}(\mathbb{R}_+, \mathrm{C}(X,D))$ modulo $\mathrm{C}_0(\mathbb{R}_+, \mathrm{C}(X,D))$.

Ad(iii): By Theorem B(i) there exists for $z \in \mathrm{KK_{nuc}}(A, \mathrm{C}(X,D))$ a nuclear C^*-monomorphism $\varphi \colon A \otimes \mathbb{K} \to \mathrm{C}(X,D) \otimes \mathbb{K}$ with $[\varphi] = z$, because $\mathrm{C}(X,D)$ contains a unital copy of $\mathcal{O}_2$.

Then $[\varphi(1 \otimes p_{11})] = z \otimes_A [1_A] = 0$ in $\mathrm{K}_0(\mathrm{C}(X,D))$.

$[(\varphi \oplus h_0)] = [\varphi] + [h_0] = [\varphi]$ in $\mathrm{KK}(A, \mathrm{C}(X,D))$ because $2[h_0] = [h_0]$.

Since $[\varphi(1 \otimes p_{11})] = 0$ in $\mathrm{K}_0(\mathrm{C}(X,D))$, there is a unitary V in $M(\mathrm{C}(X,D) \otimes \mathbb{K})$ such that

$$1 \otimes p_{11} = V^*(\varphi(1 \otimes p_{11}) \oplus (1 \otimes p_{11}))V = V^*(\varphi \oplus h_0)(1 \otimes p_{11})V.$$

Thus there is a unital C^*-morphism $h\colon A \to \mathrm{C}(X, B)$ such that, for $a \in A$

$$h(a) \otimes p_{11} = V^*(\varphi \oplus h_0)(a \otimes p_{11})V.$$

$A \otimes p_{11}$ is a full corner of $A \otimes \mathbb{K}$. Therefore, $h \otimes \mathrm{id}_{\mathbb{K}}$ is unitarily homotopic to $V^*(\varphi \oplus h_0)V$ and thus to $\varphi \oplus h_0$. If we apply the evaluation maps $\pi_y \otimes \mathrm{id}_{\mathbb{K}}$ to this unitary homotopy, then we see that $\pi_y h$ is a monomorphism for every $y \in X$.

From the definition of a unitary homotopy it follows that a morphism is nuclear, if it is unitarily homotopic to a nuclear morphism. □

Let X be a compact space and D a unital C^*-algebra. Then cone(X) means the one-point compactification of of $\mathbb{R}_+ \times X$.

By the isomorphism $[0, 1) \cong \mathbb{R}_+$, the C^*-algebra $\mathrm{C}(cone(X), D)$ is the unital subalgebra of $\mathrm{C}([0, 1] \times X, D) \cong \mathrm{C}([0, 1], \mathrm{C}(X, D))$ which is naturally isomorphic to the unital split extension of $\mathrm{C}_0(\mathbb{R}_+, \mathrm{C}(X, D))$ by $D \subset \mathrm{C}(X, D)$.

Now we consider the case $D = \mathcal{O}_2$.

Corollary 11.2.3. *Suppose that X is a compact space, B is a unital separable exact C^*-algebra, and $h\colon B \to \mathrm{C}(X, \mathcal{O}_2)$ is a unital C^*-morphism such that $\pi_y h$ is a monomorphism for every $y \in X$.*

Then there exists $k\colon B \to \mathrm{C}(cone(X), \mathcal{O}_2)$ with $\pi_y k = \pi_y h$ for every $y \in X \cong X \times \{0\}$ and $\pi_y k$ is a monomorphism for every $y \in cone(X)$.

Proof. Since $\mathrm{KK}(A, \mathrm{C}(X) \otimes \mathcal{O}_2) = 0$, h is unitarily homotopic to h_0^u by Proposition 11.2.2(ii). This homotopy yields a strongly continuous family of morphisms $k_1(\tau, y)\colon B \to \mathcal{O}_2$ ($\tau \in [0, 1/2]$) such that $k_1(0, y) = h(y) := \pi_y h$ for $y \in X$. And there is a continuous map $u\colon (0, 1/2] \times X \to U(\mathcal{O}_2)$ such that $k_1(\tau, y) = u(\tau, y)^* h_0^u u(\tau, y)$ for $y \in X$ and $\tau \in (0, 1/2]$. The unitary $v \in \mathrm{C}(X, \mathcal{O}_2)$ with $v(y) := u(1/2, y)$ is homotopic to 1 in the unitaries of $\mathrm{C}(X, \mathcal{O}_2) \cong \mathrm{C}(X) \otimes \mathcal{O}_2$ by Lemma 11.2.1.

Thus there is an extension w of u to $(0, 1] \times X$ with $w(1, y) = 1$ for $y \in X$ and $w(\tau, y) = u(\tau, y)$ for $y \in X$, $\tau \in [0, 1/2]$, $k(\tau, y) := k_1(\tau, y)$ for $y \in X$, $\tau \in [0, 1/2]$, $k(\tau, y) := w(\tau, y)^* h_0(.) w(\tau, y)$ for $y \in X$, $\tau \in (1/2, 1]$ is the desired extension of h to $cone(X)$. □

Lemma 11.2.4.
(i) *If $\varphi\colon B \to \mathrm{C_b}(\mathbb{R}_+, \mathcal{O}_2)$ is a unital C^*-morphism such that $\pi_\tau \varphi$ is a monomorphism for every $\tau \in \mathbb{R}_+$ then there exists a unitary $U \in \mathrm{C_b}(\mathbb{R}_+, \mathcal{O}_2)$ such that $\varphi(a) - U^* h_0^u(a) U \in \mathrm{C}_0(\mathbb{R}_+, \mathcal{O}_2)$ for every $a \in B$, where $h_0^u\colon B \to \mathcal{O}_2$ is as defined before Theorem B in Chapter 1.*

    *In particular, every unital *-monomorphism $k\colon B \to \mathcal{O}_2$ is unitarily homotopic to h_0^u.*

(ii) *Suppose that $h := \mathrm{id}_B \oplus_{s,t} h_0^u$, and that u_k are unitaries in $\mathcal{O}_2$ with $u_k s = s^{k+1}$, $u_0 = 1$.*

    Then $h^{k+1} = u_k(\mathrm{id}_B \oplus_{s,t} h_k) u_k^*$, where $h_k\colon B \to \mathcal{O}_2$ is a unital C^*-morphism.

In particular, h^2 is unitarily homotopic to h by unitaries $\tau \in [0,1) \mapsto u(\tau) \in \mathcal{O}_2$ such that $u(1/2) = u_1$, $u(0) = 1$, $u(1/2+\tau) = u_1(1 \oplus_{s,t} v(2\tau))$ for $\tau \in [0,1/2)$, where $h_1(b) = \lim_{\tau\to 1} v(\tau)h_0(b)v(\tau)^*$ is a unitary homotopy between h_1 and h_0 with $v(x) \in \mathcal{O}_2$ and $v(0) = 1$.

(iii) *For $k \in \mathbb{N}$ there exist unitaries $v_k \in \mathcal{O}_2$ with $v_k(s^k) = s$.*

*If $k \geq 2$ and v_k is a unitary in $\mathcal{O}_2$ with $v_k(s^k) = s$, then there is exactly one unital *-monomorphism $\psi_k \colon B \to \mathcal{O}_2$ such that $h^k = v_k^*(\mathrm{id}_B \oplus \psi_k)v_k$, where Cuntz addition is taken with $\{s,t\}$.*

(iv) *Let $u(t)$ as in (ii), and define a unital C*-morphism φ from B into $\mathrm{C_b}(\mathbb{R}_+, B)$ by $\varphi(b)(t) := h(b)$ for $t \in [0,1]$ $\varphi(b)(n) := h^n(b)$ for $n = 1,2,\ldots$ and $\varphi(b)(n+t) := u(t)\varphi(b)(n)u(t)^*$ for $n = 1,2,\ldots$, $t \in [0,1)$.*

Suppose $n+k \geq 1$ and that u_{k+n+2} are unitaries in $\mathcal{O}_2$ with

$$u_{k+n+1} \cdot s^{k+n+1} = s \quad \textit{and} \quad u_{k+n+2} \cdot s^{k+n+2} = s.$$

Then there are a continuous map $u \colon [0,1] \to \mathcal{O}_2$ into the unitaries of $\mathcal{O}_2$ and a strongly continuous map $\psi \colon [0,1] \to \mathrm{Hom}(B, \mathcal{O}_2) \subset \mathcal{L}(B)$ into the unital C-morphisms from B into $\mathcal{O}_2$ such that $u(0) = u_{k+n+1}$, $u(1) = u_{k+n+2}$ and*

$$h^k\varphi(1+\tau)h^n = u(\tau)^*(\mathrm{id}_B \oplus (h_0 \oplus \psi(\tau)))u(\tau).$$

Proof. Ad(i): Since $\mathrm{KK_{nuc}}(B, \mathcal{O}_2) = \mathrm{KK}(B, O_2) = 0$, (i) follows as a special case from Proposition 11.2.2(ii) where X= point, $k = h_0^u$ and $D = \mathcal{O}_2$.

Ad(ii): Above we have seen that $(s^k)^*h^k(b)s^k = b$, cf. construction of E_n.

Suppose that $h_{k-1} \colon B \to \mathcal{O}_2$ and $u_{k-1} \in \mathcal{O}_2$ with $h^k = u_{k-1}(\mathrm{id} \oplus_{s,t} h_{k-1})u_{k-1}^*$ are given.

Let $h'_k := h_0 \oplus_{s,t} (h_{k-1} \circ h)$. Then h'_k is a unital morphism from B into O_2. We have

$$h^{k+1}(b) = u_{k-1}(s^2b(s^*)^2 + sth_0(b)t^*s^* + t(h_{k-1}\circ h)(b)t^*)u_{k-1}^*.$$

Let w be the unitary in $\mathcal{O}_2$ with $ws^2 = s$, $wst = ts$, $wt = t^2$.

Then $(\mathrm{id} \oplus_{s,t} h_{k-1})h = h \oplus_{s,t} (h_{k-1} \circ h) = (\mathrm{id}_B \oplus_{s,t} h_0) \oplus_{s,t} (h_{k-1} \circ h) = w^*(\mathrm{id}_B \oplus_{s,t} (h_0 \oplus_{s,t} h_{k-1} \circ h))w = w^*(\mathrm{id}_B \oplus_{s,t} h'_k)w$.

It follows $h^{k+1} = u_{k-1}w^*(\mathrm{id}_B \oplus_{s,t} h'_k)w(u_{k-1})^*$.

On the other hand, $u_{k-1}w^*s = s^{k+1} = u_k s$ and $u_{k-1}, u_k, w \in \mathcal{O}_2$.

Thus $u_k = u_{k-1}w^*(1 \oplus_{s,t} v)$ for some unitary $v \in \mathcal{O}_2$. Now let $h_k := v^*h'_k v$.

Ad(iii): There exist unitaries v_k in $\mathcal{O}_2$ with $v_k(s^k) = s$, because $s^k(s^k)^*$ and $1 - s^k(s^k)^*$ are all Murray–von Neumann equivalent for $k \in \mathbb{N}$, by [**172**].

The existence of ψ_k follows from (ii): Let $\psi_k := h_{k-1}$ for $u_{k-1} := (v_k)^*$.

ψ_k is uniquely determined by $\psi_k(b) = t^*v_kh^k(b)(v_k)^*t$.

Ad(iv): By definition of φ, we have $\varphi(1+\tau)(b) = u(\tau)^*(b \oplus h(\tau)(b))u(\tau)$, where $u \colon [0,1] \to \mathcal{O}_2$ is a continuous map into the unitaries of O_2 with $u(0) = 1$,

$u(1)s^2 = s$, and $h\colon [0,1] \to \mathrm{Hom}(B, \mathcal{O}_2)$ is a strongly continuous map into the unital *-monomorphisms from B into $\mathcal{O}_2$ with $h(0) = h_0$.

If u_1, u_2 in $\mathcal{O}_2$ are unitaries with $u_0^* s = s^k$, $u_1^* s = s^{k+1}$ such that

$$\lambda(\tau)(b) = u(\tau)^*(b \oplus \psi(\tau)(b))u(\tau) \tag{*}$$

where $\psi\colon \tau \mapsto \psi(\tau) \in \mathrm{Hom}(B, \mathcal{O}_2)$, and $u\colon \tau \mapsto u(\tau) \in U(\mathcal{O}_2)$ are chosen with $u(0)^* s = s^k$, $u(1)^* s = s^{k+1}$ then $u(0) = (1 \oplus v_0)u_0$, $u(1) = (1 \oplus v_1)u_1$, where v_0 and v_1 are unitaries in $\mathcal{O}_2$.

Let $v\colon [0,1] \to U(\mathcal{O}_2)$ be continuous with $v(0) = v_0$, $v(1) = v_1$, then $\chi(\tau)(b) = w(\tau)^*(\oplus\chi(\tau)(b))w(\tau)$ where $\chi(\tau)(b) := v(\tau)^*\psi(\tau)(b)v(\tau)$, $w(\tau) := (1 \oplus v(\tau))^* u(\tau)$.

Thus in all cases in question it suffices to find a decomposition (*) for at least one pair $(\psi(\tau), u(\tau))$ for every $\tau \in O_2$, such that $\psi(\tau)$ is a unital monomorphism and $u(0)s^k = s$, $u(1)s^{k+1} = s$. This is the case for $\lambda(\tau) := \varphi(1+\tau)$ by definition of φ. If $\lambda(\tau)$ has the decomposition (*) of the desired type, then (by a simple computation) $h\lambda(\tau) = u_1(\tau)^*(b \oplus \psi_1(\tau)(b))u_1(\tau)$ and $\lambda(\tau) = u_2(\tau)^*(b \oplus \psi_2(\tau)(b))u_2(\tau)$ where $u_1(\tau) := w(u(\tau) \oplus 1)$, $u_2(\tau) := wu(\tau)$, $\psi_1(\tau) := \psi(\tau)(b) \oplus h_0(\lambda(\tau)(b))$, $\psi_2(\tau) := h_0(b) \oplus \psi(\tau)((b))$ and $w := s(t^*)^2 + tst^*s^* + t^2 s^*$. Thus by induction we get (iv). □

Now we define a unital C^*-morphism $\varphi\colon B \to \mathrm{C_b}(\mathbb{R}_+, B)$ by $\varphi(b)(t) := h(b)$ for $t \in [0,1]$ $\varphi(b)(n) := h^n(b)$ for $n = 1, 2, \ldots$ and $\varphi(b)(n+t) := u(t)\varphi(b)(n)u(t)^*$ for $n = 1, 2, \ldots$, $t \in [0,1)$, where $u(t)$ is as in Lemma 11.2.4(ii). The definition fits because $u(0) = 1$.

Then by the above Lemma 11.2.4(iv) we have $\varphi(b) = w(b \oplus_{s,t} \psi(b))w^*$, where $w \in \mathrm{C_b}(\mathbb{R}_+, \mathcal{O}_2)$ is defined inductively by $w(t) = 1$ for $t \in [0,1]$, $w(n+t) = u(t)w(n)$ for $n = 1, 2, \ldots$, $t \in [0,1)$ (note that $u(0) = 1$), $w(n+t) = u(1/2)w(n)$ for $n = 1, 2, \ldots$, $t \in (1/2, 1]$ and where $\psi(b) := t^* w^* \varphi(b) w t$ is a unital C^*-morphism from B into $\mathcal{O}_2 \subset B$.

Thus by Lemma 11.2.4(i) there exists a unitary $v \in \mathrm{C_b}(\mathbb{R}_+, \mathcal{O}_2)$ such that $\psi(b) - v h_0^u(b) v \in \mathrm{C_0}(\mathbb{R}_+, \mathcal{O}_2)$ for every $b \in B$ and thus $\varphi(b) - (w(1 \oplus v))h(b)(w(1 \oplus v))^*$ is in $\mathrm{C_0}(\mathbb{R}_+, \mathcal{O}_2)$ for every b in B, and $w(1 \oplus v)$ is a unitary in $\mathrm{C_b}(R_+, O_2)$.

Lemma 11.2.5. *There exist unital C^*-morphisms*

$$\theta_n\colon B \to \mathrm{C}([0,1] \times [0,1], B)$$

that satisfy the following boundary conditions for $\sigma \in [0,1]$, $\tau \in [0,1]$:

$\theta_n(0, \sigma) = h\varphi(1 + n\sigma)$, $\theta_n(1, \sigma) = h\varphi(1 + (n+1)\sigma)$,

$\theta_n(\tau, 0) = h^2$, and $\theta_n(\tau, 1) = h^{n+1}\varphi(1 + \tau)$.

Proof. By Lemma 11.2.1 and Corollary 11.2.3 it is enough to show that there is a continuous map $u\colon \partial([0,1] \times [0,1]) \to \mathcal{O}_2$ into the unitaries of $\mathcal{O}_2$ and a strongly continuous map $h\colon \partial([0,1] \times [0,1]) \to \mathrm{Hom}(B, \mathcal{O}_2) \subset \mathcal{L}(B, \mathcal{O}_2)$ into the unital *-monomorphisms from B into $\mathcal{O}_2$, such that the boundary conditions on θ_n are given by $\psi\colon \partial([0,1] \times [0,1]) \to \mathrm{Hom}(B, B)$ with $\psi(b)(\tau, s) = u(\tau, s)^*(b \oplus h(\tau, s)(b))u(\tau, s)$

for $(t,s) \in \partial([0,1]\times[0,1])$ because then $\theta_n(b)(\tau,s) := w(\tau,s)^*(b\oplus k(\tau,s)(b))w(\tau,s)$, $(\tau,s) \in [0,1]\times[0,1]$ is as desired, where $w\colon [0,1]\times[0,1] \to U(\mathcal{O}_2)$ is a continuous extension of u and $k\colon [0,1]\times[0,1] \to \mathrm{Hom}(B,\mathcal{O}_2)$ is a strongly continuous map from $[0,1]\times[0,1] \cong cone(\partial([0,1]\times[0,1]))$ into the unital *-monomorphisms from B into $\mathcal{O}_2$ such that $h = k|\partial([0,1]\times[0,1])$.

On the sides of the square $[0,1]\times[0,1]$, the boundary conditions are given by strongly continuous maps into $\mathrm{Hom}(B,B)$, which coincide on the vertices: h^2 in $(0,0)$ and $(1,0)$, h^{n+2} in $(0,1)$ and h^{n+3} in $(1,1)$. By the construction of φ we have $\varphi(1+k+\xi) = \varphi(1+\xi)h^k$ for $\xi \in [0,1]$. Thus we find $m = 2n+3$ points $z_1, z_2, \ldots, z_m$ on $\partial([0,1]\times[0,1])$ (containing the vertices $z_1 = (0,0), z_2 = (1,0)$) such that $\lambda_k(\tau) := \theta_n(z_{k+1} + \tau(z_{k+1} - z_k))$ is one of the following functions: $\lambda_1(\tau) \equiv h^2, \lambda_2(\tau) = \varphi(1+\tau)h,\ \lambda_3(\tau) = \varphi(1+\tau)h^2,\ \ldots\ ,\ \lambda_{n+2}(\tau) = \varphi(1+\tau)h^{n+1}$, $\lambda_{n+3}(\tau) = h^{n+1}\varphi(2-\tau),\ \lambda_{n+4}(\tau) = h\varphi((n+1)-\tau) = h\varphi(2-\tau)h^{n+1},\ \ldots\ ,$ $\lambda_{2n+3}(\tau) = h\varphi(2-\tau)$.

Now apply Lemma 11.2.4(iv) to this function to get the above desired particular form.

□

3. Proof of (β)

We construct in some sense a "completely positive liftable unsuspended E-equivalence" as an element of $\mathrm{R}(P(A),B)$, given by by a path of u.c.p. maps $V_t\colon P(A) \to B$ with the property that $V_t \circ h_{1,\infty}\colon B \to B$ is equivalent in $\mathrm{R}(B,B)$ to $h\colon B \to B$. for the maps $h_{1,\infty}\colon B \to P(A)$ and $h\colon B \to B$:

Since $h\colon B \to B$ is a KK-equivalence, (and is equivalent to id_B in $\mathrm{R}(B,B)$), it is sufficient to define a unital completely positive map $V\colon P(A) \to \mathrm{C_b}(\mathbb{R}_+,B)$ with the following properties:

(i) $V(b^*b) - V(b)^*V(b) \in \mathrm{C_0}(\mathbb{R}_+,B)$ for every $b \in P(A)$, i.e., V defines a unital and completely positively liftable homomorphism from $P(A)$ into $\mathrm{Q}(\mathbb{R}_+,B)$.

(ii) There are a *- homomorphism $\varphi_1\colon B \to \mathrm{C_b}(\mathbb{R}_+,B)$ and a unitary $U \in \mathrm{C_b}(\mathbb{R}_+,\mathcal{O}_2)$ such that $\varphi_1(a) - U^*h(a)U \in \mathrm{C_0}(\mathbb{R}_+,B)$

(Is not necessary! "Stable" homotopy of φ_1 with $h\colon B \to B$ is enough.)

and

$\{\varphi_1(a)(t) - V(h_{1,\infty}(a))(t)\} \in \mathrm{C_0}(\mathbb{R}_+,B)$ for $a \in B$, $\tau \in \mathbb{R}_+$.

(It gives – by $\mathrm{R}(C,D) = \mathrm{KK}(C,D)$ for unitally $\mathcal{O}_\infty$-containing C,D – $[V]\circ[h_{1,\infty}] = [h] = [\mathrm{id}_B]$ in $\mathrm{KK}(B,B)$)

This is equivalent to $V \circ h_{1,\infty}$ homotopic to $U^*h(\cdot)U$ for suitable path $U(t)$. Thus $[h] = [V]\circ[h_{1,\infty}]$ in $\mathrm{KK}(B,B)$

(iii) Need a proof that $h_{1,\infty}(V(\cdot)(t))$ is homotopic to $[\mathrm{id}_{P(A)}]$ in $\mathrm{R}(P(A),P(A))$.

(A kind of "reconstruction".)

(iv) Another way to describe it would be the following:

There is unital completely positive $W\colon P(A) \to \mathrm{C_b}(\mathbb{R}_+ \times [0,1], P(A))$, such that $\lim_{\tau\to\infty} \|W(b^*b)(\tau,t) - W(b)(\tau,t)^* W(b)(\tau,t)\| = 0$

and

$\lim_{\tau\to\infty} \|W(b)(\tau,1) - b\| = 0$

and

$\lim_{\tau\to\infty} \|W(b)(\tau,0) - h_{1,\infty}(V(b)(\tau))\| = 0.$

This means that $[\pi \circ V] \in \mathrm{Ext}^{-1}(P(A), SB) \cong \mathrm{KK}(P(A), B)$ has the property that

$$[h_1^\infty] \otimes_B [\pi \circ V] = [\mathrm{id}_{P(A)}] \in \mathrm{KK}(P(A), P(A))$$

and

$$[\pi \circ V] \otimes_{P(A)} [h_1^\infty] = [h] \cong [\mathrm{id}_B] \in \mathrm{KK}(B, B).$$

Thus Theorem I is proved if we have shown the existence of V, φ_1, U and W with the above listed properties (i)-(iii).

We define the unital completely positive map $V\colon P(A) \to \mathrm{C_b}(\mathbb{R}_+, B)$ by the following constructions.

For $n = 1, 2, \ldots$ let $\varphi_n(b)(\tau) := \varphi(b)(\tau - n)$ for $\tau \geq n$ and $\varphi_n(b)(\tau) := h(b)$ for $0 \leq \tau < n$. Then $\varphi_n(n + k) = h^k(b)$, $\varphi_n(b)(n + \tau) = h(b)$ for $k = 1, 2, \ldots$, $\tau \in [0, 1]$ and $\varphi_{n+k}(h^k(b))(\tau) = \varphi_n(b)(\tau)$ for $\tau \geq n + k$. We let $V_n := \varphi_n(h_n^\infty)^{-1} E_n$.

Then $V_n h_n^\infty = \varphi_n$, and we have $V_m(h_n^\infty(b))(\tau) = V_n(h_n^\infty(b))(\tau)$ for $m > n$, $\tau \geq m$:

$$V_m \circ h_n^\infty = V_m \circ h_m^\infty h^{m-n} = \varphi_m h^{m-n}.$$

For the parameter $\tau \geq m$ we get $\varphi_m(h^{m-n}(b))(\tau) = \varphi_n(b)(\tau) = V_n(h_n^\infty(b))(\tau)$. Let

$$V(d)(\tau) := (n + 2 - \tau) V_n(d)(\tau) + (\tau - n - 1) V_{n+1}(d)(\tau)$$

for $n + 1 \leq \tau \leq n + 2$ and $V(d)(\tau) := V_1(d)(\tau)$ for $0 \leq \tau \leq 2$.

The definition is fits, because on the boundary points of the intervals in question we have $V(d)(n+1) = V_n(d)(n+1)$ and $V(d)(n+2) = V_{n+1}(d)(n+2)$ for $n = 1, 2, \ldots$.

Then $V\colon P(A) \to \mathrm{C_b}(\mathbb{R}_+, B)$ is a unital completely positive map and

$$V(h_n^\infty(b))(\tau) = \varphi_n(b)(\tau)$$

for $\tau \geq n+1$, $n \geq 1$, because if $\tau \geq n+1$ then there is an $m \in \mathbb{N}$ with $n+1 \leq m+1 \leq \tau \leq m+2$ and for this m we get $V(h_n^\infty(b))(\tau) = (m+2-\tau) V_m(h_n^\infty(b))(\tau) + (\tau - m - 1) V_{m+1}(h_n^\infty(b))(\tau)$ and the right hand side is equal to $V_n(h_n^\infty(n))(\tau) = \varphi_n(b)(\tau)$.

In particular, since $P(A)$ is the closure of $\bigcup h_n^\infty(B)$, we get that V is asymptotically multiplicative, i.e., $V(d^*d) - V(d)^*V(d) \in \mathrm{C_0}(\mathbb{R}_+, B)$ for $d \in P(A)$.

Thus V is an asymptotic morphism (which is not nuclear if B is not nuclear) from $P(A)$ in B with $V(h_1^\infty(b)) - \varphi_1(b) \in \mathrm{C_0}(\mathbb{R}_+, B)$. As we have seen above, φ_1 (as a scaling of φ) is unitarily equivalent to $h\colon B \to B \subset \mathrm{C_b}(\mathbb{R}_+, B)$ by a unitary U in $\mathrm{C_b}(\mathbb{R}_+, \mathcal{O}_2)$. Thus

$$[V] \otimes_{P(A)} [h_1^\infty] = [h] = [\mathrm{id}_B]$$

in $\mathrm{KK}(B, B)$.

We construct an asymptotic morphism

$$W\colon P(A) \to \mathrm{C_b}(\mathbb{R}_+ \times [0,1], P(A))$$

with

$$W(d)(\tau, 0) - h_1^\infty(V(d)(\tau)) \in \mathrm{C}_0(\mathbb{R}_+, P(A)) \quad \text{and} \quad W(d)(\tau, 1) - d \in \mathrm{C}_0(\mathbb{R}_+, P(A)).$$

We use the unital C^*-morphisms $\theta_n\colon B \to \mathrm{C}([0,1] \times [0,1], B)$ of Lemma 11.2.5.

Let us list some equations for V, h_n^∞, φ and θ_n that we have shown above or are obtained by straight forward calculations from the definitions:

Just from the definition of φ, φ_n, V and from $V(h_n(b))(n+1+\sigma) = \varphi_n(n+1+\sigma)$ we get $\varphi(1+\sigma)(b) = V(h_n^\infty(b))(n+1+\sigma))$ for $\sigma \in [0,1]$.

Then we need moreover the equations $h_{m+k}^\infty(h^k(b)) = h_m(b)$ and the boundary conditions listed in Lemma 11.2.5.

From the boundary conditions it follows that $h(\theta_n(b)(1,\tau)) = \theta_{n+1}(h(b))(1,\tau)$.

At first we define unital, completely positive maps W_n.

Let $W_n\colon P(A) \to \mathrm{C}([n+1, n+2] \times [0,1], P(A))$ be defined for $\tau, \sigma \in [0,1]$ by

$$W_n(d)(n+1+\sigma, \tau) := h_{n+2}^\infty(\theta_n((h_n^\infty)^{-1} E_n(d))(\sigma,\tau)).$$

It implies

$$W_n(h_n^\infty(b))(n+1+\sigma,\tau) = h_{n+2}^\infty(\theta_(b)(\sigma,\tau)),$$

and from $E_n(P(A)) = h_n^\infty(B)$ and the above listed equations (and the boundary conditions of θ_n in Lemma 11.2.5) the reader easily get by straight forward calculations (by replacing $E_n(d)$ by $h_n^\infty(b)$) the following three equations (where $n \in \mathbb{N}$, $d \in P(A)$, and $\sigma, \tau \in [0,1]$):

$$W_n(E_n(d))(n+1+\sigma, 0) = E_n(d),$$

$$W_n(E_n(d))(n+1+\sigma, 1) = h_1^\infty(V(E_n(d))(n+1+\sigma))$$

and

$$W_n(E_n(d))(n+2,\tau) = W_{n+1}(E_n(d))(n+2,\tau).$$

The latter equation shows that

$$W(d)(n+1+\sigma,\tau) := W_n((1-\sigma)E_{n-1}(d) + \sigma E_n(d))(n+1+\sigma,\tau)$$

for $n = 2, 3, \ldots$ and $\sigma, \tau \in [0,1]$ and $W(d)(\eta,\sigma) := W_2(E_1(d))(3,\sigma)$ for $\tau, \sigma \in [0,1]$, $0 \le \eta \le 3$ is a well-defined completely positive and unital map from $P(A)$ into $\mathrm{C_b}(\mathbb{R}_+, P(A))$.

Since the union of the $E_n(P(A))$ is dense in $P(A)$ we see from first two the above listed three equations for the W_n's that

$$\lim_{\sigma\to\infty} \|W(d)(\sigma,0) - d\| = 0$$

and

$$\lim_{\sigma \to \infty} \| W(d)(\tau, 1) - h_1^{\infty}(V(d)(\tau)) \| = 0$$

for every $d \in P(A)$.

This means $[h_1^{\infty} \circ (\pi \circ V)] = [\mathrm{id}]$ in $\mathrm{KK}(P(A), P(A))$. On the other hand $[h_1^{\infty} \circ (\pi \circ V)] = [h_1^{\infty}] \otimes_B [V]$.

This completes the proof of (β) and ends the proof of Theorem I.

4. Examples via Cuntz-Pimsner algebras

The following (X, G)-equivariant construction of generalized Fock–Toeplitz algebra (respectively of a Cuntz–Krieger–Pimsner algebra) using a suitable Hilbert bi-module.

THEOREM 11.4.1. *Text from lectures on equivariant reconstruction.*

PROOF. □

Cite from Chapter 1: One starts with a suitable "universal" Hilbert bimodule and builds the corresponding Cuntz–Krieger–Pimsner algebra.

The universality of the construction has the advantage that G-actions of locally compact groups G on $(A_x)_{x\in X}$ lead in a natural way to G-actions on $(P(A_x)\otimes \mathbb{K})_{x\in X}$

Next taken from Toronto 2014 lectures

Definition (in Chp.1??) of regular subalgebras:
Let $C \subset A$ a C^*-subalgebra. C is regular for A if

(i) C separates the ideals J of A: $J_1 \cap C = J_2 \cap C$ implies $J_1 = J_2$.
(ii) $C \cap (J_1 + J_2) = (C \cap J_1) + (C \cap J_2)$ for all $J_1, J_2 \in \mathcal{I}(A)$.

THEOREM 11.4.2 (Realization of Ψ, H.H.,E.K.). *Suppose that B is separable and stable. Let $\Psi \colon \mathcal{I}(B) \to \mathcal{I}(A)$ a non-degenerate lower s.c. action of* Prim(B) *on A.*

*If $B \otimes \mathcal{O}_2$ contains a regular abelian C^*-subalgebra C then $\Psi = \Psi_{\mathcal{C}}$ for $\mathcal{C} := \mathcal{C}_\Psi$. In particular, Ψ comes from a non-degenerate *-monomorphism $h \colon A \otimes \mathbb{K} \to \mathcal{M}(B)$, that is unique up to unitary homotopy of its infinite repeats.*

COROLLARY 11.4.3 (Reconstruction Theorem, H.H.,E.K.). *Suppose that A is a nuclear and stable, that Ω is a* sup–inf *closed sub-lattice of $\mathcal{I}(A) \cong \mathbb{O}(\mathrm{Prim}(A))$ with* $\mathrm{Prim}(A), \emptyset \in \Omega$. *Then there is a non-degenerate *-monomorphism $H_0 \colon A \to \mathcal{M}(A)$ with following properties:*

(i) *The infinite repeat $\delta_\infty \circ H_0$ is unitarily equivalent to H_0.*
(ii) *For every $U \in \mathbb{O}(\mathrm{Prim}(A))$ holds $H_0(J(V)) = H_0(A) \cap \mathcal{M}(A, J(U))$ where $V \in \Omega$ is given by $V = \bigcup\{W \in \Omega\,;\ W \subset U\}$.*

The H_0 is uniquely determined up to unitary homotopy.

The uniques up to unitary homotopy means by Definition 5.0.1:

If $H_1 \colon A \to \mathcal{M}(A)$ also satisfies the conditions (i) and (ii) then there is a norm-continuous path $t \in \mathbb{R}_+ \to U(t) \in \mathcal{U}(\mathcal{M}(A))$ such that $U(t)^* H_2(a) U(t) - H_0(a) \in A$ for all $a \in A$ and $t \in \mathbb{R}_+$ and $\lim_{t\to\infty} U(t)^* H_2(a) U(t) = H_0(a)$.

COROLLARY 11.4.4 (Continuation of Reconstruction Theorem). *The Cuntz-Pimsner algebra $\mathcal{O}_{\mathcal{H}}$ of the Hilbert A-A-module $\mathcal{H} := (A, H_0)$ is stable and strongly purely infinite; and it is the same as the C^*-Fock algebra $\mathcal{F}(\mathcal{H})$ of $\mathcal{H}$.*

The natural embedding of A into $\mathcal{O}_{\mathcal{H}}$ defines a lattice isomorphism from Ω onto $\mathbb{O}(\mathrm{Prim}(\mathcal{O}_{\mathcal{H}}))$ and is a $\mathrm{KK}(X;\cdot,\cdot)$-equivalence for $X := \mathrm{prime}(\Omega) \cong \mathrm{Prim}(\mathcal{O}_{\mathcal{H}})$.

`Discussion of some general ways:`

The algebra A will be changed to nice Cuntz "standard" form $B := A_t$ up to KK, such that $\mathcal{O}_2 \subseteq \mathcal{M}(B)$, $\alpha\colon A \to B$ is $\mathrm{KK}(\mathcal{C}\,;\,A,B)$ a KK-equivalence (!!!!), e.g. given by tensoring with $\mathcal{O}_2 \otimes \mathbb{K}$ and "adding" $\mathcal{O}_2$ or $\mathcal{O}_2 \otimes \mathbb{K}$, depending on $\mathcal{C}$.

Better would be: Can it be chosen stably homotopic to direct sum $A \oplus_{s_1,s_2} \mathcal{O}_2$ sitting in $B = A_t$?

`What is the inverse? Can stabilize ? Use` $\mathcal{C}\widehat{\otimes}\,\mathrm{CP}(\mathcal{O}_\infty)$`?`

– after stabilization also an E-equivalence?? –

and the endomorphism $\gamma := \mathrm{id}_B \oplus \gamma_0$, γ_0, $\mathcal{C}$-compatible "inner homotopic": γ_0^2 and $\gamma_0 \oplus \gamma_0$ "controlled" (inner?) homotopic to γ_0, γ should have has in $\mathrm{KK}(\mathcal{C};\,B,B)$ the same class as id_B.

$C := \mathrm{indlim}_n(\gamma_n\colon B \to B)$ with $\gamma_n = \gamma$, $\tau\colon C \to \mathrm{Q}([0,\infty),B)$ by intertwining γ_n and γ_{n+1} in suitable way and using conditional expectations onto ????,

given by moving the conditional expectations from C onto $\gamma_{n,\infty}(B)$ to that of with $\gamma_{1,\infty}\colon B \to C$, satisfies $\tau \circ \gamma_{1,\infty}\ {}_h\epsilon_B$ in a controlled sense ("inner" sense ?), with $\epsilon_B(b) = b + B[0,\infty)$.

An idea would be convex combinations $T_s := (n+1-s)T_n + (s-n)T_{n+1}$ for $s \in [n,n+1]$ as maps from C into $B[n,n+1]$, where $T_n := \gamma_{1,n}^{-1} \circ P_n\colon C \to B$, $P_n\colon C \to \gamma_{1,n}(B) \subset C$.

Thus, $[\epsilon_B] = [\mathrm{id}_B]$ in $E(B,B) \cong \mathrm{KK}(\mathcal{C};B,B)$, $[\tau] \circ [\gamma_{1,\infty}] = [\epsilon_B] = [\mathrm{id}_B]$, $\gamma_{1,\infty}\colon\ \mathrm{Q}([0,\infty),B)$

`Does it explain the KK-equivalence ??`

It gives classes X =???? $\in \mathrm{KK}(\mathcal{C}\,;\,C,B)$, $Y \in \mathrm{KK}(\mathcal{C}\,;\,B,C)$ inclusion, with $Y = [\gamma_{1,\infty}]$, $X = [\tau]$ corresponds to asymptotic morphism from C to B.

that is $\mathrm{KK}(\mathcal{C};\cdot,\cdot)$ equivalent to A.

B has equivariant endomorphism that is $\mathrm{KK}(\mathcal{C};\,\cdot,\cdot)$ equivalent to id_B, ...

Use the "fact" that certain kinds of ??? and a non-commutative variant of a classical result of J. Milnor ???? given by L.G. Brown [**?**]. give simply ref to Blackadar Rosenberg [1987, 1.12]. not found????

Countable additivity w.r.t. first variable: Blackadar's K-theory book, [**73**, thm. 19.7.1]

Continuity in first variable [**73**, thm. 21.5.2] with Milnor $\lim^1$-sequence.

CHAPTER 12

Non-commutative Selection and Proof of Thm. K

In this chapter we use the in Chapters 4 -11 confirmed results for a complete proof of Theorems K (e.g. using Corollary 6.3.2) and Theorem O in Chapter 1 (e.g. using Theorem **??**). As it was explained in the introductory Chapter 1, this completes the proofs of *all* the results stated in Chapter 1, because we have already proved Theorem M in Chapter 9 under the *additional assumption*, that *there exists* $h_0: A \hookrightarrow B$ with the properties that h_0 is injective, non-degenerate, nuclear, is unitarily homotopic to $h_0 \oplus h_0$, and realizes the given non-degenerate action $\Psi: \mathcal{I}(B) \to \mathcal{I}(A)$ via $\Psi(J) = h_0^{-1}(J \cap h_0(A))$. The existence of h_0 is now the main point of Theorem K, because we have seen the uniqueness of such h_0 up to unitary homotopy in Chapter 9. Moreover we have shown there, that, for σ-unital stable B, there is — up to unitary equivalence (by unitaries in $\mathrm{Q}(\mathbb{R}_+, \mathcal{M}(B))$) — at most one nuclear *-monomorphism $k_0: A \to \mathrm{Q}(\mathbb{R}_+, B)$ with k_0 approximately unitarily equivalent (by unitaries in the bigger algebra $\mathcal{M}(\mathrm{Q}(\mathbb{R}_+, B))$) to $k_0 \oplus k_0$, such that k_0 realizes the given action Ψ of $\mathrm{Prim}(B)$ on A via $\Psi(J \cap B) = k_0^{-1}(J \cap h_0(A))$ for any closed ideal J of $\mathrm{Q}(\mathbb{R}_+, B)$. We have seen in Chapter 9, that this properties of k_0 imply that such k_0 must be unitarily equivalent to some $h_0: A \to B$ of the desired kind ([1]).

The Theorem 6.3.1 implies the existence of $h_0: A \to B$ (realizing Ψ) under the *additional* assumptions that B is separable and contains a regular abelian C^*-subalgebra in the sense of Definition 1.2.9.

Thus, to complete the proof of Theorem K, we must show only the following (but get more general) results:

(i) B can be replaced by a suitable separable subalgebra B_0 of B and Ψ by a suitable action Ψ_0 of $\mathrm{Prim}(B_0)$ on B_0, i.e., there exists a *separable* C^*-subalgebra B_0 of B such that
  (a) B_0 is stable and contains a strictly positive element of B.
  (b) Each ideal I of B_0 is the intersection $I = B_0 \cap J$ of an ideal J of B with B_0.
  (c) $\Psi(J_1) = \Psi(J_2)$ if $J_1 \cap B_0 = J_2 \cap B_0$, $J_1, J_2 \in \mathcal{I}(B)$.
  (d) B_0 is strongly purely infinite.

[1] Combine Corollaries 9.1.6 and 9.1.4 – with the B in 9.1.4 replaced by our $k_0(A)\,\mathrm{Q}(\mathbb{R}_+, B) k_0(A)$.

(2) If B is separable ([2]), then we show the existence of a separable C^*-subalgebra $B_1 \subset \mathrm{Q}(\mathbb{R}, B)$ such that
  (e) $B \subset B_1$ and B contains a strictly positive element of B_1 (in particular, B_1 is stable).
  (f) Each ideal I of B_1 is the intersection $I = B_1 \cap J$ of an ideal J of $\mathrm{Q}(\mathbb{R}_+, B)$ with B_1.
  (g) B_1 contains a regular abelian C^*-algebra $C \subset B_1$.
  (h) B_1 is strongly purely infinite.

If we consider B_1 (in place of B) and the action $\Psi_1(I) := \Psi(I \cap B)$ of $\mathrm{Prim}(B_1)$ on A, then it turns out that the action Ψ_1 is non-degenerate, lower semi-continuous and monotone upper semi-continuous ([3]). Thus, Theorem 6.3.1 (respectively Corollary 6.3.2 — a special case of Theorem K) applies to (A, B_1, Ψ_1) and gives that there is nuclear

$$k_0 \colon A \hookrightarrow B_1 \subset \mathrm{Q}(\mathbb{R}_+, B_0) \subset \mathrm{Q}(\mathbb{R}_+, B)$$

with k_0 unitarily equivalent to $k_0 \oplus k_0$, and $k_0(A) \cap J = k_0(\Psi_1(B_1 \cap J)) = k_0(\Psi(J \cap B))$ for all closed ideals J of $\mathrm{Q}(\mathbb{R}_+, B)$. Then Corollaries 9.1.6 and 9.1.4 imply that there is non-degenerate nuclear $h \colon A \otimes \mathcal{O}_2 \to B$ such that $h_0 := h((\cdot) \oplus 1)$ is unitarily equivalent to k_0. Thus, h_0 is as desired, and Theorem K follows from the existence of (B_0, Ψ_0) and (B_1, Ψ_1) with the above listed (1a)–(2h).

The technical preparations for the existence of (B_0, Ψ_0) and (B_1, Ψ_1) lead also to the asymptotic non-commutative 'selection' Theorem 12.1.8.

The below given characterization of the Dini functions on $\mathrm{Prim}(A)$, Proposition 12.2.6, the reduction result in Lemma 12.2.14, together with the results in the last sections of Chapters 5 and 6 yield a proof of Proposition 12.2.15.

For notations we refer the reader to Chapter 1, Definitions 1.2.1–1.2.8.

1. Non-commutative asymptotic Selection

First we need some lemmata for our proof of the asymptotic non-commutative Selection Theorem 12.1.8.

Lemma 12.1.1. *Suppose that $H \colon A \to \mathcal{M}(B)$ is a C^*-morphism, where A and B are σ-unital. For $J \in \mathcal{I}(B)$, let*

$$\Psi(J) := H^{-1}(\Psi^{\mathrm{up}}_{B,H(A)}(J)) := H^{-1}(H(A) \cap \mathcal{M}(B, J)).$$

(i) *Ψ is a lower semi-continuous action of $\mathrm{Prim}(B)$ on A, i.e., it satisfies parts (iii) and (iv) of Definition 1.2.6.*

[2]The separability of B can be supposed, because we can replace B by B_0, and Ψ by $\Psi_0(J) := \Psi(K)$ for arbitrary $K \triangleright B$ with $J = B_0 \cap K$. The properties (b) and (c) imply that Ψ_0 is well-defined and is lower s.-c. and monotone upper s.-c., because $\Phi(J) := \overline{\mathrm{span}(BJB)}$ is upper semi-continuous, satisfies $B_0 \cap \Phi(J) = J$, and $B_0 \cap \bigcap_\tau \Phi(J_\tau) = \bigcap_\tau J_\tau$, and Ψ is lower s.-c. and monotone upper s.-c.

[3]The l. s.-continuity and monotone u. s.-continuity of Ψ_1 follows from the that continuity properties of Ψ and of $I \mapsto I \cap B$.

(ii) $\Psi(0) = \ker(H)$, *and* $\Psi^{-1}(A)$ *is the set of* $J \in \mathcal{I}(B)$ *with* $BH(A)B \subset J$.

(iii) Ψ *satisfies (ii) of Definition 1.2.6 if* $H(A) \subset B$.

(iv) *If* C *is a* σ*-unital* C^**-subalgebra of* $\mathcal{M}(B)$*, such that* CB *is dense in* B*,* $H(A) \subset \mathcal{M}(C)$ *(i.e.* $H(A)C \subset C$*), and, for* $I \in \mathcal{I}(C)$*,*

$$\Phi(I) := H^{-1}(\Psi^{\mathrm{up}}_{C,H(A)}(I)) \;=\; H^{-1}(H(A) \cap \mathcal{M}(C, I))\,,$$

then, for $J \in \mathcal{I}(B)$*,*

$$\Psi(J) = \Phi(\Psi^{\mathrm{up}}_{B,C}(J))\,.$$

(v) *The morphism* $H \colon A \to \mathcal{M}(B)$ *is weakly* Ψ*-residually nuclear if* H *satisfies at least one of the following properties (a)–(c):*

(a) $H \colon A \to \mathcal{M}(C)$ *is* Φ*-residually nuclear.*

(b) A *is exact and* $H \colon A \to \mathcal{M}(C)$ *is weakly nuclear.*

(c) C *is nuclear.*

Proof. (i)-(iv) follow straight from the definitions. The details are left to the reader. E.g., (iv) follows from the easily poved identity

$$\mathcal{M}(C) \cap \mathcal{M}(B, J) = \mathcal{M}(C, C \cap \mathcal{M}(B, J))$$

for *non-degenerate* C^*-subalgebras C of $\mathcal{M}(B)$.

Note that (iv) implies (v,a), because, for $J \in \mathcal{I}(B)$, $I := \Psi^{\mathrm{up}}_{B,C}(J)$, we have the natural inclusions

$$[H] \colon A/\Phi(I) \hookrightarrow \mathcal{M}(C/I) \subset \mathcal{M}(B/J),$$

the map $a + \Phi(I) \mapsto b^*(d^*(H(a) + \mathcal{M}(C, I))d)b$ is a nuclear map from $A/\Phi(I)$ into B/J for $b \in B/J$, $d \in C/I \subset \mathcal{M}(B/J)$, and C/I is a non-degenerate C^*-subalgebra of $\mathcal{M}(B/J)$.

It is obvious that (v,c) implies (v,a). By Proposition **??**, $H \colon A \to \mathcal{M}(C)$ is (norm-) nuclear if A is exact and H is weakly nuclear. Then all the quotient maps $[H] \colon A/\Phi(I) \to \mathcal{M}(C)/\mathcal{M}(C, I) \subset \mathcal{M}(C/I)$ are nuclear by exactness of A (cf. Remark **??**). □

Lemma 12.1.2. *Suppose that* A *and* B *are stable and separable* C^**-algebras, and that* $\Psi \colon \mathcal{I}(B) \to \mathcal{I}(A)$ *is a lower semi-continuous action of* $\mathrm{Prim}(B)$ *on* A*, such that* $\Psi(0) = 0$ *and* $\Psi^{-1}(A) = \{B\}$*.*

Then the following are equivalent:

(i) *There exists a non-degenerate weakly* Ψ*-residually nuclear *-monomorphism* $H_0 \colon A \to \mathcal{M}(B)$*, such that* $\delta_\infty H_0$ *is unitarily equivalent to* H_0*, and, for* $J \in \mathcal{I}(B)$*,*

$$\Psi(J) = H_0^{-1}(H_0(A) \cap \mathcal{M}(B, J)).$$

(ii) *For every* $J \in \mathrm{Prim}(B)$*,* $a \in A \setminus \Psi(J)$ *there exist a* Ψ*-residually nuclear completely positive map* $V \colon A \to B$ *such that* $V(a) \notin J$*.*

If H_0 *with (i) exists, then* H_0 *is unique up to unitary homotopy.*

Proof. (i)⇒(ii): If $a \in A$ and $H_0(a) \notin \mathcal{M}(B, J)$, then there exists $b \in B_+$ with $bH_0(a)b \notin J$. $V = bH_0(.)b$ is a Ψ-residually nuclear map from A to B with $V(a) \notin J$.

(i)⇒(ii): If I is a closed ideal of B, and if $a \in A$ is not in $\Psi(I)$, then there exists a primitive ideal $J \in \mathrm{Prim}(B)$, such that $I \subset J$ and $a \notin \Psi(J)$, because Ψ is lower semi-continuous and I is the intersection of the primitive ideals J which contain I.

Thus, there is a Ψ-residually nuclear map $V \colon A \to B$ with $V(a) \notin I$.

The set K of Ψ-residually nuclear completely positive contractions V from A to B is a convex set. It is a separable metric space as a subset of $\mathrm{CP}(A, B) \subset \mathcal{L}(A, B)$ with strong topology on $\mathcal{L}(A, B)$ (i.e., topology of point-wise convergence in norm, given by the system of semi-metrics $\rho_a(V_1, V_2) := \|V_1(a) - V_2(a)\|$).

Let $V_1, V_2, \ldots$ be a dense sequence in K. We get weakly Ψ-residually nuclear C^*-morphisms d_n from A to $\mathcal{L}(\mathcal{H}_B)$, if we apply Stinespring-Kasparov dilation to V_n, $n = 1, 2, \ldots$. Here $\mathcal{H}_B$ denotes the (right) Hilbert-B-module which is given by the sequences $(b_1, b_2, \ldots)$ with norm convergent series $\sum b_n^* b_n$ in B. Since B is stable and σ-unital, we get that there is a natural isomorphism $\mathcal{H}_B \cong B$ as (right) Hilbert-B-modules and $\mathcal{L}(\mathcal{H}_B) \cong \mathcal{M}(B)$ as C^*-algebras under this isomorphism. If we use this isomorphism, we get weakly Ψ-residually nuclear C^*-morphisms $h_n \colon A \to B$, such that V_n is the point-norm limit of Ψ-residually nuclear completely positive contractions of form $W = b^* h_n(.)b$, with $b \in B$ a contraction.

Let $h \colon A \to \mathcal{M}(B)$ be the direct sum of $h_1, h_2, \ldots$, i.e., $h(a) := \sum_n s_n h_n(a) s_n^*$ for $a \in A$, where $s_1, s_2, \ldots$ is a sequence of isometries in $\mathcal{M}(B)$ with $\sum s_n (s_n)^*$ strictly convergent to 1 in $\mathcal{M}(B)$.

Then h is weakly Ψ-residually nuclear and every Ψ-residually nuclear completely positive contraction $V \colon A \to B$ is the point-norm limit of maps $b^* h(.)b$ with contractions $b \in B$.

It follows, that $h(\Psi(I)) \subset \mathcal{M}(B, I)$ and $h(a) \notin \mathcal{M}(B, I)$ for $I \in \mathcal{I}(B)$, $a \notin \Psi(I)$.

Thus $h \colon A \to \mathcal{M}(B)$ is a weakly Ψ-residually nuclear *-monomorphism, such that, for $I \in \mathcal{I}(B)$,

$$h(\Psi(I)) = h(A) \cap \mathcal{M}(B, I).$$

The hereditary C^*-subalgebra D of B, which is generated by $h(A)Bh(A)$, is stable, because A is stable.

The existence of an approximate unit in A shows that $h(A)D \subset D$ and that $h(a)Bh(a^*)$ is contained in the closure of $h(a)Dh(a^*)$ for $a \in A$.

Let $k(a) := h(a)|D$ for $a \in A$. It follows, that $k \colon A \to \mathcal{M}(D)$ is a non-degenerate *-monomorphism from A into $\mathcal{M}(D)$, such that, for $J \in \mathcal{I}(B)$ and $a \in A_+$, $k(a) \in \mathcal{M}(D, D \cap J)$ if and only if $h(a) \in \mathcal{M}(B, J)$. Since every closed ideal of D is the intersection of a closed ideal of B with D, we get that k is weakly Φ-residually nuclear for $\Phi := \Psi^{D,B}_{\mathrm{down}}$, and that $\Phi(D \cap J) = \Psi(J)$ for $J \in \mathcal{I}(B)$. In particular, $\Psi(J_1) = \Psi(J_2)$ if $J_1 \cap D = J_2 \cap D$.

The ideal I which is generated by D, satisfies $h(A) \subset \mathcal{M}(B, I)$. Thus $\Psi(I) = A$ and, by assumption, $I = B$. By Corollary 5.5.6, there is a *-isomorphism γ from B onto D, which is approximately inner as a *-monomorphism from B to B and satisfies $\gamma(I) = D \cap I$ for $I \in \mathcal{I}(B)$.

Let H_0 denote the infinite repeat of $\mathcal{M}(\gamma)^{-1}k$. Then H_0 is a non-degenerated weakly $(\Phi \circ \gamma)$-residually nuclear *-monomorphism from A to B with $H_0(a) \in \mathcal{M}(B, I)$, if and only if, $k(a) \in \mathcal{M}(D, \gamma(I))$. Since δ^2 is unitarily equivalent to δ, $\gamma(I) = D \cap I$, and $\Psi = \Phi\gamma$, we get that H_0 has the desired properties.

By Corollary 5.9.15, H_0 with (i) is unique up to unitary homotopy. □

LEMMA 12.1.3. *Suppose that C is a separable commutative C*-algebra, that A is a separable C*-algebra, and that*

$$\Psi \colon \mathcal{I}(C) \cong \mathbb{O}(\mathrm{Prim}(C)) \to \mathcal{I}(A)$$

is a lower semi-continuous action of $X := \mathrm{Prim}(C)$ on A with $\Psi(0) = 0$ and $\Psi^{-1}(A) = \{C\}$.

*Then, there is a *-monomorphism H from A into $\mathcal{M}(C \otimes \mathbb{K})$ such that, for every closed ideal J of C,*

$$H(\Psi(J)) \; = \; H(A) \cap \mathcal{M}(C \otimes \mathbb{K}, J \otimes \mathbb{K})\,.$$

*If A is stable, then H can be taken as a non-degenerate *-monomorphism, i.e., such that $H(A)(C \otimes \mathbb{K})$ is dense in $C \otimes \mathbb{K}$.*

PROOF. Since $J \mapsto J \otimes \mathbb{K}$ defines a lattice isomorphism from $\mathcal{I}(A)$ onto $\mathcal{I}(A \otimes \mathbb{K})$, it suffices to consider the case where A is stable. Moreover, it suffices to show that condition (ii) of Lemma 12.1.2 is satisfied for $B := C \otimes \mathbb{K}$ under the above natural identification $J \otimes \mathbb{K} \leftrightarrow J$ of $\mathcal{I}(B)$ and $\mathcal{I}(C)$.

Note that here $X := \mathrm{Prim}(C)$ is the maximal ideal space of C, and that X itself or its one point compactification $Y := X \cup \{C\}$ is a metrizable compact space.

We define a map g from Y into the set of closed split faces of the quasi-state space $S_q(A) := \{f \in A^* \colon 0 \le f, \|f\| \le 1\}$ of A as follows: For $J \in Y$ let

$$g(J) := \{f \in S_q(A) \colon f(\Psi(J)) = 0\}.$$

Then the lower semicontinuity of Ψ implies that the map $(J, f) \mapsto J$ is an open map from $\{(J, f) \colon J \in Y, f \in g(J)\} \subset Y \times S_q(A)$ onto Y.

Let $a \in A$ and I a closed ideal of C. The lower semicontinuity of Ψ implies that, if $a \notin \Psi(I)$, then there is a maximal ideal J_0 of C such that $I \subset J_0$ and $a \notin \Psi(J_0)$. Thus there is a quasi-state $f_0 \in g(J_0)$ with $f_0(a) = \|a + \Psi(J_0)\|$. Since g satisfies the requirements of the Michael selection principle [**553**], we find a continuous map $J \in Y \mapsto f(J) \in S_q(A)$ such that $f(J) \in g(J)$ and $f(J_0) = f_0$. In particular, $f(C) = 0$. The map

$$V \colon b \in A \mapsto \{f(J)(b)\}_{J \in X} \in \mathrm{C}_0(X) \cong C \otimes p_{11}$$

is a Ψ-equivariant completely positive contraction from A into B with $V(a) \notin I \otimes \mathbb{K}$. □

Lemma 12.1.4. *Suppose that B, C and D are separable C^*-subalgebras of a C^*-algebra G, such that*

(i) *B and D are stable,*
(ii) *D contains B and $\overline{DBD} = D$, and,*
(iii) *C is a commutative C^*-subalgebra of D with the following properties (α) and (β):*
  (α) *For every closed ideals J_1 and J_2 of D, $J_1 \cap C = J_2 \cap C$ implies $J_1 \cap B = J_2 \cap B$.*
  (β) *There exists a sequence of (in D) approximately inner completely positive contractions $V_n \colon D \to C$ with $\lim_{n\to\infty} V_n(a) = a$ for every $a \in C$.*

Suppose moreover that A is a separable stable C^*-algebra and that $\Psi\colon \mathcal{I}(B) \to \mathcal{I}(A)$ is a lower semi-continuous action of $\mathrm{Prim}(B)$ on A with $\Psi(0) = 0$ and $\Psi^{-1}(A) = \{B\}$.

Let $E := \overline{B \cdot G \cdot B} \subseteq G$ and $\Phi(J) := \Psi(B \cap J)$ for $J \in \mathcal{I}(E)$.

*Then there exists a non-degenerate weakly Φ-residually nuclear *-monomorphism $H_1\colon A \hookrightarrow \mathcal{M}(E)$, such that $\delta_\infty H_1$ is unitarily equivalent to H_1, and, for every closed ideal J of E,*

$$H_1(\Phi(J)) = H_1(\Psi(B \cap J)) = H_1(A) \cap \mathcal{M}(E, J).$$

H_1 with this property is unique up to unitary homotopy.

In particular, for every automorphism φ of E with $\varphi|B = \mathrm{id}_B$, the composition $\mathcal{M}(\varphi)H_1 = \varphi H_1 \varphi^{-1}$ is unitarily homotopic to H_1.

Condition (iii,β) implies that $(J_1 \cap C) + (J_2 \cap C) = (J_1 + J_2) \cap C$ for all closed ideals J_1 and J_2 of D. If a commutative C^*-subalgebra $C \subseteq D$ satisfies this condition and has property (iii,α) then C is called **regular Abelian C^*-subalgebra** of D.

The map $I \lhd C \mapsto J(I) \lhd D$ considered in the *proof* of Lemma 12.1.4 is lower semi-continuous. Thus, the family of c.p. maps $W\colon D \to C$ with $W(J(I)) \subset I$ is closed under point-norm convergence, satisfies $W(J) \subset J \cap C$ for all $J \lhd D$ by $J(J \cap C) \supseteq J$ (hence W is approximately inner in D). Since C is nuclear, it follows that W is residually nuclear.

Can we find, for $c_1, \ldots, c_n \in C_+$ and $\varepsilon > 0$, a contraction $V \in \mathrm{CP_{in}}(A, A)$ with $V(C) \subset C$ and $\|V(c_k) - c_k\| < \varepsilon$?

Proof. The hereditary C^*-subalgebra E of G is σ-unital and stable because B is σ-unital and stable. Therefore, the uniqueness of H_1 follows from Lemma 12.1.2. The φ-invariance up to unitary homotopy follows from the uniqueness.

Let $J_1, J_2 \subset D$ closed ideals, then $C \cap J_i \subset C \cap (J_1 + J_2)$ for $i = 1, 2$. Now let $a \in (J_1 + J_2) \cap C$. There exist $b \in J_1$ and $c \in J_2$ with $a = b + c$. By assumption (iii, β), for $\varepsilon > 0$ there is an approximately inner completely positive contraction $V \colon D \to C$ with $\|V(a) - a\| < \varepsilon$. Then $V(b) \in J_1 \cap C$, $V(c) \in J_2 \cap C$ and $V(a) \in (C \cap J_1) + (C \cap J_2)$. But $(C \cap J_1) + (C \cap J_2)$ is a closed ideal of C.

Thus, for closed ideals J_1 and J_2 of D,

$$C \cap (J_1 + J_2) = (C \cap J_1) + (C \cap J_2)\,.$$

Therefore, for every closed ideal I of C, the set of closed ideals J of D with $C \cap J \subset I$ is upward directed. It is easy to see, that this set is also upward monotonous closed. Hence, for every closed ideal I of C, there is a biggest ideal $J(I)$ in the set of closed ideals J of D with $J \cap C \subset I$.

Let $\Psi_D(I) := J(I)$ for $I \in \mathcal{I}(C)$.

The definition of Ψ_D shows that $\Psi_D \colon \mathcal{I}(C) \to \mathcal{I}(D)$ defines a lower semi-continuous action of $\mathrm{Prim}(C)$ on D.

$\mathrm{Prim}(D)$ acts lower semi-continuous on B by $J \in \mathcal{I}(D) \mapsto B \cap J \in \mathcal{I}(B)$.

It follows that the composition with the given action Ψ of $\mathrm{Prim}(B)$ on A,

$$\Psi_A \colon J \in \mathcal{I}(C) \mapsto \Psi(B \cap \Psi_D(J))$$

is a lower semi-continuous action of $\mathrm{Prim}(C)$ on A.

Let $J \in \mathcal{I}(D)$, then, by definition of Ψ_D, $J \subset \Psi_D(C \cap J)$ and $C \cap \Psi_D(C \cap J) \subset C \cap J$. By assumption (iii,$\alpha$), this implies $B \cap J = B \cap \Psi_D(C \cap J)$. Thus, for every $J \in \mathcal{I}(D)$,

$$\Psi(B \cap J) = \Psi_A(C \cap J).$$

In particular, $\Psi_A(0) = \Psi(0) = 0$ and $\Psi_A(C) = \Psi(B) = A$.

Let $I \in \mathcal{I}(C)$ and suppose that $\Psi_A(I) = A$, i.e., $\Psi(B \cap \Psi_D(I)) = A$. Since, by assumption on Ψ, $\Psi^{-1}(A) = \{B\}$, this implies $B \subset \Psi_D(I)$. By (ii) and definition of Ψ_D, it follows $\Psi_D(I) = D$, $C = \Psi_D(I) \cap C \subset I$, and therefore, $(\Psi_A)^{-1}(A) = \{C\}$.

Thus, Ψ_A is a lower semi-continuous action of $\mathrm{Prim}(C)$ onto A with $\Psi_A(0) = 0$ and $(\Psi_A)^{-1}(A) = \{C\}$.

By Lemma 12.1.3, there exists a non-degenerate *-monomorphism H from A into $\mathcal{M}(C \otimes \mathbb{K})$ such that, for $I \in \mathcal{I}(C)$,

$$H(\Psi_A(I)) = H(A) \cap \mathcal{M}(C \otimes \mathbb{K}, I \otimes \mathbb{K}).$$

We have $D \cap E = \overline{BDB}$, because both are hereditary C^*-subalgebras of D which are generated by B. Therefore, $D \cap E$ is σ-unital and stable. By (ii), D is the smallest closed ideal of D which contains B. Let $J := \overline{DCD}$ the closed ideal of D which is generated by C. Then $C \cap J = C = C \cap D$, thus $J \cap B = D \cap B = B$ and $J = D$, by (iii,α) and (ii). It follows, that $(D \cap E) \otimes p_{11}$ and $C \otimes \mathbb{K}$ are stable σ-unital C^*-subalgebras of $D \otimes \mathbb{K}$ which both generate the same ideal $D \otimes \mathbb{K}$.

By Corollary 5.5.6, there is a *-monomorphism

$$k\colon C\otimes\mathbb{K}\hookrightarrow D\cap E$$

such that $k(C\otimes\mathbb{K})$ contains a strictly positive element of $D\cap E$, and that, for every closed ideal J of D,

$$k(C\otimes\mathbb{K})\cap J=k((C\cap J)\otimes\mathbb{K}).$$

Since k is non-degenerate, $\mathcal{M}(k(C\otimes\mathbb{K}))\subset\mathcal{M}(E)$ and, for $I\in\mathcal{I}(G)$,

$$\mathcal{M}(k(C\otimes\mathbb{K}))\cap\mathcal{M}(E,I\cap E)=\mathcal{M}(k(C\otimes\mathbb{K}),k((C\cap I)\otimes\mathbb{K})).$$

Here we used that $C\cap I=C\cap(I\cap D)$.

Let $H_1:=\mathcal{M}(k)\delta_\infty H=k\delta_\infty(H(.))k^{-1}$. Then H_1 is a non-degenerate *-monomorphism, $H_1(A)$ is contained in $\mathcal{M}(k(C\otimes\mathbb{K}))$, and, for every closed J of E, and

$$H_1(\Phi(J))\;=\;H_1(\Psi(B\cap J))\;=\;H_1(A)\cap\mathcal{M}(E,J)\,.$$

Note here that $B\cap J=B\cap(I\cap D)$, and $C\cap I=C\cap(I\cap D)$ for the unique ideal I of G with $J=I\cap E$.

Since $H_1(A)$ is contained in $\mathcal{M}(k(C\otimes\mathbb{K}))$, we get from Lemma 12.1.1(v) that H_1 is weakly Φ-residually nuclear. $\delta_\infty H_1$ is unitarily equivalent to H_1, because $\delta_\infty\mathcal{M}(k)\delta_\infty$ is unitarily equivalent to $\mathcal{M}(k)\delta_\infty$ by Lemma 5.1.2. □

We denote by $[a,b]$ the commutator $ab-ba$ in the following.

LEMMA 12.1.5. *For every $n\in\mathbb{N}$, there is a continuous function f_n with $f_n(0)=0$ which has the following universal property:*

If A is a C^*-algebra with $A\cong A\otimes\mathcal{O}_\infty\otimes\mathcal{O}_\infty\otimes\ldots$, $a_1,\ldots,a_n,b\in A_+$ are contractions, and $\varepsilon>0$, with $\|[a_j,a_k]\|<\varepsilon$ for $j,k=1,\ldots,n$, then, there exists a contraction $c\in A$ with

$$\|[a_j,c]\|<f_n(\varepsilon)\,,\quad \|(1-c^*c)a_j\|<f_n(\varepsilon)\quad\textit{and}\quad \|[a_j,c^*bc]\|<f_n(\varepsilon)\,.$$

PROOF. Let C be a commutative C^*-subalgebra of a C^*-algebra D. Then the set $K(C)$ of completely positive maps $V(a):=\sum(c_i)^*ac_i$ with $c_1,\ldots,c_m\in C$ and $\|V(1)\|\le 1$ is convex. Its point weak closure on D^{**} is $K(C^{**})$, where we identify C^{**} naturally with the weak closure of C in D^{**}. For $b\in D$, $a_1,\ldots,a_n\in C$, and $\delta>0$, there exist $V\in K(C^{**})$ with

$$\|(1-V(1))a_j\|<\delta\qquad\text{and}\qquad\|[a_j,V(b)]\|\;<\;\delta. \tag{*}$$

To see this, approximate $a_1,\ldots,a_n$ by elements in the span of mutually orthogonal projections $p_1,\ldots,p_k\in C^{**}$ and consider $\sum_j p_jbp_j$. A Hahn-Banach separation argument shows that we can find V with (*) even in $K(C)$.

Suppose that there is a C^*-algebra B and a *-monomorphism φ from $B\otimes\mathcal{O}_\infty$ into D, such that $C\subset\varphi(B\otimes 1)$ and $b\in\varphi(B\otimes 1)$. Let $c:=\sum_{1\le i\le m}\varphi(d_i\otimes s_i)$, where $\varphi(d_i\otimes 1)=c_i$ and s_i denote the canonical generators of $\mathcal{O}_\infty$. Then c satisfies $c^*bc=V(b)$, $V(1)=c^*c$, and $[a_j,c]=0$. Therefore, $\|(1-c^*c)a_j\|<\delta$, $\|[a_j,c^*bc\|<\delta$, and c is a contraction in D commuting with a_j for $j=1,\ldots,n$.

Now we define numbers $g(a,b) := \|[a,b]\|$, where $[a,b] = ab - ba$,

$$\eta(a_1,\ldots,a_n) := \max\{g(a_j,a_k)\colon j,k = 1,\ldots,n\},$$

$$\mu(a;b;c) := \max(g(a,c), g(a,c^*bc), \|(1-c^*c)a\|),$$

and, for C^*-algebras A and contractions $a_1,\ldots,a_n,b,c \in A_+$,

$$v(a_1,\ldots,a_n;b;A) := \inf_c\{\max(\mu(a_1;b;c),\ldots,\mu(a_n;b;c))\},$$

where the infimum runs over all contractions $c \in A$.

For every $t \in \mathbb{R}_+$, and for every C^*-subalgebra A, we denote by $Y(t,A)$ the set of sequences $(a_1,\ldots,a_n,b)$ of contractions in A_+ such that $\eta(a_1,\ldots,a_n) \le t$. Now we define increasing functions $F(t,A)$ and $F(t)$ as follows:

$$F(t,A) := \sup\{v(a_1,\ldots,a_n;b;A)\colon\ (a_1,\ldots,a_n,b) \in Y(t,A)\},$$

and $F(t) := \sup_A\{F(t,A)\}$, where the supremum runs over all separable C^*-subalgebras A of $\mathcal{L}(\ell_2)$ with $A \cong A \otimes \mathcal{O}_\infty \otimes \mathcal{O}_\infty \otimes \ldots$. $F(t,A)$ and $F(t)$ are increasing on $\mathbb{R}_+$.

It is not hard to see, that f_n with the desired properties exists if and only if $\lim_{t\to 0} F(t) = 0$. Since $F(t)$ is increasing, we have $\lim_{t\to 0} F(t) = \inf\{F(1/k)\colon k \in \mathbb{N}\}$.

Suppose that $F(1/k) \ge 3\gamma > 0$ for $k \in \mathbb{N}$. Then we can find, for $k = 1,2,\ldots$,

(i) separable C^*-algebras A_k with $A_k \cong A_k \otimes \mathcal{O}_\infty \otimes \mathcal{O}_\infty \otimes \ldots$, and
(ii) $(a_1^{(k)},\ldots,a_n^{(k)},b^{(k)}) \in Y(1/k,A_k)$ such that $v(a_1^{(k)},\ldots,a_n^{(k)};b^{(k)};A_k) > 2\gamma$.

Now we use ultrapowers: Let $D := \prod_\omega(A_k)$, and $a_1,\ldots,a_n,b \in D$ with representatives $(a_j^{(1)},a_j^{(2)},\ldots)$ of a_j, and $(b^{(1)},b^{(2)},\ldots)$ of b. Let C and B be the C^*-subalgebras of D that are generated by $\{a_1,\ldots,a_n\}$ and $\{b,a_1,\ldots,a_n\}$ respectively. Then C is commutative and B is separable. By Proposition 7.4.11, there exists a *-monomorphism φ from $B \otimes \mathcal{O}_\infty$ into D, such that $\varphi(d \otimes 1) = d$ for $d \in B$. As we have seen above, there is a contraction $c \in D$ such that

$$\max(\mu(a_1;b;c),\ldots,\mu(a_n;b;c)) \,<\, \gamma\,.$$

This contradicts the above property (ii). □

LEMMA 12.1.6. *Suppose that $B \cong B \otimes \mathcal{O}_\infty \otimes \mathcal{O}_\infty \otimes \ldots$. Let $G := \mathrm{Q}(\mathbb{R}_+,B)$, the corona of B, or let $G := B_\omega$, the ultrapower of B.*

If D is a separable C^*-subalgebra of G and C a separable commutative C^*-subalgebra of D, then there exist a contraction $d \in C' \cap G$ and a commutative C^*-subalgebra A of G such that $C \subset A$, $d^*da = a$ for $a \in C$, and $d^*Dd \subset A$.

PROOF. We consider the case $G = \mathrm{Q}(\mathbb{R}_+,B)$. The proof for the case $G = B_\omega$ is similar.

Let $e_1,e_2,\ldots$ be a dense sequence in the positive contractions of D.

By Corollary 7.4.10, the approximately inner completely positive contractions $T\colon D \to G$ are one-step inner, i.e., there is a contraction $d \in G$ such that $T(b) =$

d^*bd. If $T|C = \mathrm{id}\,|C$, then $[a,d] = (1-dd^*)ad$ and $\|(1-dd^*)^{1/2}ad\|^2 = \|T(a^*a) - T(a^*)T(a)\| = 0$ for $a \in C$. It follows $d \in C' \cap G$ and and $d^*da = d^*ad = a$ for $a \in C$.

Thus it suffices to construct a sequence of approximately inner completely positive maps $T_n\colon G \to G$, such that $T_n|C = \mathrm{id}\,|C$, $\lim_n [T_n(e_k), T_n(e_j)] = 0$ and that $\lim_n T_n(e_k)$ exists for $k, j \in \mathbb{N}$.

The approximately inner completely positive contractions $T\colon G \to G$ with $T|C = \mathrm{id}\,|C$ form a semigroup for every C^*-subalgebra $C \subset G$. Therefore, we attempt to construct a sequence of approximately inner completely positive contractions $T_n\colon G \to G$ in the special way $T_n := S_{n+1}S_n \ldots S_1$. Here $S_n\colon G \to G$ should be approximately inner completely positive contractions which satisfy $S_n|C_n = \mathrm{id}\,|C_n$ and $S_n(g_n)$ commutes with C_n, where $C_1 := C$, $g_1 := e_1$, and, by induction, $g_n := S_{n-1}\ldots S_1(e_n)$, $C_{n+1} := C^*(C_n, S_n(g_n))$.

Then the sequence of restrictions $T_n|D$ has the desired properties, and $A := \mathrm{indlim}\, C_n$, $T(b) := \lim T_n(b)$ for $b \in D$ have the properties as stated in Lemma 12.1.6.

Thus it remains to show that for every separable commutative C^*-subalgebra $C \subset G$ and every contraction $g \in G_+$ there is an approximately inner completely positive contraction $S\colon G \to G$ with $S|C = \mathrm{id}\,|C$ such that $S(g)$ commutes elementwise with C.

Let $a_1, a_2, \ldots$ a sequence of positive contractions in $\mathrm{C_b}(\mathbb{R}_+, B)$, such that the sequence of the $c_n := a_n + \mathrm{C_0}(\mathbb{R}_+, B)$ is dense in the positive contractions in C. Let $b \in \mathrm{C_b}(\mathbb{R}_+, B)_+$ a contraction which represents g. With the notation of Lemma 12.1.5, we find a sequence $s_1 > s_2 > \ldots$ in $(0,1]$ such that $f_m(\varepsilon) < 1/n$ for $\varepsilon \in (0, s_n]$, $m \le n$. This is possible by Lemma 12.1.5.

Since $[c_j, c_k] = 0$, there are positive real numbers x_n with $x_{n+1} > \max(x_n, n)$, such that $\|[a_i(y), a_j(y)]\| < s_n$ for $y \ge x_n$ and $1 \le i, j \le n$.

Let $I_n := [x_n, x_{n+2}]$. Since $\mathrm{C}(I_n, B)$ absorbs $\mathcal{O}_\infty$ tensorial, we can apply Lemma 12.1.5 to $\mathrm{C}(I_n, B)$, $a_j|I_n$, $j = 1, \ldots, n$, and $b|I_n$, and find contractions $d_n \in \mathrm{C}(I_n, B)$ such that, for $j = 1, \ldots, n$, $\|(1 - d_n^* d_n)(a_j|I_n)\|$, $\|(a_j|I_n) - d_n^*(a_j|I_n)d_n\|$ and $\|[(a_j|I_n), d_n^*(b|I_n)d_n]\|$ are smaller then $1/n$.

Now we choose a continuous function $\mu_1(y)$ on $\mathbb{R}_+$ with $0 \le \mu_1(y) \le 1$, $\mu_1(x_{2n}) = 0$ and $\mu_1(x_{2n-1}) = 0$, for $n \in \mathbb{N}$. Let $\mu_2(y) := 1 - \mu_1(y)$.

We define elements $h_1, h_2 \in \mathrm{C_b}(\mathbb{R}_+, B)$ as follows:

Let $h_k(y) = 0$ for $y \in [0, x_k]$, $k = 1, 2$, and, for $y \in [x_{2n-k}, x_{2n+2-k}]$, $n \in \mathbb{N}$,

$$h_k(y) := (\mu_k(y))^{1/2} d_{2n-k}.$$

Then the corresponding elements $d_1, d_2 \in G$ satisfy $\|d_1^*d_1 + d_2^*d_2\| \le 1$ and define an inner completely positive contraction $S(a) := d_1^* a d_1 + d_2^* a d_2$ on G with $S|C = \mathrm{id}\,|C$, such that $S(g)$ commutes with C. □

LEMMA 12.1.7. *Suppose that B is separable and stable, and that B is isomorphic to $B \otimes \mathcal{O}_\infty \otimes \mathcal{O}_\infty \otimes \dots$.*

Let $G := \mathrm{Q}(\mathbb{R}_+, B)$. Then there exist separable C^*-subalgebras C and D such that B, C, D and G satisfy the assumptions (i), (ii) and (iii) of Lemma 12.1.4.

PROOF. Below, we show the existence of sequences of separable C^*-subalgebras $C_n \subset D_n \subset F_n \subset D_{n+1}$ of G, of contractions $d_n \in G$, and of *-monomorphisms h_n from $F_n \otimes \mathcal{O}_\infty \otimes \mathbb{K}$ into G, such that

(i) $D_1 := B$,
(ii) F_n is the C^*-subalgebra of G generated by D_n and d_n,
(iii) $h_n(f \otimes 1 \otimes p_{11}) = f$ for every $f \in F_n$
(iv) D_{n+1} is the image $h_n(F_n \otimes \mathcal{O}_\infty \otimes \mathbb{K})$ of h_n,
(v) C_n is a commutative C^*-subalgebra of D_n such that, for every closed ideal J of D_n, J is the smallest closed ideal of D_n which contains $C_n \cap J$, and
(vi) d_n commutes elementwise with C_n, $d_n^* d_n a = a$ for every $a \in C_n$, and $d_n^* D_n d_n$ generates a commutative C^*-subalgebra A_n of F_n with $C_n \subset A_n$,
(vii) $A_n \subset C_{n+1}$.

In particular, we have $B \subset D_n \subset D_{n+1}$ and $C_n \subset A_n \subset C_{n+1} \subset D_{n+1}$.

Let D and C be the closures of the unions of the sequences (D_n) and (C_n) respectively. Then $C \subset D$ and $B \subset D$. D is stable by (iv) and [**373**]. B is stable by assumption. By (ii),(iii) and (iv), D_{n+1} is the closed span of $D_{n+1} D_n D_{n+1}$. Thus, by (i), the span of DBD is dense in D. C is commutative.

Let J_1 and J_2 be closed ideals of D with $J_1 \cap C = J_2 \cap C$. Then $J_1 \cap C_n = J_2 \cap C_n$ and, by (v), $J_1 \cap D_n = J_2 \cap D_n$. But J_k is the inductive limit of $J_k \cap D_n$ for $n = 1, 2, \dots$ and $k = 1, 2$.

We can define approximately inner completely positive contractions $T_n \colon D \to C$ with $T_n | C_n = \mathrm{id} | C_n$, as follows: Let $e_{nk} := d_n d_{n+1} \dots d_{n+k}$ and $T_n(a) := \lim_{k\to\infty} (e_{nk})^* a e_{nk}$ Note here that e_{nm} is in D_{n+m+1} and that, therefore, by (vi) and (vii), $(e_{nk})^* a (e_{nk})$ is in C_{n+m+2} and $(e_{nk})^* a(e_{nk}) = (e_{nl})^* a(e_{nl})$ for $a \in D_{n+m+1}$, and $k, l > m$.

Thus, *B, C, D and G satisfy the assumptions (i), (ii) and (iii) of Lemma 12.1.4.*

Now we show the existence of C_n, D_n, d_n, A_n, F_n and h_n by induction:

We start at $n = 0$. Let $C_0 := 0$, $d_0 := 0$, $A_0 := 0$ and let φ denote an isomorphism from $B \otimes \mathcal{O}_\infty \otimes \mathbb{K}$ onto $B \subset G$. φ exists by our assumptions on B.

We define $F_0 \subset G$ as $\varphi(B \otimes 1 \otimes p_{11})$. Then there is a unique *-monomorphism h_0 from $F_0 \otimes \mathcal{O}_\infty \otimes \mathbb{K}$ onto B, such that, for $b \in B$, $e \in \mathcal{O}_\infty$ and $k \in \mathbb{K}$,

$$h_0(\varphi(b \otimes 1 \otimes p_{11}) \otimes e \otimes k) = \varphi(b \otimes e \otimes k).$$

In particular, $h_0(f \otimes 1 \otimes p_{11}) = f$ for $f \in F_0$.

In other words, $h_0(f \otimes e \otimes k) = \varphi(\psi(f) \otimes e \otimes k)$, where ψ denotes the inverse of the isomorphism $b \mapsto \varphi(b \otimes 1 \otimes p_{11})$ from B onto F_0.

By (ii), for $n = 1, 2, \ldots$, $F_n := C^*(D_n, d_n)$ is defined by D_n and d_n.

If we have found F_n, we find a *-monomorphism h_n from $F_n \otimes \mathcal{O}_\infty \otimes \mathbb{K}$ into G with property (iii) by Corollary 7.4.9.

Since D_{n+1} is the image of h_n, we have $B = D_1$, and it is enough to to define d_n and C_n with properties (v), (vi) and (vii). If $C_n \subset D_n$ are given, then the existence of d_n and $A_n := C^*(d_n^* D_n d_n)$ with (vi) follows from Lemma 12.1.6.

So we may assume that $A_n \subset F_n$ and h_n are given. It remains to construct C_{n+1} with properties (vii) and (v), where n has to be replaced by $n+1$ in (v).

Let $(f_k) \subset F_n$ a dense sequence in the set of positive contractions in F_n, andlet X_n denote the commutative C^*-subalgebra of $F_n \otimes \mathbb{K}$ which is generated by $A_n \otimes p_{11}$ and the set $\{f_k \otimes p_{kk} \colon k = 2, 3, \ldots\}$.

We identify $F_n \otimes \mathbb{K}$ with the subalgebra $F_n \otimes 1 \otimes \mathbb{K}$ of $K_n := F_n \otimes \mathcal{O}_\infty \otimes \mathbb{K}$. For every closed ideal J of K_n, we have that $X_n \cap J$ generates J as a closed ideal of K_n. Since $h_n(K_n) = D_{n+1}$, we can define C_{n+1} as $h_n(X_n)$. Now properties (v) and (vii) follow from property (iii) of h_n. □

THEOREM 12.1.8 (Asymptotic non-commutative Selection). *Suppose that A and B are separable and stable C^*-algebras, where B is isomorphic to $B \otimes \mathcal{O}_\infty \otimes \mathcal{O}_\infty \otimes \ldots$, and that*

$$\Psi \colon \mathcal{I}(B) \to \mathcal{I}(A)$$

defines a lower semi-continuous action of $\operatorname{Prim}(B)$ *on A in the sense of Definition 1.2.6 with $\Psi(0) = 0$ and $\Psi^{-1}(A) = \{B\}$.*

Let E denote the hereditary C^*-subalgebra of $\mathrm{Q}(\mathbb{R}_+, B)$ *which is generated by B, and let $\Phi(I) := \Psi(I \cap B)$ for $I \in \mathcal{I}(E)$.*

*Then, there exists a non-degenerate weakly Φ-residually nuclear *-monomorphism H_0 from A into the multiplier algebra $\mathcal{M}(E)$ of E such that $\delta_\infty H_0$ is unitarily equivalent to H_0, and, for $I \in \mathcal{I}(E)$,*

$$\Psi(I \cap B) = \Phi(I) = H_0^{-1}(H_0(A) \cap \mathcal{M}(E, I)).$$

H_0 with this property is unique up to unitary homotopy.

Conversely H_0 determines Ψ in the sense of Lemma 12.1.1, i.e., for $J \in \mathcal{I}(B)$,

$$\Psi(J) := H_0^{-1}(H_0(A) \cap \mathcal{M}(E, E \cap \mathrm{Q}(\mathbb{R}_+, J)))\,.$$

In particular, H_0 and $\widehat{\sigma} \circ H_0$ are unitarily homotopic, for every automorphism $\widehat{\sigma}$ of $\mathcal{M}(E)$, which is induced by a scaling homeomorphism σ of $\mathbb{R}_+$.

PROOF. The existence of H_0 is the logical sum of Lemma 12.1.4 and Lemma 12.1.7, because B is separable, stable and is isomorphic to $B \otimes \mathcal{O}_\infty \otimes \mathcal{O}_\infty \otimes \ldots$.

The uniqueness up to unitary homotopy of a non-degenerate weakly Φ-residually nuclear *-monomorphism $H_0\colon A \to \mathcal{M}(E)$ with

$$\Phi(I) = H_0^{-1}(H_0(A) \cap \mathcal{M}(E, I)).$$

and $\delta_\infty H_0$ unitarily equivalent to H_0 follows from Lemma 12.1.2.

For $J \in \mathcal{I}(B)$, $\mathrm{Q}(\mathbb{R}_+, J)$ is an ideal of $\mathrm{Q}(\mathbb{R}_+, B)$ and $J = B \cap \mathrm{Q}(\mathbb{R}_+, J)$.

Note that $\widehat{\sigma}$ fixes the elements of B and that $B \cap \widehat{\sigma}(I) = B \cap I$ for every $I \in \mathcal{I}(E)$ and every homeomorphism σ of $\mathbb{R}_+$. Thus $\Phi\widehat{\sigma} = \Phi$, and, therefore the uniqueness result applies to $\widehat{\sigma}H_0$.

Since $\Psi(J) = \Phi(E \cap \mathrm{Q}(\mathbb{R}_+, J))$ for $J \in \mathcal{I}(B)$, H_0 determines Ψ in the sense of Lemma 12.1.1. □

2. Selections and Ψ-equivariant embedding

We give now some definitions and lemmata that are needed for the generalization of Theorem A to the case of non-simple strongly purely infinite algebras as target algebras instead of $\mathcal{O}_2$ (cf. Theorem K).

Definition 12.2.1. Let $\mathcal{I}(A)$ denote the set of closed ideals of A with the below described topology and let $\mathrm{Prim}(A)$ denote the space of primitive ideals of A with the hull-kernel topology, i.e. $J \in \mathcal{I}(A)$ is in $\mathrm{Prim}(A)$ if it is the kernel of a (non-zero) irreducible representation of A, and the closed subsets of $\mathrm{Prim}(A)$ are given by the sets of "hulls" $h(I) := \{J \in \mathrm{Prim}(A)\colon I \subset J\}$. Thus the closure operation $X \subseteq \mathrm{Prim}(A) \mapsto \overline{X} \subset \mathrm{Prim}(A)$ is given by $\overline{X} := h(k(X))$, where the "kernel" ideal $k(X)$ of X is defined as $k(X) := \bigcap_{J\in X} J$.

We define a sort of **generalized Gelfand transform** $b \in A \mapsto \widehat{b}$ from A into the bounded functions on $\mathcal{I}(A)$, where $\widehat{b}\colon \mathcal{I}(A) \to \mathbb{R}_+$, for $b \in A$, is defined by

$$\widehat{b}(J) := \|b + J\| := \inf\{\|b + c\|\colon c \in J\}.$$

Recall that the ideal space $\mathcal{I}(A)$ of a C^*-algebra A is a compact Hausdorff space if we take the coarsest topology under which every generalized Gelfand transform is continuous. The latter is the *Fell topology* on $\mathcal{I}(A)$, cf. [**559**].

The compactness follows simply from the fact that every character on the commutative C^*-algebra $C^*(\{\widehat{b};\ b \in A\})$ defines a C^*-seminorm on A. Here $C^*(\{\widehat{b};\ b \in A\})$ means the C^*-subalgebra of $\ell_\infty(\mathcal{I}(A)_{\mathrm{discrete}})$ that is generated by the Gelfand transforms $\widehat{b}$ $(b \in A)$. All Gelfand transforms vanish on the point $J = A$, i.e. $\widehat{b}(A) = 0$. Thus, for every $b \in A$, $\widehat{b}$ is in $\mathrm{C}_0(\mathcal{I}(A) \setminus \{A\})$.

We shall use also the notation $\widehat{b}$ for the restriction $\widehat{b}\,|\,\mathrm{Prim}(A)$ of $\widehat{b}$ to $\mathrm{Prim}(A) \subset \mathcal{I}(A)$. This is justified, because $\widehat{b}$ is determined by its restriction to $\mathrm{Prim}(A)$, for $I \in \mathcal{I}(A)$, i.e.,

$$\widehat{b}(I) = \sup\{\,\widehat{b}(J)\,;\ J \in h(I)\,\}.$$

If A is commutative, then $\mathrm{Prim}(A)$ is the space of maximal ideals of A and $\widehat{b}$ is the ordinary Gelfand transform of the absolute value $|b| = \sqrt{b^*b}$ of $b \in A$.

REMARK 12.2.2. If A is separable, then, with the homeomorphism which we have introduced in Chapter 1, $\mathcal{I}(A)$ becomes a closed subspace of the Hilbert cube $[0,1]^\infty$, which contains $(0,0,\ldots)$ and is closed under component-wise maximum $\alpha\vee\beta$ for $\alpha,\beta\in\mathcal{I}(A)$. Since $\mathcal{I}(A)$ is compact, it follows that, for every subset $K\subset\mathcal{I}(A)$, $\bigvee K\in\mathcal{I}(A)$, and, for every decreasing sequence $\alpha_1\geq\alpha_2\geq\ldots$, $\bigwedge_{n=1}^\infty\alpha_n$ is in $\mathcal{I}(A)$.

Note here, that the natural map from the ideals of A into the Hilbert cube reverses the natural order, i.e., the elements α in the corresponding subset of the Hilbert cube correspond better to the closed subsets of the primitive ideal space of A. If $A\cong\mathrm{C}(X)$ for a compact metric space X, the image is just the classical compact space of closed subsets of X, the topology is then given by the Hausdorff distance metric.

The reader should note that, as explained in Chapter 1, $\mathrm{Prim}(A)$ has *not* the relative topology induced by $\mathcal{I}(A)$:

$\mathrm{Prim}(A)$ is a subset of $\mathcal{I}(A)$, but is not a topological subspace. The topology of $\mathrm{Prim}(A)$ is given by the above cited hull-kernel topology (Jacobson topology). It is easy to see, that the system $\mathbb{O}(\mathrm{Prim}(A))$ of open sets is the coarsest T_0-topology on $\mathrm{Prim}(A)$ under which every generalized Gelfand transform $\widehat{a}$ of an element a in A is *lower semi-continuous*. Thus, $\mathrm{Prim}(A)$ has the topology that is induced by the T_0 topology on the Hilbert cube $[0,1]^\infty$ given by the family of open subsets in Hausdorff topology, that are upward directed (with respect to the coordinate-wise order on elements of $[0,1]^\infty$).

If A is separable, one can re-discover $\mathrm{Prim}(A)$ as the $\vee$-prime elements of $\mathcal{I}(A)$ with system of closed sets induced by the intersection of $\mathcal{I}(A)$ with the set $\{\beta\colon\beta\vee\alpha=\alpha\}$ of points below $\alpha\in\mathcal{I}(A)$.

The reader, who is not familiar with this topics, could learn from considering the following simple example:

Let X a point-complete T_0-space with a countable base of its topology (e.g. $X\cong\mathrm{Prim}(A)$ with separable A), and let $f\colon X\to\mathbb{R}_+$ be a bounded non-negative function on X with $\|f\|_\infty:=\sup f(X)=1$. We can define an action of $\mathbb{O}(X)$ on $\mathrm{C}_0((0,1])$ by $\Psi_f(Z):=\mathrm{C}_0((\sup f(X\setminus Z),1])$ for open subsets Z of X. Here we define $\sup(\emptyset):=0$, because we consider only subsets and elements of $[0,1]$.

The reader easily checks that the action Ψ_f is lower semi-continuous if and only if f is lower semi-continuous.

It is interesting to note, that Ψ_f satisfies property (ii) of Definition 1.2.6, if and only if, for every decreasing sequence $K_1\supset K_2\supset\ldots$ of closed subsets K_n of X,

$$\sup f(\bigcap K_n)=\inf\{\sup f(K_n)\colon n=1,2,\ldots\}.$$

Now let $X:=\mathrm{Prim}(A)$ for a separable C^*-algebra A. As we shall see below, Ψ_f satisfies properties (ii), (iii) and (iv) of Definition 1.2.6, if and only if, $J\mapsto f(h(J))$ is a continuous function on $\mathcal{I}(A)$, and this is the case, if and only if, $f=\widehat{b}$ for an element $b\in A\otimes\mathcal{O}_2$.

The property (i) of Definition 1.2.6 is satisfied for Ψ_f only in the rare and exceptional case where f nsatisfies $\sup f(K_1 \cap K_2) = \min(\sup f(K_1), \sup f(K_2))$ for every closed subsets $K_1, K_2 \subset \mathrm{Prim}(A)$. E.g., this happens for commutative A, if and only if, f is 0 except on one point of $\mathrm{Prim}(A)$.

Let $s, t \in \mathcal{M}(A)$ isometries, $a, b, c, d \in A$ elements and denote by $\beta(a, b; t)$ the maximum of $\|t^*bt - a\|$, $\|t^*b^*bt - a^*a\|$ and $\|t^*bb^*t - aa^*\|$. Clearly $t \in \mathcal{M}(A) \mapsto \beta(a, b; t)$ is strictly continuous and $\beta(c, d; t) \le \beta(a, b; t) + \|a - c\| + \|b - d\|$.

In the following Lemma 12.2.3, let

$$D(a, b; s, t) \;:=\; \max(\beta(b, a, s), \beta(a, b, t))\,.$$

The definition causes $D(a, b; s, t) \le D(c, d; s, t) + \|a - c\| + \|b - d\|$. A similar argument shows that $D(a, b; s, t)$ is strictly continuous in $s, t \in \mathcal{M}(A)$. We define a sort of "distance" ρ_1 of contractions $a, b \in A$ by

$$\rho_1(a, b) := \rho_1(a, b, A) := \inf\{D(a, b; s, t) \colon\; s, t \in \mathcal{M}(A),\; s^*s = t^*t = 1\,\}\,.$$

Lemma 12.2.3. *For every C^*-algebra A with $A \cong A \otimes \mathcal{D}_2$, and for every contractions $a, b \in A$ with $\rho_1(a, b, A) < \varepsilon$, there exists a unitary $U \in \mathcal{M}(A)$ such that $\|U^*aU - b\| < 8\sqrt{\varepsilon}$.*

Proof. It suffices to consider separable C^*-algebras A (up to isomorphisms). The properties of $D(a, b; s, t)$ imply $\rho_1(a, b) \le \rho_1(c, d) + \|a - c\| + \|b - d\|$. Obviously $\|U^*aU - b\| \le \|U^*cU - d\| + \|a - c\| + \|b - d\|$ for $a, b, c, d \in A$ by triangle inequality for unitary $U \in \mathcal{M}(A)$.

Recall that $\mathcal{D}_2 := \mathcal{O}_2 \otimes \mathcal{O}_2 \otimes \cdots$. By the above inequalities we can suppose for our estimates that $a = c \otimes 1, b = d \otimes 1 \in A \otimes 1$ and that there are isometries $s, t \in \mathcal{M}(A)$ with $D(a, b; s \otimes 1, t \otimes 1) = D(c, d; s, t) < \varepsilon$, by approximation of contractions $a, b \in A \cong A \otimes \mathcal{D}_2$ by those in $A \otimes 1$ and by strict approximation of the isometries $s, t \in \mathcal{M}(A)$ by those in $\mathcal{M}(A) \otimes 1 \subset \mathcal{M}(A)$. Then we have to find $U \in \mathcal{M}(A) \otimes \mathcal{O}_2 \subset \mathcal{M}(A)$ with $\|U^*(c \otimes 1)U - d \otimes 1\| \le 8 \cdot D(c, d; s, t)^{1/2}$.

Let $B := C^*(x)$ denote the universal C^*-algebra generated by a single contraction $x \in B$ and define representations $h, k \colon B \to E := \mathcal{M}(A)$ by $h(x) := c$, $k(x) := d$, then we find a unitary $U \in E \otimes \mathcal{O}_2$ that satisfies the inequality

$$\|U^*(h(x) \otimes 1)U - k(x) \otimes 1\| \;<\; 8 \cdot \mu(s, t;\, h, k;\, x)^{1/2}\,,$$

by Corollary 4.5.2, where $\mu(s, t;\, h, k;\, x)$ denotes the maximum of the 6 values

$$\big\{\|s^*h(y)s - k(y)\|\,,\; \|t^*k(y)t - h(y)\|\,;\; y \in \{\, x,\, x^*x,\, xx^*\,\}\big\}\,.$$

This definition of $\mu(s, t;\, h, k;\, x)$ shows that $D(c, d; s, t) = \mu(s, t;\, h, k; x)$, i.e., U is as desired. □

Lemma 12.2.4. *Suppose that A is a separable C^*-algebra, and that F a simple and exact C^*-algebra (e.g. $F = \mathcal{O}_2$ or $F = \mathbb{K}$). Let $B := A \otimes \mathcal{O}_2$ and $X := \mathrm{Prim}(A)$. Then:*

(i) *The map* $J \mapsto J \otimes F$ *defines a natural topological isomorphism* $X \cong \mathrm{Prim}(A \otimes F)$.
(ii) $\{\widehat{a} :\ a \in A \otimes \mathbb{K}\}$ *is closed under point-wise maximum.*
(iii) *Every lower semi-continuous non-negative function* f *on* X *is the point-wise l.u.b. of a sequence* $(\widehat{a_n})$ *with* $a_n \in A_+$.
(iv) $\{\widehat{a}\colon a \in B\} \subset \ell_\infty(X_{\mathrm{disk}})$ *is a maximum-closed and* $\|.\|_\infty$ *norm-closed subset of* $\ell_\infty(X_{\mathrm{disk}})$,
(v) *The* $\|\,.\,\|_\infty$*- closure of* $\{\widehat{a}\colon a \in A \otimes \mathbb{K}\}$ *is* $\{\widehat{a}\colon a \in B\}$.

Proof. Ad(i): By Proposition B.4.2, $J \mapsto J \otimes F$ defines topological isomorphism from $\mathrm{Prim}(A)$ onto $\mathrm{Prim}(A \otimes F)$, for every simple separable exact C^*-algebra F, e.g. $F = \mathcal{O}_2$ or $F = \mathbb{K}$.

Ad(ii): Let s, t be canonical generators of a unital copy of $\mathcal{O}_2$ in $\mathcal{M}(A \otimes \mathbb{K})$. The Cuntz sum $a \oplus b := sas^* + tbt^*$ satisfies

$$\|(a \oplus b) + J\| = \max(\|sas^* + J\|, \|tbt^* + J\|) = \max(\|a + J\|, \|b + J\|)\,,$$

i.e., $\widehat{a \oplus b} = \max(\widehat{a}\,, \widehat{b}\,)$.

Ad(iii): Let $f\colon X \to \mathbb{R}_+$ be a lower semi-continuous function on X. For $c \in \mathbb{R}_+$, let $Y(c) := f^{-1}((c, \infty))$, and let $\chi(c)$ denote the characteristic function of $Y(c)$. Then $c\chi(c) \le f$. If $z \in X$ and $0 < c < f(z)$, then $c = c\chi(c)(z)$. Thus f is the point-wise the l.u.b. of the at most countable set $\{c\chi(c) : c = m/n, m, n \in \mathbb{N}\}$. Since f is lower semi-continuous, $Y(c)$ is an open subset of X and, therefore $\chi(c)$ is lower semi-continuous. Moreover, by the definition of the topology on X, there is a closed ideal $I(c)$ of A such that $Y(c) = X \setminus h(I(c))$.

Thus it suffices to show that, for every closed ideal I of A and $c \in \mathbb{R}_+$, there exist $a \in A_+$, such that the characteristic function χ of $X \setminus h(I)$ is the l.u.b. of $g_n := \widehat{b_n} = \widehat{a}^{\,1/n}$ where $b_n = a^{1/n}$. Since I is separable, we find a strictly positive contraction a in I_+. But this means: $0 < \|a + J\| \le 1$ if $J \in X$ is a primitive ideal of A which is not in $h(I)$, and $\|a + J\| = 0$ for $J \in h(I)$, i.e., $\widehat{a} \le \chi$ and $\widehat{a}(J) > 0$ if $\chi(J) > 0$. Thus, $\sup \widehat{a}(J)^{1/n}$ is the characteristic function χ of $X \setminus h(I)$.

Ad(iv): Let $b \in B$, $d := (b^*b)^{1/2}$ and $c \in (\mathcal{O}_2)_+$ with $Spec(c) = [0, 1]$, then

$$\|b + J\| = \|(d \otimes c) + J \otimes \mathcal{O}_2\|.$$

There is an isomorphism φ from $B \otimes \mathcal{O}_2$ onto B, such that $g \mapsto \varphi(g) \otimes 1$ is an approximately inner endomorphism of $B \otimes \mathcal{O}_2$. In particular $\varphi(J \otimes \mathcal{O}_2) = J$, and, for $a := \varphi(d \otimes c)$,

$$\|b + J\| = \|a + J\|.$$

This, together with the logical sum of Corollary 3.10.11 and Lemma 12.2.3, says that, for every uniformly convergent sequence $f_n = \widehat{b_n}$ with $b_n \in B$, there is a sequence $(a_n) \subset B_+$, such that (a_n) converges in B and $\widehat{b_n} = \widehat{a_n}$. $a \mapsto \widehat{a}$ is a norm-continuous map from B into $\ell_\infty(\mathrm{Prim}(B)_{\mathrm{discrete}})$. Thus $\lim f_n = \widehat{b}$ for $b = \lim a_n$.

Part (v) follows from (iv), because $\mathcal{O}_2$ is nuclear. □

DEFINITION 12.2.5. Suppose X is a T_0-space and that $f\colon X \to \mathbb{R}_+ := [0,\infty)$ is a non-negative function on X. We say that f is a **Dini function** on X (or say f **is Dini**) if f is lower semi-continuous and, for every increasing sequence $g_1 \leq g_2 \leq \ldots$ of lower semi-continuous functions $g_n\colon X \to \mathbb{R}_+$, (g_n) converges uniformly to f in $\ell_\infty(X)$, i.e., $\lim_{n\to\infty} \|f - g_n\|_\infty = 0$, if f is point-wise the supremum of the sequence (g_n), i.e., if $f(x) = \sup\{g_n(x)\colon n \in N\}$.

Every Dini function on X is automatically bounded, because we can consider $g_n := \min(n, f)$.

If X is a metrizable, locally compact and σ-compact Hausdorff space, then a function f is a non-negative Dini function in the sense of the above given Definition, if and only if, $f \in \mathrm{C}_0(X)$. This follows from the classical Lemma of Dini.

The following is a weak version of a stronger result in [**447**], where $B = A \otimes \mathcal{O}_2$ in (ii) is replaced by A itself.

PROPOSITION 12.2.6. *Suppose that A is a separable C^*-algebra and let $B := A \otimes \mathcal{O}_2$, $X := \mathrm{Prim}(A)$ and $h(I) := \{J \in X\colon I \subseteq J\}$ for $I \in \mathcal{I}(A)$.*

Then for a non-negative function f on X the following properties are equivalent:

(i) *f is a Dini function.*

(ii) *There exists $b \in B$ with $\widehat{b} = f$, i.e., $f(J) = \widehat{b}(J \otimes \mathcal{O}_2)$ for $J \in X$.*

(iii) *f is lower semi-continuous, bounded, and, for every increasing sequence $I_1 \subset I_2 \subset \ldots$ of closed ideals I_n of A,*

$$\sup f(h(I)) = \inf\{\sup f(h(I_n))\colon n = 1, 2, \ldots\},$$

where I is the closure of $\bigcup_{n=1}^\infty I_n$.

PROOF. (i)⇒(ii): Suppose that $f\colon X \to \mathbb{R}_+$ is a Dini function. By Lemma 12.2.4(iii), there is a sequence (a_n) in A such that f is the point-wise supremum of the sequence $(\widehat{a_n})$. Let $g_n(J) := \max(\widehat{a_1}(J), \ldots, \widehat{a_n}(J))$ for $J \in X$. Then g_n is an increasing sequence of non-negative lower semi-continuous functions on X with $f = \sup\{g_n\colon n \in \mathbb{N}\}$ point-wise. Since f is Dini, (g_n) converges uniformly to f.

Let $b_n := (a_1 \otimes 1) \oplus \ldots \oplus (a_n \oplus 1)$ in B, then $g_n(J) = \|b_n + (J \otimes \mathcal{O}_2)\|$.

Thus $g_n \in \{\widehat{b}\colon\ b \in B\}$. By Lemma 12.2.4(iv), $f = \widehat{b}$ for some $b \in B$.

(ii)⇒(iii): Suppose that there is $b \in B$ such that $f(J) = \widehat{b}(J \otimes \mathcal{O}_2)$ for $J \in X$. Let $g(I) := \|b + (I \otimes \mathcal{O}_2)\|$ for every closed ideal I of B. Then, for every subset $Z \subset \mathcal{I}(A)$, $g(I) = \sup\{g(J)\colon J \in Z\}$, where $I := \bigcap\{J\colon J \in Z\}$. If K is the closure of an increasing sequence $I_1 \subset I_2 \subset \ldots$ of closed ideals I_n in A, $g(K) = \inf\{g(I_n)\colon n \in \mathbb{N}\}$.

Since $g|X = f$, it follows that f satisfies $\sup f(Z) = g(k(Z))$ for every subset Z of X, where $k(Z) = \bigcap\{J\colon J \in Z\}$ is the kernel-operation on $\mathcal{I}(A)$.

But $hk(Z)$ is the closure of Z in X and $kh(I) = I$ for every closed ideal I of A. We get that f is lower semi-continuous, and that $\sup f(h(I)) = g(I)$ for every closed ideal I of A. Now the upward monotone continuity of g implies, for every increasing sequence $I_1, I_2, \ldots$ of closed ideals I_n of A, that, for the closure I of $\bigcup\{I_1, I_2, \ldots\}$,

$$\sup f(h(I)) = \inf\{\sup f(h(I_n)) \colon n = 1, 2, \ldots\}.$$

(iii)⇒(i): We define a map T from the bounded functions f on X into the functions F on $\mathcal{I}(A)$, by $T(f)(I) := \sup f(h(I))$ for $I \in \mathcal{I}(A)$. Then $T(g) \leq T(f)$ if $g \leq f$. If $I_1, I_2 \in \mathcal{I}(A)$ then $T(f)(I_1 \cap I_2) = \max(T(f)(I_1), T(f)(I_2))$, because $h(I_1 \cap I_2) = h(I_1) \cup h(I_2)$. In particular, $T(f)$ is monotone, i.e., $T(f)(I) \leq T(f)(J)$ if $J \subset I$.

If f is lower semi-continuous on X, then $T(f)(J) = f(J)$ for every primitive ideal J of A:

The set $\{y \in X \colon f(y) \leq f(J)\}$ is closed and contains J. The closure of the one-point set $\{J\}$ is $h(J)$. Thus $f(J) \leq T(f)(J) = \sup f(h(J)) \leq f(J)$.

If f is lower semi-continuous on X, then $T(f)$ is also a lower semi-continuous function on $\mathcal{I}(A)$:

Let M be a subset of $\mathcal{I}(A)$, and let $J(M)$ denote the intersection of the ideals $I \in M$. Then $h(J(M))$ is the closure in X of of the union of the subsets $h(I) \subset X$ for $I \in M$. Since f is lower semi-continuous,

$$\sup f(h(J(M))) = \sup f(\bigcup\{h(I) \colon I \in M\}) = \sup\{\sup f(h(I)) \colon I \in M\}.$$

The right hand equality comes from $f(\bigcup\{h(I) \colon I \in M\}) = \bigcup\{f(h(I)) \colon I \in M\}$.

Let $c \in \mathbb{R}_+$ and $P \in \mathcal{I}(A)$ a point in the closure of the set $\mathcal{M}(c) := \{I \in \mathcal{I}(A) \colon T(f)(I) \leq c\}$. Then $J(\mathcal{M}(c)) \subset P$ and, therefore, $T(f)(P) \leq T(f)(J(\mathcal{M}(c)))$. By the above formula for f, $T(f)(J(\mathcal{M}(c))) \leq \sup\{T(f)(I) \colon I \in \mathcal{M}(c)\} \leq c$. Thus $T(f)$ is lower semi-continuous on $\mathcal{I}(A)$.

Now suppose that f satisfies the assumptions of (iii).

We show that $T(f)$ is then also an upper semi-continuous function, i.e., $T(f)$ is a continuous function on the metrizable compact Hausdorff space $\mathcal{I}(A)$:

Let $c \in \mathbb{R}_+$, and let (P_n) be a convergent sequence in $\mathcal{I}(A)$ with limit $P \in \mathcal{I}(A)$ such that $c \leq T(f)(P_n)$ for $n = 1, 2, \ldots$. Let $I_n = \bigcap_{k \geq n} P_k$. Then $I_n \subset I_{n+1}$, $I_{n+1} \subset P_{n+1}$ and, therefore, $c \leq T(f)(P_{n+1}) \leq T(f)(I_{n+1}) \leq T(f)(I_n)$.

It follows $c \leq T(f)(I)$ for the closure I of $\bigcup\{I_1, I_2, \ldots\}$.

Let $a \in P$, then $\widehat{a}(P) = 0$, $\widehat{a}(I_n) = \sup\{\widehat{a}(P_k) \colon k \geq n\}$, and

$$\widehat{a}(P) = \lim \widehat{a}(P_n) = \lim_n \widehat{a}(I_n) = \widehat{a}(I).$$

Thus, $P \subset I$ and $c \leq T(f)(I) \leq T(f)(P)$. Which proves the upper semicontinuity of $T(f)$.

Let $0 \leq g_1 \leq g_2 \leq \ldots$ be an increasing sequence of lower semi-continuous functions on X, such that $f(y) = \sup\{g_n(y) \colon n \in \mathbb{N}\}$ for every $y \in X$. Let $I \in \mathcal{I}(A)$ and $\varepsilon > 0$. We find $y \in h(I) \subset X$ such that $f(y) + \varepsilon > \sup f(h(I))$. There is $n \in \mathbb{N}$ with $g_n(y) + \varepsilon > \sup f(h(I))$. Thus $T(g_1) \leq T(g_2) \leq \ldots$ is an increasing sequence of lower semi-continuous functions on $\mathcal{I}(A)$, which converges point-wise to the continuous function $T(f)$.

By the lemma of Dini, the sequence $T(g_n)$ converges uniformly to $T(f)$ on $\mathcal{I}(A)$. This happens also with $g_n = T(g_n)|X$ and $f = T(f)|X$.

Hence, f is a Dini function. □

Corollary 12.2.7. *Suppose that A and B are separable C^*-algebras, and that γ is a topological isomorphism from* Prim(A) *onto* Prim(B). *Let $E := A \otimes \mathcal{O}_2$ and $F := B \otimes \mathcal{O}_2$. Then $f \mapsto f \circ \gamma$ defines an isomorphism from $\{\widehat{b} \colon b \in F\}$ onto $\{\widehat{a} \colon a \in E\}$, where we naturally identify* Prim(A) *with* Prim(E) *and* Prim(B) *with* Prim(F).

Proof. $f \mapsto f \circ \gamma$ defines an isomorphism from the Dini functions on Prim(B) onto the Dini functions on Prim(A). Now apply Proposition 12.2.6. □

Corollary 12.2.8. *Suppose that A and B are separable C^*-algebras, and that Ψ is a map from $\mathcal{I}(B)$ into $\mathcal{I}(A)$ with $\Psi(J_1) \subset \Psi(J_2)$ for $J_1 \subset J_2$, $J_1, J_2 \in \mathcal{I}(B)$. Then:*

(i) *Ψ is lower semi-continuous, if and only if, for every $a \in A$, $J \mapsto \widehat{a}(\Psi(J))$ is a lower semi-continuous function on* Prim(B), *and for every $I \in \mathcal{I}(B)$ and $a \in A$ with $\widehat{a}(\Psi(I)) > 0$ there exists $J \in$* Prim(B) *with $\widehat{a}(\Psi(J)) > 0$ and $I \subset J$.*

(ii) *Ψ is, moreover, countably monotone upper semi-continuous, i.e., satisfies (ii) of Definition 1.2.6, if and only if, for every $a \in A$, $J \mapsto \widehat{a}(\Psi(J))$ is a Dini function on* Prim(B).

Proof. Let $X :=$ Prim(B) and $f_a := \widehat{a}\Psi|X$ for $a \in A$.

Suppose that Ψ is lower semi-continuous. Then, for every subset Z of X,

$$\widehat{a}(\Psi(\bigcap J \in Z) = \widehat{a}(\bigcap_{J \in Z} \Psi(J)) = \sup\{\widehat{a}(J) \colon J \in Z\}.$$

In particular, $\sup f_a(Z) = \sup f_a(hk(Z))$ and $\widehat{a}(\Psi(I)) = \sup f_a(h(I))$, because $\bigcap\{J \in Z\} = \bigcap\{J \in hk(Z)\}$ and $I = kh(I) = \bigcap\{J \in h(I)\}$. But this means that f_a is lower semi-continuous on X and that $\widehat{a}(\Psi(I)) > 0$ implies the existence of $J \in h(I)$ with $f_a(J) > 0$.

Conversely, suppose that f_a is lower semi-continuous for every $a \in A$ and that for every $I \in \mathcal{I}(B)$ and $a \in A$ with $\widehat{a}(\Psi(I)) > 0$ there exists $J \in h(I)$ with $f_a(J) > 0$. This says that $f_a(Z) = \{0\}$ implies $f_a(hk(Z)) = \{0\}$ and that $\widehat{a}(\Psi(I)) = 0$ if and only if $f_a(h(I)) = \{0\}$.

Let $I := \bigcap_\alpha I_\alpha$, $K := \bigcap_\alpha \Psi(I_\alpha)$ and $Z := \bigcup_\alpha h(I_\alpha)$. By monotony of Ψ, we have $\Psi(I) \subset K$. If $a \in K$, then $\widehat{a}(\Psi(I_\alpha)) = 0$ for every α in the index set. Thus $\{0\} = f_a(Z) = f_a(hk(Z))$. But $k(Z) = I$. Therefore, $\widehat{a}(\Psi(I)) = 0$, i.e., $a \in \Psi(I)$. Hence $K = \Psi(I)$ and Ψ is lower semi-continuous.

Ad(ii): We have seen in the proof of the first part, that $\widehat{a}(\Psi(I)) = \sup f_a(h(I))$ for $I \in \mathcal{I}(B)$ and that f_a is lower semi-continuous, if Ψ is lower semi-continuous. f_a is bounded by $\|a\|$.

Let $I_1 \subset I_2 \subset \ldots$ an increasing sequence of closed ideals of B, and let I and K denote the closures of $\bigcup I_n$ and $\bigcup \Psi(I_n)$, respectively. Then

$$\widehat{a}(K) = \inf\{\sup f_a(h(I_n)) \colon n = 1, 2, \ldots\}.$$

By Proposition 12.2.6(iii), it follows that $\widehat{a}(\Psi(I)) = \widehat{a}(K)$ if f_a is a Dini function. Thus, Ψ satisfies (ii) of Definition 1.2.6 if f_a is a Dini function on X for every $a \in A$.

If Ψ satisfies (ii) of Definition 1.2.6 then $\Psi(I) = K$ and, therefore,

$$\sup f_a(h(I)) = \inf\{\sup f_a(h(I_n)) \colon n = 1, 2, \ldots\}.$$

Thus, by Proposition 12.2.6(iii), f_a is a Dini function on X for every $a \in A$, if Ψ satisfies property (ii) of Definition 1.2.6. □

REMARK 12.2.9. Recall from Remark 3.11.3 that for a C^*-algebra B the following Properties (i)–(iv) are equivalent to each other:

(i) *B strongly purely infinite in the sense of Definition 1.2.2.*
(ii) *For every $a, b \in B_+$ and $\varepsilon > 0$ there exist contractions $s, t \in B$ such that $\|a^2 - s^*a^2s\|$, $\|b^2 - t^*b^2t\|$ and $\|s^*abt\|$ are all less then ε.*
(iii) *The ultrapower B_ω of B is strongly purely infinite.*
(iv) *The asymptotic corona $\mathrm{Q}(\mathbb{R}_+, B)$ of B is strongly purely infinite.*
(v) *$\mathrm{Q}(\mathbb{R}_+, B)$ has the WvN-property of Definition 1.2.3.*
(vi) *B admits no non-zero character, and for every separable C^*-subalgebra C of $\mathrm{Q}(\mathbb{R}_+, B)$ the following holds:*

If $t \in \mathbb{R}_+ \mapsto V(t)$ is a strongly continuous map from $\mathbb{R}_+$ into the approximately inner completely positive contractions from B into B, T is the completely positive contraction from $\mathrm{Q}(\mathbb{R}_+, B)$ into $\mathrm{Q}(\mathbb{R}_+, B)$ given by

$$T(a + \mathrm{C}_0(\mathbb{R}_+, B)) := V(a) + \mathrm{C}_0(\mathbb{R}_+, B),$$

where $a \in \mathrm{C_b}(\mathbb{R}_+, B)$ and $V(a)(t) := V(t)(a(t))$, and if $T|C$ is residually nuclear, then, there exists a contraction $d \in \mathrm{Q}(\mathbb{R}_+, B)$ such that $T(b) = d^*bd$ for $b \in C$.

From (ii) it follows that *the class of strongly purely infinite algebras is closed under inductive limits.*

It is obvious that quotient algebras and hereditary C^*-subalgebras of strongly purely infinite C^*-algebras are strongly purely infinite.

REMARK 12.2.10. In [**431**, sec. 3] we have discussed several equivalent properties of C^*-subalgebras A of a C^*-algebra B, among them the property, that there is a normal conditional expectation from the second conjugate B^{**} of B onto the second conjugate A^{**} of A, where we have naturally identified A^{**} with the weak closure of A in B^{**}.

Among others, in [**431**] it was shown that this property is equivalent to the **relative weak injectivity** (in short: rwi) of A in B, which means that the natural C^*-morphism from the maximal C^*-algebra tensor product $A \otimes^{max} C$ to $B \otimes^{max} C$ is injective, and thus isometric, for every C^*-algebra C, cf. [**431**, prop. 3.1]. Here it suffices even to take $C = C^*(F_\infty)$, the full group C^*-algebra of the free group on countably many generators.

It follows immediately that the closure A of the union of an increasing sequence $A_1 \subset A_2 \subset \ldots$ of relatively weakly injective subalgebras of B is again relatively weakly injective in B.

Unfortunately, relative weak injectivity does not pass to quotients in general:

There exist B, $A \subset B$, closed ideals J of A, and $I_1 \subset I_2$ of B such that

(i) $J := I_1 \cap A = I_2 \cap A$ and A is relatively injective in B,
(ii) A/J is relatively injective in B/I_1, but
(iii) A/J is *not* relatively weakly injective in B/I_2.

We define a stronger property as the relative weak injectivity such that it plays together with some particular quotient maps in a natural manner:

We say that $A \subset B$ is **residually relatively weakly injective** in B, if, for every $J \in \mathcal{I}(A)$, the natural monomorphism maps $A/(A \cap \Psi^{A,B}_{\text{down}}(J))$ onto a relatively weakly injective C^*-subalgebra of $B/\Psi^{A,B}_{\text{down}}(J)$ ([4]).

The above mentioned results from [**431**] and the short exactness of the maximal C^*-algebra tensor product imply immediately the following equivalent formulation:

$A \subset B$ *is residually relatively weakly injective in* B*, if and only if,*

$$A \otimes^{max} C^*(F_\infty) \subset B \otimes^{max} C^*(F_\infty)$$

and, for every $J \in \mathcal{I}(A)$*,*

$$(A \cap \Psi^{A,B}_{\text{down}}(J)) \otimes^{max} C^*(F_\infty) = (A \otimes^{max} C^*(F_\infty)) \cap (\Psi^{A,B}_{\text{down}}(J) \otimes^{max} C^*(F_\infty)).$$

If A is relatively weakly injective in B, and if I is a closed ideal of $B \otimes^{max} C$ such that

$$I \cap (A \otimes^{max} C) = (A \cap \Psi^{A,B}_{\text{down}}(J)) \otimes^{max} C,$$

then I contains $\Psi^{A,B}_{\text{down}}(J) \otimes^{max} C$.

It follows, that $A \subset B$ *is residually relatively weakly injective in* B *if, e.g.,* A *is relatively weakly injective in* B *and every closed ideal of* $A \otimes^{max} C^*(F_\infty)$ *is the intersection of* $A \otimes^{max} C^*(F_\infty)$ *with a closed ideal of* $B \otimes^{max} C^*(F_\infty)$*.*

[4]Recall that $\Psi^{A,B}_{\text{down}}(J)$ is the smallest closed ideal of B which contains $J \in \mathcal{I}(A)$.

Lemma 12.2.11. *Suppose that $A_1 \subset A_2 \subset \dots$ is a sequence of C^*-subalgebras of B which are residually relatively weakly injective in B. Then the closure A of its union is residually relatively weakly injective in B.*

Proof. First, A is again relatively weakly injective in B, i.e., $A \otimes^{max} C$ and $A_n \otimes^{max} C$ are naturally C^*-subalgebras of $B \otimes^{max} C$ for every C^*-algebra C, because the functor $(.) \otimes^{max} C$ is continuous with respect to inductive limits.

Let $J \in \mathcal{I}(A)$. Then $(A \cap \Psi^{A,B}_{\text{down}}(J)) \otimes^{max} C$ is contained in $\Psi^{A,B}_{\text{down}}(J) \otimes^{max} C$, and $\Psi^{A,B}_{\text{down}}(J)$ is the closure of the union of the increasing sequence of closed ideals $\Psi^{A_n,B}_{\text{down}}(A_n \cap J)$.

For $n < m$, the intersection of $\Psi^{A_n,B}_{\text{down}}(A_n \cap J) \otimes^{max} C$ with $A_m \otimes^{max} C$ is contained in $\big(A \cap \Psi^{A_m,B}_{\text{down}}(A_m \cap J)\big) \otimes^{max} C$.

Thus, the intersection of $\Psi^{A_n,B}_{\text{down}}(A_n \cap J) \otimes^{max} C$ with $A \otimes^{max} C$ is contained in $(A \cap \Psi^{A,B}_{\text{down}}(J)) \otimes^{max} C$.

By continuity of $(.) \otimes^{max} C$, we get that $(A \cap \Psi^{A,B}_{\text{down}}(J)) \otimes^{max} C$ is the intersection of $A \otimes^{max} C$ with $\Psi^{A,B}_{\text{down}}(J) \otimes^{max} C$. □

Lemma 12.2.12. *Suppose that $A \subset B$ is non-degenerate and residually relatively weakly injective in B, and that $A \cap \Psi^{A,B}_{\text{down}}(J) = J$ for every $J \in \mathcal{I}(A)$.*

Let C be a C^*-subalgebra of $\mathcal{M}(A)$ and $V \colon C \to \mathcal{M}(A)$ a completely positive map.

Then V is weakly residually nuclear as a map into $\mathcal{M}(A)$, if and only if, it is weakly residually nuclear as a map into $\mathcal{M}(B)$.

Proof. By Lemma 12.1.1(iv), since $\mathcal{M}(A) \subset \mathcal{M}(B)$ unitally, we have $\mathcal{M}(A) \cap \mathcal{M}(B, I) = \mathcal{M}(A, A \cap I)$ for $I \in \mathcal{I}(B)$. It follows that $\mathcal{M}(A, J) = \mathcal{M}(A) \cap \mathcal{M}(B, \Psi^{A,B}_{\text{down}}(J))$. Therefore, $V(C \cap \mathcal{M}(B, I)) \subset \mathcal{M}(B, I)$ for every $I \in \mathcal{I}(B)$, if and only if, $V(C \cap \mathcal{M}(A, J)) \subset \mathcal{M}(A, J)$ for every $J \in \mathcal{I}(A)$.

The argument for the proof of Lemma 12.1.1(v) shows, that V is also weakly residually nuclear as a map from $C \subset \mathcal{M}(B)$ into $\mathcal{M}(B)$, if V is weakly residually nuclear as a map from C into $\mathcal{M}(A)$.

Now suppose that V is weakly residually nuclear as a map from C into $\mathcal{M}(B)$, and let $J \in \mathcal{I}(A)$ and $I := \Psi^{A,B}_{\text{down}}(J)$. Then $J = A \cap I$, and $C \cap \mathcal{M}(B, I) = C \cap \mathcal{M}(A, J)$, because $C \subset \mathcal{M}(A)$. $C/(C \cap \mathcal{M}(A, J))$ is in a natural way a C^*-subalgebra of $\mathcal{M}(A/J) \subset \mathcal{M}(B/I)$. The natural map $[V]_I \colon C/(C \cap \mathcal{M}(B, I)) \to \mathcal{M}(B/I)$ is weakly nuclear as a map from $C/(C \cap \mathcal{M}(B, I)) \subset \mathcal{M}(B/I)$ into $(B/I)^{**}$, and $[V]_I(C/(C \cap \mathcal{M}(B, I)))$ is contained in $\mathcal{M}(A/J)$. By assumption, $A/J \subset B/I$ is a non-degenerate and relatively weakly injective C^*-subalgebra of B/I, i.e., there is a normal conditional expectation P from $(B/E)^{**}$ onto the weak closure $(A/J)^{**}$ of A/J in $(B/E)^{**}$. The natural map $[V]_J$ from $C/(C \cap \mathcal{M}(A, J))$ into $(A/J)^{**}$ equals $P[V]_I$. Thus $[V]_J$ is weakly nuclear.

Thus $V \colon C \to \mathcal{M}(A)$ is weakly residually nuclear. □

REMARK 12.2.13. Recall that, by Definition 1.2.3, a C^*-algebra B has **residually nuclear separation** if, for every separable C^*-subalgebra $C \subset B$, every $a \in C_+$ and every $\varepsilon > 0$, there exists a residually nuclear completely positive contraction $V: C \to B$ such that $\|V(a) - a\| < \varepsilon$. Obviously, residually nuclear separation passes to hereditary C^*-subalgebras and to quotient algebras. An application of Lemma 12.1.2 to $A := B$ and $\Psi := \Psi_B$ shows that

*a separable stable C^*-algebra B has residually nuclear separation, if and only if, there is a non-degenerate weakly residually nuclear *-monomorphism $H_0: B \to \mathcal{M}(B)$, such that $\delta_\infty H_0$ is unitarily equivalent to H_0, and, for $J \in \mathcal{I}(B)$,*

$$H_0(J) = H_0(B) \cap \mathcal{M}(B, J).$$

On can conlude from [**463**] and [**443**] that

a C^*-algebra B with residually nuclear separation has the WvN-property if and only if it is strongly purely infinite.

LEMMA 12.2.14. *Suppose that B is strongly purely infinite, and that A is a separable C^*-subalgebra of $\mathcal{M}(B)$.*

Then, for every separable C^*-subalgebra C of B, there exists a separable C^*-subalgebra D of B, such that

(i) *$C \subset D$,*
(ii) *D is strongly purely infinite,*
(iii) *for every closed ideal J of D, there exists a closed ideal I of B such that $J = D \cap I$, i.e., $J = D \cap \Psi^{D,B}_{\text{down}}(J)$,*
(iv) *there is a weakly continuous conditional expectation from $(B/\Psi^{D,B}_{\text{down}}(J))^{**}$ onto $(D/J)^{**}$, i.e., D is residually relatively weakly injective in B, and*
(v) *$AD \subset D$ and $aD = \{0\}$ implies $a = 0$ for $a \in A$, i.e., the natural C^*-morphism $L: a \in A \to L_a|D \in \mathcal{M}(D)$ from A to $\mathcal{M}(D)$ is a monomorphism, where $L_a(b) := ab$.*

The subalgebras D of B with the properties (i)-(v) are closed under inductive limits, i.e., closures D of increasing sequences $D_1 \subset D_2 \subset \dots$ of C^*-subalgebras of B with properties (i)-(v) satisfy again (i)-(v).

If B is stable, then D can be chosen as stable subalgebra of B.

*If B is stable and has residually nuclear separation, then D can be chosen such that D is stable and there exists a non-degenerate residually nuclear *-monomorphism $H_0: D \to \mathcal{M}(D)$, such that $\delta_\infty H_0$ and H_0 are unitarily equivalent, and $H_0(J) = H_0(D) \cap \mathcal{M}(D, J)$ for every closed ideal J of D.*

If B is σ-unital (with strictly positive element $e \in B_+$) then D with (i)-(iv) for C replaced by $C^*(C, e)$ satisfies $IL(A \cap \mathcal{M}(B, I)) = L(A) \cap \mathcal{M}(D, D \cap I)$ for every $I \in \mathcal{I}(B)$.

If $\mathrm{id}|A: A \hookrightarrow \mathcal{M}(B)$ is weakly residually nuclear, then $L: A \to \mathcal{M}(D)$ is weakly residually nuclear.

PROOF. If $a_1, a_2, \ldots$ is a dense sequence in A, then we find contractions $b_n \in B_+$ with $\|a_n b_n\| + 1/n > \|a_n\|$. The smallest C^*-subalgebra C_1 of B with $AC_1 \subset C_1$, $C \subset C_1$ and $\{b_1, b_2, \ldots\} \subset C_1$ is separable, and $L \colon a \mapsto L_a | C_1$ is a *-monomorphism from A to $\mathcal{M}(C_1)$.

Let C_1 be a separable C^*-subalgebra of B, and let M be a countable dense subset of the positive cone of C_1.

By Remark 12.2.9 we can choose, for $a, b \in M$ and $k \in \mathbb{N}$, contractions $c, d \in B$, such that $\|a^2 - c^* a^2 c\|$, $\|b^2 - d^* b^2 d\|$ and $\|c^* abd\|$ are less then $1/k$. The chosen elements are in a countable subset S of B. Let C_2 be the separable C^*-subalgebra of B which is generated by C_1 and S.

Then for positive elements $a, b \in C_1$ and $\delta > 0$ there exist contractions $c, d \in C_2$ such that $\|a^2 - c^* a^2 c\|$, $\|b^2 - d^* b^2 d\|$ and $\|c^* abd\|$ are less then δ.

In the same way we construct an increasing sequence $C_1 \subset C_2 \subset \ldots$ of separable C^*-subalgebras C_n of B such that, for positive elements $a, b \in C_n$ and $\delta > 0$ there exist contractions $c, d \in C_{n+1}$ such that $\|a^2 - c^* a^2 c\|$, $\|b^2 - d^* b^2 d\|$ and $\|c^* abd\|$ are less then δ.

Let D_1 be the closure of the union of the C_n. Then, for positive elements $a, b \in D_1$ and $\delta > 0$ there exist contractions $c, d \in D_1$ such that $\|a^2 - c^* a^2 c\|$, $\|b^2 - d^* b^2 d\|$ and $\|c^* abd\|$ are less then δ. Thus D_1 is a separable strongly purely infinite C^*-subalgebra of B and contains C_1.

Now let G be a C^*-algebra. For every C^*-subalgebra C of G and $a, b \in G$, $k \in \mathbb{N}$, we denote by $\rho(a, b, k, C)$ the infimum of the numbers $\|a - \sum c_j^* b c_j\|$, where $c_j \in C$, $1 \leq j \leq k$, with $\|\sum c_j^* c_j\| \leq 1$. If $C_1 \subset C_2$ then $\rho(a, b, k, C_2) \leq \rho(a, b, k, C_1)$. For fixed C and k, $\rho(a, b, k, C)$ is uniformly continuous in a and b.

Let $C \subset G$ and $a, b \in C$ positive contractions. Then a is in the closed ideal generated by b if and only if the infimum of $\{\rho(a, b^{1/n}, k, C) \colon n, k \in N\}$ is zero.

Thus, the equations $\rho(a, b, k, C) = \rho(a, b, k, G)$ for every $a, b \in C_+$, $k \in \mathbb{N}$, imply that, for every $J \in \mathcal{I}(C)$,

$$\Psi_{\text{down}}^{C,G}(J) \cap C = J.$$

Now let E_1 be a separable C^*-subalgebra of G and let M denote a dense countable subset of $(E_1)_+$.

By definition of ρ, we can choose, for $a, b \in M$ and $k, m \in \mathbb{N}$, contractions $c_1, \ldots, c_k \in G$ with $\|\sum_{j=1}^k c_j^* c_j\| \leq 1$ such that $\|a - \sum_{j=1}^k c_j^* b c_j\|$ is less then $\rho(a, b, k, G) + 1/m$. The chosen elements are in a countable subset S of G. Let E_2 be the separable C^*-subalgebra of G which is generated by E_1 and S.

Then $\rho(a, b, k, E_2) = \rho(a, b, k, G)$ for positive elements $a, b \in E_1$ and $k \in \mathbb{N}$.

In the same way we construct an increasing sequence $E_1 \subset E_2 \subset \ldots$ of separable C^*-subalgebras E_n of G such that $\rho(a, b, k, E_{n+1}) = \rho(a, b, k, G)$ for positive elements $a, b \in E_n$ and $k \in \mathbb{N}$.

Let E be the closure of the union of the E_n. Then E is separable, $E_1 \subset E$, and $\rho(a, b, k, E) = \rho(a, b, k, G)$ for positive elements $a, b \in E$ and $k \in \mathbb{N}$. Here we used the uniform continuity of ρ in a and b.

Thus, for every separable C^*-subalgebra E_1 of a C^*-algebra G, there exist a separable C^*-subalgebra E of G, such that $E_1 \subset E$ and every closed ideal J of E is the intersection of E with a closed ideal of G, i.e., $E \cap \Psi^{E,G}_{\text{down}}(J) = J$.

By [**431**, lem. 3.4], for every separable C^*-subalgebra D_1 of B, there is a separable relatively weakly injective C^*-subalgebra D_2 of B with $D_1 \subset D_2$.

Let $F := C^*(F_\infty)$. Thus $E_1 := D_2 \otimes^{max} F$ is in natural way a separable C^*-subalgebra of $G := B \otimes^{max} F$.

We find a separable C^*-subalgebra E_2 of G which contains E_1 and has the property that every closed ideal of E_2 is the intersection of E_2 with a closed ideal of G. Since the algebraic tensor product $B \odot F$ is dense in G, there is a separable C^*-subalgebra D_3 of B such that $D_2 \subset D_3$, and the closure in G of the algebraic tensor product $D_3 \odot F$ contains E_2.

By [**431**, lem. 3.4], we find a separable relatively weakly injective C^*-subalgebra D_4 of B with $D_3 \subset D_4$. Then $E_2 \subset D_4 \otimes^{max} F$.

In this way we get sequences $D_1 \subset D_2 \subset \ldots$ and $E_1 \subset E_2 \subset \ldots$ of separable C^*-subalgebras of B and G, respectively, such that D_{2n} is relatively weakly injective in B, $D_{2n} \otimes^{max} F = E_{2n-1}$, and every closed ideal of E_{2n} is the intersection of E_{2n} with a closed ideal of G.

Let $D \subset B$ denote the closure of the union of algebras D_n. Then D is relatively weakly injective in B, and $D \otimes^{max} F$ is just the closure E of the union of the algebras E_n.

Let $J \in \mathcal{I}(E)$. The closure I of the union of $I_n := \Psi^{E_{2n},G}_{\text{down}}(E_{2n} \cap J)$ contains J, because the union of $E_{2n} \cap J$ is dense in J.

$I_n \cap E$ is contained in J, because, for $n \leq m$, $I_n \subset I_m$, and

$$E_{2m} \cap I_n \subset E_{2m} \cap I_m = E_{2m} \cap J,$$

and the union of $E_{2m} \cap I_n$ is dense in $I_n \cap E$. Thus $J = I \cap E$. By the last observation in Remark 12.2.10, D is residually relatively weakly injective in B.

Now let $J \in \mathcal{I}(D)$. Then $\Psi^{D,B}_{\text{down}}(J) \otimes^{max} F$ is the closed ideal of $B \otimes^{max} F$ which is generated by the closed ideal $I := J \otimes^{max} F$ of $E = D \otimes^{max} F$, i.e., is $\Psi^{E,G}_{\text{down}}(I)$. It contains $(D \cap \Psi^{D,B}_{\text{down}}(J)) \otimes^{max} F$, and its intersection with $E = D$ is I. Thus $J \otimes^{max} F$ contains $(D \cap \Psi^{D,B}_{\text{down}}(J)) \otimes^{max} F$. If we apply a character χ of F to this, we get that $J = D \cap \Psi^{D,B}_{\text{down}}(J))$.

Now we change the notation and iterate the constructions:

We find inductively sequences (C_n), (D_n) and (E_n) of separable C^*-subalgebras of B, such that $C \subset C_1$, $C_n \subset D_n \subset E_n$, and $E_n \subset C_{n+1}$, $AC_n \subset C_n$,

$\|L_a|C_1\| = \|a\|$ for $a \in A$, D_n is strongly p.i., E_n is residually relatively weakly injective in B, and $\Psi_{\text{down}}^{E_n,B}(J) \cap E_n = J$ for every $J \in \mathcal{I}(E_n)$.

Let D be the closure of the union of this sequence. D contains C. By Remark 12.2.9, D is strongly p.i. and, by Remark 12.2.10, D is residually relatively weakly injective in B. It is easy to see that D satisfies condition (v).

Let $J \in \mathcal{I}(D)$ and $J_n := E_n \cap J$. Then $\Psi_{\text{down}}^{D,B}(J)$ is the closure of the increasing sequence of closed ideals $I_n := \Psi_{\text{down}}^{E_n,B}(J_n)$, and $I_n \cap E_m \subset I_m \cap E_m = J_m$ for $n < m$. Thus $I_n \cap D \subset J$ and, therefore $\Psi_{\text{down}}^{D,B}(J) \cap D = J$. Thus D satisfies (i)-(v).

Now let $D_1 \subset D_2 \subset \ldots$ be an increasing sequence of separable C^*-algebras D_n of B, and suppose that D_n satisfies (i)-(v).

Let D the closure of $\bigcup D_n$. By Remarks 12.2.9 and 12.2.10, D has also properties (ii) and (iv). Above we have seen that (iii) is preserved under inductive limits, i.e. D satisfies (iii). It is easy to check that D satisfies (v).

Now suppose that B is stable. By Remark 5.1.1(8), this means that there exists a sequence $t_1, t_2, \ldots$ of isometries in $\mathcal{M}(B)$, such that $\sum t_n(t_n)^*$ strictly converges to 1. We replace A by the separable C^*-subalgebra A_1 of $\mathcal{M}(B)$ which is generated by A and $\{t_1, t_2, \ldots\}$. Then a separable C^*-subalgebra D of B is stable, if D satisfies (i)-(v) for A_1 in place of A:

$s_n := L_{t_n}|D$ are isometries in $\mathcal{M}(D)$ such that $\sum s_n(s_n)^*$ strictly converges to 1 in $\mathcal{M}(D)$.

Suppose that B is stable and has residually nuclear separation.

Let $D_1 := D$ be above found separable stable C^*-subalgebra D of B with (i)-(v) for A_1, let B_1 denote the closure of DBD, and let M_1 be a countable dense subset of the positive cone of D_1.

Residually nuclear separation passes to hereditary C^*-subalgebras. Therefore we can find a countable set S_1 of residually nuclear completely positive contractions from D_1 into B_1 such that, for $a \in M_1$ and $n \in \mathbb{N}$, there is a $V \in S_1$ with $\|a - V(a)\| < 1/n$.

The union the images of the $V \in S_1$ is a separable subset of B_1. Thus it is contained in a separable C^*-subalgebra C_2 of B_1. Necessarily, C_2 contains M_1 and, therefore, also D_1.

We find a separable C^*-subalgebra D_2 of B_1 with (i)-(v) for A_1, C_2 and B_1 in place of A, C and B, because B_1 is again strongly purely infinite, $C_2 \subset B_1$, and $A_1 \cong L(A_1)|B_1$ is contained in $\mathcal{M}(B_1)$. If M_2 is a countable dense subset of the positive cone of D_2, then we can again find a countable set S_2 of residually nuclear completely positive contractions from D_2 into B_1 such that, for $a \in M_2$ and $n \in \mathbb{N}$, there is a $V \in S_2$ with $\|a - V(a)\| < 1/n$.

If we go so on, we get sequences $D_1 \subset D_2 \subset \ldots$, $S_1, S_2, \ldots$ of separable C^*-subalgebras D_n of B_1 and of countable sets S_n of residually nuclear completely positive contractions from D_n to B_1 such that, for $n \in \mathbb{N}$:

(i) $C \subset D_1$, D_1 is stable and contains a strictly positive element of D_n
(ii) D_n is strongly purely infinite,
(iii) for every closed ideal J of D_n, $J = D_n \cap \Psi_{\mathrm{down}}^{D_n,B}(J)$, and,
(iv) D_n is residually relatively weakly injective in B,
(v) $A_1 D_n \subset D_n$ and $\|a\| = \|L_a|D_1\|$ for $a \in A$.
(vi) $V(D_n) \subset D_{n+1}$ for $V \in S_n$, and,
(vii) for every $a \in (D_n)_+$ and every $\delta > 0$ there is $V \in S_n$ with $\|V(a) - a\| < \delta$.

Let D denote the closure of the union of the C^*-algebras D_n. Then D satisfies conditions (i)-(v) of Lemma 12.2.14 and D is stable. By Lemma 12.2.12, the completely positive maps $V \in S_n$ are also residually nuclear if we consider them as maps from D_n to D.

Now we argue as in the proof of the implication (ii)⇒(i) in the proof of Lemma 12.1.2:

Since, by Kasparov stabilization theorem, $\mathcal{H}_D \cong D$ as (left) Hilbert D-module, we can take Kasparov-Stinespring dilations of the V in S_n, infinite repeats and direct sums. We get a sequence of non-degenerate weakly residually nuclear *-monomorphisms $h_n \colon D_n \to \mathcal{M}(D)$, such that $\delta_\infty h_n$ is unitarily equivalent to h_n, and $h_n(J \cap D_n) = h_n(D_n) \cap \mathcal{M}(D, J)$ for $J \in \mathcal{I}(D)$. By Lemma 12.1.2, it follows that $h_n|D_m$ is unitarily homotopic to h_m for $m < n$.

This allows to replace the h_n by unitarily equivalent *-monomorphisms k_n such that the sequence k_n is convergent in point-norm on every D_m.

The limit is a *-monomorphism h from D into $\mathcal{M}(D)$ with $h(J) = h(D) \cap \mathcal{M}(D, J)$ for $J \in D$, and $h|D_n$ is weakly residually nuclear for every $n \in \mathbb{N}$. It follows that h is residually nuclear, and that D is the closure of $Dh(D)D$.

By Lemma 12.1.2, we can construct from h with the above properties a non-degenerate residually nuclear *-monomorphism H_0 from D into $\mathcal{M}(D)$ with $H_0(J) = H_0(D) \cap \mathcal{M}(D, J)$ for $J \in \mathcal{I}(D)$ such that H_0 is unitarily equivalent to its infinite repeat $\delta_\infty H_0$.

Now suppose that B is σ-unital and let $e \in B_+$ strictly positive.

Then we can find D with the properties (i)-(v) and $e \in D$ (simply by replacing C by $C^*(C, e)$). It holds $L(A \cap \mathcal{M}(B, I)) = L(A) \cap \mathcal{M}(D, D \cap I)$ for every $I \in \mathcal{I}(B)$, because, for $a \in A$

$$a \in \mathcal{M}(B, I) \quad \Leftrightarrow \quad ae \in I \quad \Leftrightarrow \quad aD \subset D \cap I \quad \Leftrightarrow \quad a \in \mathcal{M}(D, D \cap I)\,.$$

If $\mathrm{id}\,|A \colon A \hookrightarrow \mathcal{M}(B)$ is weakly residually nuclear, then $L \colon A \to \mathcal{M}(D)$ is weakly residually nuclear, by (iv) and Lemma 12.2.12, because we replace B by its hereditary C^*–subalgebra DBD (with strictly positive $e \in D_+$). □

The following Proposition 12.2.15 generalizes the first part of Theorem A. Here the target algebra B replaces $\mathcal{O}_2$ in Theorem A, and B is in general not simple.

Theorem A(i) is implied by Proposition 12.2.15, because a separable exact algebra A always has a nuclear *-monomorphism into $\mathcal{L}(\ell_2) \subset \mathcal{M}(\mathcal{O}_2 \otimes \mathbb{K})$.

PROPOSITION 12.2.15 (Trivialization and Embedding).

Suppose that B is strongly purely infinite, stable, σ-unital and has residually nuclear separation, and that A is stable, separable and exact.

*Let H be a non-degenerate *-monomorphism from A into $\mathcal{M}(B)$, such that $a \in A \mapsto b^*H(a)b \in B$ is nuclear for every $b \in B$.*

The following properties (i) and (ii) are equivalent:

(i) *There exists a non-degenerate nuclear *-monomorphism $h\colon A \otimes \mathcal{O}_2 \hookrightarrow B$ such that $\delta_\infty h_0$ and $\delta_\infty H$ are unitarily homotopic, where $h_0(a) := h(a \otimes 1)$ for $a \in A$, and $\delta_\infty\colon \mathcal{M}(B) \to \mathcal{M}(B)$ is the infinite repeat, as defined in Remark 5.1.1(8).*

(ii) *The lower semi-continuous action*

$$\Psi\colon J \in \mathcal{I}(B) \mapsto H^{-1}(H(A) \cap \mathcal{M}(B, J)) \in \mathcal{I}(A),$$

of Prim(B) *on A is also monotone upper semi-continuous (i.e., satisfies condition (ii) of Definition 1.2.6).*

Note that $h_0 = h_0 \oplus_{s,t} h_0$ if we use the isometries $s, t \in \mathcal{M}(B)$ which are given by $s := \mathcal{M}(h)(1 \otimes r_1)$ and $t := \mathcal{M}(h)(1 \otimes r_2)$ if r_1 and r_2 denote the canonical generators of $\mathcal{O}_2$.

PROOF. (i)⇒(ii): For $a \in A$, $\delta_\infty(H(a)) \in \mathcal{M}(B, J)$ if and only if $\delta_\infty(h_0(a)) \in \mathcal{M}(B, J)$, because they are unitarily homotopic in $\mathcal{M}(B)$. For stable σ-unital B, we have that

$$\delta_\infty(\mathcal{M}(B)) \cap \mathcal{M}(B, J) = \delta_\infty(\mathcal{M}(B, J)),$$

i.e., $b \in \mathcal{M}(B, J)$ if and only if $\delta_\infty(b) \in \mathcal{M}(B, J)$ for $b \in \mathcal{M}(B)$. Since $B \cap \mathcal{M}(B, J) = J$, it follows, that $h_0(A) \cap J = h_0(\Psi(J))$. By Lemma 12.1.1(iii), $J \mapsto h_0^{-1}(h_0(A) \cap J)$ satisfies condition (ii) of Definition 1.2.6.

(ii)⇒(i): We consider at first the case that B is separable.

By Remark 5.1.1(8), there is a strictly continuous unital C^*-morphism from $\mathcal{M}(\mathbb{K})$ into the relative commutant R of $\delta_\infty(H(A))$ in $\mathcal{M}(B)$. It follows that R contains a unital copy of $\mathcal{O}_2$ and a sequence of isometries $r_1, r_2, \ldots$, such that the isometries r_n commute with the elements of $\mathcal{O}_2$, and that $\sum r_n(r_n)^*$ strictly converges to 1 in $\mathcal{M}(B)$.

There is a non-degenerate *-monomorphism $K\colon A \otimes \mathcal{O}_2 \to \mathcal{M}(B)$ with $K(a \otimes b) = \delta_\infty(H(a))b$ for $a \in A$ and $b \in \mathcal{O}_2$. The isometries r_n commute with the image of K. Thus, by Lemma 5.1.2(i), $\delta_\infty K$ is unitarily equivalent to K.

If we can find a non-degenerate nuclear *-monomorphism h from $A \otimes \mathcal{O}_2$ into B, such that $\delta_\infty h$ is unitarily homotopic to $\delta_\infty K$, then the infinite repeat of $h_0 := h((.) \otimes 1)$ is unitarily homotopic to $(\delta_\infty)^2 H$. But δ_∞^2 is unitarily equivalent to δ_∞ by Lemma 5.1.2(i).

Thus, by Theorem 6.3.1, it suffices to show that, for $a_1, \ldots, a_n \in K(A \otimes \mathcal{O}_2)$ and for $\varepsilon > 0$, there exist completely positive contractions $V \colon \mathcal{M}(B) \to B$ and $W \colon B \to \mathcal{M}(B)$ such that

(a) $\|W \circ V(a_j) - a_j\| < \varepsilon$, for $j = 1, \ldots, n$.

(b) V is strictly continuous and is residually equivariant, i.e., $\lim_n \|V(b_n) - V(b)\| = 0$ if $b_n \to b$ in $\mathcal{M}(B)$ strictly and $V(J) \subset J \cap B$ for $J \in \mathcal{I}(\mathcal{M}(B))$.

`Old version was only:` V is weakly residually nuclear.

(c) $W \colon B \to \mathcal{M}(B)$ is weakly residually nuclear, i.e., $W(J)B \subset J$ for $J \in \mathcal{I}(B)$, and the c.p. maps $W_a \colon b \in B \mapsto a^*W(b)a \in B$ are residually nuclear for all $b \in B$. I.e. the maps $[W]_J \colon B/J \to \mathcal{M}(B/J) \cong \mathcal{M}(B)/\mathcal{M}(B,J)$ have the property that $([W]_J)_d \colon b \in B/J \mapsto d^*[W]_J(b)d \in B/J$ is a nuclear map for all $d \in B/J$. Here $[W]_J(a + J) := W(a) + \mathcal{M}(B, J)$, i.e., $d^*[W]_J(b)d = \pi_J(f^*W(a)f)$ for $b = a + J$ and $d = f + J$.

`Old version was only:` W is weakly residually equivariant, i.e. $W(J) \subset \mathcal{M}(B, J)$ for $J \in \mathcal{I}(B)$.

`change the old version for Thm. 6.3.1, as executed below:` ??

`NEXT comes from some beamer presentation:`

(1) $H_0(A)$ is non-degenerate, i.e., $H_0(A)B$ is dense in B, and is in "general position" (i.e., there exists a unitary $U \in \mathcal{M}(B)$ $U^*H_0(\cdot)U = \delta_\infty \circ H_0$).

(2) The given lower s.c. action $\Psi \colon \mathcal{I}(B) \to \mathcal{I}(A)$ is realized by $\Psi(J) := H_0^{-1}(H_0(A) \cap \mathcal{M}(B, J))$ and Ψ is monotone upper semi-continuous, i.e., $\bigcup_n \Psi(J_n)$ is dense in $\Psi(J)$ for $J := \overline{\bigcup_n J_n}$, if the sequence $J_n \in \mathcal{I}(B)$ is increasing: $J_1 \subset J_2 \subset \cdots$.

(3) For every $b \in B$, the Ψ_A-compatible map $A \ni a \mapsto b^*H_0(a)b \in B$ is nuclear, and can be approximated by compositions $V_2 \circ V_1$ of the residually nuclear maps $V_1 \colon a \in A \mapsto b_1^*H_1(a)b_1 \in B$ and $V_2 \colon b \in B \mapsto b_2^*\lambda(b)b_2$. I.e. V_2 satisfies $V_2(J) \subset J$ for all $J \in \mathcal{I}(B)$ and that $[V_2]_J \colon B/J \to B/J$ is nuclear for all $J \in \mathcal{I}(B)$.

Step 2:
If A satisfies (1)–(3), then, – with $a \in A$ identified with $H_0(a) \in H_0(A) \subset \mathcal{M}(B)$ – for every $a_1, \ldots, a_n \in A$ and $\varepsilon > 0$, there exist completely positive contractions $V \colon \mathcal{M}(B) \to B$ and $W \colon B \to \mathcal{M}(B)$ that satisfy the above listed conditions (a), (b) and (c).

More on Step 2:

Consider the set of maps $V := V_c \colon \mathcal{M}(B) \to B$ given by $V_c \colon b \in \mathcal{M}(B) \mapsto c^*\mathcal{M}(\lambda)(b)c$. The point-norm closure is an m.o.c. cone $\mathcal{C}_1$.

`What is` $\lambda \colon B \to \mathcal{M}(B)$??

Perhaps $\lambda \colon B \to \mathcal{M}(B)$ a residually nuclear separation?

Do the same with the maps $W := W_T \colon B \to \mathcal{M}(B)$ given by $W_T(b) := T^*\lambda(b)T$, for $T \in \mathcal{M}(B)$, and we denote this m.o.c. cone by $\mathcal{C}_2$.

Both cones are singly generated (as m.o.c.c.), e.g. $\mathcal{C}_1$ by $e\mathcal{M}(\lambda)(\cdot)e$ where $e \in B_+$ is strictly positive, and $\mathcal{C}_2$ by λ (as u.c.p. map).

The above listed properties (b) and (c) for suitable $V = V_c$ and $W = W_T$ follow from the properties of λ and the fact that $\mathcal{M}(\lambda)$ is the unique strictly continuous extensions of λ.

Continuation 1: More on Step 2:

Notice that $\lambda(b)$ and $\delta_\infty(b)$ for each self-adjoint $b \in B$ must be unitarily homotopic in $\mathcal{M}(B)$ by the generalized W-vN theorem, because both define *-mono-morphisms from $C^*(b)$ into $\mathcal{M}(B)$ that are in "general position" and define the same action of $\mathrm{Prim}(B)$ on $C^*(b)$ by definition of λ, namely the action $J \in \mathcal{I}(B) \mapsto \mathcal{M}(B, J) \cap C^*(b)$.

It follows that each $W \in \mathcal{C}_2$ maps B into the closure I_0 of $\mathcal{M}(B)\delta_\infty(B)\mathcal{M}(B)$, the closed ideal of $\mathcal{M}(B)$ generated by $\delta_\infty(B)$.

Moreover, $b \in \mathcal{M}(B)_+$ will be mapped by all $P \in \mathcal{C}_2 \circ \mathcal{C}_1$ into the ideal of $\mathcal{M}(B)$ that is the norm-closure of the union of the ideals $\mathcal{M}(B, J((ebe - 1/n)_+))$, with $J(b) \in \mathcal{I}(B)$ as defined above, $e \in B_+$ strictly positive contractions.

`The following Lemma supports the conjectures in ''Continuation 1'' and ''Continuation 2''.`

LEMMA 12.2.16. *Let B a σ-unital stable C^*-algebra, $e \in B_+$ a strictly positive contraction, and let $a \in \mathcal{M}(B)_+$ such that the natural l.s.c. action of* $\mathrm{Prim}(B)$ *on $C^*(a) \cong \mathrm{C}_0(\mathrm{Spec}(a) \setminus \{0\})$ is also monotone upper semi-continuous.*

Then a is in the closed ideal of $\mathcal{M}(B)$ that is generated by $\delta_\infty(eae)$.

*Suppose that – more generally – $\lambda\colon B \to \mathcal{M}(B)$ is a non-degenerate *-monomorphism such that $\delta_\infty \circ \lambda$ is approximately unitarily equivalent to λ and that* $\overline{\mathrm{span}(BbB)} = \overline{\mathrm{span}(B\lambda(b)B)}$ *for each $b \in B_+$.*

Then a is in the closed ideal of $\mathcal{M}(B)$ that is generated by $\lambda(eae)$.

PROOF. Let $I(b)$ denote the closed ideal of $\mathcal{M}(B)$ generated by $b \in \mathcal{M}(B)_+$ and let $J(b)$ the closed ideal of B generated by BbB. Note $J(\delta_\infty(b)) = J(b) = J(ebe) = J(b^{1/2}e^2b^{1/2}) = J(beb)$.

For $b \in \mathcal{M}(B)_+$ and $\gamma > 0$ holds, by Lemma 5.9.10, that

$$\delta_\infty((b-\gamma)_+) \in \mathcal{M}(B, J((b-\gamma)_+)) \subseteq I(\delta_\infty(b))\,.$$

Let $\varepsilon > 0$. Since, the natural action of $\mathrm{Prim}(B)$ on $C^*(a) \cong \mathrm{C}_0(\mathrm{Spec}(a) \setminus \{0\})$ is monotone upper semi-continuous, and since $J(eae)$ is the closure of $\bigcup_n J((eae - 1/n)_+)$, we get that a is in the closed union of the ideals $C^*(a) \cap \mathcal{M}(B, J((eae-\gamma)_+))$ for $\gamma \in (0,1)$.

It follows that $(a-\varepsilon)_+ \in \mathcal{M}(B, J((eae-\gamma)_+))$ for some suitable $\gamma > 0$. Then $(a-\varepsilon)_+ \in I(\delta_\infty(eae))$. Since $I(\delta_\infty(eae))$ is closed it follows $a \in I(\delta_\infty(eae))$.

`Add the missing cross references:`

The conditions on λ imply that, for $b \in B_+$, the upper s.c. action of $\mathrm{Prim}(C^*(b))$ on B defined by $C^*(b) \subset \mathcal{M}(B)$ and $\lambda\colon C^*(b) \to \mathcal{M}(B)$ are the same. This implies that the l.s.c. actions of $\mathrm{Prim}(B)$ on $C^*(b)$ defined by $\mathrm{id}\,|C^*(b)$ or $\lambda|C^*(b)$ are the same, because they are both the Galois adjoint of the same upper s.c. action, cf. Proposition **??**.

It follows by Corollary **??** that $\delta_\infty(\lambda(b))$ and $\delta_\infty(b)$ are approximately unitarily equivalent in $\mathcal{M}(B)$. This implies $I(\delta_\infty(\lambda(b))) = I(\delta_\infty(b))$. Since $\lambda(b)$ is approximately unitary equivalent to $\delta_\infty(\lambda(b))$ it follows $I(\lambda(b)) = I(\delta_\infty(b))$.

This applies in particular to $b := eae$.

`What about the` a `and` e `here ??`

It implies that $a \in I(\delta_\infty(eae)) = I(\lambda(eae))$. □

Continuation 2: More on Step 2:

This ideal is contained in the closed ideal of $\mathcal{M}(B)$ generated by $\delta_\infty(ebe)$ for a strictly positive element $e \in B_+$ of B.

?????????????????????

$b \in I(\delta_\infty(ebe))$ if and only if $b \in I(\delta_\infty(e)) =$ the closed ideal of $\mathcal{M}(B)$ generated by $\delta_\infty(B)$.

?????????????????????

`Conjecture:` There exists a sequence $P_n \in \mathcal{C}_2 \circ \mathcal{C}_1$ with $\|P_n(b) - b\| \to 0$ if and only if $b \in I(\delta_\infty(e))$.

¡– Seems to require further assumptions.

Continuation 3: More on Step 2:

The condition (a) is equivalent to $H_0 \in \mathcal{C}_3 := \mathcal{C}_2 \circ \mathcal{C}_1 \circ \mathcal{C}_{H_0}$. The m.o.c. cone $\mathcal{C}_3$ is contained in the cone of (norm-) nuclear c.p. maps from A into $\mathcal{M}(B)$, and the elements of $\mathcal{C}_3$ map A into the norm-closed ideal $I(\delta_\infty(B))$ of $\mathcal{M}(B)$ that is generated by $\delta_\infty(B)$.

More precisely, the elements of $\mathcal{C}_3$ map $a \in A_+$ into the closed ideal of $I(\delta_\infty(B)) \subset \mathcal{M}(B)$ generated by the element $\delta_\infty(e)\delta_\infty^2(e)\delta_\infty^3(a)\delta_\infty^2(e)\delta_\infty(e)$.

If there is $b \in B_+$ such that $\delta_\infty(b)$ and a generate the same closed ideal of $\mathcal{M}(B)$, then there are $T_n \in \mathcal{C}_2 \circ \mathcal{C}_1$ such that $\|T_n(a) - a\| \to 0$.

`END of TEXT from old beamer presentation`

`Idea: take unital weakly residual nuclear monomorphism` H `of` $\mathcal{M}(B)$ `in general position and use that` $H|C$ `and` id_C `are approximately unitarily equivalent by unitaries` $u_1, u_2, \ldots$.

`Then replace` W `by suitable` $u_n^* H(W(\cdot))u_n$.

Let $C := K(A \otimes \mathcal{O}_2)$, let $a_1, a_2, \ldots$ be a dense sequence in the unit ball of C, and let X_n denote the span of $\{a_1^*, a_1, \ldots, a_n^*, a_n\}$.

$\mathrm{id}_{\mathcal{M}(B)}|C$ is weakly residually nuclear, because C is exact and $\delta_\infty|A = K((\,\cdot\,)\otimes 1)$ is nuclear by the exactness of A. In fact, $\mathrm{id}\,|C\colon C \hookrightarrow \mathcal{M}(B)$ is even nuclear, see Chapters 3 and 5, where we have discussed those topics in every detail.

Since K is unitarily equivalent to δ_∞, $\mathrm{id}\,|C$ is unitarily equivalent to $\delta_\infty|C$.

By Remark 12.2.13, there exists a non-degenerate weakly residually nuclear *-monomorphism $d\colon B \to \mathcal{M}(B)$ such that $\delta_\infty d$ is unitarily homotopic to d, and, for $J \in B$,

$$d(J) = d(B) \cap \mathcal{M}(B, J).$$

Thus $\mathcal{M}(d)\,(\mathcal{M}(B,J)) = \mathcal{M}(d)(\mathcal{M}(B)) \cap \mathcal{M}(B,J)$ for $J \in \mathcal{I}(B)$.

It follows, that the *-monomorphisms $\mathcal{M}(d)|C$ and $\mathrm{id}\,|C$ from C to $\mathcal{M}(B)$ are both nuclear *-monomorphisms and induce the same action of $\mathrm{Prim}(B)$ on C, i.e., for $J \in \mathcal{I}(B)$,

$$\mathcal{M}(d)(C \cap \mathcal{M}(B,J)) = \mathcal{M}(d)(C) \cap \mathcal{M}(B,J).$$

Therefore, by Corollary 5.9.16, $\delta_\infty\mathcal{M}(d)|C$ and $\delta_\infty|C$ are unitarily homotopic. This implies, together with the unitary equivalence of $\delta_\infty|C$ and $\mathrm{id}\,|C$, the existence of a sequence $U_1, U_2, \ldots$ of unitaries in $\mathcal{M}(B)$, such that, for $n = 1, 2, \ldots$ and $b \in X_n$,

$$\|U_n^*\delta_\infty\mathcal{M}(d)(b)U_n - b\| \;<\; 4^{-n}\|b\|\,. \tag{1}$$

Let $e \in B_+$ a strictly positive contraction in B of norm one. By Remark 5.1.1(3), we find a sequence of functions $g_n \in \mathrm{C}_0((0,1])_+$, such that $g_n g_{n+1} = g_n$, $\|g_n\| = 1$, $g_n \to 1$ point-wise, and, for $b \in X_n$ and $m > n$,

$$\|[g_n(e), b]\| + \|[(g_m(e) - g_n(e))^{1/2}, b]\| < 4^{-n}\|b\|.$$

We define real numbers $\gamma(n,k,m,T)$, $\gamma(n,k,m)$ and $\gamma(n,k)$ for $k,m,n \in \mathbb{N}$ and for inner completely positive contractions $T\colon B \to B$ as follows:

$$\begin{aligned}
\gamma(n,k,m,T) &:= \sup\{\|T(g_k(e)ag_k(e)) - g_m(e)ag_m(e)\|\;;\; a \in X_n, \|a\| \le 1\}\\
\gamma(n,k,m) &:= \inf_T \gamma(n,k,m,T)\\
\gamma(n,k) &:= \sup_m \gamma(n,k,m).
\end{aligned}$$

Then $\gamma(n,k,m) = 0$ for $m \le k$, $\gamma(n,k,m) \le \gamma(n+1,k,m)$, $\gamma(n,k,m) \le \gamma(n,k+1,m)$ and $\gamma(n,k,m) \le \gamma(n,k,m+1)$.

Thus, $\gamma(n,k+1) \le dz\gamma(n,k) \le \gamma(n+1,k)$.

Now we show that $\lim_{k\to\infty}\gamma(n,k) = 0$.

Since $k \mapsto \gamma(n,k)$ is decreasing and $m \mapsto \gamma(n,k,m)$ is increasing, it is enough to show that $\lim_{j\to\infty}\gamma(n,k_j,k_{j+1}) = 0$ for every sequence $k_1 < k_2 < \ldots$.

Let $p_j := g_{k_j}(e)$ for $j \in \mathbb{N}$, and $P\colon C \to \ell_\infty(B)$, $Q\colon C \to \ell_\infty(B)$ the completely positive maps which are defined by $P(c) := (p_1cp_1, p_2cp_2, \ldots)$ and $Q(c) := (p_2cp_2, p_3cp_3, \ldots)$.

To see $\lim_{j\to\infty} \gamma(n, k_j, k_{j+1}) = 0$, it suffices to show that, for every $\varepsilon > 0$, there exists an inner completely positive contraction T on $\ell_\infty(B)$, such that, for $a \in X_n$,

$$\operatorname{dist}(T(P(a)) - Q(a), c_o(B)) < \|a\|\varepsilon.$$

Let h_1 denote the C^*-morphism from $C \otimes \mathrm{C}_0((0,1]) \cong \mathrm{C}_0((0,1], C)$ to $\ell_\infty(B)/c_0(B)$, with $h_1(c\otimes f) = \pi((cf(p_1), cf(p_2), \ldots))$ for $c \in C$ and $f \in \mathrm{C}_0((0,1])$, where π means the natural quotient map from $\ell_\infty(B)$ onto $\ell_\infty(B)/c_0(B)$.

Further let h_2 the *-epimorphism from $C \otimes \mathrm{C}_0((0,1])$ onto C, with $h_2(c\otimes f) = f(1)c$.

Note that $h_1(c \otimes f_0^2) = \pi(P(c))$, where $f_0(t) = t$. We show that h_1 approximately inner dominates $V := \pi Q h_2$. Then the proof of $\lim_k \gamma(n,k) = 0$ is ready, because it follows that, for $\varepsilon > 0$, there is an inner completely positive contraction T' on $\ell_\infty(B)/c_0(B)$, such that, for $a \in X_n$,

$$\|T'(\pi(P(a))) - \pi(Q(a))\| < \|a\|\varepsilon/2.$$

(because C is exact).

Since every completely positive contraction $c \mapsto p_j c p_j$, for $j > 1$, is a nuclear map, its direct sum Q is a nuclear map from C into $\ell_\infty(B) \subset \mathcal{M}(c_0(B))$. By Corollary 5.6.3, Q is nuclear, because C is exact. Thus V is nuclear.

Now we show that $V(a \otimes f) = f(1)\pi(Q(a))$ is in the closed ideal generated by $h_1(a \otimes f)$ for $a \in C_+$, $f \in \mathrm{C}_0((0,1])_+$:

$V(a \otimes f) = 0$, if $f(1) = 0$. But if $f(1) > 0$, then there is $\delta \in (0,1)$, such that $f(t) > f(1)/2$ for $t \in (\delta, 1]$. Define $\lambda \in \mathrm{C}_0((0,1])$ by $\lambda(t) := 0$ on $[0,\delta]$, $\lambda(t) :=], \min(1, 2(t-\delta)/(1-\delta))$ for $t \in (\delta, 1]$. Then $f(1)(a \otimes \lambda) \le a \otimes f$, and it suffices to show that $\pi Q(a)$ is in the closed ideal generated by $\pi(b)$, where

$$b := (a^{1/2}\lambda(p_1)a^{1/2}, a^{1/2}\lambda(p_2)a^{1/2}, \ldots).$$

By Corollary 3.10.12 and Proposition 2.12.8(iii),

what is needed: prop:2.24 ??? ??

this follows if we can show that the sequence of real numbers

$$\lambda_n = \max(0, \sup\{\|p_{n+1}ap_{n+1} + J\| - \|a^{1/2}\lambda(p_n)a^{1/2} + J\| \colon J \in \operatorname{Prim}(B)\})$$

converges to zero. We have

$$\|p_{n+1}ap_{n+1} + J\| = \|a^{1/2}p_{n+1}^2 a^{1/2} + \mathcal{M}(B,J)\| \le \|a + \mathcal{M}(B,J)\|.$$

By definition of λ, $\lambda(p_n)\lambda(p_{n+1}) = \lambda(p_n)$, $\|\lambda(p_n)\| = 1$ and $\lim \|\lambda(p_n)e - e\| = 0$.

Since $a^{1/2}\lambda(p_n)a^{1/2} \le a$ and $\lambda(p_n)$ is an increasing approximate unit of B, we get that $\xi_n(J) := \|a^{1/2}\lambda(p_n)a^{1/2} + J\|$ converges to $\|a + \mathcal{M}(B,J)\|$ for every $J \in \operatorname{Prim}(B)$.

The natural lower semi-continuous action $\Psi^{\mathrm{up}}_{B,C}$ from $\operatorname{Prim}(B)$ on C satisfies, for $J \in \mathcal{I}(B)$,

$$\delta_\infty(H(\Psi(J))) = \delta_\infty(H(A)) \cap \Psi^{\mathrm{up}}_{B,C}(J)\,.$$

Here we used that $\delta_\infty(\mathcal{M}(B,J))$ is the same as $\delta_\infty(\mathcal{M}(B)) \cap \mathcal{M}(B,J)$. Since $\mathcal{O}_2$ is simple and nuclear, and since $K(A \otimes 1) = \delta_\infty(H(A))$, we get that, for $J \in \mathcal{I}(B)$,

$$\Psi^{\mathrm{up}}_{B,C}(J) = K(\Psi(J) \otimes \mathcal{O}_2)\,.$$

Thus $\Psi^{\mathrm{up}}_{B,C}$ satisfies the condition (ii) of Definition 1.2.6, because Ψ satisfies this condition by assumption.

By Corollary 12.2.8(ii), the property (ii) of Definition 1.2.6 for $\Psi^{\mathrm{up}}_{B,C}$ implies that, for every $a \in C_+$, the real function

$$J \mapsto \widehat{a}(\Psi^{\mathrm{up}}_{B,C}(J) = \|a + \mathcal{M}(B,J)\|$$

is a Dini function on $\mathrm{Prim}(B)$.

Therefore, the functions ξ_n converge on $\mathrm{Prim}(B)$ uniformly to the function $J \mapsto \|a + \mathcal{M}(B,J)\|$, because ξ_n is an increasing sequence of lower semi-continuous functions which converges point-wise to $J \mapsto \|a + \mathcal{M}(B,J)\|$ on $\mathrm{Prim}(B)$.

Let $\theta_n := \sup\{\|a + \mathcal{M}(B,J)\| - \xi_n(J)\,;\ J \in \mathrm{Prim}(B)\}$.

Then $0 \le \lim \lambda_n \le \lim \theta_n = 0$. Thus $V(a \otimes f)$ is in the closed ideal generated by $h_1(a \otimes f)$ for $a \in C_+$, $f \in \mathrm{C}_0((0,1])_+$.

By Proposition B.4.2(ii), it follows now that, for every closed ideal J of $C \otimes \mathrm{C}_0((0,1])$, $V(J)$ is in the closed ideal of $\ell_\infty(B)/c_0(B)$ that is generated by $h_1(J)$. Thus, the kernel of h_1 is contained in the kernel of V, and the natural completely positive map S from the image of h_1 into $\ell_\infty(B)/c_0(B)$ is residually equivariant.

Since $C \otimes \mathrm{C}_0((0,1])$ is exact, by Remark 3.1.2(iv), $h_1(C \otimes \mathrm{C}_0((0,1]))$ is exact and S is nuclear.

By Corollary 3.10.7, S is approximately inner.

This completes the proof of $\lim_{k\to\infty} \gamma(n,k) = 0$.

We can take a sequence $1 < k_1 < k_2 < \ldots$ of positive integers such that $\gamma(n,k_n) < 4^{-n}$, and get an approximate unit $e_n := g_{k_n}(e) \in B_+$, of B with $e_{n+1}e_n = e_n$, $\|e_n\| = 1$, and, for $b \in X_n$,

$$\|[e_n, b]\| + \|[(e_{n+1} - e_n)^{1/2}, b]\| < 4^{-n}\|b\|. \tag{2}$$

Since $\gamma(n,k_n) < 4^{-n}$, we find inner completely positive contractions $T_n \colon B \to B$, such that, for $b \in X_n$

$$\|T_n(e_n b e_n) - e_{n+1} b e_{n+1}\| < 4^{-n}\|b\|. \tag{3}$$

`check next construction with new (a),(b),(c) of 6.3.1` ??

We define the desired weakly residually equivariant completely positive contractions $W_n \colon B \to \mathcal{M}(B)$ and $V_n \colon \mathcal{M}(B) \to B$, such that V_n is weakly residually nuclear, and $(W_n \circ V_n)|C$ tends to $\mathrm{id}\,|C$ in point-norm topology:

Let $n \in \mathbb{N}$ fixed and $k > n$. The inner completely positive contractions

$$L_k := T_{k+1} \circ T_k \circ \ldots \circ T_{n+1} T_n$$

of B are given by $L_k(b) := \sum_{j=1}^{m_k}(c_{k,j})^* b c_{k,j}$ for $b \in B$, where $c_{k,j} \in B$, $j = 1, \ldots, m_k$, $\sum_{j=1}^{m_k}(c_{k,j})^* c_{k,j}$ is a contraction. Note that, by induction, (3) implies

$$\|L_k(e_n b e_n) - e_{k+2} b e_{k+2}\| < 4^{1-n}/3, \tag{4}$$

for $b \in X_n$ and $k > n$.

Let $t_1, t_2, \ldots$ denote the sequence of isometries in $\mathcal{M}(B)$ with $\sum t_k(t_k)^*$ strictly convergent to 1, such that our infinite repeat δ_∞ is defined by $\sum t_k(\cdot)t_k^*$, cf. Remark 5.1.1(8).

Let $f_n := e_n^{1/2}$, and $f_k := (e_{k+1} - e_k)^{1/2}$ for $k > n$. We define, by induction, integers $p(n+1) := 1$ and, $p(k+1) = p(k) + m_k$ for $k > n$, and elements of $\mathcal{M}(B)$ by $d_n := 1$, $d_k := \sum_{j=1}^{m_k}(t_{p(k)+j})c_{k,j}$. Note d_k is a contraction, because $(d_k)^* d_l = \delta_{k,l} \sum_j (c_{k,j})^* c_{k,j}$.

Then $\sum_{k>n} d_k f_k$ is strictly convergent in $\mathcal{M}(B)$ and

$$S_n := \sum_{k \geq n} d_k f_k$$

is a contraction in $\mathcal{M}(B)$, cf. Remark 5.1.1(???????). **??**

Let, for $b \in \mathcal{M}(B)$,

$$W_n(b) := S_n^* \delta_\infty(b) S_n,$$

and

$$V_n(b) := e_n U_n^* \delta_\infty(\mathcal{M}(d)(b)) U_n e_n.$$

Then, $W_n|B$ is a weakly residually equivariant contraction from B into $\mathcal{M}(B)$, V_n is a weakly residually nuclear contraction from $\mathcal{M}(B)$ to B, and, for $b \in X_n$,

$$\|W_n V_n(b) - b\| \, < \, 4^{1-n} 3 \|b\|.$$

This estimate summarizes the estimate (1) and the estimates for $\|\Gamma(x-y)\|$ and $\|\Gamma(y) - b\|$ otained by summing the inequalities (4) and (2). Here Γ denotes the completely positive contraction from $\ell_\infty(B)$ into $\mathcal{M}(B)$, which is given by

$$\Gamma(b_1, b_2, \ldots) \; := \; (e_n)^{1/2} b_n (e_n)^{1/2} + \sum_{k>n} f_k b_k f_k,$$

and x, y denote the elements of $\ell_\infty(B)$, which are defined by $x_k := L_k(e_n b e_n)$ and $y_k := e_{k+2} b e_{k+2}$ for $k = 1, 2, \ldots$.

Note that $\Gamma(x) = W_n(e_n x e_n)$ and $\Gamma(y) = (e_n)^{1/2} b (e_n)^{1/2} + \sum_{k>n} f_k b f_k$. (See Remark 5.1.1(?????) **??** for the calculation of the needed estimates from those of (2) and (4).)

Thus Theorem 6.3.1 applies in the separable case.

`Here end of use of 6.3.1`

If B is *not* separable, then we can consider instead of B a separable C^*-subalgebra D of B, which contains a strictly positive element of B, is invariant by right and left multiplication by elements of $H(A)$, and satisfies all the properties listed in Lemma 12.2.14 with respect to $H(A)$, B and D. In particular,

D is residually weakly injective in B, $H(A)D \subset D$, and $D \cap \Psi_{\text{down}}^{D,B}(I) = I$ for $I \in \mathcal{I}(D)$. It follows $H(A) \subset \mathcal{M}(D) \subset \mathcal{M}(B)$ and, therefore, by Lemma 12.1.1(iv), $H(A) \cap \mathcal{M}(B, J) = H(A) \cap \mathcal{M}(D, D \cap J)$ for $J \in \mathcal{I}(B)$. Thus, $\Psi(J) = \Phi(D \cap J)$ for $J \in \mathcal{I}(B)$, where $\Phi(I) := H^{-1}(H(A) \cap \mathcal{M}(D, I))$ for $I \in \mathcal{I}(D)$.

By Lemma 12.2.12, it follows that $H\colon A \to \mathcal{M}(D)$ is is a weakly Φ-residually nuclear map from A to $\mathcal{M}(D)$.

Since $\Psi_{\text{down}}^{D,B}$ is upper semi-continuous, and $\Phi(I) = \Psi(\Psi_{\text{down}}^{D,B}(I))$ for $I \in \mathcal{I}(D)$, we get from (ii), that the lower semi-continuous action Φ also satisfies condition (ii) of Definition 1.2.6.

By construction, D is again strongly purely infinite and has residually nuclear separation.

Thus, by the above considered separable case, there exists a non-degenerated nuclear *-monomorphism $h\colon A \otimes \mathcal{O}_2 \to D \subset B$, such that the infinite repeat of $h_0 := h((\cdot) \otimes 1)$ is unitarily homotopic to the infinite repeat of H in $\mathcal{M}(D)$. Since D is a stable and non-degenerate C^*-subalgebra of B, this implies that $\delta_\infty h_0$ is unitarily homotopic to $\delta_\infty H$ in $\mathcal{M}(B)$. □

Remark 12.2.17. For every C^*-algebra B, every separable C^*-subalgebra D of $\mathrm{Q}(\mathbb{R}_+, B)$ and every commutative separable C^*-subalgebra C of D, there exists a strongly continuous map $t \mapsto V(t)$ from $\mathbb{R}_+$ into the approximately inner completely positive contractions on B, such that the completely positive contraction T on $\mathrm{Q}(\mathbb{R}_+, B)$ defined by V fixes the elements of C and $T(D)$ is contained in a commutative C^*-algebra of $\mathrm{Q}(\mathbb{R}_+, B)$.

This can be seen as follows: If g is a contraction in $\mathrm{C_b}(\mathbb{R}_+, B \otimes \mathcal{O}_\infty)$ and f a pure state on $\mathcal{O}_\infty$ then

$$V(t)(b) := (\mathrm{id} \otimes f)(g(t)^*(b \otimes 1)g(t))$$

defines an approximately inner completely positive contraction $V(t)$ of B such that $t \mapsto V(t)$ is strongly continuous. For the corresponding completely positive contraction T on $\mathrm{Q}(\mathbb{R}_+, B)$ and the contraction $d := g + \mathrm{C}_0(\mathbb{R}_+, B)$ in $\mathrm{Q}(\mathbb{R}_+, B \otimes \mathcal{O}_\infty)$ holds $T(a) = P(d^*(a \otimes 1)d)$ for $a \in \mathrm{Q}(\mathbb{R}_+, B)$. Here the completely positive contraction P from $\mathrm{Q}(\mathbb{R}_+, B \otimes \mathcal{O}_\infty)$ onto $\mathrm{Q}(\mathbb{R}_+, B)$ is given on representatives $e \in \mathrm{C_b}(\mathbb{R}_+, B \otimes \mathcal{O}_2)$ by $e(t) \mapsto (\mathrm{id} \otimes f)(e(t))$ for $t \in \mathbb{R}_+$, and $\mathrm{Q}(\mathbb{R}_+, B) \otimes \mathcal{O}_\infty$ is naturally embedded in $\mathrm{Q}(\mathbb{R}_+, B \otimes \mathcal{O}_\infty)$. Now choose d for $D \otimes 1$ and $C \otimes 1$ as in Lemma 12.1.6 to get the desired result.

If B is purely infinite then, for every positive element a in $\mathrm{Q}(\mathbb{R}_+, B)$, $T(a)$ is in the closed ideal generated by a: For $\delta > 0$, $(T(a) - \delta)_+ = e^*ae + f^*af$ for some $e, f \in \mathrm{Q}(\mathbb{R}_+, B)$. It follows that then $T|D$ is residually nuclear. This shows:

For every purely infinite C^*-algebra B the asymptotic corona $\mathrm{Q}(\mathbb{R}_+, B)$ has residually nuclear separation in the sense of Definition 1.2.3 (cf. Remark 12.2.10).

If, moreover, B is strongly purely infinite then there exists a contraction d in $\mathrm{Q}(\mathbb{R}_+, B)$ with $T(b) = d^*bd$ for $b \in D$. d commutes elementwise with C, as we have shown on the beginning of the proof of Lemma 12.1.6.

LEMMA 12.2.18. *Suppose that B is stable and σ-unital. Let $B_1 := B \otimes F$, where $F := \mathcal{O}_\infty \otimes \mathcal{O}_\infty \otimes \ldots$. Then there is a non-degenerate *-monomorphism $d\colon B_1 \hookrightarrow \mathcal{M}(B)$, such that*

(i) *$\delta_\infty d$ is unitarily equivalent to d, and*
(ii) *$d(B_1) \cap \mathcal{M}(B, J) = d(J \otimes F)$ for $J \in \mathcal{I}(B)$.*

PROOF. Since B is stable, we can apply the infinite repeat δ_∞ to $\mathcal{M}(B)$. There is a unital copy of $\mathcal{L}(\ell_2)$ in the relative commutant of $\delta_\infty(\mathcal{M}(B))$ in $\mathcal{M}(B)$. Therefore, a unital copy of $F \subset \mathcal{M}(B)$ commutes with $\delta_\infty(B)$.

Since F is nuclear and simple, it follows that there is a unique C^*-morphism $h\colon B_1 \to \mathcal{M}(B)$ with $h(b \otimes f) = \delta_\infty(b)f$ for $b \in B$, $f \in F$. h is a non-degenerate *-monomorphism, because $\delta_\infty|B := h((.)\otimes 1)$ is a non-degenerate *-monomorphism and F is simple.

Let $d := \delta_\infty h$. Then d is non-degenerate *-monomorphism, because $d(B\otimes 1) = \delta_\infty^2(B)$ is a non-degenerate C^*-subalgebra of $\mathcal{M}(B)$.

$\delta_\infty d$ is unitarily equivalent to d, because δ_∞^2 is unitarily equivalent to δ_∞.

Let $J \in \mathcal{I}(B)$. Then $I := d^{-1}(d(B_1) \cap \mathcal{M}(B, J))$ is a closed ideal of B_1. By Proposition B.4.2(iii), there is a closed ideal K of B such that $K \otimes F = \Psi_1(J)$. We get that $b \in K$ if and only if $\delta_\infty^2(b)B \subset J$. Since $b \in B$, this is the case if and only if $b \in J$. Thus $K = J$. □

PROOF OF THEOREM K:. Let $\Psi(J) := \Psi_A(Z_J)$ for $J \in \mathcal{I}(B)$. Here $Z_J \subset \mathrm{Prim}(B)$ denotes the hull of J.

The uniqueness up to unitary homotopy of the nuclear *-monomorphism $h_0 := h((.) \otimes 1)$ follows from $h_0(\Psi(J)) = h_0(A) \cap J$ for $J \in \mathcal{I}(B)$ and from the unitary homotopy of h_0 with $h_0 \oplus h_0$, cf. Corollary 9.1.4.

We reduce the general case to the case where B is separable and Ψ is non-degenerate.

If B is separable, it suffices to consider, instead of of B, the smallest ideal I of B with $\Psi(I) = A$, to prove the existence of h. The existence of I follows from the lower semicontinuity of Ψ.

Thus, we may assume, in addition, that $\Psi^{-1}(A) = \{B\}$.

Let $F := \mathcal{O}_\infty \otimes \mathcal{O}_\infty \otimes \ldots$, $B_1 := B \otimes F$, and let E_1 and E denote the hereditary C^*-subalgebras of $\mathrm{Q}(\mathbb{R}_+, B_1)$ and $\mathrm{Q}(\mathbb{R}_+, B)$ which are generated by B_1 and B, respectively. By Remarks 12.2.9 and 12.2.17, E_1 and E are strongly purely infinite and have residually nuclear separation.

Since F is simple and nuclear, we get from Proposition B.4.2(iii), that

$$J \leftrightarrow J \otimes F$$

defines a natural topological isomorphism from $\mathrm{Prim}(B)$ onto $\mathrm{Prim}(B_1)$ and, therefore, a lattice isomorphism from $\mathcal{I}(B)$ onto $\mathcal{I}(B_1)$. We denote the action of $\mathrm{Prim}(B_1)$ on A by Ψ_1, i.e., $\Psi_1(J \otimes F) = \Psi(J)$. Then Ψ_1 is again lower semi-continuous, satisfies property (ii) of Definition 1.2.6, $\Psi_1(0) = 0$ and $\Psi_1^{-1}(A) = \{B_1\}$.

The action $\Phi(J) := \Psi_1(B_1 \cap J)$ for $J \in \mathcal{I}(E_1)$ is a lower semi-continuous action of $\mathrm{Prim}(E_1)$ on A, and satisfies property (ii) of Definition 1.2.6, $\Phi(0) = 0$ and $\Phi^{-1}(A) = \{E_1\}$. This is the case, because Ψ_1 and $\Psi^{\mathrm{up}}_{E_1,B_1} \colon J \mapsto B_1 \cap J$ satisfy conditions (ii)-(iv) of Definition 1.2.6, and $B_1 \subset J$ implies $J = E_1$.

By Theorem 12.1.8, there is a non-degenerate weakly residually nuclear monomorphism G_0 from A to $\mathcal{M}(E_1)$ such that G_0 is unitarily equivalent to $\delta_\infty G_0$, and, for $J \in \mathcal{I}(E_1)$,

$$G_0(\Phi(J)) = G_0(A) \cap \mathcal{M}(E_1, J).$$

By Proposition 12.2.15, there is a non-degenerate nuclear *-monomorphism $k \colon A \otimes \mathcal{O}_2 \to E_1$ such that, for $k_0 := k((.) \otimes 1)$, $\delta_\infty k_0$ is unitarily homotopic to G_0 in $\mathcal{M}(E_1)$, and k_0 is unitarily equivalent to $k_0 \oplus k_0$.

In particular, for $J \in \mathcal{I}(E_1)$,

$$\delta_\infty k_0(\Phi(J)) = \delta_\infty(k_0(A)) \cap \mathcal{M}(E_1, J).$$

This implies $k_0(\Psi_1(B_1 \cap I)) = k_0(A) \cap I$ for every closed ideal I of $\mathrm{Q}(\mathbb{R}_+, B_1)$.

E_1 is a hereditary C^*-subalgebra of $\mathrm{Q}(\mathbb{R}_+, B_1)$. Therefore, k is also nuclear as a *-monomorphism from $A \otimes \mathcal{O}_2$ into $\mathrm{Q}(\mathbb{R}_+, B_1)$.

Since $\Psi_1^{-1}(A) = \{B_1\}$, it follows from Corollary 9.1.7, that there exists a nuclear *-monomorphism h from $A \otimes \mathcal{O}_2$ into B_1, such that $h_0 := h((.) \otimes 1)$ is non-degenerate and satisfies $h_0(\Psi_1(I)) = h_0(A) \cap I$ for $I \in \mathcal{I}(B)$. Thus, for $J \in \mathcal{I}(B)$,

$$h_0(\Psi(J)) = h_0(A) \cap (J \otimes F).$$

Now, it follows from Lemma 12.2.18, that $H_0 = dh_0$ is a non-degenerate nuclear *-monomorphism from from A into $\mathcal{M}(B)$, such that $\delta_\infty H_0$ is unitarily equivalent to H_0, and, for $J \in \mathcal{I}(B)$,

$$H_0(\Psi(J)) = H_0(A) \cap \mathcal{M}(B, J).$$

Since B contains a strictly positive element of E, we get from Lemma 12.1.1 that $\mathcal{M}(B) \cap \mathcal{M}(E, I) = \mathcal{M}(B, B \cap I)$ for $I \in \mathcal{I}(E)$, and we can consider H_0 as a non-degenerate nuclear *-monomorphism from A into $\mathcal{M}(E)$. Thus, for $I \in \mathcal{I}(E)$,

$$H_0(\Psi(B \cap I)) = H_0(A) \cap \mathcal{M}(E, I).$$

Now we can repeat the above applications of Proposition 12.2.15 and Corollary 9.1.7, where we have to replace B_1 by B, E_1 by E, and G_0 by $H_0 \colon A \to \mathcal{M}(E)$.

We get the desired non-degenerate nuclear *-monomorphism h from $A \otimes \mathcal{O}_2$ into B with $h_0(\Psi(J)) = h_0(A) \cap J$ for $J \in \mathcal{I}(B)$ and $h_0 = h((.) \otimes 1)$. □

COROLLARY 12.2.19. *Suppose that B is strongly purely infinite, separable and stable.*

Then $\{\widehat{b} : \ b \in B\}$ is the set of all Dini functions on $\mathrm{Prim}(B)$.

PROOF. Let $B_1 := B \otimes \mathcal{O}_2$, and let f be a Dini function on X.

By Proposition 12.2.6, there exists $a \in (B_1)_+$ with $f(J) = \widehat{a}(J \otimes \mathcal{O}_2)$ for $J \in \mathrm{Prim}(B)$. Let C denote the commutative C^*-subalgebra of B_1 which is generated by a, and let $A := C \otimes \mathbb{K}$. Then A is a nuclear C^*-subalgebra of $B_1 \otimes \mathbb{K}$.

Let $\Phi(J) := \ J \otimes \mathcal{O}_2 \otimes \mathbb{K}$.

By Lemma 12.2.4, Φ is a lattice isomorphism from $\mathcal{I}(B)$ onto $\mathcal{I}(B_1 \otimes \mathbb{K})$.

It follows that $\Psi(J) := A \cap \Phi(J)$ for $J \in \mathcal{I}(B)$ defines a lower semi-continuous action of $\mathrm{Prim}(B)$ on A. It satisfies $\Psi(0) = 0$, $\Psi(B) = A$, and the condition (ii) of Definition 1.2.6.

By Theorem K, there is a *-monomorphism $h_0\colon A \hookrightarrow B$, such that, for $J \in \mathcal{I}(B)$,

$$h_0(\Psi(J)) = h_0(D) \cap J.$$

Let $b := h_0(a \otimes p_{11})$. Then, for $J \in \mathrm{Prim}(B)$,

$$\|b + J\| = \|(a \otimes p_{11}) + \Phi(J)\| = \widehat{a}(J \otimes \mathcal{O}_2).$$

This means $\widehat{b} = f$. □

The following Corollary 12.2.20 is an equivalent reformulation of Corollary L.

COROLLARY 12.2.20. *Suppose that A and B are separable, stable and nuclear C^*-algebras, and that there is a topological isomorphism γ from $X :=$ $\mathrm{Prim}(A)$ onto* $\mathrm{Prim}(B)$.

Then there exists an isomorphism φ from $A \otimes \mathcal{O}_2$ onto $B \otimes \mathcal{O}_2$, such that φ induces γ, i.e., for $J \in$ $\mathrm{Prim}(A)$,

$$\varphi(J \otimes \mathcal{O}_2) = \gamma(J) \otimes \mathcal{O}_2\,.$$

φ with this properties is unique up to unitary homotopy.

In particular, the natural group morphism from $\mathrm{Aut}(A \otimes \mathcal{O}_2)$ *to the homeomorphisms of* $\mathrm{Prim}(A)$ *is an epimorphism with kernel equal to the group of automorphisms of $A \otimes \mathcal{O}_2$ that are unitarily homotopic to* id.

In particular, every approximately inner automorphism of $A \otimes \mathcal{O}_2$ is unitarily homotopic to id.

PROOF OF COROLLARY L AND OF COROLLARY 12.2.20. By Theorem K, there exist non-degenerate *-monomorphisms $h\colon A \otimes \mathcal{O}_2 \hookrightarrow B \otimes \mathcal{O}_2$ and $k\colon B \otimes \mathcal{O}_2 \hookrightarrow A \otimes \mathcal{O}_2$ such that h and k induce the corresponding actions of

X on B, i.e., for $J \in \operatorname{Prim}(A)$, $h(J \otimes \mathcal{O}_2)$ is the intersection of $h(A \otimes \mathcal{O}_2)$ with $\gamma(J) \otimes \mathcal{O}_2$, and similar for k. By Corollary 10.3.10(ii), h is unitarily homotopic to an *-isomorphism φ from $A \otimes \mathcal{O}_2$ onto $B \otimes \mathcal{O}_2$ with the desired property. Here we have used that every unital *-endomorphism of $\mathcal{O}_2$ is unitarily homotopic to id, and that $\mathcal{O}_2 \cong \mathcal{O}_2 \otimes \mathcal{O}_2$, cf. Corollary F(iii) and Corollary H(ii).

The uniqueness of φ follows from Corollary 10.3.10(i). □

3. Interjection: Non-commutative Selection Conjecture

COROLLARY 12.3.1. *Suppose that A is a separable, stable and exact C^*-algebra. Then there are*

(i) *a separable stable nuclear C^*-algebra B such that $B \cong B \otimes \mathcal{O}_2$, and*
(ii) *a non-degenerate *-monomorphism $\varphi \colon A \hookrightarrow B$ such that φ induces an isomorphism λ from $\mathcal{I}(B)$ onto $\mathcal{I}(A)$ by $\lambda(I) := \varphi^{-1}(I \cap \varphi(A))$, i.e., for closed ideals $I_1, I_2 \in \mathcal{I}(B)$, $I_1 \cap \varphi(A) = I_2 \cap \varphi(A)$ implies $I_1 = I_2$, and, $\lambda(I) = J$ for $J \in \mathcal{I}(A)$ and $I := \overline{B\varphi(J)B} \in \mathcal{I}(B)$.*

B is unique up to λ-equivariant isomorphisms, and φ is unique up unitary homotopy.

*If, in addition, A strongly purely infinite, then there is also a non-degenerate *-monomorphism $\psi \colon B \hookrightarrow A$ that induces a "kind of inverse" for λ. The map $\varphi \circ \psi$ is unitarily homotopic to* id_B.

The nuclear map $\psi \circ \varphi$ is unitarily homotopic to $\mathrm{id}_A \colon A \to A$, *if and only if, A is nuclear and $A \cong A \otimes \mathcal{O}_2$.*

PROOF. The uniqueness of B follows from Corollary L. The uniqueness, up to unitary homotopy, of φ follows from Corollary 7.4.8.

We can replace A by $A \otimes \mathcal{O}_2$, to prove the existence of B and φ. Here we use that $\mathcal{O}_2 \otimes \mathcal{O}_2 \cong \mathcal{O}_2$ and that every unital *-endomorphism of $\mathcal{O}_2$ is unitarily homotopic to the identity map of $\mathcal{O}_2$, cf. Corollary F(ii) and Corollary H(ii).

Suppose $A \cong A \otimes \mathcal{O}_2$. Then A is strongly purely infinite. By Theorem K, there is a non-degenerate *nuclear* *-monomorphism $h \colon A \to A$, such that h induces the natural action of $\operatorname{Prim}(A)$ on A, i.e. $h(J) = h(A) \cap J$ for every closed ideal J of A.

Let B denote the inductive limit $\operatorname{indlim}(h_n \colon A \to A)$ where $h_n = h$ for $n = 1, 2, \ldots$. Since h is nuclear, B is a nuclear C^*-algebra. By Corollary 10.3.11, B is separable, stable and $B \cong B \otimes \mathcal{O}_2$.

By Corollary 7.4.8, the nuclear maps h^n and h are unitarily homotopic for $n = 2, 3, \ldots$, because $h^n(J) = h^n(A) \cap J$ (by induction). This implies that J is the closure of $Ah^n(J)A$ for every $J \in \mathcal{I}(A)$.

If we apply the canonical maps $h^\infty_{n+k} h^n = h^\infty_k$, we obtain that, for $J \in \mathcal{I}(A)$,

$$h^\infty_k(J) = h^\infty_k(A) \cap h^\infty_{n+k}(J),$$

and $h_n^\infty(J)$ is the closure of $h_n^\infty(A)h_1^\infty(J)h_n^\infty(A)$.

Let φ denote the canonical C^*-morphism h_1^∞ from A into $B := \operatorname{indlim}(h_n \colon A \to A)$, and, for $J \in \mathcal{I}(A)$, let $\mu(J)$ denote the closure of $B\varphi(J)B$. Then $\mu(J)$ is the inductive limit of $h_n^\infty(J)$, and $\varphi(A) \cap \mu(J) = \varphi(J)$.

If $I \in \mathcal{I}(B)$, then I is the inductive limit of $h_n^\infty(A) \cap I$, because $\bigcap_n h_n^\infty(A)$ is dense in A. If we apply the above observations to

$$J_n := (h_n^\infty)^{-1}(h_n^\infty(A) \cap I)$$

we get $J_n = J_m$ for $m, n \in \mathbb{N}$ and

$$h_n^\infty(\varphi^{-1}(\varphi(A) \cap I)) = h_n^\infty(A) \cap I.$$

Thus $I = \mu(\varphi^{-1}(\varphi(A) \cap I))$, and λ defines a lattice isomorphism from $\mathcal{I}(B)$ onto $\mathcal{I}(A)$ with inverse μ. (In particular, it preserves prime elements and the hk-topology on them.)

If A strongly purely infinite, then, by Theorem K there is also a non-degenerate *-monomorphism $\psi \colon B \hookrightarrow A$ that defines the "inverse" $\mu = \lambda^{-1}$ of $\lambda \colon \mathcal{I}(B) \to \mathcal{I}(A)$, i.e., $J \cap \psi(B) = \psi(\mu(J))$.

Then $\varphi \circ \psi$ induces the identity on $\mathcal{I}(B)$, and $\varphi \circ \psi$ is unitarily homotopic to id_B by Theorem K.

If the nuclear map $\psi \circ \varphi$ is *unitarily* homotopic to $\mathrm{id}_A \colon A \to A$ then A is nuclear and id_A is approximately unitarily equivalent to $\mathrm{id}_A \oplus \mathrm{id}_A$, because ψ and φ can be taken non-degenerate (which implies that $\psi \circ (\mathrm{id}_B \oplus \mathrm{id}_B) \circ \varphi$ is unitarily equivalent to $(\psi \circ \varphi) \oplus (\psi \circ \varphi)$), and id_B is unitarily homotopic to $\mathrm{id}_B \oplus \mathrm{id}_B$.

If A is nuclear and $A \cong A \otimes \mathcal{O}_2$, then Theorem K applies also to $\psi \circ \varphi$, and is unitarily homotopic to $\mathrm{id}_A \colon A \to A$. □

CONJECTURE 12.3.2. *Suppose that B is a separable stable C^*-algebra with $B \cong B \otimes \mathcal{O}_\infty$. Let E denote the closure of $B\,\mathrm{Q}(\mathbb{R}_+, B)B$, let $H \colon A \to \mathcal{M}(E)$ a non-degenerate C^*-morphism from a separable stable C^*-algebra A into the multiplier algebra $\mathcal{M}(E)$ of E, and let Ψ_1 denote the lower semi-continuous actions of* $\mathrm{Prim}(E)$ *on A which is defined, for $I \in \mathcal{I}(E)$, by*

$$\Psi_1(I) = H^{-1}(H(A) \cap \mathcal{M}(E, I)).$$

Furthermore, suppose that

(i) *H is unitarily equivalent to its infinite repeat $\delta_\infty H$,*
(ii) *H and $\widehat{\sigma}H$ are unitarily homotopic, for every automorphism $\widehat{\sigma}$ of $\mathcal{M}(E)$, which is induced by a scaling homeomorphism σ of $\mathbb{R}_+$, and*
(iii) *H is weakly Ψ_1-residually nuclear.*

The conjecture *is:*
Then there exists a C^*-morphism H_0 from A into $\mathcal{M}(B)$, which is in $\mathcal{M}(E)$ unitarily homotopic to H.

REMARK 12.3.3. If the Conjecture 12.3.2 is true, then (i)-(iii) imply the additional condition

(iv) $\Psi_1(I_1) = \Psi_1(I_2)$ if $I_1 \cap B = I_2 \cap B$.

This is because $\mathcal{M}(B) \cap \mathcal{M}(E, I) = \mathcal{M}(B, I \cap B)$. The latter formula comes from $B \subset BEB = E$.

One could believe that the proof of Conjecture 12.3.2 can be given with ideas from Section 1. But there is a difficult point:
Let $b \in B_+$ a strictly positive contraction of B. Let X be a compact subset of A_+ with linear span dense in A. For T in $\mathcal{M}(E)$ let $\|T\|_\# := \|Tb\| + \|bT\|$.

The difficulty consists in the proof the following additional condition:

(v) For every linearly generating compact subset X of A, there exists a sequence of functions $f_n \in \mathrm{C}_0((0,1])_+$ with

$$\|f_n\| = 1, \quad f_n f_{n+1} = f_n \quad \text{and} \quad \|[f_n(b), H(a)]\|_\# < 2^{-n}$$

for $n \in \mathbb{N}$ and $a \in X$, such that, in addition, for every $\varepsilon > 0$ and every homeomorphism σ of $\mathbb{R}_+$, there is a unitary $U \in \mathcal{M}(E)$ with the following properties:
For every $a \in X$ and $n \in \mathbb{N}$, $\|[f_n(b), U]\|_\# < 2^{-n}$, and

$$\|U^* H(a) U - \widehat{\sigma} H(a)\|_\# + \|H(a) - U \widehat{\sigma} H(a) U^*\|_\# < \varepsilon.$$

Note that the existence of approximately commutative approximate units implies that, for every countable set S of homeomorphisms σ of $\mathbb{R}_+$, such a sequence f_n exists (uniformly for all $\varepsilon > 0$ and $\sigma \in S$).

If, conversely, H is approximately unitarily equivalent to a "constant" H_0, then the same argument shows the existence of the desired sequence (f_n) and the unitary $U \in \mathcal{M}(E)$. I.e., the sequence (f_n) exists, if Conjecture 12.3.2 is true.

If we make the additional assumption of the above described "uniform" existence of the sequence f_n, then the proof of the Conjecture 12.3.2 is similar to the proofs of Proposition 9.1.2 and its Corollary 9.1.3 together. But the operator norms, that we have considered there, must be replaced by the above strictly continuous norms $\|\,.\,\|_\#$. This norm is invariant under scaling automorphisms $\widehat{\sigma}$, but it is only quasi-invariant with respect to inner automorphisms.

REMARK 12.3.4. Let A, B, E and $H \colon A \to \mathcal{M}(E)$ as in Conjecture 12.3.2. Suppose that there exists a non-degenerate C^*-morphism H_0 from A into $\mathcal{M}(B)$, such that H_0 is unitarily homotopic to H in $\mathcal{M}(E)$.

Let Ψ_2 denote the lower semi-continuous actions of $\mathrm{Prim}(B)$ on A defined by

$$\Psi_2(J) := H_0^{-1}(H_0(A) \cap \mathcal{M}(B, J)).$$

Then $\Psi_1(J) = \Psi_2(J \cap B)$ for $J \in \mathcal{I}(E)$ and H_0 is weakly Ψ_2-residually nuclear.

Indeed:
Since H_0 and H are unitarily homotopic in $\mathcal{M}(E)$, $H_0(a)$ is in $\mathcal{M}(B) \cap \mathcal{M}(E, J)$

if and only if $H(a)$ is in $\mathcal{M}(E, J)$. But it is easy to see that $\mathcal{M}(B, J \cap B) = \mathcal{M}(B) \cap \mathcal{M}(E, J)$. Thus $\Psi_1(J) = \Psi_2(J \cap B)$ for $J \in \mathcal{I}(E)$.

Let $I \in \mathcal{I}(B)$. Then $J := \mathrm{Q}(\mathbb{R}_+, I) \cap E$ is a closed ideal of E, such that $J \cap B = I$. B/I is relatively weakly injective in E/J, because E/J is naturally isomorphic to the hereditary C^*-subalgebra of $\mathrm{Q}(\mathbb{R}_+, B/I)$, that is generated by B/I.

It follows, that $I = B \cap \Psi^{B,E}_{\mathrm{down}}(I)$, and that B/I is relatively weakly injective in $E/\Psi^{B,E}_{\mathrm{down}}(I)$. Therefore, B is residually relatively weakly injective in E.

Thus H_0 is Ψ_2-residually nuclear by Lemma 12.2.12, where we have to replace (C, A, B) by $(H_0(A), B, E)$.

Definition 12.3.5. A separable C^*-algebra B has the (non-commutative) **selection property** if, for every separable C^*-algebra A and every lower semi-continuous action

$$\Psi\colon \mathcal{I}(B) \to \mathcal{I}(A)$$

of $\mathrm{Prim}(B)$ on A in the sense of Definition 1.2.6 with $\Psi(0) = 0$ and $\Psi^{-1}(A) = \{B\}$, there exists a non-degenerate weakly Ψ-residually nuclear *-monomorphism H_0 from A into the multiplier algebra $\mathcal{M}(B)$ of B such that $\delta_\infty H_0$ is unitarily equivalent to H_0, and, for $J \in \mathcal{I}(B)$,

$$\Psi(J) = H_0^{-1}(H_0(A) \cap \mathcal{M}(B, J))\,.$$

(By Corollary 5.9.16, H_0 is unique up to unitary homotopy.)

Lemma 12.1.2(ii) allows to give an equivalent definition which also works for non-stable B.

In other words (in the terminology of Section **??**):
For every separable A and for every non-degenerate lower semi-continuous action Ψ of $\mathrm{Prim}(B)$ on A, $\mathrm{CP}_{\mathrm{rn}}(\Psi; A, B)$ *realizes* the action Ψ in the sense that $\Psi = \Psi_{\mathcal{C}}$ for $\mathcal{C} := \mathrm{CP}_{\mathrm{rn}}(\Psi; A, B)$.

The "selection" procedure is the following:
Let be given $a_0 \in A_+$ and a pure state λ_0 on B with $\lambda_0(\Psi(\overline{\mathrm{span}(Aa_0A)}) \neq \{0\}$. Then we have to construct a continuous map f from the Polish space $P(B)$ of pure states on B into the compact metric space $S(A^*)$ of positive linear functionals ρ on A with $\|\rho\| \leq 1$ with properties:

(i) $f(\lambda)(\Psi(J_\lambda)) = 0$ for all $\lambda \in S(A^*)$, where J_λ is the kernel of the irreducible representation d_λ corresponding to λ.

(ii) For each $a \in A_+$ there is $b \in B$ with $\lambda(b) = f(\lambda)(a)$ for all $\lambda \in S(A^*)$.

The condition (ii) is not covered by usual selection theorems.

Conjecture 12.3.6 (Non-commutative Michael selection principle). *Every separable and stable C^*-algebra B has the selection property of Definition 12.3.5.*

`Now there exists a proof of the NC Micheal selection principle.`
??

It uses that coherent Dini spaces are primitive ideal spaces of nuclear separable C^*-algebras and that every lower s.c. action of an Abelian separable C^*-algebra C on a separable and stable C^*-algebra B comes from a $H_0 \colon C \to \mathcal{M}(B)$.

Remark 12.3.7.

(1) It is known that every *exact* separable stable C^*-algebra B *has the selection property*, because $B \otimes \mathcal{O}_2$ contains a "regular" commutative C^*-subalgebra $C \subset B \otimes \mathcal{O}_2$ if B is exact and separable (cf. Remark 12.3.8).

(2) Since B has the selection property, if and only if, $B \otimes \mathcal{O}_2$ has the selection property, we may suppose that $B \cong B \otimes \mathcal{O}_2$ and let $D \subset B$ a non-degenerate copy of $C \otimes \mathbb{K}$ that is also regular in B. Then the non-commutative Michael selection principle, the observation that $\mathcal{M}(B, B \cap J)$ is equal to the set of $T \in \mathcal{M}(B)$ with $TD \subset J$, Lemma 12.1.2 and Corollary 5.9.15 imply together a proof of Conjecture 12.3.2 for all stable separable B with the property that $B \otimes \mathcal{O}_2$ contains an Abelian regular C^*-subalgebra.

(3) If the Conjecture 12.3.2 is true then also the non-commutative Michael selection principle of Conjecture 12.3.6 holds:

Let $B_1 := B \otimes \mathcal{O}_\infty$. By Theorem 12.1.8 and Conjecture 12.3.2, there is a weakly Ψ-residually nuclear C^*-morphism $H_1 \colon A \to \mathcal{M}(B_1)$ such that, for $J \in \mathcal{I}(B)$,

$$\Psi(J) = H_1^{-1}(H_1(A) \cap \mathcal{M}(B_1, J \otimes \mathcal{O}_\infty)).$$

Let $J \in \mathcal{I}(B)$ and $a \in A \setminus \Psi(J)$. Then there is $f \in B_1$, such that $f^* H_1(a) f$ is not in $J \otimes \mathcal{O}_\infty$.

Let $d \colon B_1 \to \mathcal{M}(B)$ denote the non-degenerate *-monomorphism of Lemma 12.2.18.

By Lemma 12.2.18(ii), $d(f^* H_1(a) f)$ is not in $\mathcal{M}(B, J)$, i.e., there is $e \in B$, such that $V(a)$ is not in J, where we let $V(c) := e^* d(f^* H_1(c) f) e$ for $c \in A$.

V is Ψ-residually nuclear for $f \in B_1$ and $e \in B$, because $f^* H_1(.) f$ is Ψ-residually nuclear, and $e^* \delta_\infty(d(.)) e$ is equivariant on $\mathcal{I}(B) \cong \mathcal{I}(B_1)$.

By Lemma 12.1.2, there exists the desired Ψ-residually nuclear non-degenerate *-monomorphism H_0 from A to $\mathcal{M}(B)$.

Thus a proof of Conjecture 12.3.2 would imply a proof of the non-commutative Michael selection principle.

Remark 12.3.8. If one limits to those separable C^*-algebras B such that $\mathrm{Prim}(B)$ is homeomorphic to $\mathrm{Prim}(C)$ for a separable exact C^*-algebra C, then, by Corollary 12.3.1, Theorem K, Corollary L and Lemma 12.2.18, it suffices to prove the selection property for the unique stable separable nuclear C^*-algebra A with $\mathrm{Prim}(A)$ homeomorphic to $\mathrm{Prim}(B)$, and with $A \cong A \otimes \mathcal{O}_2$. Thus, in this class of C^*-algebras B, the selection property is essentially a property of the T_0-space $\mathrm{Prim}(B)$.

Lemma 12.1.3 implies, that every separable stable C^*-algebra B with Hausdorff primitive ideal space has the selection property.

Lemma 12.1.4 and the below given Lemma 12.3.10 show that *stable separable B has the selection property if B contains a commutative C^*-subalgebra C which is regular in B in the sense of Definition B.4.1.*

This implies, e.g., that B has the selection property if its primitive ideal space is isomorphic to the primitive ideal space of an inductive limit of C^*-algebras with Hausdorff primitive ideal spaces. But the second example considered after Corollary N in Chapter 1, is not such an inductive limit but contains a commutative C^*-subalgebra which is regular in the algebra.

Examples of those B where considered by Mortensen [**559**]. We generalize his construction as follows:

Let S be a compact metric semi-group with jointly continuous multiplication, and let $C := \mathrm{C}(S)$. The multiplication defines a unital C^*-morphism $d\colon C \to C \otimes C$, which is given by $d(f)(x, y) = f(xy)$. Let $A := C \otimes \mathcal{O}_2$. We choose a unital *-monomorphism h from C into $\mathcal{O}_2$, and a *-isomorphism k from $\mathcal{O}_2 \otimes \mathcal{O}_2$ onto $\mathcal{O}_2$. Let g denote the unital *-endomorphism of A, which is given by

$$g := (\mathrm{id}_C \otimes k)((\mathrm{id}_C \otimes h)d) \otimes \mathrm{id}_{\mathcal{O}_2}).$$

Now let $B := \mathrm{indlim}(h_n\colon A \to A)$, with $h_n = h$ for $n = 1, 2, \ldots$.

Then $\mathcal{I}(B)$ is the projective limit of the iterates of the map from $\mathbb{O}(S)$ into $\mathbb{O}(S)$, which is given, for open subsets Z of S, by

$$Z \mapsto S \setminus ((S \setminus Z)S).$$

If S is a linearly ordered space, which is separable and compact in its interval topology, then S is topologically and order isomorphic to a closed subset of the interval $[0, 1]$ (cf. [**360**]). S carries semigroup structures, e.g. the multiplication $(x, y) \mapsto \min(x, y)$. The corresponding map on $\mathbb{O}(S)$ is given by

$$Z \mapsto S \cap (\max(S \setminus Z), 1],$$

and the T_0-space of the corresponding is S with S, $\emptyset$ and $S \cap (t, 1]$, $t \in [0, 1)$ as open subsets. (Together with Corollary L, this implies the main result of [**559**].)

REMARK 12.3.9. The realization $H_0\colon A \to \mathcal{M}(E)$ of a *lower* semi-continuous actions $\Psi_B\colon \mathcal{I}(A) \to \mathcal{I}(B)$ of $\mathrm{Prim}(A)$ on B (as given Theorem 12.1.8 with $E := B\,\mathrm{Q}(\mathbb{R}_+, B)B$) can be used to obtain realizations of *upper* semi-continuous actions $\Psi_A\colon \mathcal{I}(B) \to \mathcal{I}(A)$ of $\mathrm{Prim}(B)$ on A, if the action Ψ_A is 'residually non-singular' in the following sense:

We call an action $\Psi_A\colon \mathcal{I}(B) \to \mathcal{I}(A)$ of $\mathrm{Prim}(B)$ on A **residually non-singular**, if $\Psi_A(J_1) = \Psi_A(J_2)$ and $J_1 \subset J_2$ imply $J_1 = J_2$.

If Ψ_A satisfies the condition (i) or the condition (iii) of Definition 1.2.6, then Ψ_A is residually non-singular if and only if Ψ_A is an injective map from $\mathcal{I}(B)$ into $\mathcal{I}(A)$.

Let B and A stable and separable, and let $X := \operatorname{Prim}(B)$. Since in the following considerations only the lattices of ideals are considered, we assume — for simplicity — that $B \otimes F \cong B$ and $A \otimes F \cong A$, where $F \cong \mathcal{O}_\infty \otimes \mathcal{O}_\infty \otimes \ldots$.

Suppose that $\Psi_A \colon \mathcal{I}(B) \cong \mathbb{O}(X) \to \mathcal{I}(A)$ satisfies the conditions (i) and (ii) of Definition 1.2.6, and $\Psi_A(0) = 0$, $\Psi_A^{-1}(A) = \{B\}$.

We define, for $I \in \mathcal{I}(A)$, a subset of $\mathcal{I}(B)$ by

$$\gamma(I) := \{J \in \mathcal{I}(B) \colon \Psi_A(J) \subset I\}\,.$$

The set $\gamma(I)$ is closed under sums $J_1 + J_2$ of closed ideals, and $J \in \gamma(I)$ if J is the closure of an increasing sequence in $\gamma(I)$. Therefore $\gamma(I)$ contains a unique maximal element $\Psi_B(I)$. $\Psi_B(I)$ is the closure of the sum of all elements in $\gamma(I)$.

It is easy to see that $\Psi_B \colon \mathcal{I}(A) \to \mathcal{I}(B)$ is a lower semi-continuous action of $\operatorname{Prim}(A)$ on B, that $\Psi_B^{-1}(B) = \{A\}$, and that, for $J \in \mathcal{I}(B)$, $I \in \mathcal{I}(A)$, $J \subset \Psi_B(I)$ if and only if $\Psi_A(J) \subset I$. In particular, $J \subset \Psi_B(\Psi_A(J))$. It follows that, for $J \in \mathcal{I}(B)$,

$$\Psi_A(J) = \bigcap\{I \in \mathcal{I}(A) \colon J \subset \Psi_B(I)\}.$$

If Ψ_A is residually non-singular, it implies that $\Psi_B(0) = 0$, and that Ψ_B is a left inverse of Ψ_A.

Let E denote the closure $A\,\mathrm{Q}(\mathbb{R}_+, A)A$, and let $H_0 \colon B \to \mathcal{M}(E)$ be the Ψ_B-residually nuclear non-degenerated *-monomorphism of Theorem 12.1.8 for Ψ_B, then an easy calculation shows that, for $J \in \mathcal{I}(B)$,

$$\Psi_A(J) = A \cap \Psi_{\mathrm{down}}^{H_0(B),E}(H_0(J))\,.$$

If, moreover, A has the selection property, then even H_0 can be found such that $H_0(B) \subset \mathcal{M}(A)$, and we get, for $J \in \mathcal{I}(B)$,

$$\Psi_A(J) = A \cap \Psi_{\mathrm{down}}^{H_0(B),A}(H_0(J))\,.$$

Lemma 12.3.10. *Suppose that A is a nuclear stable C*-subalgebra of a separable stable C*-algebra B, and that A has the selection property of Definition 12.3.5.*

Then the following are equivalent:

(i) *A is a regular subalgebra of B in the sense of Definition B.4.1.*
(ii) *$\Psi_{B,A}^{\mathrm{up}} \colon J \in \mathcal{I}(B) \mapsto A \cap J \in \mathcal{I}(A)$ is a residually non-singular action, which is continuous in the sense of Definition 1.2.5, (i)-(iv).*
(iii) *A separates the ideals of B, and, for every $I \in \mathcal{I}(A)$, the set $\gamma(I) := \{J \in \mathcal{I}(B) \colon A \cap J \subset I\}$ contains a unique maximal element.*
(iv) *A separates the ideals of B, and there exists a sequence (T_n) of residually equivariant maps from B into B, such that $T_n(B) \subset A$ for $n \in \mathbb{N}$, and $T_n|A$ converges in point-norm topology to $\mathrm{id}\,|A$.*

PROOF. If $J_1, J_2 \in \mathcal{I}(B)$, $I := (A \cap J_1) + (A \cap J_2)$, and $\gamma(I)$ of (iii) contains a maximal element K, then $J_1 \subset K$ and $J_2 \subset K$. Therefore $J_1 + J_2 \subset K$, which means $I = A \cap (J_1 + J_2)$.

This observation shows that (iii) and (ii) are obvious equivalent formulations of (i).

(iv)⇒(i): Since A separates $\mathcal{I}(B)$, it remains to show that $A \cap (J_1 + J_2)$ is contained in $(A \cap J_1) + (A \cap J_2)$, for $J_1, J_2 \in \mathcal{I}(B)$. The argument in the second part of the proof of Lemma 12.1.4 can be easily adapted, to get this.

(iii)⇒(iv): $\Psi_B(I) := \max \gamma(I)$ is the lower semi-continuous action of $\mathrm{Prim}(A)$ on B, which corresponds to the upper semi-continuous action $\Psi_A := \Psi^{\mathrm{up}}_{B,A}$ in the sense of Remark 12.3.9.

$\Psi_B(0) = 0$ and $\Psi_B^{-1}(B) = \{A\}$, because A separates the ideals of B.

Since A is separable, stable, and has the selection property, there is a non-degenerate weakly Ψ_B-residually nuclear *-monomorphism H_0 from B into $\mathcal{M}(A)$, such that, for $I \in \mathcal{I}(A)$

$$H_0(\Psi_B(I)) = H_0(B) \cap \mathcal{M}(A, I).$$

It follows $A \cap \Psi_B(I) \subset I$, and

$$H_0^{-1}(H_0(A) \cap \mathcal{M}(A, I)) = A \cap \Psi_B(I)\,.$$

Thus, by Corollary 3.10.6(II), $H_0|A$ approximately dominates $V := \mathrm{id}_A$, because A is also nuclear.

The hereditary C^*-subalgebra $D \subset B$ generated by A is stable and generates B as an ideal, because A is stable and separates $\mathcal{I}(B)$.

If we consider $H_0|D$ as a *-monomorphism from D into $\mathcal{M}(D)$, then $H_0|D$ is weakly residually nuclear, because A is nuclear, $H_0(D) \subset \mathcal{M}(A)$, and, for $J \in \mathcal{I}(B)$, $J = \Psi_B(A \cap J)$ and

$$H_0(D) \cap \mathcal{M}(D, D \cap J) = H_0(\Psi_B(A \cap J))\,.$$

Thus $T := a^* H_0(b^*(.)b)a$ is a residually nuclear map from B into B with image in A, if $a \in A$ and $d \in D$.

The convex combinations of restrictions $T|A$ approximate $\mathrm{id}\,|A$ in the point-norm topology, because, the map $H_0|A$ approximately dominates $V := \mathrm{id}_A$. □

The following Proposition 12.3.11 generalizes part (ii) of Theorem A.

PROPOSITION 12.3.11. *Suppose that A, B are stable and separable, that A is nuclear and has the selection property, B is strongly purely infinite, and that $\Psi \colon \mathcal{I}(B) \to \mathcal{I}(A)$ is a residually non-singular lower semi-continuous action of* $\mathrm{Prim}(B)$ *on A with $\Psi(0) = 0$ and $\Psi(B) = A$.*

Then the following are equivalent.

(i) *Ψ is a continuous action in the sense of Definition 1.2.6, (i)-(iv).*

(ii) *There is a non-degenerate *-monomorphism* $h_0 \colon A \hookrightarrow B$ *with* $h_0(\Psi(J)) = h_0(A) \cap J$ *and* $[h_0] = [h_0] + [h_0]$ *and a residually equivariant conditional expectation* P *from* B *onto* $h_0(A)$*.*

(iii) *Every non-degenerate *-monomorphism* h *from* A *into* B*, with* $h(\Psi(J)) = h(A) \cap J$ *and* $[h] = [h] + [h]$*, maps* A *onto a regular subalgebra of* B*.*

PROOF. Combine Theorem K, Lemma 12.3.10, and the last part of Theorem 6.3.1. □

The next observations allows to extend the main results of this section considerably (see Corollary 12.3.18).

`Alternative version from Dini3 :`

Suppose that A is a stable separable C^*-algebra, and that $g \colon \operatorname{Prim}(A) \to [0, \infty)$ is a bounded lower semi-continuous function,such that the set $X := \{\sup g(F)\,;\ F \in \mathbb{F}(\operatorname{Prim}(A))\}$ is *closed* in $[0, \sup g(X)]$.

Then there exists $a \in \mathcal{M}(A)_+$ with the following properties (i)-(iii).

(i) $\operatorname{Spec}(a) = X$,
(ii) $g(J) = \|a + \mathcal{M}(A, J)\|$ for all $J \in \operatorname{Prim}(A)$, and
(iII) $\operatorname{Spec}(a + \mathcal{M}(A, I)) = X \cap [0, \sup g(\operatorname{hull}(I))]$ for every closed ideal $I \lhd A$.

If $a \in \mathcal{M}(A)_+$ satifies (i)-(iii) then its infinite repeat $\delta_\infty(a)$ also satisfies (i)-(iii). If $b \in \mathcal{M}(A)_+$ satisfies (i)-(iii) (with b in place of a), then there is norm-continuous map $t \in [0, \infty) \mapsto U(t) \in \mathcal{U}(\mathcal{M}(A))$ such that $U(0) = 1$ and $\lim_{t\to\infty} U(t)\delta_\infty(a)U(t)^* = \delta_\infty(b)$.

PROPOSITION 12.3.12. *Suppose that* B *is stable and separable,* $1 \in K \subset [0, 1]$ *a closed set and that* $f \colon \operatorname{Prim}(B) \to K$ *is a lower semi-continuous function on* $\operatorname{Prim}(B)$ *with supremum* $\sup f(\operatorname{Prim}(B)) = 1$*. Then there is* $a \in \mathcal{M}(B)_+$ *with following properties:*

(i) $\operatorname{Spec}(a) = K$
(ii) $\|a + \mathcal{M}(B, J)\| = f(J)$ *for all* $J \in \operatorname{Prim}(B)$*,*
(iii) a *is unitarily equivalent to* $\delta_\infty(a)$*.*
(iv) *The action of* $\operatorname{Prim}(B)$ *on* $K = \operatorname{Spec}(a) \cong \operatorname{Prim}(C^*(a, 1))$ *is given by* $\Psi(I) = (\|a + \mathcal{M}(B, I)\|, 1] \cap K$ *for all closed ideals* I *of* B*.*

The $a \in \mathcal{M}(B)_+$ *with (i)–(iv) is unique up to unitary homotopy.*

PROOF. We find isometries $r, t, s_1, s_2, \ldots \in \mathcal{M}(B)$ with $tt^* + rr^* = 1$ and with $\sum_n s_n(s_n)^*$ strictly converges to 1. We define $\Delta \colon \ell_\infty(\mathcal{M}(B)) \to \mathcal{M}(B)$ by $\Delta(b_1, b_2, \cdots) := \sum s_n b_n (s_n)^*$. If we identify $\ell_\infty(\mathcal{M}(B))$ with $\mathcal{M}(c_0 \otimes B)$ then we can see that Δ is a unital non-degenerate strictly continuous *-monomorphism.

If J is closed ideal of B, then J is stable, and $tBt^* + sJs^*$ is stable and generates a full hereditary C^*–subalgebra D of B. Then D is stable, and, by Corollary 5.5.6 (which is the Ψ-equivariant version of the Brown stable isomorphism theorem), there exists an approximately inner isomorphism ψ from B onto D. Thus, there is an projection $p \in \mathcal{M}(B)$ such that pBp and $(1-p)B(1-p)$ are stable, pBp generates J and $(1-p)B(1-p)$ is full in B. It follows that there is an isometry $v \in \mathcal{M}(B)$ with $vv^* = 1-p$, and that the strictly closed ideal of $\mathcal{M}(B)$ generated by p is just $\mathcal{M}(B, J)$.

We define a lower semi-continuous increasing function $\gamma\colon K \to K$ by $\gamma(0) := 0$ and $\gamma(s) := \sup(K \cap [0, s))$ for $s > 0$. The function γ satisfies $t \le \gamma(s) \le s$ for all $t < s \in K$, and $\gamma(s) < s$ holds if and only if $(\gamma(s), s) \cap K = \emptyset$.

It holds $\inf\{\gamma(s)\,;\ s \in (t, 1] \cap K\} = t$ for all $t \in K$. Indeed, if $t = \inf K \cap (t, 1]$, then there is a sequence $s_1 > s_2 > \cdots$ in K with $\lim s_n = t$, then $s_{n+1} \le \gamma(s_n) \le s_n$, thus $\lim \gamma(s_n) = t$. For each $s \in (t, 1] \cap K$ there is $n \in \mathbb{N}$ with $s > s_n$. Hence $\gamma(s) \ge \gamma(s_n) \ge t$ and $\inf\{\gamma(s)\,;\ s \in (t, 1] \cap K\} = t$. If $t < s_0 := \inf K \cap (t, 1]$, then $s_0 \in K$ (by compactness of K) and $(t, s_0) \cap K = \emptyset$. It follows $(t, 1] \cap K = [s_0, 1] \cap K$, $[0, s_0) \cap K = [0, t] \cap K$ and $\inf\{\gamma(s)\,;\ s \in (t, 1] \cap K\} = g(s_0) = t$.

Now let $(x_1, x_2, \ldots)$ a dense sequence of (pairwise different) points in $K \setminus \{0\}$ that contains all boundary points of K (in $(0, 1]$).

Let J_n denote the ideal of B corresponding to the open subset $f^{-1}(\gamma(x_n), \infty)$ of $\mathrm{Prim}(B)$. For each $n \in \mathbb{N}$, we find a projection $p_n \in \mathcal{M}(B, J_n)$ such that $p_n B p_n$ is stable and generates J_n.

Define $a := \Delta(x_1 p_1, x_2 p_2, \ldots)$. We show that $a \in \mathcal{M}(B)$ satisfies (i) and (ii), and we modify a later to get also (iii) and (iv).

(i): Let $p_0 := 1 - \Delta(p_1, p_2, \ldots)$, and define a unital *-morphism $\lambda\colon \mathrm{C}(K) \to \mathcal{M}(B)$, for $g \in \mathrm{C}(K)$, by

$$\lambda(g) := g(0)p_0 + \Delta(g(x_1)p_1, g(x_2)p_2, \ldots)\,.$$

Then λ is faithful, because $\{0, x_1, x_2, \ldots\}$ is dense in K. Clearly $a = \lambda(f_0)$ for $f_0(t) := t$, $t \in K$. Thus $\mathrm{Spec}(a) = \mathrm{Spec}(f_0) = K$ by spectral permanence.

(ii): Notice that $(s_n)^* B s_n = B$, $(s_n)^* J s_n = J$ and $p_n B$ generates J_n. Thus $p_n (s_n)^* B s_n \subset (s_n)^* J s_n$ is equivalent to $J_n \subset J$. If J is primitive, then the inclusion $J_n \subset J$ means that $f(J) \le \gamma(x_n)$ (by definition of J_n).

Let $J \in \mathrm{Prim}(B)$. Then $\|a + \mathcal{M}(B, J)\| \le t$, if and only if, $\|(a-t)_+ + \mathcal{M}(B, J)\| = 0$, if and only if, $(a-t)_+ B \subset J$, if and only if, $\min(x_n - t, 0) p_n (s_n)^* B s_n \subset (s_n)^* J s_n$ for all $n \in \mathbb{N}$, if and only if, $f(J) \le \gamma(x_n)$ for all n with $t < x_n$.

Thus, $\|a + \mathcal{M}(B, J)\| \le t$, if and only if, $f(J) \le t$, because

$$\inf\{\gamma(x_n)\,;\ t < x_n\} = \inf\{\gamma(s)\,;\ s \in (t, \infty) \cap K\} = t\,.$$

It follows (ii).

(iii): Replace a by $\delta_\infty(a)$ (if necessary) and use that $\delta_\infty \circ \delta_\infty$ is unitarily equivalent to δ_∞ by Lemma 5.1.2(i).

(iv): Suppose that $a' \in \mathcal{M}(B)$ satisfies (i)–(iii) (in place of a). By property (iii) and by Lemma 5.1.2(ii), one can find a unital *-monomorphism $\varphi\colon \mathrm{C}(K) \otimes \mathcal{O}_2 \to \mathcal{M}(B)$ with $\varphi(f_0 \otimes 1)$ unitarily equivalent to a' with property (i)–(iii), where $f_0(t) = t$ for $t \in K$. Take a unital monomorphism $\rho\colon \mathrm{C}(K) \to \mathcal{O}_2$ (e.g. using a continuous epimorphism of the Cantor set onto K), and let $g \in \mathrm{C}(K \times K) \cong \mathrm{C}(K) \otimes \mathrm{C}(K)$ denote the function $g(s,t) := \min(s,t)$.

Then $\mathrm{Spec}(g) = g(K \times K) = K$, and, for every closed subset F of K, one has $g(F \times K) = [0, \max F] \cap K$. It follows that $b := (\mathrm{id} \otimes \rho)(g) \in \mathrm{C}(K) \to \mathcal{O}_2$ has spectrum $\mathrm{Spec}(b) = F$ and that a natural action of $\mathrm{Prim}(\mathrm{C}(K) \otimes \mathcal{O}_2) \cong K$ on $\mathrm{Prim}(C^*(b,1)) \cong K$ is given by $F \mapsto K \cap [0, \max F]$ (all expressed by the maps for the closed subsets F). In particular, if I is a closed ideal of $\mathrm{C}(K) \otimes \mathcal{O}_2$ (corresponding to the open subset U of K), then $I \cap (\mathrm{C}(K) \otimes 1) = \mathrm{C}_0(U) \otimes 1$ and $I \cap C^*(b,1) = \mu(\mathrm{C}_0(K \cap (\max(K \setminus U), 1]))$, for the unital *-monomorphism $\mu\colon h \in \mathrm{C}(K) \to h(b) = (\mathrm{id} \otimes \rho)(h \circ g) \in \mathrm{C}(K) \to \mathcal{O}_2$. It implies $\|b + I\| = \|f_0 \otimes 1 + I\|$ and $I \cap C^*(b,1) = \mu(\mathrm{C}_0(K \cap (\|b + I\|, 1])$, for all closed ideals of $\mathrm{C}(K) \to \mathcal{O}_2$.

Let $a := \delta_\infty(\varphi(b))$. Then a satisfies (i)–(iv), because the l.s.c. action of $\mathrm{Prim}(B)$ on $C^*(a,1)$ (respectively on $C^*(a')$) factorizes over the action on of $\mathrm{Prim}(\mathrm{C}(K) \to \mathcal{O}_2) \cong K$ on $\mathrm{C}(K) \otimes 1$ (respectively on $\mathrm{C}(K) \otimes 1$). □

LEMMA 12.3.13. *Suppose that B is a σ-unital C^*–algebra, and that $J, K \in \mathcal{I}(B)$.*

(i) $(J + K)_+ = J_+ + K_+$, *and*
(ii) $\mathcal{M}(B, J + K) = \mathcal{M}(B, J) + \mathcal{M}(B, K)$.

PROOF. (i): See [**401**, exercise 4.6.64]. Alternatively: It is easy to see that the set $J + K$ is a closed ideal. Let $c \in (J + K)_+$, and $d := c^{1/2}$. There are selfadjoint $a \in J$ and $b_0 \in K$ with $a + b_0 = d$. Then $c \leq a^2 + b^2$ for $b := (b_0^2 + (ab_0 + b_0 a)_-)^{1/2}$ and $b \in K_+$. By asymmetric Riesz decomposition [**616**, prop. 1.4.10], there are $e, f \in B$ with $ee^* \leq a^2$, $ff^* \leq b^2$ and $c = e^*e + f^*f$.

(ii): Since J, K and $J + K$ are closed ideals of B, the $\mathcal{M}(B, J)$, $\mathcal{M}(B, K)$, $\mathcal{M}(B, J) + \mathcal{M}(B, K)$ and $\mathcal{M}(B, J + K)$ are closed ideals of $\mathcal{M}(B)$. The inclusion

$$\mathcal{M}(B, J) + \mathcal{M}(B, K) \subset \mathcal{M}(B, J + K)$$

comes immediately from the Definition of $\mathcal{M}(B, \cdot)$. Let $T \in \mathcal{M}(B, J + K)_+$ and $\varepsilon > 0$. Since B is σ-unital, there is an approximate unit $e_0 = 0 \leq e_1 \leq e_2 \leq \cdots \leq 1$ in B with $e_n e_{n+1} = e_n$ for $n \in \mathbb{N}$, such that $\sum_n (e_{n+1} - e_n)$ and $\sum_{n \geq 0} (e_{n+1} - e_n)^{1/2} T (e_{n+1} - e_n)^{1/2}$ are strictly convergent with sums 1 and T_1 and $\|T_1 - T\| < \varepsilon$. Let $e_{-1} := 0$ and $f_n := e_{n+2} - e_{n-1}$. By part (i), there are $a_n \in J_+$ and $b_n \in K_+$ with $a_n + b_n = f_n T f_n$. Then $S_1 := \sum_{n \geq 0} (e_{n+1} - e_n)^{1/2} a_n (e_{n+1} - e_n)^{1/2}$ and $S_2 := \sum_{n \geq 0} (e_{n+1} - e_n)^{1/2} b_n (e_{n+1} - e_n)^{1/2}$ are strictly convergent, $S_1 \in \mathcal{M}(B, J)_+$, $S_2 \in \mathcal{M}(B, K)_+$, $T_1 = S_1 + S_2$. Thus, T has distance $< \varepsilon$ from $\mathcal{M}(B, J) + \mathcal{M}(B, K)$ (for each $\varepsilon > 0$). □

REMARK 12.3.14. The (algebraic) definition of $\mathcal{M}(B,J)$ immediately shows that $\bigcap_\gamma \mathcal{M}(B,J_\gamma) = \mathcal{M}(B,\bigcap_\gamma J_\gamma)$ for for every family $\{J_\gamma\} \subset \mathcal{I}(B)$, i.e., that $\mathcal{M}(B,\cdot)$ is *lower* semi-continuous.

The monotone map $\mathcal{M}(B,\cdot)$ is *not* monotone upper semi-continuous, e.g. if $B := c_0 = \mathrm{C}_0(\mathbb{N})$ and $J_n := \mathrm{C}(\{1,2,\ldots,n\})$ (respectively $B := \mathrm{C}_0(\mathbb{N},\mathcal{O}_2\otimes\mathbb{K})$ and $J_n := \mathrm{C}(\{1,2,\ldots,n\},\mathcal{O}_2\otimes\mathbb{K})$), then $B = \overline{\bigcup_n J_n}$, but $\bigcup_n \mathcal{M}(B,J_n)$ is not dense in $\mathcal{M}(B) = \mathcal{M}(B,B)$.

`Next need Def.'s of Dini function and Dini space`

LEMMA 12.3.15. *Suppose that B is separable and stable, that X is a* Dini space, *and that $\Psi\colon \mathcal{I}(B)\cong \mathbb{O}(\mathrm{Prim}(B))\to\mathbb{O}(X)$ is a lower semi-continuous action.*

Let $J\in\mathcal{I}(\mathcal{M}(B))$ and let $\Psi^*(J) :=$ the biggest open subset U of X such that, for every Dini function $g\colon X\to[0,\infty)$ on X with support in U and $\sup g(X)=1$, $a_f\in J$ for the element $a_f\in\mathcal{M}(B)_+$ of Proposition 12.3.12 for the l.s.c. function $f(J) := \sup g(X\setminus\Psi(J))$ for every Dini function $g\colon X\to[0,\infty)$ on X with support in U and $\sup g(X)=1$.

It holds

(o) *$\Psi^*\colon \mathcal{I}(\mathcal{M}(B))\to\mathbb{O}(X)$ is well-defined.*
(i) *$U\subset\Psi^*(J)$, if and only if, $\mathcal{M}(B,\Phi(V))\subset J$ for all $V << U$ and the upper s.c. adjoint Φ of Ψ.*

COROLLARY 12.3.18. *Suppose that A and B are separable C^*-algebras, A is exact and B is stable. If $\Psi\colon\mathcal{I}(B)\to\mathcal{I}(A)$ is a lower semi-continuous action of $\mathrm{Prim}(B)$ on A with $\Psi(\{0\})=\{0\}$ and $\Psi^{-1}(A)=\{B\}$, then there is a non-degenerate (norm-) nuclear C^*-morphism $H\colon A\to\mathcal{M}(B)$ with $\delta_\infty\circ H$ unitarily equivalent to H and $\Psi(J)=H^{-1}(H(A)\cap\mathcal{M}(B,J))$ for all $J\in\mathcal{I}(B)$.*

The nuclear morphism H is unique up to unitary homotopy.

PROOF. `to be filled in` ?? □

4. Proof of (old !!!) Theorem O

We conclude this chapter with the proof of the old !!!! Theorem O.

`beginning from here, old text has to be replaced` ??

The proof is fairly elementary and allows the reader to check his insight in the above developed methods for Ψ-residually nuclear maps.

We show that any C^*-algebra with primitive ideal space homeomorphic to $[0,1]$ and fibres $\cong \mathcal{O}_2$ respectively $\cong \mathcal{O}_2 \otimes \mathbb{K}$ are isomorphic to $\mathrm{C}([0,1], \mathcal{O}_2)$ respectively to $\mathrm{C}([0,1], \mathcal{O}_2 \otimes \mathbb{K})$.

??

`Next there is only a proof of the old Theorem O`

Suppose that A is a unital separable C^*-algebra with $\mathrm{Prim}(A) \cong [0,1]$, the interval $[0,1]$ with ordinary topology, and that the fibers, i.e. the simple quotients, are isomorphic to $\mathcal{O}_2$. Thus, A is as a C^*-algebra bundle with base space $[0,1]$ and fibers isomorphic to $\mathcal{O}_2$. This implies that A nuclear and is strongly p.i., cf. ends of Chapters 2 and 3. The K-theory of A is trivial, see below.

For nuclear C^*-algebra bundles A, B over a locally compact σ-compact metrizable spaces X, we have that $\mathrm{KK}_{\mathrm{nuc}}(X; A, B) = \mathcal{R}\,\mathrm{KK}^{trivial}(X; A, B)$. By Corollary N, the bundle is stably isomorphic to $\mathrm{C}([0,1], \mathcal{O}_2)$ if and only if $\mathcal{R}\,\mathrm{KK}^{trivial}([0,1], A, A) = 0$.

This allows to use the tautological epimorphism and the six-term exact sequence to check

`the ''following proposition'', that has been erased,`

which reduces the triviality question to the ordinary KK-theory.

We show the non-trivial direction of the statement of the old version of Theorem O, i.e., that A *is isomorphic to* $\mathrm{C}([0,1], \mathcal{O}_2)$*, if* A *is a separable unital* C^**-algebra with* $\mathrm{Prim}(A) \cong [0,1]$*, if every primitive quotient of* A *is isomorphic to* $\mathcal{O}_2$*, and if* A *satisfies the UCT for the ordinary* KK*-theory of* C^**-algebras.*

All non-zero projections in $\mathrm{C}([0,1], \mathcal{O}_2 \otimes \mathbb{K})$ are equivalent. Therefore, it suffices to show that $A \otimes \mathbb{K}$ and $\mathrm{C}([0,1], \mathcal{O}_2 \otimes \mathbb{K})$ are isomorphic.

Every primitive quotient of A is nuclear. Since A is separable, this implies that every factor representation of A generates an injective factor. Thus, A is a nuclear C^*-algebra.

By Corollary L, $A \otimes \mathcal{O}_2 \cong \mathrm{C}([0,1], \mathcal{O}_2)$ with an isomorphism that implements the isomorphism χ from $[0,1]$ onto $\mathrm{Prim}(A)$.

The isomorphism and the natural embedding of $A \otimes 1$ into $A \otimes \mathcal{O}_2$ maps $\chi(t)$ onto the intersection of $A \otimes 1$ with the kernel of the epimorphism $g \mapsto g(t)$ from

$C([0,1],\mathcal{O}_2)$ onto $\mathcal{O}_2$, and it maps the center of A onto $C([0,1])$. This gives a unital isomorphism λ from $C([0,1])$ onto the center of A such that

$$\chi(t) = \lambda(C_0([0,1]\setminus\{t\}))A \quad \text{and} \quad \pi_t(\lambda(f)a) = f(t)\pi_t(a).$$

Thus A is a (continuous) C^*-bundle with quotient maps $\pi_t\colon A \to A/\chi(t)$ in the sense of [**92**], [**471**]. Since $[0,1]$ has dimension one, and since the fibers $A/\chi(t)$ are simple and purely infinite, by Remarks 2.15.12 and 3.11.6(ii), the algebra A is strongly purely infinite, cf. [**93**]. (The latter can be seen also directly and elementary with a modification of the idea in step one, below.)

It follows that Theorem M applies to A:

$A\otimes\mathbb{K}$ is isomorphic to $C([0,1],\mathcal{O}_2\otimes\mathbb{K})$, if and only if, $KK([0,1];A,A)=0$.

We show the equation $KK([0,1];A,A)=0$ in the following five steps.

Let $A|X$ denote the *restriction of the bundle A to X*: Let Ψ denote the action of $[0,1]$ on A, which is defined by a homeomorphism χ from $[0,1]$ onto $\mathrm{Prim}(A)$. Then $\Psi(Z)=\lambda(C_0(Z))A$ for open subsets Z of $[0,1]$ and the primitive ideal $\chi(t)$ is the ideal $\Psi([0,1]\setminus\{t\})$. If X is a relatively closed subset of an open subset Z of $[0,1]$, we define $A|X$ as $\Psi(Z)/\Psi(Z\setminus X)$. Then $\pi_t\colon A\to A|\{t\}$ is the natural epimorphism on the fiber at t. Let $0<x<y\le 1$, then the natural epimorphisms $A|[0,y]\to A|[0,x]$ and $A|[0,y]\to A|[x,y]$ define just the pull back of the natural epimorphisms $A|[0,x]\to A|\{x\}$ and $A|[x,y]\to A|\{x\}$, i.e., we can compose elements of $A|[0,x]$ and $A|[x,y]$ to an element of $A|[0,y]$ if they coincide at x.

First, A contains a copy of $\mathcal{O}_2$ unitally:

Since $A|\{x_0\}$ is isomorphic to $\mathcal{O}_2$ there exist contractions a and b in A such that $a^*b=0$ and that the continuous functions $x\mapsto\|\pi_x(c)\|$ are zero at $x=x_0$ for c in $G:=\{1-a^*a, 1-b^*b, 1-aa^*-bb^*\}$.

It follows that there exists $\delta>0$ such that $\|\pi_Y(c)\|<1/8$ for $c\in G$, where $Y:=[\max(0,x_0-\delta),\min(x_0+\delta,1)]$ and π_Y denotes the natural epimorphism from A onto $A|Y$. Then $s:=\pi_Y(a)\pi_Y(a^*a)^{-1/2}$ and $t:=\pi_Y(b)\pi_Y(b^*b)^{-1/2}$ are canonical generators of a unital copy of $\mathcal{O}_2$ in $A|Y$.

We find $x_0=0<x_1<\ldots<x_n=1$ such that $A|[x_j,x_{j+1}]$ contains isometries s_j and t_j with $s_js_j^*+t_jt_j^*=1$ for $j=0,\ldots,n-1$, because $[0,1]$ is compact.

We modify them by induction, fit them together and get a unital copy of $\mathcal{O}_2$ in A:

Suppose that $k<n$ and that s,t are canonical generators of $\mathcal{O}_2$ in $A|[0,x_k]$. Let π_+ and π_- denote the natural epimorphisms $A|[0,x_k]\to A|\{x_k\}$ and $A|[x_k,x_{k+1}]\to A|\{x_k\}$ respectively.

Then $u:=\pi_+(s)\pi_-(s_k^*)+\pi_+(t)\pi_-(t_k^*)$ is a unitary in $A|\{x_k\}\cong\mathcal{O}_2$. Since the unitary group of $\mathcal{O}_2$ is connected, we find a unitary v in $A|[x_k,x_{k+1}]$ such that $\pi_-(v)=u$. Let $\tilde{s}:=vs_k$ and $\tilde{t}:=vt_k$. Then $\pi_-(\tilde{s})=\pi_+(s)$ and $\pi_-(\tilde{t})=\pi_+(t)$.

Thus there are S, T in $A|[0, x_{k+1}]$ with restrictions to $[0, x_k]$ and $[x_k, x_{k+1}]$ equal to s, t and $\tilde{s}, \tilde{t}$ respectively. Thus $S^*S = 1 = T^*T$ and $SS^* + TT^* = 1$.

Second, $\mathrm{K}_0(A) = 0$: Since A contains copy of $\mathcal{O}_2$ unitally, it suffices to show that, for every non-zero projection p in A, pAp contains a copy of $\mathcal{O}_2$ unitally. $t \in [0,1] \mapsto \|\pi_t(p)\|$ is continuous, non-zero and takes 1 or 0 as its values. Thus this function is one on $[0,1]$, and, therefore, $\mathrm{Prim}(pAp) = \mathrm{Prim}(A) = [0,1]$, and the primitive quotients are isomorphic to $\mathcal{O}_2$. The first step shows that the unital algebra pAp contains a copy of $\mathcal{O}_2$ unitally.

Third, $\mathrm{K}_1(A) = 0$: Let $B := A \otimes P_\infty$, where P_∞ is the unique unital pi-sun algebra in the UCT-class with $K_0(P_\infty) = 0$ and $K_1(P_\infty) = \mathbb{Z}$, cf. Corollary H(ii). Then $\mathrm{K}_1(A) = \mathrm{K}_0(B)$ by Künneth theorem. But $\mathrm{Prim}(B) = [0,1]$ and every simple quotient of B is isomorphic to $\mathcal{O}_2 \cong \mathcal{O}_2 \otimes P_\infty$. Thus from the second step we see that $\mathrm{K}_0(B) = 0$.

Fourth, separable A with $\mathrm{K}_*(A) = 0$ satisfies the UCT if and only if $\mathrm{KK}(A, B) = 0$ for all separable C^*-algebras B.

The six term exact sequence implies that $\mathrm{KK}(A|I, A|I) = 0$ for every half-open interval $I = [0, t)$ or $I = (t, 0]$, because there is a natural semi-split short exact sequence

$$0 \to A|[0,t) \oplus A|(t,1] \to A \to \mathcal{O}_2 \to 0,$$

and KK is additive in each variable with respect to direct sums. It follows that $\mathrm{KK}(A|I, A|I) = 0$ for every closed subinterval $I = [s,t] \subset [0,1]$ of $[0,1]$, because $A|I = A/(A|[0,s) + A|(t,1])$. For open or half-open subintervals I of $[0,1]$ we have short exact sequences $0 \to A|I \to A|K \to B \to 0$ where K is the closure of I and B is $\mathcal{O}_2$ or $\mathcal{O}_2 \oplus \mathcal{O}_2$.

Fifth: To calculate $\mathrm{KK}([0,1]; A, A)$, we use the six-term exact sequence with respect to the second variable and the following $\mathrm{C}([0,1])$-equivariant semi-split short exact sequence:

$$0 \to J \to \mathrm{C}([0,1]) \otimes A \to A \to 0,$$

where the action on $\mathrm{C}([0,1]) \otimes A$ is induced by

$$d\colon f \in \mathrm{C}([0,1]) \mapsto f \otimes 1 \in \mathrm{C}([0,1]) \otimes A$$

and the map $\mathrm{C}([0,1]) \otimes A \to A$ is the tautological epimorphism given by

$$f \otimes a \in \mathrm{C}([0,1]) \otimes A \mapsto fa \in A\,.$$

The Ψ-equivariant semi-splitness of the exact sequence can be seen as follows: Tensor with $\mathcal{O}_2$, use that $A \otimes \mathcal{O}_2 \cong \mathrm{C}([0,1], \mathcal{O}_2)$, take the obvious lift and cut it down to A and $\mathrm{C}([0,1], A)$ with help of a state on $\mathcal{O}_2$.

J is the closed sum of ideals $\mathrm{C}_0(K) \otimes A|I$ with certain open subintervals K and I of $[0,1]$, cf. Proposition B.4.2(ii).

We consider now the action of $[0,1]$ on $\mathrm{C}_0(K) \otimes A|I$ which is induced by d.

For open or closed sub-intervals I and K of $[0,1]$,

$$\mathrm{KK}([0,1]; \mathrm{C}_0(K) \otimes A|I, \mathrm{C}_0(K) \otimes A|I) = 0,$$

because $A|I$ is KK-equivalent to $\mathcal{O}_2$ and we can tensor the identity map of $\mathrm{C}_0(K)$ with this KK-equivalence to obtain a $\mathrm{KK}([0,1]; .,.)$-equivalence of $\mathrm{C}_0(K) \otimes A|I$ and $\mathrm{C}_0(K) \otimes \mathcal{O}_2$.

The Mayer-Vietoris sequence gives that also $\mathrm{KK}([0,1]; B, C) = 0$ if $B \subset J$ and B is finite sum of ideals $\mathrm{C}_0(K) \otimes A|I$ of $\mathrm{C}([0,1]) \otimes A$.

$\mathrm{KK}([0,1]; .,.)$ is in the first variable continuous with respect to Ψ-equivariant monomorphic inductive limits of nuclear C^*-algebras J_n which are $\mathrm{KK}([0,1]; .,.)$-equivalent to $\mathrm{C}([0,1], \mathcal{O}_2)$. It follows $\mathrm{KK}([0,1]; J, \cdot) = 0$, because the corresponding Milnor $\lim^{(1)}$-sequence vanishes.

Since also $\mathrm{KK}([0,1]; \mathrm{C}([0,1]) \otimes A, \mathrm{C}([0,1]) \otimes A) = 0$, the six term exact sequence shows that $\mathrm{KK}([0,1]; A, A) = 0$.

$\mathcal{U}_0(\mathcal{E}(M_m, M_n))$ of 1 in the unitaries of it?

1. (*) The algebras $\mathcal{O}_n$, $\mathcal{E}_n$ and $\mathcal{O}_\infty$

We outline an approach to get the used basic facts on $\mathcal{E}_n$ and $\mathcal{O}_n$, $n \in \{2, 3, \ldots, \infty\}$. All is based on elementary observations (or can be replaced by such observation in our particular cases). We work with formal algebras generated by relations, because it allows to see what carries over to general non-commutative rings... and what does not so ... E.g. the existence of suitable very important C^*-subalgebras in the central sequence algebra requires the analytic theory of some rather special types of operator algebras, defined by their defining relations.

(1) ***C*-algebras defined by relations*** .
Let A denote an algebraic *-algebra over $\mathbb{C}$ (or likewise over $\mathbb{R}$) that has finitely, countable or uncountably many generators $a_1, a_2, \ldots$ and defining relations $R_1, R_2, \ldots$ that are given explicitly by non-commutative polynomials $P_n(a_1, \ldots, a_n, a_1^*, \ldots, a_n^*)$ with coefficients in $\mathbb{C}$ (or $\mathbb{R}$ in case of real C^*-algebras) and the relation are given by requiring the equations $P_n = 0$, A is the quotient of the free *-algebra by the ideal generated by the polynomials P_n. Sometimes the relations are written more efficient as matrix conditions and then the P_n are matrix polynomials. But this can be described also by ordinary n.c. polynomials by writing the conditions for the entries separately.

If we require bounds, e.g. that certain expressions $P(a_1, \ldots, a_n^*)$ should become a contractions in any representation then we can do this by introducing new elements, say x, y, and then $Q_1(a_1, \ldots, a_n^*, x) := P(a_1, \ldots, a_n^*) - x$ and $Q_2(x, x^*, y, y^*) = 1 - x^*x - y^*y$, but consider $C^*(a_1, \ldots, a_n; R)$ with system of relations R containing P as a C^*-subalgebra of the unital C^*-algebra $C^*(a_1, \ldots, a_n, x, y, 1; R \cup \{Q_1, Q_2\})$. We go here not into details, because we use only very special types of relations that are easily to understand and are usually "bounded" in the following sense:

The algebraic *-algebra A is called "**bounded**" if, for each generator a_n, there exist $c_1, \cdots, c_m \in \widetilde{A} := A + \mathbb{C}1$, $0 \leq \gamma_n < \infty$ such that $a_n^* a_n + c_1^* c_1 + \cdots + c_m^* c_m = \gamma_n^2 1$. If A is bounded then every *-representation d of A on a pre-Hilbert space $\mathcal{H}$ is bounded in the sense that $\|d(a_n)\| \leq \gamma_n$ for all generating elements. (Compare [**426**, lem. 5.3(iii)] that was inspired by ideas of T. Tannaka [**768**] and its abstract version introduced for the study of block-algebras of M.G. Krein [**493**]). (Today: dual of compact "quantum groups"?)

In particular, the supremum $\|a\| := \sup_{\{d\}} \|d(a)\|$ of all C^*-semi-norms on A exists and is finite for *all* elements on A. The set $J_0 := \{a \in A\,;\, \|a\| = 0\}$ is a

*-ideal of A, and the C^*-completion of A/J_0 with respect to the induced (maximal) C^*-norm is a C^*-algebra, that we denote by $C^*(a_1, a_2, \ldots ; R_1, R_2, \ldots)$.

One can check that the *below considered*(!) special examples A all have the property that $J_0 = \{0\}$ (exercises for the reader). – But in more general cases and other types of relations it can happen that $J_0 \neq \{0\}$. –

To make this definitions more flexible, one can here the "scalar coefficients" replace by elements in some other ring/algebra.

(2) **On the defining relations for $\mathcal{E}_n$ and $\mathcal{O}_{\mathrm{n}}$**

One can easily show – on a fairly algebraic level – that the *universal* C^*-algebras

$$\mathcal{O}_{\mathrm{n}} := C^*(s_1, \ldots, s_n \,;\; s_j^* s_j = 1 = s_1 s_1^* + \cdots + s_n s_n^*)$$

with $n > 1$ is "naturally" isomorphic to the *universal* unital C^*-algebra

$$C^*(B_n \cup \{S\} \,;\; S^*S = 1 \in B_n,\, SaS^* = e_{1,1} \otimes a,\, a \in B_n) \tag{1.1}$$

that contains $B_n := M_{n^\infty}$.

Notice that this formula is only a formal "reminder" if we hold up our restricted view that we, if possible, are willing to describe the basic model algebras as quotients of "free" algebras by ideals generated by "relations" (as above described in an informal manner), then B_n or a suitable dense *-subalgebra itself has to be described as quotient of free *-algebra. It means here that we first have to define B_n as the competition of the inductive limit of $A_{k,n} := M_{n^k}$ with $a \in A_{k,n} \mapsto A_{k+1,n}$ given by $a \mapsto a \otimes 1_n$ and S is an "additional variable" that satisfies the relation polynomials $P_1(S) := S^*S - 1 = 0$ with $1 = \mathrm{indlim}_{k\to\infty} 1_{n^k}$, and $S(a_n \otimes 1_n)S^* = e_{11} \otimes a_n \in A_{k+1,n}$ for all $a_n \in A_{k,n}$. It looks childish, but careful consistence would require a detailed list of generators and how the generators of one algebra can be expressed by the generators of the other algebra and vice versa. All this should be done on the algebraic level. With other words: to compare this relation-defined algebras we should her replace – for calculation with (countably many) relations on the pure algebraic level – the algebra B_n by its algebraic inductive limit of the sequence $M_{n^k} \to M_{n^{k+1}}$ given by the maps $a \mapsto a \otimes (e_{11} + \cdot + e_{nn}) = a \otimes 1_n$ and the proceed as e.g. in [**686**, proof thm. 4.2.2] or in proof of [**169**, thm. 1.13]. The isomorphism of $\mathcal{O}_{\mathrm{n}}$ with the corner cross-product in Equation (1.1) becomes true for the C^*-algebras *after completion* with the maximal C^*-norm on them. In more detail it goes as follows:

Let $I_k := \{1, \ldots, n\}^k$ and define

$$W(i_1, \ldots, i_k) := W_p := s_{i_1} \cdot \ldots \cdot s_{i_k}$$

for the "word" $p := (i_1, \ldots, i_k) \in I_k$. Then the linear span of the elements 1, W_p, $(W_p)^*$ and $W_p(W_q)^*$ $(p \in I_k,\, q \in I_\ell)$ is a dense *-subalgebra of $\mathcal{O}_{\mathrm{n}}$. Take $S := s_1$ and identify M_{n^k} with the linear span of the elements $W_p W_q^*$, $p, q \in I_k$ $(k = 1, 2, \ldots)$.

It shows that $\mathcal{O}_{\mathrm{n}} \cong B_n \rtimes_\psi \mathbb{N}$ for the corner endomorphism $\psi\colon B_n \ni a \mapsto e_{1,1} \otimes a \in B_n$. This algebra is stably isomorphic to the crossed product of a trace-scaling automorphism α of $B_n \otimes \mathbb{K}$. Trace-scaling automorphisms α of simple C^*-algebras have always the property that α^k is strictly outer for $k \in \mathbb{N}$, and therefore, $(B_n \otimes \mathbb{K}) \rtimes_\alpha \mathbb{Z}$ is simple (use here the more general results of Kishimoto [**478**] or of Olesen and Pedersen [**578**]). Crossed products of nuclear C^*-algebras by Abelian groups are always nuclear ????? give citation ?????????? (more generally crossed products of nuclear C^*-algebras by amenable groups are nuclear).

Missing citation/reference to place?

A proof would be:

Let G locally compact group, that acts point-norm continuous ([1]) on a C^*-algebra A by $\rho\colon G \to \mathrm{Aut}(A)$, and let B any C^*-algebra. There are natural isomorphisms of full crossed products

$$C^*(G, A; \rho) \otimes^{\max} B \cong C^*(G, A \otimes^{\max} B; \rho(\cdot) \otimes^{\max} \mathrm{id}_B)$$

and of reduced crossed products

$$C^*_{red}(G, A;\, \rho) \otimes^{\min} B \cong C^*_{red}(G, A \otimes^{\min} B;\, \rho(\cdot) \otimes^{\min} \mathrm{id}_B)$$

and an obvious canonical epimorphism from the first to the second that is compatible with the canonical epimorphism $(\cdot) \otimes^{\max} B \to (\cdot) \otimes^{\min} B$.

Thus, if A nuclear and G amenable, then $C^*(G, A, \rho) = C^*_{red}(G, A, \rho)$ is again nuclear.

`Here is what we need:`

But in our case we use the following general observation:

Suppose that G is a *compact* group that acts point-norm continuous on a C^*-algebra A and that the fix-point algebra $A^{\rho(G)}$ of the action ρ of G on A is nuclear. Then A nuclear.

Indeed: The kernel J of $A \otimes^{\max} B \to A \otimes^{\min} B$ is $\rho(g) \otimes^{\max}$ id-invariant. And the integral over G defines a faithful conditional expectation from J to the kernel of $A^{\rho(G)} \otimes^{\max} B \to A^{\rho(G)} \otimes^{\min} B$ that is trivial by nuclearity of $A^{\rho(G)}$. Thus, $J = \{0\}$ and A must be nuclear.

We have used here the following variant of the Definition of Nuclearity of C*-algebras (compare cite :
Choi–Effros , [**141**], [**142**], Nuclear C*-algebras and injectivity: the general case. (Shows: A is nuclear , if and only if, A^{**} is an injective W*-algebra.) [**145**]

A C^*-algebra A is nuclear, if and only if, the natural *-epimorphisms $A \otimes^{\max} B \to A \otimes^{\min} B$ are faithful (= are isomorphisms) for every C^*-algebra B.

In fact, it suffices to take here as B the algebras $C^*(F_\infty)$, $\mathcal{L}(\ell_2)$ and $\mathcal{L}(\ell_2)/\mathbb{K}(\ell_2)$. (¡ – is this from Kirchberg, E. [**426**], or from one of the upper citations?)

[1] Means that $g \in G \mapsto \rho(g)(a)$ is a continuous map from G into A for each $a \in A$

It follows that $\mathcal{O}_n$ is *simple and nuclear.* By definition, $\mathcal{O}_n$ ($2 \leq n < \infty$) is finitely generated and $\mathcal{O}_\infty$ is countably generated, in particular they all are *separable.*

`We have this ‘‘exercise in footnote’’ carried out somewhere! Find and Cite the place of it!!`

([2]).

The simplicity of the corner-endomorphism crossed product $B_n \rtimes_\psi \mathbb{N}$ and the property that
for each $a, b \in (B_n)_+$ with $\|b\| = 1 \geq \|a\|$ and for each $\varepsilon > 0$ there are $k \in \mathbb{N}$ and a contraction $d \in B_n$ with $\|\psi^k(a) - d^*bd\| < \varepsilon$
imply that $B_n \rtimes_\psi \mathbb{N}$ is purely infinite (cf. Corollary 2.18.3). Hence, $\mathcal{O}_n$ *is a pi-sun algebra in the UCT-class.*

(Urgent Question:
Where it is shown that the $\mathcal{O}_n$ are in the UCT-class, and what has to be shown to recognize the "pi-sun" algebras are in the UCT-class? For the $\mathcal{O}_n$ one has "only" to show first that all AF-algebras are in the UCT-class, and what imply the products of UCT-class algebras by circle actions, action by an endomorphism or automorphisms.)

The above mentioned property can be seen directly by the following argument of J. Cuntz:
Let $b \in B_n \subseteq \mathcal{O}_n$ with $b \geq 0$ and $\|b\| = 1$. Then we find $k \in \mathbb{N}$ and $c \in (M_{n^k})_+$ with $\|b - c \otimes 1\| < \varepsilon$ and $\|c\| = 1$. Since the k-fold tensor product e_k of $e_{1,1} \in M_n$ is a minimal idempotent in M_{n^k} there is a unitary $u \in M_{n^k}$ with $e_k u^* c u e_k = e_k$. Let $d := (u \otimes 1)\psi^k(a^{1/2})$, then $\|d\| \leq 1$ and $d^*(c \otimes 1)d = \psi^k(a)$. Thus $\|d^*bd - \psi^k(a)\| < \varepsilon$.

The Pimsner–Voiculescu exact sequence for crossed products (more precisely: its variant for crossed products by $\mathbb{N}$, [**636**]) gives "immediately" the exact sequence

$$0 \to \mathrm{K}_1(\mathcal{O}_n) \to \mathbb{Z}[\frac{1}{n}] \overset{\times(n-1)}{\longrightarrow} \mathbb{Z}[\frac{1}{n}] \to \mathrm{K}_0(\mathcal{O}_n) \to 0\,,$$

?? to be checked again !!!

where $1 \in \mathbb{Z}[\frac{1}{n}]$ maps to $[1] \in \mathrm{K}_0(\mathcal{O}_n)$. It shows that $\mathrm{K}_1(\mathcal{O}_n) = 0$ and $\mathrm{K}_0(\mathcal{O}_n) \cong \mathbb{Z}_{n-1}$ (in a way that the class of $[1]$ generates $\mathbb{Z}_{n-1}$). In particular, $\mathcal{O}_2$ is K_*-trivial.

(3) **The non-simple algebras $\mathcal{E}_n$.**

We consider the (non-simple) universal C^*-algebras

$$\mathcal{E}_n := C^*(s_1, \ldots, s_n\,;\; s_i^* s_j = \delta_{i,j} 1)\,,$$

and its (simple) natural inductive limit

$$\mathcal{O}_\infty := C^*(s_1, s_2, \ldots\,;\; s_i^* s_j = \delta_{i,j} 1)\,.$$

[2] In fact, it is easy to see (as an exercise for the readers?) that every separable C^*-algebra A with properly infinite multiplier algebra $\mathcal{M}(A)$, i.e., with $1_{\mathcal{M}(A)} \in \mathcal{E}_2 \subseteq \mathcal{M}(A)$, is single generated. This applies to all separable pi-sun algebras, in particular to $\mathcal{E}_n$, $\mathcal{O}_n$ and $\mathcal{O}_\infty$.

It turns out ([3]), that $e := e_n := 1 - (s_1 s_1^* + \cdots + s_n s_n^*)$

The element e_n is called ''p'' on some other places.

is a non-zero projection in $\mathcal{E}_n$ with $e\mathcal{E}_n e = \mathbb{C}e$, that the closed ideal $I(e)$ (generated by e) is naturally isomorphic to $\mathbb{K}$, and that the left multiplication of $\mathcal{E}_n$ on $I(e)$ is faithful (as one can see with help of the gauge action $z \in S^1 \mapsto \sigma_z \in \mathrm{Aut}(\mathcal{E}_n)$ with $\sigma_z(s_n) = zs_n$ that fixes e).

Indeed:
$X \cdot \mathcal{E}_n \cdot e = \{0\}$ implies $X^*X \cdot \mathcal{E}_n \cdot e = \{0\}$. Since $\sigma_z(\mathcal{E}_n \cdot e) = \mathcal{E}_n \cdot e$ for all $z \in S^1$, we get also $\sigma_z(X^*X) \cdot \mathcal{E}_n \cdot e = \{0\}$ for all $z \in S^1$. Thus $P(X^*X) \cdot \mathcal{E}_n \cdot e = \{0\}$. Here $P(a) := \int_{S^1} \sigma_z(a)dz$ for $a \in \mathcal{E}_n$.

It is not difficult to see: The fix-point algebra of any (continuous) circle action on the compact operators $\mathbb{K}$ of a separable Hilbert space has a non-degenerate fix-point C^*-subalgebra of $\mathbb{K}$. (Because $p \in \overline{P(p) \cdot \mathbb{K} \cdot P(p)}$ for all continuous circle actions $\sigma(z)$ on $\mathbb{K}$.)

It follows that $P(\mathcal{E}_n)$ acts faithful on the ideal $I(e)$ by left-multiplication if and only if $P(\mathcal{E}_n)$ acts faithful on $I(e) \cap P(\mathcal{E}_n)$.

It is not difficult to see that the fix-point algebra $P(\mathcal{E}_n)$ of the circle action on $\mathcal{E}_n$ is an AF-algebra that contains p. If $P(\mathcal{E}_n)$ acts not faithful on $I(e)$ then there must exist a non-zero projection in the kernel of this action.

Such a projection must be equivalent to a projection in the canonical filtration of $P(\mathcal{E}_n)$ by finite AF-algebras and each “smaller” projection is also on the kernel. It causes that for some $W := s_{k_1} \cdot \ldots \cdot s_{k_m}$ holds $WW^* \cdot I(e) = \{0\}$, in particular $WW^*(We) = 0$. But this is impossible, because W is an isometry, i.e., $W^*W = 1$ and $W^*(We) = e$.

Thus, $P(\mathcal{E}_n)$ acts faithful on $\mathcal{E}_n \cdot e$ and on $I(e)$. By above considerations it implies that $P(X^*X) = 0$ if $X\mathcal{E}_n \cdot e = \{0\}$. Since P is a faithful conditional expectation (for any continuous circle action) it follows that $X = 0$ if $X \in \mathcal{E}_n$ and $X \cdot \mathcal{E}_n \cdot e = \{0\}$. Thus, $I(e)$ is a non-degenerate ideal of $\mathcal{E}_n$, i.e., there exists no ideal orthogonal to $I(e)$.

(This arguments show that every $\sigma(z)$-invariant non-zero ideal of $\mathcal{E}_n$ has non-zero intersection with $P(\mathcal{E}_n)$.)

Therefore, $I(e)$ is an *essential* ideal of $\mathcal{E}_n$.

Clearly, the quotient $\mathcal{E}_n/I(e)$ is naturally isomorphic to the – simple – C^*-algebra $\mathcal{O}_{\mathrm{n}}$.

(This way of arguments requires to prove *before !!!* the simplicity of $\mathcal{O}_{\mathrm{n}}$, to obtain above conclusion.)

[3]Use that $\mathcal{E}_n$ is the span of elements $W_r W_s^*$ of words, where W_r and W_s are $= 1$ or are products of some of the generators $s_1, \ldots, s_n$.

Above we have seen, that there is a short-exact sequence

$$0 \to \mathbb{K} \to \mathcal{E}_n \to \mathcal{O}_{\rm n} \to 0\,.$$

In particular, $\mathcal{E}_n$ must be nuclear (if $\mathcal{O}_{\rm n}$ is proven to be nuclear). The corresponding six-term exact sequence in K_*-theory shows that (necessarily) $\mathrm{K}_1(\mathcal{E}_n) = 0$ and that there is an exact sequence

$$0 \to \mathbb{Z} \to \mathrm{K}_0(\mathcal{E}_n) \to \mathbb{Z}_{n-1} \to 0\,,$$

such that the class $[1] \in \mathrm{K}_0(\mathcal{E}_n)$ is mapped onto the $1 \in \mathbb{Z}_{n-1}$ and $1 \in \mathbb{Z}$ is mapped into $[e] \in \mathrm{K}_0(\mathcal{E}_n)$. The definition of e shows that $[e] = (n-1)[1]$ in $\mathrm{K}_0(\mathcal{E}_n)$.

The only remaining possibility is now $\mathrm{K}_0(\mathcal{E}_n) \cong \mathbb{Z}$ with generator $[1]$ of $\mathbb{Z}$.

One can see now (e.g. from $[e] = (n-1)[1]$) that the extension $\mathcal{E}_n$ of $\mathcal{O}_{\rm n}$ by $\mathbb{K}$ is not a split extension.

One can show also directly that the natural C^*-morphisms $\mathcal{E}_{n-1} \to \mathcal{E}_n \to \mathcal{O}_{\rm n}$ for $n \geq 2$ define a faithful embedding from $\mathcal{E}_{n-1}$ into $\mathcal{O}_{\rm n}$, – and therefore also a faithful embedding from $\mathcal{E}_{n-1}$ into $\mathcal{E}_n$ that does not intersect the closed ideal of $\mathcal{E}_n$ generated by $e_n := 1 - \sum_{k=1}^{n} s_k s_k^*$.

Indeed: Let $\rho\colon \mathcal{E}_{n-1} \to \mathcal{L}(\mathcal{H})$ a faithful unital *-representation of $\mathcal{E}_{n-1}$. We can here take a separable Hilbert space $\mathcal{H}$, because $\mathcal{E}_{n-1}$ is separable. The $\mathcal{H}$ has infinite dimension because $\mathcal{L}(\mathcal{H})$ contains a non-unitary isometry. Thus $\mathcal{H} \cong \ell_2(\mathbb{N})$. If we let $L := \rho(e_{n-1})\mathcal{H}$, then there exists an isometry $T \in \mathcal{L}(\mathcal{H} \otimes_2 \mathcal{H})$ with $TT^* = \rho(e_{n-1}) \otimes \mathrm{id}_{\mathcal{H}}$. The isometries $t_k := \rho(s_k) \otimes \mathrm{id}_{\mathcal{H}}$ for $k = 1, \ldots, n-1$ and $t_n := T$ satisfy the relation $\sum_{k=1}^{n} t_k t_k^* = 1$. Thus $C^*(t_1, \ldots, t_n)$ is a natural image of $\mathcal{O}_{\rm n}$ and the C^*-representation $a \mapsto \rho(a) \otimes \mathrm{id}_{\mathcal{H}}$ is a faithful unital C^*-morphism from $\mathcal{E}_{n-1}$ into $C^*(t_1, \ldots, t_n)$ that factorizes through the canonical unital C^*-morphisms $\mathcal{E}_{n-1} \to \mathcal{E}_n \to \mathcal{O}_{\rm n} \to C^*(t_1, \ldots, t_n)$. It shows that the natural unital C^*-morphism $\mathcal{E}_{n-1} \to \mathcal{E}_n$ is injective and does not intersect the ideal of $\mathcal{E}_n$ generated by e_n.

It follows that the natural unital *-morphisms from $\mathcal{E}_n$ into $\mathcal{O}_\infty$ are injective (because they factorize over the natural C^*-morphism $\mathcal{E}_n \to \mathcal{E}_{n+1}$, and that is injective) and that, therefore, $\mathrm{K}_*(\mathcal{O}_\infty) = \mathrm{indlim}_n\, \mathrm{K}_*(\mathcal{E}_n)$ by continuity of $\mathrm{K}_*(\cdot)$ with respect to inductive limits ...

(Unfortunately, it is bit more complicate ...!!!)

We get that $\mathcal{O}_\infty$ is separable, unital and nuclear, that $\mathrm{K}_0(\mathcal{O}_\infty) \cong \mathbb{Z}$ with generator $[1] \in \mathrm{K}_0(\mathcal{O}_\infty)$ and that $\mathrm{K}_1(\mathcal{O}_\infty) = 0$. The unital C^*-morphisms $\eta_n\colon \mathcal{E}_n \to \mathcal{E}_{n+1}$ satisfy the sufficient criteria in part (iv) of Proposition 2.2.5, because $I(e) \cong \mathbb{K}$ is an essential ideal.

Indeed: It implies that, for each $a \in (\mathcal{E}_n)_+$ with $\|a\| = 1$, there is a contraction $c \in I(e)$ with $\|c^* a c - e\| < \varepsilon$, thus $\|d^* \eta_n(a) d - 1\| < \varepsilon$ for $d := \eta_n(c) s_{n+1}$.

Thus $\mathcal{O}_\infty$ is simple and *purely infinite* by Proposition 2.2.5(iv), i.e., if we all above put together the we see that $\mathcal{O}_\infty$ is a (simple) pi-sun algebra with

$\mathrm{K}_0(\mathcal{O}_\infty) \cong \mathbb{Z}$ with generator [1] and $\mathrm{K}_1(\mathcal{O}_\infty) = \{0\}$. The pure infiniteness implies that $\mathrm{K}_1(\mathcal{O}_\infty) = 0$ is equivalent to $\mathcal{U}_0(\mathcal{O}_\infty) = \mathcal{U}(\mathcal{O}_\infty)$.

(4) δ_n **is homotopic to** id **in** $\mathrm{End}(\mathcal{O}_\mathrm{n})$

δ_2 is unitarily homotopic to id in the space of unital *-endomorphism of $\mathcal{O}_2$ (with point-norm topology).

Indeed: Notice that $X := \{s^2, st, ts, t^2\}$ are four isometries with range sum $= 1$ (X defines a unital embedding of $\mathcal{O}_4$ into $\mathcal{O}_2$). Thus $B := \mathrm{span}\{ab^*\,;\ a, b \in X\}$ is naturally isomorphic to M_4. Let $u_1 := \delta_2(s)s^* + \delta_2(t)t^* = s^2(s^*)^2 + ts(st)^* + st(ts)^* + t^2(t^*)^2$. Then u_1 is a selfadjoint unitary in B, $\delta_2(s) = u_1 s$ and $\delta_2(t) = u_1 t$. It follows that there is a (norm-)continuous path $[0, 1] \ni \tau \mapsto u(\tau) \in \mathcal{U}(B)$ with $u(0) = 1$ and $u(1) = u_1$. The unital endomorphisms h_τ of $\mathcal{O}_2$ with $h_\tau(s) = u(\tau)s$ and $h_\tau(t) = u(\tau)t$ define a point-norm continuous path in the unital endomorphisms of $\mathcal{O}_2$ with $h_0 = \mathrm{id}$ and $h_1 = \delta_2$.

Similarly, one can see that δ_n *is homotopic to* id *in the unital *-endomorphisms of* $\mathcal{O}_\mathrm{n}$ *for* $3 \le n < \infty$*,* by showing that

$$u_1 := \sum_{k=1}^{n} \delta_n(s_k)s_k^* = \sum_{k,\ell=1}^{n} s_k s_\ell (s_\ell s_k)^*$$

is a selfadjoint unitary in the natural image of $M_{n^2}(\mathcal{Z})$ spanned by

$$\{s_k s_\ell s_j^* s_i^*\,;\ k, \ell, j, i \in \{1, \dots n\}\}\ .$$

(5) **The unitary groups are contractible** $\mathcal{U}(\mathcal{O}_\mathrm{n}) = \mathcal{U}_0(\mathcal{O}_\mathrm{n})$

For the case of the *real* C^*-algebras generated by $s_1, \dots, s_n$, one can consider the unitary $u := \sum_{k=1}^{n} \delta_n(s_k)s_k^*$ in the bigger C^*-subalgebra M_{n^3} of $\mathcal{O}_\mathrm{n}$ spanned by $W_p(W_q)^*$ ($p, q \in \{1, \dots, n\}^3$).

The determinant of $u \otimes 1_n$ in $O(n^3)$ is always ± 1, but if $n = 2m$ then again $u \in 1_n \in SO(n^3)$ and $SO(k)$ is connected for all $k \in \mathbb{N}$.

Thus, for even $n \in 2\mathbb{N}$, we have again that δ_n is homotopic to id inside the unital endomorphisms of the real version $(\mathcal{O}_\mathrm{n})_\mathbb{R}$ of $\mathcal{O}_\mathrm{n}$.

`check next again?  was used!  Where??` The sign of the determinant of $u \otimes 1 \in M_{2^2} \otimes 1_2 \subseteq M_{2^3}$ is positive. Thus $u \otimes 1 \in SO(2^3)$, ... ????? But elements of $SO(2^3)$ are connected to 1 in $SO(2^3)$. This implies also the K_*-triviality of ${\mathcal{O}_2}^\mathbb{R}$. (Moreover $F({\mathcal{O}_2}^\mathbb{R}) = 0$ for every homotopy invariant “additive” functor from the category of “real” C^*-algebras into “additive” categories of groups.)

For the other “real” ${\mathcal{O}_\mathrm{n}}^\mathbb{R}$ the situation is more complicate ... Compare e.g. [**718**] in conjunction with [**173**].

(6) **The groups** $\mathcal{U}(B \otimes \mathcal{O}_2)$ **are contractible.**

$\mathcal{U}(B \otimes \mathcal{O}_2)$ is connected for all unital separable C^*-algebras: The application of the path $\mathrm{id}_B \otimes h_\tau$ from id to $\mathrm{id}_B \otimes \delta_2$ to U defines a path from U to $\delta_2(U)$ in $\mathcal{U}(B \otimes \mathcal{O}_2)$.

Now proceed as in Chapter 11. `more general? ??`.

Notice that every continuous map $\lambda\colon S^n \to \mathcal{U}(B\otimes\mathcal{O}_2)$ is an element of $\mathcal{U}(C(S^n,B)\otimes\mathcal{O}_2)$. Thus, $\mathcal{U}(B\otimes\mathcal{O}_2)$ has trivial homotopy groups. Since $\mathcal{U}(B\otimes\mathcal{O}_2)$ is a Polish space, that is locally homeomorphic to the self-adjoint part of $B\otimes\mathcal{O}_2$, it follows that $\mathcal{U}(B\otimes\mathcal{O}_2)$ is *contractible* (By a classical result of J. Milnor [**556**]). In particular, *the unitary group of* $\mathrm{C}(S^1,\mathcal{O}_2)$ *is simply connected.*

(7) **A proof that $\mathcal{O}_{\mathrm{n}}$ is pi-sun**

There is an alternative direct proof of the simplicity, nuclearity and pure infiniteness of $\mathcal{O}_{\mathrm{n}}$, considered as the *universal* C^*-algebras

$$C^*(s_1,\ldots,s_n\,;\; s_j^*s_j = 1 = s_1s_1^* + \cdots + s_ns_n^*)\,,$$

that does *not imply* (immediately) the above derived additional informations that $\mathcal{O}_{\mathrm{n}}$ is in the UCT class and $\mathrm{K}_*(\mathcal{O}_{\mathrm{n}}) \cong \mathbb{Z}_{n-1}\oplus 0$ with generator [1].

If $z\in S^1\subset\mathbb{C}$ is a complex number with $|z|=1$ then, by universality of $\mathcal{O}_{\mathrm{n}}$, there is a unique automorphism σ_z of $\mathcal{O}_{\mathrm{n}}$ with $\sigma_z(s_j)=zs_j$. It is easy to check on elementary products of the s_j and s_k^* that $z\to\sigma_z$ is a (point-norm continuous) circle action on $\mathcal{O}_{\mathrm{n}}$, and that the fixed point algebra of σ is just B_n , i.e., $P(\mathcal{O}_{\mathrm{n}}) = B_n$ for the faithful conditional expectation

$$P(x) := \frac{1}{2\pi}\int_0^{2\pi}\sigma_{e^{it}}(x)\,\mathrm{d}t\,.$$

Let F any C^*-algebra and $h\geq 0$ in the kernel J of $\mathcal{O}_{\mathrm{n}}\otimes^{\max}F\to\mathcal{O}_{\mathrm{n}}\otimes^{\min}F$. Since the kernel is invariant under the action $\sigma_z\otimes^{\max}\mathrm{id}_F$ by the functoriality of the maximal and minimal C^*-tensor products, we can integrate and get that $\frac{1}{2\pi}\int_0^{2\pi}(\sigma_{e^{it}}\otimes\mathrm{id})(h)\,\mathrm{d}t$ is in J. The conditional expectation defined by this integral can be calculated on elementary tensors, and is just $P\otimes^{\max}\mathrm{id}_F$. It is necessarily a faithful conditional expectation from $\mathcal{O}_{\mathrm{n}}\otimes^{\max}F$ onto $B_n\otimes^{\max}F = B_n\otimes^{\min}F$ (because B_n is nuclear). It follows that $J\cap(B_n\otimes^{\max}F) = P\otimes^{\max}\mathrm{id}(J) = 0$ and, thus $P\otimes^{\max}\mathrm{id}_F(h)=0$ and $h=0$, i.e., $J=\{0\}$ and $\mathcal{O}_{\mathrm{n}}$ *is nuclear.*

The proof of the simplicity and pure infiniteness uses that the faithful conditional expectation P is one-step approximately inner (by a sequence of isometries $D_1, D_2,\ldots\in\mathcal{O}_{\mathrm{n}}$). Refer to the place where the D_n are defined.

`What is here` D_k`?  How is it defined?  See further below.`

An argument of J. Cuntz in [**172**] implies that $\mathcal{O}_{\mathrm{n}}$ is both simple and purely infinite:
Let $\varepsilon>0$ and $a\in\mathcal{O}_{\mathrm{n}}$ with $0\leq a$ and $\|a\|=1$, then $P(a)\neq 0$ (because P is faithful on $(\mathcal{O}_{\mathrm{n}})_+$ by continuity of the circle action σ_z), and we find $k\in\mathbb{N}$ and a *minimal* projection $p\in M_{n^k}$ with $\|D_k^*aD_k - P(a)\| < (\varepsilon\|P(a)\|)/2$ and $\|pP(a)p - \|P(a)\|p\| < (\varepsilon\|P(a)\|)/2$.

There is an isometry T in $\mathcal{O}_{\mathrm{n}}$ with $T(T^*)=p$. We get $\|\,d^*ad-1\,\|<\varepsilon$ for $d := \|P(b)\|^{-1/2}D_kT$. Then calculation shows that $\|T^*D_k^*aD_kT - 1\|P(a)\|\| < (2/3)\varepsilon\|P(a)\|$.

(8) **Approximate Innerness of $P\colon\mathcal{O}_{\mathrm{n}}\to M_{n^\infty}$**

An algebraically defined explicit sequence of isometries $D_1, D_2, \ldots \in \mathcal{O}_n$, first described by De Schreye and Van Daele in [**209**, prop. 6], with property

$$\lim_k \| D_k^* x D_k - P(x) \| = 0 \quad \text{for all } x \in \mathcal{O}_n$$

can be given by the following modification of definitions by De Schreye and Van Daele in [**209**, prop. 5] (it uses an argument of J. Cuntz in [**169**, lem. 1.8]):
We let $I_k := \{1, \ldots, n\}^k$ and define isometries $W_p := s_{i_1} s_{i_2} \cdot \ldots \cdot s_{i_k}$ for $p = (i_1, \ldots, i_k) \in I_k$. The linear span of the elements $W_r W_s^*$ is a dense *-subalgebra of $\mathcal{O}_n$, and each element $W_r W_s^*$ $(r \in I_\ell,\ s \in I_m)$ with $\ell \le m \le k$ is in the linear span of elements $W_p W_q^*$ with $q \in I_k$ and $p \in I_{k-(m-\ell)}$. Notice that M_{n^k} is naturally isomorphic to the linear span of $W_r W_s^*$ with $r, s \in I_k$. Define $Y_k := s_1 (s_2)^k$ and

$$D_k := \sum_{p \in I_k} W_p Y_k W_p^* .$$

The W_p are isometries with mutually orthogonal ranges that sum up to 1. Therefore D_k is an isometry, and satisfies $D_k^* W_r W_s^* D_k = P(W_r W_s^*)$ if $r \in I_\ell$, $s \in I_m$ and $\max(\ell, m) \le k$.
Indeed:
It suffices to consider the case $m = k \ge \ell$, then $W_s^* D_k = Y_k W_s^*$, which implies that $D_k^* b D_k = b$ for all $b \in M_{n^k}$. In case $\ell < k$, one has $D_k^* W_r = \sum_{i \in I_j} W_r W_i Y_k^* W_i^*$ for $j := k - \ell$. Thus, the remaining case $m = k > \ell$ leads (with $j := k - \ell > 0$) to

$$D_k^* W_r W_s^* D_k = D_k^* W_r Y_k W_s^* = \sum_{i \in I_j} W_r (W_i Y_k^* W_i^* Y_k) W_s^*$$

which is zero: If $W_i Y_k^* \neq 0$ then necessarily $W_i = s_2^j$, which gives $W_i Y_k^* W_i^* Y_k = s_2^j (s_2^k)^* s_1^* (s_2^j)^* s_1 (s_2)^k = 0$, because $(s_2^j)^* s_1 = 0$.

`Change to more consistent notation!!`

(9) **Question if flip has algebraic approximation**

An interesting question for application to flip maps is the following:

It holds that $\lim_k (D_k \otimes D_k)^* (x \otimes y)(D_k \otimes D_k) = P(x) \otimes P(y)$ for all $x, y \in \mathcal{O}_n$ using suitable contractions $D_1, D_2, \ldots \in \mathcal{O}_n$ with the property

$$\lim_k \| D_k^* x D_k - P(x) \| = 0 \quad \text{for} \quad x \in \mathcal{O}_n .$$

(It would be desirable to have them also for $\mathcal{E}_n$ in place of $\mathcal{O}_n$ to get it also for $\mathcal{O}_\infty$.)

If this is the case then the question about the simplicity of the fixed point algebra of the flip map on $\mathcal{O}_n \otimes \mathcal{O}_n$ becomes a question about the simplicity of the fix-point algebra F_{n^∞} of the flip on $M_{n^\infty} \otimes M_{n^\infty}$. This is because F_{n^∞} is the range of the restriction of $P \otimes P$ to the fix-point algebra of the flip map on $\mathcal{O}_n \otimes \mathcal{O}_n$: Each (possibly existing) non-trivial ideal J of the fix-point algebra of the flip map on $\mathcal{O}_n \otimes \mathcal{O}_n$ has a nontrivial intersection with the F_{n^∞} with help of the in the flip-algebra contained $D_k \otimes D_k$.

??? Is there an opposite application ???: To show simplicity (!) of $\mathcal{O}_n$, could we show directly that the flip of $\mathcal{O}_n \otimes \mathcal{O}_n$ is approximately inner as c.p. map?

???

The unitary $u = \sum_n s_n^* \otimes s_n$ that satisfies $u^*u = 1 = uu^*$, $u(s_k \otimes 1) = 1 \otimes s_k$, and $u^*(1 \otimes s_k) = s_k \otimes 1$.

$\sum_{n,m} s_n^* s_m \otimes s_n s_m^* = \sum_n 1 \otimes s_n s_n^* = 1$ and $\sum_{n,m} s_n s_m^* \otimes s_n^* s_m = 1$ and $\sum_n \ldots = 1$

(applies also to the ultrapower ?).

$u(s_k \otimes 1) = (1 \otimes s_k)u$??? $\sum_n s_n^* s_k \otimes s_n$?? =?? $\sum_n s_n^* \otimes (s_k s_n)$ No !!!!

`Can not work??`
`because extremal ideals need not be maximal.`
`Could only work with` *extremal* S_1`-invariant ideals,`
`and would show that` $\mathbb{K} \subseteq \mathcal{E}_n$
`is the only non-trivial` S_1`-invariant ideal.`

Attempt: Go the following way:

The kernel ideal of $\mathcal{E}_n \to \mathcal{O}_n$ is generated by $p := 1 - s_1 s_1^* - \ldots - s_n s_n^*$, and the projection p satisfies $pW_i W_j^* p = 0$ and $pW_i = 0$ for $W_i \in I_k$ and $W_j \in I_\ell$. It follows that p is a minimal projection, i.e., satisfies $p(\mathcal{E}_n)p = \mathbb{C} \cdot p$ and the ideal generated by p is isomorphic to $\mathbb{K}(\ell_2(\mathbb{N}))$.

(Question: In the real case one has to take ± 1 actions (by $\mathbb{Z}_2$ or $\mathbb{Z}_2^n$) ??)

Moreover, the circle action fixes the projection p. Thus, the ideal generated by p is invariant under circle action.

`next is nonsense, because ''extremal'' is not ''maximal''.`
`Check if this used on other places!!!`

Since $\mathcal{O}_n$ and $\mathcal{E}_n$ are unital, they

???? have a maximal (? only extremal !! ?) nontrivial closed ideal (say J) that contains the ideal generated by p.

Without knowing first the existence or non-existence of an ideal we have to proof with other means that the conditional expectation P is approximately inner. Just this is established with $D_1, D_2, \ldots$.

The fixed points of the circle action on "this maximal ideal" must be necessarily an ideal of the fixed point algebra.

(10) **On simplicity of algebraic $\mathcal{O}_n$ version**

The reader can check, that the above arguments show also that the universal algebraic *-algebra (over $\mathbb{R}$, $\mathbb{C}$ or over the rational numbers) with the above suitably generalized defining relations of $\mathcal{O}_n$ is a simple *-algebra.

In fact, the above arguments also show that the (algebraic) algebra generated by elements $s_1, \ldots, s_n, t_1, \ldots, t_n$ with defining relations $t_j s_k = \delta_{jk} 1$ and $\sum_k s_k t_k = 1$ is simple.

(With suitably modified $D_1, D_2, \ldots$.)

One can easily see that there is a unique anti-isomorphism $x \mapsto x^*$ of order 2 with $s_k^* = t_k$. (The involution * has to be defined as conjugate linear if we consider the algebraic algebra over $\mathbb{C}$ defined by this relations.)

(11) **List** $\mathrm{K}_*(\mathcal{O}_\mathrm{n})$

$(\mathrm{K}_0(\mathcal{O}_\mathrm{n}), [1], \mathrm{K}_1(\mathcal{O}_\mathrm{n})) = (\mathbb{Z}_{n-1}, 1, 0)$ $(n = 3, \ldots)$, $(\mathrm{K}_0(\mathcal{O}_2), \mathrm{K}_1(\mathcal{O}_2)) = (0, 0)$ and $(\mathrm{K}_0(\mathcal{O}_\infty), [1], \mathrm{K}_1(\mathcal{O}_\infty)) = (\mathbb{Z}, 1, 0)$.

Has been discussed above in Old(0.1) ?= New (3)? .

(12) **Unital endomorphisms of $\mathcal{O}_\mathrm{n}$ are homotopic.**

Every unital endomorphism of $\mathcal{O}_\mathrm{n}$ is homotopic to id (in particular δ_n is homotopic to id).

[And thus, $(n-1)\,\mathrm{K}_*(\mathcal{O}_\mathrm{n}) = 0$]

(See Old (0.2) ?= ? New (4) or (A1.4, it follows also from UCT and classification for $n = 3, 4, \ldots$).

But we need before that $\mathcal{O}_\infty$ and $\mathcal{O}_2$ are pi-sun with $(\mathrm{K}_0(\mathcal{O}_2), \mathrm{K}_1(\mathcal{O}_2)) = (0, 0)$

(It follows from: δ_2 unitarily homotopic to id) and $(\mathrm{K}_0(\mathcal{O}_\infty), [1], \mathrm{K}_1(\mathcal{O}_\infty)) = (\mathbb{Z}, 1, 0)$ (should come from $\mathrm{K}_*(\mathcal{E}_n) = (\mathbb{Z}, [1_{\mathcal{E}_n}] = 1, 0)$ and $\mathcal{O}_\infty = \mathrm{indlim}_n\, \mathcal{E}_n$ with unital $\mathcal{E}_n \to \mathcal{E}_{n+1}$).

$\mathcal{E}_n \to \mathcal{E}_2 \to \mathcal{E}_n$ homotopic to id, and $\mathcal{E}_2 \to \mathcal{E}_n \to \mathcal{E}_2$ homotopic to id, where $\mathcal{E}_m \to \mathcal{E}_n$ for $n \geq m$ natural $s_k \mapsto s_k$, and $\mathcal{O}_\infty \to \mathcal{E}_2$ given by $s_1 \mapsto s_1$ and $s_{n+1} \mapsto s_2^n s_1$. Notice $s_1^*(s_2^m)^* s_2^n s_1 = 0$ for $m = 0, 1, 2, \ldots$, $m < n$.

The proof of homotopy follows from the K_1-injectivity implied by the squeezing property (sq) of the $\mathcal{E}_n$.

We must show before that $\mathcal{O}_2 \cong \mathcal{D}_2 := \mathcal{O}_2 \otimes \mathcal{O}_2 \otimes \cdots$ and $\mathcal{O}_\infty \cong \mathcal{D}_\infty := \mathcal{O}_\infty \otimes \mathcal{O}_\infty \otimes \cdots$???.

(How to get that shortly, elementary, sufficient ???)

(13) **General $F(\mathcal{O}_2) = 0$ for homotopy functors.**

For every

(enough: "with respect to unitary homotopy" ??)

homotopy-invariant additive functor $F \colon C^* \to G$ into an Abelian (or only additive) category G holds $F(\mathcal{O}_2) = 0$ where C is a subcategory of the category of C^*-algebras that contains $\mathcal{O}_2$ (as object) and all unital endomorphisms of $\mathcal{O}_2$ (as morphisms).

Also every functor F that takes on approximately unitary equivalent C^*-morphisms into the same element/morphism in G.

(14) $\mathcal{O}_n$ **as Cuntz-Pimsner algebras.**

There is another way to study $\mathcal{O}_n$ (and $\mathcal{E}_n$) – including all the former results on nuclearity, simplicity, pure infiniteness, UCT and the calculation of the K-theories.

This algebras are very special cases of Cuntz-Pimsner algebras (respectively generalized Fock–Toeplitz algebras) as considered by M. Pimsner in [**633**], because $\mathcal{O}_n \cong \mathcal{O}(\mathcal{H})$ and $\mathcal{E}_n \cong \mathcal{T}(\mathcal{H})$ for the Hilbert $\mathbb{C}$ –$\mathbb{C}$- bimodule $\mathcal{H} := \ell_2(n)$, $\mathcal{O}_\infty \cong \mathcal{O}(\mathcal{H}) = \mathcal{T}(\mathcal{H})$ for the $\mathbb{C}$ –$\mathbb{C}$-bimodule $\mathcal{H} := \ell_2(\mathbb{N})$. The paper of M. Pimsner unifies and generalizes some parts of related work of J. Cuntz.

1.1. Remarks on $\mathcal{O}_n$ and $\mathcal{O}_\infty$ (2). Where is the homotopy $a \otimes 1 \sim 1 \otimes a$ in $\mathcal{O}_\infty$, $\mathcal{O}_2$?

(and $\mathcal{O}_n$?? depends on the class in $K_1(\mathcal{O}_n \otimes \mathcal{O}_n)$ of ??? a possible flipping unitaries v_n, discussed somewhere below ?? with $\lim_n v_n^*(s_k \otimes 1)v_n = 1 \otimes s_k$, $\lim_n v_n^*(1 \otimes s_k)v_n = s_k \otimes 1$??? or $V := n^{-1/2} \sum_{k,\ell} s_k^* \otimes s_\ell$??? with $V^* = V$)

constructed respectively described?

For $\mathcal{O}_2 \otimes A$ we have always $K_*(\mathcal{O}_2 \otimes A) = 0$. Indeed, $\delta_2 \otimes \mathrm{id}_A$ is (unitary) homotopic to id on $\mathcal{O}_2 \otimes A$, because δ_2 on $\mathcal{O}_2$ has this property.

If A is unital, then this implies $\mathcal{U}(\mathcal{O}_2 \otimes A) = \mathcal{U}_0(\mathcal{O}_2 \otimes A)$ by Proposition 4.2.15 because $\mathcal{O}_2$ satisfies as a quotient of $\mathcal{E}_2$ the "squeezing" Property (sq) of Definition 4.2.14 and $\mathcal{O}_2 \otimes A$ inherits it from $\mathcal{O}_2$.

It follows moreover that $\mathcal{U}(\mathcal{O}_2 \otimes A)$ is contractible, because $\mathcal{O}_2 \otimes (A \otimes C(S_n))$ has also contractible $C(S_n, \mathcal{U}(\mathcal{O}_2 \otimes A)) \cong \mathcal{U}(\mathcal{O}_2 \otimes (A \otimes C(S_n)))$.

The case of $\mathcal{O}_\infty$ requires to show that $K_1(\mathcal{O}_\infty) = 0$ and $K_1(\mathcal{O}_\infty \otimes \mathcal{O}_\infty) = 0$. It was shown in Section **??** of Chapter 2 that $\mathcal{O}_\infty$ is p.i. and simple.

< -- NO! That $\mathcal{O}_n$ is simple has to be shown -- before we can apply this arguments !!

The definitions of $\mathcal{O}_\infty$, $\mathcal{O}_n$ and $\mathcal{E}_n$ show that all have an properly infinite unit element, thus are K_1-surjective by Lemma 4.2.6(v).

By Proposition 4.2.15, $\mathcal{E}_n$, $\mathcal{O}_\infty$ and $\mathcal{O}_n$ have the squeezing property (sq) of Definition 4.2.14, because the $\mathcal{E}_n$ have it and $\mathcal{O}_\infty$ respectively $\mathcal{O}_n$ inherits it as inductive limit of all $\mathcal{E}_n$ respectively quotients of $\mathcal{E}_n$.

Those C^*-algebras A that absorb $\mathcal{O}_2$ or $\mathcal{O}_\infty$ tensorial are also *strongly* purely infinite (and are simple if A is simple), and then are K_1-injective by Proposition 4.2.15 or ?????????????

Since $\mathcal{O}_\infty$ is in the "bootstrap" category (as inductive limit of the $\mathcal{E}_n$), the Künneth theorem for tensor products gives that $K_1(\mathcal{O}_\infty \otimes \mathcal{O}_\infty) = 0$ and that $K_0(\mathcal{O}_\infty \otimes \mathcal{O}_\infty) = \mathbb{Z}$ with $[1 \otimes 1] = 1$. This argument can be repeated and yields $K_1(\mathcal{O}_\infty \otimes \mathcal{O}_\infty \otimes \cdots) = 0$ and $K_0(\mathcal{O}_\infty \otimes \mathcal{O}_\infty \otimes \cdots) = \mathbb{Z}$ with $[1] = 1$ by induction.

Use v_n get what??

It needs to consider the partial isometries $v_n := \sum_{k=1}^{n} s_k \otimes s_k^*$ in $\mathcal{O}_\infty \otimes \mathcal{O}_\infty$ (respectively the unitaries in $\mathcal{O}_{\rm n} \otimes \mathcal{O}_{\rm n}$). They satisfy $v_n^* v_n = 1 \oplus (\sum_{k=1}^{n} s_k s_k^*)$ and $v_n v_n^* = (\sum_{k=1}^{n} s_k s_k^*) \oplus 1$.

Are the isometries $s_k \otimes s_\ell$ generators of $\mathcal{O}_\infty \otimes \mathcal{O}_\infty$? (Certainly the $s_k \otimes 1$ and $1 \otimes s_\ell$ are generators.)

If one uses K_1-injectivity, then one has to use also *Künneth* theorem to calculate $\mathrm{K}_1(\mathcal{O}_\infty \otimes \mathcal{O}_\infty)$.

Needs K_1-injectivity of all s.p.i. algebras:

Some has to be shown (more practical?) in Section **??** of Chapter 2.

The notion of K_1-injectivity is defined and studied in Section 2 of Chapter 4.

Gives that *all unital *-morphisms $\mathcal{O}_\infty \to E$ are unitarily homotopic if and only if E is K_1-injective*:

Let $S_1, S_2, \ldots \in E$ generators of $\mathcal{O}_\infty$. $s_n := h_1(S_n)$, $t_n := h_2(S_n)$.

$s_1, s_2, \ldots$ homotopic to $s_1, s_1 s_2^n$ and $t_1, t_1 t_2^n$, then to $t_1, t_2, \ldots$.

Gives embeddings $\mathcal{E}_2 \hookrightarrow \mathcal{E}_3 \hookrightarrow E$.

All unital *-monomorphisms $\mathcal{E}_n \hookrightarrow \mathcal{E}_{n+k}$ $(n, k \geq 1)$ are homotopic in $\mathcal{E}_{n+k}$ and are – moreover – homotopic in E – if E is K_1-injective.

If E unital and has properly infinite unit, then this means $\mathcal{U}(E)/\mathcal{U}_0(E) \cong \mathrm{K}_1(E)$ if E is K_1-bijective.

Uses $\mathcal{U}_0(\mathcal{E}_n) = \mathcal{U}(\mathcal{E}_n)$ and that $\mathcal{E}_n \cap \mathbb{K} = \{0\}$ in $\mathcal{E}_{n+1}$, because $\mathbb{K} \subseteq \mathcal{E}_m$ is an essential ideal of $\mathcal{E}_m$ for each $m \geq 2$ and otherwise the unital map $\mathcal{E}_n \to \mathcal{O}_{n+1}$ would define a unital C^*-morphism from $\mathcal{O}_{\rm n}$ into $\mathcal{O}_{n+1}$.

It follows that $\mathcal{D}_\infty$ has a flip automorphism. that is homotopic to id.

SOME COLLECTION OF RESULTS USED IN CHAPTERS 2 and 4 about $\mathcal{O}_{\rm n}$:

Transfer or Repeat ??
Needs to refer to "Property (sq)" !!!
Give the precise reference to definition and Prop. with results in Chp. 4 !!!

?? From Chp. 4:

(a): $\mathcal{E}_n := C^*(s_1, \ldots, s_n;\ s_i^* s_j = \delta_{ij})$, $n = 2, \ldots, \infty$, satisfy Property (sq):

Indeed: Let $w := k_1 k_2 \ldots k_p$, $v := \ell_1 \ell_2 \ldots \ell_q$, "words" of length $p, q \in \mathbb{N}$ with "letters" $k_j, \ell_i \in \{1, \ldots, n\}$ from the "alphabet" $\{1, \ldots, n\}$.

Define $T_0 := 1$ and an isometry by the product

$$T_p(w) := s_{k_1} s_{k_2} \cdot \ldots \cdot s_{k_p} .$$

It is easy to see ??? that the linear span of the element 1 and of the "elementary" products $T_q(w)$, $T_q(w)^*$ and $T_q(w)(T_r(v)^*)$ is dense in the C^*-algebra $\mathcal{E}_n$ (in both of real or complex case), because

(i) the product $T_q(v)^*T_p(w)$ is equal to 1 if $v = w$,
(ii) is equal to zero if there exists $g \leq r := \min(p, q)$ with $k_g \neq \ell_g$,
(iii) is equal to $T_{(p-q)}(u_1)$ if $q < p$ and $w = vu_1$ and
(iv) is equal to $T_{(q-p)}(u_2)^*$ if $p < q$ and $v = wu_2$.

We denote by G one of this elementary products or let $G = 1$.

Perhaps change $L(...)$ to $\lambda(...)$???

A sort of "length" $L(G)$ is defined by $L(1) := 0$, $L(T_q) := q$, $L((T_q)^*) := q$ and $L(T_q \cdot (T_r)^*) := q + r$. Clearly, $s_k^*T_p(w) = \delta_{k,k_1}T_{p-1}(v)$ for all $k = 1, \ldots, n$ with word $v := k_2k_3 \ldots k_n$ for $w = k_1k_2 \ldots k_n$.

Let $G := T_p(w)T_q(v)^*$ with $w = k_1 \ldots k_p$, $v = \ell_1 \ldots \ell_q$ $(p, q \geq 1)$, then, $L(s_k^*Gs_\ell) = L(G) - 2$ if and only if $k_1 = k$ *and* $\ell_1 = \ell$, otherwise only $s_k^*Gs_\ell = 0$ can happen.

In case $G = T_p(w)$, $w = k_1 \ldots k_p$ we get $s_k^*Gs_\ell \neq 0$ if and only if $k = k_1$ and then $L(s_k^*Gs_\ell) = L(G)$, because then $G = T_p(u)$ with $u = k_2 \ldots k_p\ell$. Since $L(G^*) = L(G)$ the same holds for $G = T_p(w)^*$ with the role of k and ℓ interchanged.

Therefore, one can find, for each linear combination $C = \alpha_0 1 + \sum_{j=1}^m \alpha_j G_j$ (with scalars α_j), an index $1 \leq j_0 \leq m$ and suitable $k, \ell \in \{1, \ldots, n\}$ such that $k \neq \ell$, $s_k^*G_{j_0}s_\ell = 0$ for at least one $j_0 \in \{1, \ldots, m\}$ and $L(s_k^*G_js_\ell) \leq L(G_j)$ for $j \neq j_0$. Thus $s_k^*Cs_\ell = \sum_{j\neq 0, j\neq j_0} \alpha_j s_k^*G_js_\ell$ with elementary products $s_k^*G_js_\ell$ (it can be equal to 1).

Iteration – say m-times – of this operation leads to words w and v in the alphabet $\{1, \ldots, n\}$ such that for the isometries $T_m(w)$ and $T_m(v)$ holds $T_m(w)^*T_m(v) = 0$ and $T_m(w)^*CT_m(v) = 0$. It says that $\mathcal{E}_n$ has Property (sq).

It follows that its quotients $\mathcal{O}_n$ also have Property (sq).

END OF (sq) PROOF for $\mathcal{E}_n$!

We can also use also the proof of J. Cuntz in [**172**, thm. 1.9, thm. 3.7] to get $\mathcal{U}_0(\mathcal{O}_\infty) = \mathcal{U}(\mathcal{O}_\infty)$.

On the real version $(\mathcal{O}_2)_\mathbb{R}$ of $\mathcal{O}_2$:

The homotopy id $\sim_h \delta_2$ exists also in the semi-group of unital *-endomorphisms of $(\mathcal{O}_2)_\mathbb{R}$. It follows that $\mathcal{U}((\mathcal{O}_2)_\mathbb{R}) = \mathcal{U}_0((\mathcal{O}_2)_\mathbb{R})$ and that all unital *-endomorphisms φ of $(\mathcal{O}_2)_\mathbb{R}$ are homotopic to the identity isomorphism of $(\mathcal{O}_2)_\mathbb{R}$.

Indeed, φ is uniquely defined by $\varphi(s_j) = u_\varphi s_j$ $(j = 1, 2)$, where

$$u_\varphi := \sum_{j=1}^{2} \varphi(s_j)s_j^* \,,$$

and, for each unitary $u \in (\mathcal{O}_2)_\mathbb{R}$ holds:

$u \oplus_{s_1,s_2} u \sim_h u$ in $\mathcal{U}((\mathcal{O}_2)_\mathbb{R})$. Since $u \oplus v \sim_h v \oplus u$ and $uv \oplus 1$ by Part (v,4) of Lemma 4.2.6 we get that

$$(u \oplus u) \oplus u^* \sim_h u \oplus u^* \;\sim_h\; 1 \,.$$

Since U_d or U_d^* first?

$$U_d^*((u \oplus u) \oplus u^*)U_d = u \oplus (u \oplus u^*)$$

it follows

$$u \oplus 1 \sim_h u \oplus (u \oplus u^*) \sim_h 1$$

in $\mathcal{U}((\mathcal{O}_2)_{\mathbb{R}})$. We get that

$$u \sim_h u \oplus u \sim_h (u \oplus 1) \cdot (1 \oplus u) \sim_h 1$$

for every $u \in \mathcal{U}((\mathcal{O}_2)_{\mathbb{R}})$, i.e., $\mathcal{U}((\mathcal{O}_2)_{\mathbb{R}}) = \mathcal{U}_0((\mathcal{O}_2)_{\mathbb{R}})$.

The self-adjoint unitary $C(2) := \sum_{1 \le i,j \le 2} s_i s_j s_i^* s_j^*$ in the real C^*-algebra

$$A_2 := C^*(s_i s_k (s_j s_\ell)^*; 1 \le i,j,k,\ell \le 2) \cong M_4(\mathbb{R})$$

has determinate $= -1$. But $\delta_2(C(2))$ is unitary equivalent to $C(2)$ in

$$M_8(\mathbb{R}) \cong A_3 := C^*(s_i s_k s_m (s_j s_\ell s_n)^*; 1 \le i,j,k,\ell \le 2)$$

by the unitary $C(3) := \sum_{1 \le i,j,k \le 2} s_i s_j s_k (s_j s_k s_i)^*$. This implies that $C(2) \in \mathcal{U}_0((\mathcal{O}_2)_{\mathbb{R}})$ and then that δ_2 is homotopic to id inside the unital *-endomorphisms of $(\mathcal{O}_2)_{\mathbb{R}}$.

The equality $\mathcal{U}(\mathcal{E}_2) = \mathcal{U}_0(\mathcal{E}_2)$, can be seen (in case of complex E) from the short-exact sequence $\mathbb{K} \to \mathcal{E}_2 \to \mathcal{O}_2$, and from the equalities $\mathcal{U}_0(\mathbb{K} + \mathbb{C} \cdot 1) = \mathcal{U}(\mathbb{K} + \mathbb{C} \cdot 1)$ and $\mathcal{U}_0(\mathcal{O}_2) = \mathcal{U}(\mathcal{O}_2)$.

Transfer or Repeat? FROM Chp. 2:

In proof of property (sq) for $\mathcal{E}_n$ in Chp. 4 is already some said about the algebraic version of $\mathcal{E}_n$.

The C^*-algebra $\mathcal{E}_n$ is the universal C^*-algebra generated by n isometries with orthogonal ranges, i.e., $\mathcal{E}_n := C^*(s_1, \ldots, s_n\, ;\ s_k^* s_\ell = \delta_{k\ell} 1)$. The C^*-algebra $\mathcal{O}_\infty$ is the inductive limit of the sequence of the natural unital C^*-morphisms $h_n \colon \mathcal{E}_n \to \mathcal{E}_{n+1}$ defined by $h_n(s_k) := s_k$ for $k = 1, \ldots, n$.

The *-monomorphisms h_n satisfy the criteria 2.2.5(iv):

The closed ideal $J(p_n)$ of $\mathcal{E}_n$ generated by $p_n := 1 - s_1 s_1^* - \cdots - s_n s_n^*$ is isomorphic to $\mathbb{K}(\ell_2(\mathbb{N}))$ and p_n is a minimal projection of $J(p_n) \cong \mathbb{K}$, because $p_n T_q(w_1) T_r(w_2)^* p_n = 0$ for w_1, w_2 words in the "alphabet" $\{1, \ldots, n\}$ with at least one of w_1 and w_2 is not the "empty" word (i.e., the $q + r > 0$ for the lengths q of w_1 and r of w_2).

It implies that $p_n \cdot \mathcal{E}_n \cdot p_n = \mathbb{C} \cdot p_n$.

The ideal $J(p_n)$ is an *essential* ideal of $\mathcal{E}_n$, because $\mathcal{O}_n \cong \mathcal{E}_n / J(p_n)$ is simple.

(Refer here to the place where simplicity of $\mathcal{O}_n$ is proven!)

The simplicity of $\mathcal{O}_n$ follows from the fact that M_{n^∞} is the fixed point algebra of the "gauge" circle action on $\mathcal{O}_n$ and that (!!!!) the conditional expectation from $\mathcal{O}_n$ onto M_{n^∞} defined by this action is an approximately inner u.c.p. map.

(Where is the appox innerness is shown here?)

(The point is, that one proves first – e.g. Cuntz – that the conditional expectation $P_n\colon \mathcal{O}_{\mathrm{n}} \to M_{n^\infty}$ is element-wise approximately inner by taking approximation be elementary .)

Ref's to simplicity (! where shown?) of $\mathcal{O}_{\mathrm{n}}$??:
$J(p_n) \cong \mathbb{K}$
$p_n \mathcal{E}_n p_n = \mathbb{C} p_n$
$\mathcal{O}_{\mathrm{n}}$ simple, implies that
$J(p_n)$ is essential ideal of $\mathcal{E}_n$.

(But the argument for "$J(p_n)$ essential" needs only that $\mathcal{O}_{\mathrm{n}}$ is G-simple for $G := S^1$ and the "gauge" circle action.)

Hence, $a \in \mathcal{E}_n \mapsto H(a) \in \mathcal{M}(J(p_n))$ with $H(a)b = ab$ for $b \in J(p_n)$ is a faithful C^*-morphism, and for $a \in (\mathcal{E}_n)_+$ with $\|a\| = 1$ there exists a partial isometry $z \in J(p_n) \cong \mathbb{K}$ with $z^*z = p_n$ and $\| p_n - z^*az \| < \varepsilon$.

Define $c := h_n(z)s_{n+1}h_n(b^{1/2})$. If we use that $h_n(p_n) = p_{n+1} + s_{n+1}s_{n+1}^* \in \mathcal{E}_{n+1}$ and $p_{n+1}s_{n+1} = 0$, then we get

$$\|c^* h_n(a)c - h_n(b)\| < \varepsilon\,.$$

New ?? concepts for Appendix of book:

Try to find a direct simple proof that the gauge action of $\mathcal{O}_{\mathrm{n}}$ is approximately inner ...???

NOT found yet !!!

Definitions of $\mathcal{O}_{\mathrm{n}}$, $\mathcal{E}_n$, $\mathcal{O}_\infty$.

Its K_*-groups:
$\mathrm{K}_*(\mathcal{E}_n) = (\mathbb{Z}, 0)$, $\mathrm{K}_*(\mathcal{O}_{\mathrm{n}}) = (\mathbb{Z}/(n-1)\mathbb{Z}, 0)$, $n = 2, 3, \ldots$, i.e., cyclic with generators [1] $\mathrm{K}_*(\mathcal{O}_\infty) = (\mathbb{Z}, 0)$.

$\mathcal{O}_\infty$ is the inductive limit of the inclusion maps $\mathcal{E}_n \to \mathcal{E}_{n+1}$, $n = 2, 3, \ldots$. It is stationary on [1]. Shows $(\mathbb{Z}, 1) \cong (\mathrm{K}_0(\mathcal{O}_\infty), [1])$.

It was shown in Chp.2, sec.2.2:
indlim $\mathcal{E}_n \to \mathcal{E}_{n+1}$ is simple and p.i.
But it did use that the ideal $I(p)$ is *essential* in $\mathcal{E}_n$,
with $p = p_0 = e_n$ defined below/above several times.
Requires that $I(p)$ is essential for $\mathcal{E}_n$.

$\mathcal{O}_{\mathrm{n}} := \mathcal{E}_n / I(p)$, where $I(p)$ is the closed ideal of $\mathcal{E}_n$ generated by the projection $p := 1 - s_1 s_1^* - \ldots - s_n s_n^*$.

Here $\mathcal{E}_n := C^*(s_1, \ldots, s_n\,;\, s_i^* s_j = \delta_{ij}1) = C^*(A_n)$ is the C^*-completion of A_n, defined as the universal algebraic *-algebra generated by $s_1, \ldots, s_n$ subject to the relations $s_i^* s_j = \delta_{i,j}1$.

The existence and well-defined-ness of $C^*(A_n)$ follows from an old observation of M.G. Krein in 1949 [**493**] mentioned in his study of Krein bloc-algebras:

Let A a unital *-ring with relations that allow to prove that for (some) given generators $a_1, a_2, \ldots ; a_1^*, a_2^*, \ldots$ and relations $R_1, R_2, \ldots$ of A there exists $b_{1,n}, \ldots, b_{k,n} \in A$ and $\gamma_n \geq 0$ (depending from a_n) such that in the unitization $\widetilde{A} := A + \mathbb{C} \cdot 1$ of A holds

$$a_n^* a_n + b_{1,n}^* b_{1,n} + \cdots + b_{k,n}^* b_{k,n} = \gamma_n 1 .$$

Then there is a well-defined maximal C^*-seminorm on A. We denote the corresponding C^*-algebra then by $C^*(a_1, a_2, \ldots ; R_1, R_2, \ldots)$. The natural C^*-morphism from the algebraic A into its C^*-algebraic version $C^*(a_1, a_2, \ldots ; R_1, R_2, \ldots)$ is not necessarily faithful.

(In non-unital case one can adjoin a unit element e and require that ??? for desired "contractions" $w \in A$ there exist $v \in A_e$ in an extended version $A_e \supseteq A$ with $w^* w + v^2 = 1$ or $w^* w + v^* v = 1$.)

We show that our A_n is the linear span of the expressions $W_\alpha W_\beta^*$ for α and β words in from the "alphabet" $\{1, 2, \ldots, n\}$, where $W_\alpha := 1$ for the empty word (of length 0) or $W_\alpha = s_{k_1} s_{k_2} \cdot \ldots \cdot s_{k_\ell}$ for the word $\alpha = k_1 k_2 \ldots k_\ell$ of length $\ell = \ell(\alpha)$ with $k_1, k_2, \ldots, k_\ell \in \{1, \ldots, n\}$.

Notice that W_α and W_β satisfy $W_\alpha^* W_\beta = \delta_{\alpha,\beta} 1$ if α and β have the same length. If $\ell(\alpha) < \ell(\beta)$, then we have to write β as $\beta = \beta' \gamma$ with $\ell(\beta') = \ell(\alpha)$ and get $W_\alpha^* W_\beta = \delta_{\alpha,\beta'} \cdot W_\gamma$. In this way only terms like 1 and $W_\alpha \cdot W_\beta^*$ appear in the sub-semigroup of A_n generated by $1, s_1, \ldots, s_n, s_1^*, \ldots, s_n^*$. Thus A_n is the linear span of this terms.

If we let $p_0 := 1 - s_1 s_1^* - \cdots - s_n s_n^*$ then $p_0 W_\alpha = 0$ if α has length ≥ 1, i.e., if $W_\alpha \neq 1$, because $p_0 s_k = 0$ for all $k \in \{1, \ldots, n\}$. It follows that $p_0 A_n p_0 = \mathbb{C} \cdot p_0$ and $p_0 \mathcal{E}_n p_0 = \mathbb{C} \cdot p_0$.

It follows that $W(\alpha) p_0 W(\alpha)^* W(\beta) p_0 W(\beta)^* = 0$, i.e., that the ideal $I(p_0)$ of A_n generated by $\{p_0\}$ contains a countable number of mutually orthogonal projections $p_\alpha := W(\alpha) p_0 W(\alpha)^*$ with 1-dimensional $p_\alpha A_n p_\beta$.

Clearly $p_0 = p_0^*$, and, for $k \neq \ell$ and $i = j$, or $i \neq j$,

$$(s_i)^k p_0 ((s_i)^k)^* (s_j)^\ell p_0 ((s_j)^\ell)^* = 0 .$$

It implies that the closed ideal $I(p_0)$ of $\mathcal{E}_n$ must be isomorphic to $\mathbb{K}$.

There is a circle action σ_z on A_n (by universality of A_n) given on generators by $\sigma_z(s_k) := z s_k$ for $z \in S^1 := \{z \in \mathbb{C} ;\ |z| = 1\}$. The action fixes p_0 and is compatible with the relations of A_n, i.e., the $t_k := \sigma_z(s_k)$ define the same relations $t_j^* t_k = \delta_{jk} 1$ and $p_0 := 1 - t_1^* t_1 - \cdots - t_n^* t_n$ as the $s_1, \ldots, s_n$. Moreover $\sigma_z(a^*) = \sigma_z(a)^*$, because this happens on generators.

By universality of A_n it follows that σ extends to a circle action on $\mathcal{E}_n$ that fixes p_0. In particular, it takes $I(p_0) \cong \mathbb{K}$ invariant.

(In fact one has moreover a natural $\mathcal{U}(M_n)$ action on $\mathcal{E}_n$ that fixes p_0.)

Thus, σ extends naturally to a circle action σ on $\mathcal{E}_n$, and then to an action on $\mathcal{O}_n$ respectively on $\mathcal{O}_\infty$, because they are the completions with the maximal possible C^*-norms on it.

Notation below differs from that of above:

The fix-point-algebra of σ on $\mathcal{O}_n$ is generated by the elements $W_\alpha W_\beta^*$ with W_α and W_β words in "letters" $s_1, \ldots, s_n$ of the same length $\ell(\alpha) = \ell(\beta)$. We have $\sum s_n s_n^* = 1$ in $\mathcal{O}_n$. It follows that $W_\alpha W_\beta^* = \sum_{j=1}^n (W_\alpha s_j)(W_\beta s_j)^*$ is contained in the span of the $W_\gamma W_\delta$ with $1 + \ell(\alpha) = \ell(\gamma) = \ell(\delta) = 1 + \ell(\beta)$.

It is easy to see that this is naturally isomorphic to the inductive limit of unital embeddings

$$M_{n^k} \to M_{n^k} \otimes 1_n \subseteq M_{n^{k+1}} .$$

Thus ${\mathcal{O}_n}^\sigma \cong M_{n^\infty}$ and

$$P_n(a) := \int_{z \in S^1} \sigma_z(a) dz$$

is a conditional expectation from $\mathcal{O}_n$ onto $M_{n^\infty} \subseteq \mathcal{O}_n$.

It turns out that P_n is 1-step approximately inner in $\mathcal{O}_n$ (cf. [**209**]), but this has been shown also by J. Cuntz itself.

The corresponding contractions T_m with $P_n(a) := \lim_m T_m^* a T_m$ are given by

$$T_m := \sum_{\alpha,\beta} V_\alpha W_\beta (V_\alpha)^* (W_\beta)^* = \sum_\beta \delta_n^m (W_\beta)(W_\beta)^* = \sum_\alpha V_\alpha \delta_n^m (V_\beta) ,$$

where α and β run through $\{1, \ldots, n\}^m$.

If leads to the observation that $\mathcal{O}_n$ is simple, p.i. (hence s.p.i.) and nuclear:

The nuclearity follows from the general observation that compares maximal and minimal tensor products and shows that a C^*-algebra with a continuous action of a compact group is nuclear if its fix-point-algebra is nuclear.

Where explained in detail? Refer to this.

Since $P_n(\mathcal{O}_n) \cong M_{n^\infty}$ is simple and P_n is faithful on the positive cone of $\mathcal{O}_n$, it follows that "one-step approximate innerness" of P_n would show also the simplicity of $\mathcal{O}_n$, cf. [**169**], [**172**] or [**209**].

Nothing found in the cited papers?!

The argument of J. Cuntz goes a follows:

(1a.) The conditional expectation $P_n \colon \mathcal{O}_n \to M_{n^\infty} \subseteq \mathcal{O}_n$ is faithful, because it is the integral of a circle action.

(1a is My or his argument?)

(1b.) The nonzero projections in $M_{n^\infty} \subseteq \mathcal{O}_n$ are all infinite in $\mathcal{O}_n$.

In particular Why it should be a special case of what???, there exists for each nonzero projection $p \in \mathcal{O}_n$ an isometry $s \in \mathcal{O}_n$ with $s^* p s = 1$.

(1c.) It implies that each nonzero positive element $a \in M_{n^\infty}$ is infinite in $\mathcal{O}_n$, and there exists $d \in \mathcal{O}_n$ with $d^* a d = (\|a\|/2) \cdot 1$.

(2a.) Let $b \in \mathcal{O}_n$ an element in $W_?$????? then there exists $d \in W_{??}$ such that $d^*b^*bd = P_n(b^*b)$ ...??

(Range of such d must almost commute with given finite subset in the fixed point algebra of the circle action but must have orthogonal ranges if composed with a finite subset of non-fixed points ...?)

(2b.) Let $a \in \mathcal{O}_n$ positive with $\|a\| = 1$ and $\varepsilon > 0$. Then there exists an element $e \in A$ with $\|e^*ae - P_n(a)\| \le \varepsilon$.

WHERE THIS IS SHOWN?

(2a.)

If we can show that $P_n(a)$ is contained in $\{d^*ad\,;\; d \in \mathcal{O}_n\}$ for each $a \in \mathcal{O}_n$ with $a \ge 0$.

Thus, if $0 \ne a \ge 0$ and P_n is faithful on $(\mathcal{O}_n)_+$ then $\mathcal{O}_n$ is simple.

Let $a \in \mathcal{O}_n$ positive and $\varepsilon > 0$, then find $n \in \mathbb{N}$ and $b^* = b \in W_n$ with $\|b^2 - a\| < \varepsilon$. Leads to $\|P_n(a) - P_n(b^2)\| < \varepsilon$.

Then find element (contraction?) $D \in W_m$ with $\|D^*b^2D - P_n(b_2)\| < \varepsilon$. ...

If one can show that each projection in $P_n(\mathcal{O}_n)$ dominates the range of an isometry in $\mathcal{O}_n$ then the one-step approximation of P_n shows moreover that $\mathcal{O}_n$ must be purely infinite.

That is, each minimal projection of the span of $\{W_\alpha W_\beta^*\,;\; \ell(\alpha) = \ell(\beta) = k\} = M_{n^k}$ is the range of an isometry in $\mathcal{O}_n$, because all non-zero minimal projections in M_{n^k} are equivalent.

Since $I(p) \cong \mathbb{K}$ (where shown? ref!) and $\mathcal{O}_n := \mathcal{E}_n/I(p)$ is nuclear, it follows that the algebras $\mathcal{E}_n$ are nuclear. This passes to its inductive limit $\mathcal{O}_\infty$, i.e., $\mathcal{O}_\infty$ is nuclear.

The defining element $u \in \mathcal{O}_2$ with $us_j = \delta_2(s_j)$ of the endomorphism $\delta_2 \colon \mathcal{O}_2 \to \mathcal{O}_2$ given by $a \in \mathcal{O}_2 \mapsto \delta_2(a) := s_1as_1^* + s_2as_2^*$ can be written down explicitly as

$$u := s_1s_1s_1^*s_1^* + s_2s_1s_2^*s_1^* + s_1s_2s_1^*s_2^* + s_2s_2s_2^*s_2^*\,.$$

It is a symmetry in the real C^*-algebra $M_4(\mathbb{R}) \cong A_2 := C^*_{\mathbb{R}}(s_is_ks_\ell^*s_j^*\,;\; i,j,k,\ell = 1,2)$ with determinate $= -1$.

Since $C^*_{\mathbb{R}}(s_is_ks_\ell^*s_j^*\,;\; i,j,k,\ell = 1,2)$ is a unital *-subalgebra of $M_8(\mathbb{R}) \cong A_3 := C^*_{\mathbb{R}}(s_is_ks_ms_n^*s_\ell^*s_j^*\,;\; i,j = 1,2)$, and $O(4) \otimes 1_2 \subseteq SO(8)$, there is a continuous path inside $SO(8)$ that connects $u \otimes 1_2$ in $SO(8)$ with 1. This happens then also in $\mathcal{O}_2$.

An explicit path can be found with help of suitable elementary transformations:

Bit more general for $n \in \mathbb{N}$, $n > 1$, we consider $\mathcal{O}_n$ and $\mathcal{E}_n$. Let $W(k) := \{1, \ldots, n\}^k$. If $w = (j_1, \ldots, j_k) \in W(k)$ is a "word" of length k, let $\lambda w := (j_k, j_1, \ldots, j_{k-1})$ the cyclic change of the word $w \in W(k)$ and $\overline{w} := (j_k, j_{k-1}, \ldots, j_2, j_1)$ the reversed word in $W(k)$. They define isometries $S(w) := s_{j_1} \cdot \ldots \cdot s_{j_k}$. Notice that the elements $Z(k) := \sum_{w \in W(k)} Z(\lambda w)Z(w)^*$

and $U(k) := \sum_{w\in W(k)} Z(\overline{w})Z(w)^*$ of $\mathcal{O}_{\rm n}$ are orthogonal operators in $A_k :=$ span$(\{S(w_1)S(w_2)^*\,;\ w_1, w_2 \in W_k\}) \cong M_{n^k}$ respectively a symmetry (i.e., $U(k)^* = U(k)$, $U(k)^2 = 1$).

Notice that $A_k \subseteq A_{k+1}$ because

$$S(w_1)S(w_2)^* = \sum_{\ell=1}^{n}(S(w_1)s_\ell)(S(w_2)s_\ell)^*$$

and $S(w)s_\ell = S((w,\ell)$ where $(w,\ell) := (j_1,\ldots,j_k,\ell) \in W(k+1)$.

$$Z(k+1)^*S(w_1)S(w_2)^*Z(k+1) \;=\; \delta_n(S(w_1)S(w_2)^*) \quad \text{for } w_1, w_2 \in W(k)\,.$$

This follows from $Z(k+1)^*S(w_1)s_\ell s_\ell^* S(w_2)^*Z(k+1) = s_\ell S(w_1)S(w_2)^*s_\ell^*$ or $s_\ell^* S(w_2)^*Z(k+1) = S(w_2)^*s_\ell^*$.

In case $n=2$ and $k=2$, one gets

$$U(2) = Z(2) = s_1^2(s_1^2)^* + s_2^2(s_2^2)^* + s_1s_2(s_2s_1)^* + s_2s_1(s_1s_2)^*$$

Moreover $U(2)s_\ell = \delta_2(s_\ell)$ for $\ell = 1,2$.

More generally, for $n \geq 2$, $U(2)s_\ell = \delta_n(s_\ell)$ for $\ell = 1,\ldots,n$. It follows that δ_n is homotopic to id on $\mathcal{O}_{\rm n}$, if and only if, $U(2)$ is homotopic to 1 in $\mathcal{U}(\mathcal{O}_{\rm n})$ (respectively in $O(\mathcal{O}_{\rm n})$ for the real version of $\mathcal{O}_{\rm n}$).

In case $n=2$ we get with $V := (s_1s_2^* - s_2s_1^*)$ that

$$Z(3)^*U(2)Z(3) \;=\; \delta_2(U(2)) \;=\; (s_1U(2)s_1^* + s_2s_2^*)V^*(s_1U(2)s_1^* + s_2s_2^*)V\,.$$

Notice that $\exp((\pi/2)V) = V + (1 - V^4)$ if $V^* = -V = V^3$. In particular, $V = \exp((\pi/2)V)$ if $V^* = -V$ and $V^4 = 1$. Let $C = [\alpha_{jk}] \in SO_2$ the $90°$ rotation matrix, i.e., $\alpha_{11} = \alpha_{22} = 0$ and $\alpha_{21} = -\alpha_{12} = 1$ and recall $[s_1,s_2]^* = [s_1^*, s_2^*]^\top \in M_{2,1}(\mathcal{O}_2) \subseteq M_2(\mathcal{O}_2)$. We define a unitary in (the real version of) $\mathcal{O}_2$ by

$$V_\theta := \exp(\theta(\pi/2)V) = [s_1,s_2]\exp(\theta\pi/2C)[s_1,s_2]^* \in A_3$$

Since $V^* = -V$, we get that V_θ is in $SO(A_3) \cong SO_3$ for $\theta \in [0,1]$.

It follows that

$$U_\theta := Z(3)(U(2)\oplus 1)V(\theta)^*(U(2)\oplus 1)V(\theta)Z(3)^*$$

is a path in $SO(A_3)$ that connects the unitary $U(2) = U_1 \in O(A_2)$ with $1 = U_0$.

It follows that the unital *-endomorphism δ_2 of $\mathcal{O}_2$ is homotopic inside the unital endomorphisms $\mathrm{End}_1(\mathcal{O}_2)$ of $\mathcal{O}_2$ to the identity isomorphism.

Similar considerations show that $\delta_n \in \mathrm{End}_1(\mathcal{O}_{\rm n})$ is homotopic inside the unital endomorphisms $\mathrm{End}_1(\mathcal{O}_{\rm n})$ of $\mathcal{O}_{\rm n}$ to the identity isomorphism id of $\mathcal{O}_{\rm n}$.

If one can find a unitary U in the ultra-power $(\mathcal{O}_2)_\omega$ of $\mathcal{O}_2$, or in $\mathrm{Q}(\mathbb{R}_+,\mathcal{O}_2) := \mathrm{C}_b(\mathbb{R}_+,\mathcal{O}_2)/\,\mathrm{C}_0(\mathbb{R}_+,\mathcal{O}_2)$, or in $(\mathcal{O}_2)_\infty := \ell_\infty(\mathcal{O}_2)/c_0(\mathcal{O}_2)$ with $U\delta_2(x)U^* = x$ for $x \in \mathcal{O}_2$ then one gets for $t_j := Us_j$ that t_1, t_2 commute element-wise with $\mathcal{O}_2$, i.e., $\mathcal{O}_2 \cong C^*(t_1,t_2)$ is a copy of $\mathcal{O}_2$ that is unital contained in $\mathcal{O}_2{}' \cap (\mathcal{O}_2)_\omega$ (respectively in ${\mathcal{O}_2}' \cap \mathrm{Q}(\mathbb{R}_+, \mathcal{O}_2)$ or in ${\mathcal{O}_2}' \cap (\mathcal{O}_2)_\infty)$. Then, by repeat of this construction, we find a unital copy of $\mathcal{O}_2 \otimes \mathcal{O}_2 \otimes \cdots \subseteq \mathcal{O}_{2\omega}$ that commutes with $\mathcal{O}_2$ element-wise in this asymptotic algebras. It allows to conclude that $\mathcal{O}_2 \cong \mathcal{D}_2 := \mathcal{O}_2 \otimes \mathcal{O}_2 \otimes \cdots$.

`Next is contained in proof prop. 2.2.5?`

The following argument for pure infiniteness of $\mathcal{O}_\infty$ uses (and needs) that $\mathcal{E}_n \to \mathcal{O}_\infty$ is injective. (Somewhere above proven !)
and that $e \in \mathcal{E}_n$ satisfies $s_{n+1}s_{n+1}^* \leq e$.

Claim: The algebra $\mathcal{O}_\infty$ is purely infinite.

Idea of arguments:

"Have somewhere above shown" that the natural map $\eta \colon \mathcal{E}_n \to \mathcal{E}_{n+1}$ is injective and that $e_n := 1 - \sum_{k=1}^n s_k s_k^*$ satisfies $e_n \mathcal{E}_n e_n = \mathbb{C} \cdot e_n$.

(E.g. via looking to $\mathcal{E}_{n-1} \to \mathcal{E}_n \to \mathcal{O}_\mathrm{n}$ and extending a faithful unital representation $\rho \colon \mathcal{E}_{n-1} \to \mathcal{L}(\mathcal{H})$ with separable $\mathcal{H}$ to $\rho \otimes \mathrm{id} \colon \mathcal{E}_{n-1} \otimes \mathcal{L}(\mathcal{H}) \to \mathcal{L}(\mathcal{H} \otimes \mathcal{H})$ and finding an isometry $T \in \mathcal{L}(\mathcal{H} \otimes \mathcal{H})$ with

$$TT^* = 1 \otimes 1 - \rho(s_1 s_1^* + \ldots + s_{n-1}s_{n-1}^*) \otimes 1 \,.$$

– Here we denote $\mathrm{id}_\mathcal{H}$ by 1.)

It follows that $I(e)$ embeds injective into $\mathcal{E}_{n+1}$ and $s_{n+1}^* \eta(e) s_{n+1} = 1$. If $c \in \mathcal{E}_n$ is positive and $g \in I(e)$ with $\gamma \cdot e = g^* c g \neq 0$, $g^* g = e$, then $s_{n+1}^* g^* c g s_{n+1} = \gamma 1$. In particular, c is full and properly infinite in $\mathcal{E}_{n+1}$.

Let $a \in \mathcal{O}_\infty$ positive with $\|a\| = 1$. Then there exists $n \in \mathbb{N}$ and a positive contraction $b \in \mathcal{E}_n$ with $\|a - b\| < 1/8$. Thus, $\|b\| \geq 7/8$ and $\|(b - 1/8)_+\| \geq 3/4$. There is a contraction $d \in \mathcal{O}_\infty$ with $d^* a d = (b - 1/8)_+$, cf. Lemma 2.1.9. It follows that $d^* a d \in \mathcal{E}_n$ and $\|d^* a d\| \geq 3/4$.

Rest of the proof: $e = 1 - \sum_k s_k s_k^*$ satisfies $I(e) \cong \mathbb{K}$ and $e \in I(e)$ minimal and $e \in \mathcal{E}_{n+1} \subseteq \mathcal{O}_\infty$

`Need for final conclusion that`
`(o)` $I(e) \cong \mathbb{K}$,
`(i)` e `is a properly infinite full projection in` $\mathcal{E}_{n+1} \subseteq \mathcal{O}_\infty$ `and`
`(i)` $I(e)$ `essential for` $\mathcal{E}_n$.
`To be shown:`

The closed ideal $I(e) \cong \mathbb{K}$ of $\mathcal{E}_n$ is an *essential* of $\mathcal{E}_n$.

Steps:

(1.) $I(e) \cong \mathbb{K}$, because:
It is a closed ideal of $\mathcal{E}_n$ generated by the projection $e := 1 - (s_1 s_1^* + \ldots + s_n s_n^*)$. It satisfies $e s_j = 0$ for $j = 1, \ldots, n$. Thus, $e \mathcal{E}_n e = \mathbb{C} \cdot e$, i.e., the projection e is a minimal idempotent in $\mathcal{E}_n$.
(2.) $I(e)$ is invariant under the canonical circle action, because e is fixed by the circle action
(3.) The set of positive elements orthogonal to $I(e)$ is (by (2.)) invariant under the

circle action and is a closed ideal J of $\mathcal{E}_n$ orthogonal to $I(e)$.
(4.) The image $\pi_{I(e)}(J)$ of J in $\mathcal{O}_n := \mathcal{E}_n/I(e)$ is a closed ideal of $\mathcal{O}_n$ that is isomorphic to J and is invariant under the circle action on $\mathcal{O}_n$ and ...
(5.) $\pi_{I(e)}(J)$ does not contain the class $1 + I(e) \in \mathcal{E}_n/I(e)$:
Otherwise it means that $(1 - Y) \cdot \mathcal{E}_n \cdot e = \{0\}$ for some $Y \in I(e)$ with $0 \leq Y \leq 1$. It implies that $Ya = a$ for all $a \in I(e)$ and that $Y - Y^2 = 0$. Thus, Y is a unit element of $I(e)$, but $I(e)$ is not unital.
(6.) The circle-action invariant ideal $\pi_{I(e)}(J)$ has – if it would be non-zero – a non-zero intersection with $P(\mathcal{O}_n)$ that is a closed ideal of $P(\mathcal{O}_n)$, that can not contain 1 by (5.).

Since $P(\mathcal{O}_n) \cong M_{n^\infty}$ it follows that $J \cong \pi_{I(e)}(J) = 0$.

This finishes the proof that $I(e)$ is an essential ideal of $\mathcal{E}_n$ (without showing before that $\mathcal{O}_n$ is simple).

`Follows also immediately from the` *`simplicity`* `of` $\mathcal{O}_n$ (– if this has been shown before together with the property of $e := 1 - s_1 s_1^* - \cdots - s_n s_n^*$ that $e \cdot \mathcal{E}_n \cdot e = \mathbb{C}e$ – but we give an other proof that does not use the simplicity of $\mathcal{O}_n$):

$eW(\alpha) = 0$ for $\ell(\alpha) > 0$, where $W(\alpha) :=$????.

Recall: $a \in \mathcal{O}_\infty$ with $\|a\| = 1$ there exists $n \in \mathbb{N}$ and a positive contraction $b \in \mathcal{E}_n$ with $\|a - b\| < 1/8$. Thus, $\|b\| \geq 7/8$ and $\|(b - 1/8)_+\| \geq 3/4$. There is a contraction $d \in \mathcal{O}_\infty$ with $d^*ad = (b - 1/8)_+$, cf. Lemma 2.1.9.

We find a minimal projection q in $I(p)$ with

$$\|q(b - 1/8)_+ q\| \geq \|(b - 1/8)_+\| - 1/4 \geq 1/2 .$$

Then $qd^*adq = \alpha q$ for some $\alpha \geq 1/2$. There is a contraction $z \in \mathcal{E}_{n+1}$ with $z^*qz = 1$, because there is a partial isometry $v \in I(p) \cong \mathbb{K}$ with $v^*qv = p$ and $s_{n+1}^* p s_{n+1} = 1$. Thus $f := \alpha^{-1/2} dqz$ satisfies $f^*af = 1$.

It follows that $\mathcal{O}_\infty$ *is simple and purely infinite* (if we have shown before the *simplicity* of $\mathcal{O}_n$ or only that $I(e)$ is an essential ideal of $\mathcal{E}_n$).

1.2. Remarks on Real $\mathcal{O}_n$ and $\mathcal{O}_\infty$ (2). The defining unitary $u \in \mathcal{O}_2$ with $us_j = \delta_2(s_j)$ for the endomorphism

$$\delta_2 \colon \mathcal{O}_2 \ni a \mapsto \delta_2(a) := s_1 a s_1^* + s_2 a s_2^* \in \mathcal{O}_2$$

can be written down explicitly as

$$u := s_1 s_1 s_1^* s_1^* + s_2 s_1 s_2^* s_1^* + s_1 s_2 s_1^* s_2^* + s_2 s_2 s_2^* s_2^* .$$

It is a symmetry with determinate $= -1$ in the real C^*-algebra $M_4(\mathbb{R}) \cong A_2 := C^*_{\mathbb{R}}(s_i s_k s_\ell^* s_j^* \,;\ i,j,k,\ell = 1,2)$.

But since $C^*_{\mathbb{R}}(s_i s_k s_\ell^* s_j^* \,;\ i,j,k,\ell = 1,2)$ is a unital *-subalgebra of

`Check formula for` A_3`:`

$$M_8(\mathbb{R}) \cong A_3 := \ C^*_{\mathbb{R}}(s_i s_k s_m s_n^* s_\ell^* s_j^* \,;\ i,j,k,\ell,m \in \{1,2\})$$

, and the natural embedding $A_2 \subset A_3$, $O(4) \otimes 1_2 \subseteq SO(8)$, there is a continuous path inside $SO(8)$ that connects $u \otimes 1_2$ in $SO(8)$ with 1. This happens then also in the real version of $\mathcal{O}_2$.

An explicit path can be found using an isomorphism from $M_8(\mathbb{R})$ onto A_3.

Bit more general (but only in complex case) for $n \in \mathbb{N}$, $n > 1$, we consider $\mathcal{O}_\mathrm{n}$ and $\mathcal{E}_n$. Let $W(k) := \{1, \dots, n\}^k$. If $w = (j_1, \dots, j_k) \in W(k)$ is a "word" of length k, let $\lambda w := (j_k, j_1 \dots, j_{k-1})$ the cyclic change of the word $w \in W(k)$ and $\overline{w} := (j_k, j_{k-1}, \dots, j_2, j_1)$ the reversed word in $W(k)$. The define isometries $S(w) := s_{j_1} \cdot \ldots \cdot s_{j_k}$. Notice that the elements $Z(k) := \sum_{w \in W(k)} Z(\lambda w) Z(w)^*$ and $U(k) := \sum_{w \in W(k)} Z(\overline{w}) Z(w)^*$ of $\mathcal{O}_\mathrm{n}$ are orthogonal operators in $A_k := \mathrm{span}(\{S(w_1)S(w_2)^*\,;\ w_1, w_2 \in W_k\}) \cong M_{n^k}$ respectively a symmetry (i.e., $U(k)^* = U(k)$, $U(k)^2 = 1$).

Notice that $A_k \subseteq A_{k+1}$ because

$$S(w_1)S(w_2)^* = \sum_{\ell=1}^{n} (S(w_1)s_\ell)(S(w_2)s_\ell)^*$$

and $S(w)s_\ell = S((w, \ell)$ where $(w, \ell) := (j_1, \dots, j_k, \ell) \in W(k+1)$.

$$Z(k+1)^* S(w_1) S(w_2)^* Z(k+1) \;=\; \delta_n(S(w_1)S(w_2)^*) \quad \text{for } w_1, w_2 \in W(k)\ .$$

This follows from $Z(k+1)^* S(w_1) s_\ell s_\ell^* S(w_2)^* Z(k+1) = s_\ell S(w_1) S(w_2)^* s_\ell^*$ or $s_\ell^* S(w_2)^* Z(k+1) = S(w_2)^* s_\ell^*$.

In case $n = 2$ and $k = 2$, one gets

$$U(2) = Z(2) = s_1^2 (s_1^2)^* + s_2^2 (s_2^2)^* + s_1 s_2 (s_2 s_1)^* + s_2 s_1 (s_1 s_2)^*$$

Moreover $U(2)s_\ell = \delta_2(s_\ell)$ for $\ell = 1, 2$.

More generally, for $n \geq 2$, $U(2)s_\ell = \delta_n(s_\ell)$ for $\ell = 1, \dots, n$. It follows that δ_n is homotopic to id on $\mathcal{O}_\mathrm{n}$, if and only if, $U(2)$ is homotopic to 1 in $\mathcal{U}(\mathcal{O}_\mathrm{n})$ (respectively in $O(\mathcal{O}_\mathrm{n})$ for the real version of $\mathcal{O}_\mathrm{n}$).

In case $n = 2$ we get with $V := (s_1 s_2^* - s_2 s_1^*)$

$$Z(3)^* U(2) Z(3) = \delta_2(U(2)) = (s_1 U(2) s_1^* + s_2 s_2^*) V^* (s_1 U(2) s_1^* + s_2 s_2^*) V\ .$$

Notice that $\exp((\pi/2)V) = V + (1 - V^4)$ if $V^* = -V = V^3$. In particular, $V = \exp((\pi/2)V)$ if $V^* = -V$ and $V^4 = 1$. Let $C = [\alpha_{jk}] \in SO_2$ the 90° rotation matrix, i.e., $\alpha_{11} = \alpha_{22} = 0$ and $\alpha_{21} = -\alpha_{12} = 1$ and recall $[s_1, s_2]^* = [s_1^*, s_2^*]^\top \in M_{2,1}(\mathcal{O}_2) \subseteq M_2(\mathcal{O}_2)$. We define a unitary in (the real version of) $\mathcal{O}_2$ by

$$V_\theta := \exp(\theta(\pi/2)V) = [s_1, s_2] \exp(\theta\pi/2C) [s_1, s_2]^* \in A_3$$

Since $V^* = -V$, we get that V_θ is in $SO(A_3) \cong SO_3$ for $\theta \in [0, 1]$.

It follows that

$$U_\theta := Z(3)(U(2) \oplus 1)V(\theta)^*(U(2) \oplus 1)V(\theta)Z(3)^*$$

is a path in $SO(A_3)$ that connects the unitary $U(2) = U_1 \in O(A_2)$ with $1 = U_0$.

It follows that the unital *-endomorphism δ_2 of $\mathcal{O}_2$ is homotopic inside the endomorphisms of $\mathcal{O}_2$ to the identity isomorphism.

This is an important information, because it allows to show that with an approximation argument one can apply the following observation:

If one can find a unitary U in the ultra-power $(\mathcal{O}_2)_\omega$ of $\mathcal{O}_2$, or in $\mathrm{Q}(\mathbb{R}_+, \mathcal{O}_2) := \mathrm{C}_b(\mathbb{R}_+, \mathcal{O}_2)/\,\mathrm{C}_0(\mathbb{R}_+, \mathcal{O}_2)$, or in $(\mathcal{O}_2)_\infty := \ell_\infty(\mathcal{O}_2)/c_0(\mathcal{O}_2)$ with $U\delta_2(x)U^* = x$ for $x \in \mathcal{O}_2$ then one gets for $t_j := Us_j$ that t_1, t_2 commute element-wise with $\mathcal{O}_2$ in the asymptotic algebra, i.e., $\mathcal{O}_2 \cong C^*(t_1, t_2)$ is unital contained in $\mathcal{O}_2{}' \cap (\mathcal{O}_2)_\omega$ (respectively in $\mathcal{O}_2{}' \cap \mathrm{Q}(\mathbb{R}_+, \mathcal{O}_2)$ or in $\mathcal{O}_2{}' \cap (\mathcal{O}_2)_\infty$). Then, by repeat of this construction, we find a unital copy of $\mathcal{O}_2 \otimes \mathcal{O}_2 \otimes \cdots \subseteq \mathcal{O}_{2\omega}$ that commutes with $\mathcal{O}_2$ element-wise in this asymptotic algebras. It allows to conclude that $\mathcal{O}_2 \cong \mathcal{D}_2 := \mathcal{O}_2 \otimes \mathcal{O}_2 \otimes \cdots$. See Chapter 11.

`Remarks on real` $\mathcal{O}_2$ `and` $\mathcal{O}_\infty$ `(3):`

The endomorphism $\delta_2(a) := s_1 a s_1^* + s_2 a s_2^*$ is homotopic to id in the endomorphisms of real Cuntz algebra $(\mathcal{O}_2)_\mathbb{R}$.

It follows $\mathcal{U}(\mathcal{O}_2) = \mathcal{U}_0(\mathcal{O}_2)$ by [**172**, thm. 1.9, thm. 3.7].

We have for the "real version" of $\mathcal{O}_\infty$ also $\mathcal{U}_0(\mathcal{O}_\infty) = \mathcal{U}(\mathcal{O}_\infty)$ by [**172**, thm's. 1.9, 3.7], (cf. arguments in Chapter 4, modify them for the real case).

$\mathcal{U}_0((\mathcal{O}_2)_\mathbb{R}) = \mathcal{U}((\mathcal{O}_2)_\mathbb{R})$ and $\mathcal{U}_0((\mathcal{O}_\infty)_\mathbb{R}) = \mathcal{U}((\mathcal{O}_\infty)_\mathbb{R})$ hold also for the "real" version $(\mathcal{O}_2)_\mathbb{R}$ of $\mathcal{O}_2$.

Here we use in the real cases $\mathcal{E} = \mathcal{E}_\mathbb{R}$, $(\mathcal{O}_2)_\mathbb{R}$ and $(\mathcal{E}_2)_\mathbb{R}$ also the "complex" notations "unitary" and $\mathcal{U}(E), \mathcal{U}_0(E)$ instead of $O(E)$, respectively $SO(E)$, for the orthogonal elements $u \in E$, respectively $u \in E$ in the connected component of 1 in $O(E)$.

The homotopy id $\sim_h \delta_2$ exists also in the semi-group of unital *-endomorphisms of $(\mathcal{O}_2)_\mathbb{R}$. It follows that $\mathcal{U}((\mathcal{O}_2)_\mathbb{R}) = \mathcal{U}_0((\mathcal{O}_2)_\mathbb{R})$ and that all unital *-endomorphisms φ of $(\mathcal{O}_2)_\mathbb{R}$ are homotopic to the identity isomorphism of $(\mathcal{O}_2)_\mathbb{R}$. Indeed, φ is uniquely defined by $\varphi(s_j) = u_\varphi s_j$ $(j = 1, 2)$ where

$$u_\varphi := \sum_{j=1}^{2} \varphi(s_j) s_j^*\,,$$

and, for each unitary $u \in (\mathcal{O}_2)_\mathbb{R}$ holds:

$u \oplus_{s_1,s_2} u \sim_h u$ in $\mathcal{U}((\mathcal{O}_2)_\mathbb{R})$. Since $u \oplus v \sim_h v \oplus u \sim uv \oplus 1$ by part (v,4) of Lemma 4.2.6 we get that

$$(u \oplus u) \oplus u^* \sim_h u \oplus u^* \;\sim_h\; 1\,.$$

Since U_d `or` U_d^* `first?`

$$U_d^*((u \oplus u) \oplus u^*)U_d = u \oplus (u \oplus u^*)$$

it follows

$$u \oplus 1 \;\sim_h\; u \oplus (u \oplus u^*) \;\sim_h\; 1$$

in $\mathcal{U}((\mathcal{O}_2)_\mathbb{R})$. We get that

$$u \sim_h u \oplus u \sim_h (u \oplus 1) \cdot (1 \oplus u) \sim_h 1$$

for every $u \in \mathcal{U}((\mathcal{O}_2)_\mathbb{R})$, i.e., $\mathcal{U}((\mathcal{O}_2)_\mathbb{R}) = \mathcal{U}_0((\mathcal{O}_2)_\mathbb{R})$.

The selfadjoint unitary $C(2) := \sum_{1\leq i,j\leq 2} s_i s_j s_i^* s_j^*$ in the real C^*-algebra $A_2 := C^*(s_i s_k (s_j s_\ell)^*; 1 \leq i,j,k,\ell \leq 2) \cong M_4(\mathbb{R})$ has determinate $= -1$.

But $\delta_2(C(2))$ is unitary equivalent to $C(2)$ in

$$M_8(\mathbb{R}) = A_3 := C^*(s_i s_k s_m (s_j s_\ell s_n)^*; 1 \leq i,j,k,\ell \leq 2)$$

by the unitary $C(3) := \sum_{1\leq i,j,k\leq 2} s_i s_j s_k (s_j s_k s_i)^*$. This implies that $C(2) \in \mathcal{U}_0((\mathcal{O}_2)_\mathbb{R})$ and then that δ_2 is homotopic to to id in the unital *-endomorphisms of $(\mathcal{O}_2)_\mathbb{R}$.

The equality $\mathcal{U}(\mathcal{E}_2) = \mathcal{U}_0(\mathcal{E}_2)$, can be seen (in case of complex E) from the short-exact sequence

$$\mathbb{K} \to \mathcal{E}_2 \to \mathcal{O}_2$$

and from the equalities

$\mathcal{U}_0(\mathbb{K} + \mathbb{C} \cdot 1) = \mathcal{U}(\mathbb{K} + \mathbb{C} \cdot 1)$

and $\mathcal{U}_0(\mathcal{O}_2) = \mathcal{U}(\mathcal{O}_2)$.

But one can also use the general property (sq) to prove K_1-injectivity.

[**209**, prop. 5]:

(Let $T_1, \ldots, T_n$ isometries with $\sum_k T_k T_k^* = 1$.) Define $R_k := T_2 T_1 \cdot \ldots \cdot T_1$, where we take k-times T_1.

??

`Is it not simply the original argument of J. Cuntz ?`

Let (U_k is not a unitary !)

$$U_k = \sum_{p\in\Gamma_k} V_p R_k V_p^*$$

Then $\phi(x) = \lim_{k\to\infty} U_k^* x U_k$ for $x \in \mathcal{O}_\mathrm{n}$.

???????

(What happens in $\mathcal{E}_n$ in place of $\mathcal{O}_\mathrm{n}$??)

Here $\phi(x) := \int_G \sigma(g)(x)\, \mathrm{d}\mu_G(g)$. It is different defined in the paper. (Above defined as $P(x)$ for the circle action.)

`How is the group` G `defined??` Likely by circle action – or by $\mathbb{Z}_2$-action: $\chi\colon \{-1, 1\}$?

Here

$$\Gamma_k := \{1, 2, \ldots, n\}^k := \{p = (p_1, \ldots, p_k);\ p_j \in \{1, 2, \ldots, n\}\}$$

and $V_p := T_{p_1} \cdot \ldots \cdot T_{p_k}$.

(Also written somewhere as $T_k(w)$ for $w = p_1 \dots p_k$, $p_j \in \{1, \dots, n\}$).

2. Semi-Projectivity of the $\mathcal{E}_n$ and $\mathcal{O}_n$

Recall that $\mathcal{E}_2 := C^*(s_1, s_2\,;\, s_j^* s_k = \delta_{jk}1)$. The C^*-algebra $\mathcal{E}_2$ satisfies a version of *weak semi-projectivity* shown in the following lemma.

LEMMA A.2.1. *If A is the closure of an increasing sequence of C^*-subalgebras $A_1 \subseteq A_2 \subseteq \cdots$ and $\psi\colon \mathcal{E}_2 \to A$ is a (not necessarily unital) C^*-morphism, then for every $\varepsilon \in (0,1)$ there exist $n = n(\varepsilon) \in \mathbb{N}$, a C^*-morphism $\psi_n\colon \mathcal{E}_2 \to A_n$ and elements $h_1, h_2 \in A$ of norm $\|h_k\| \leq \varepsilon$ $(k = 1, 2)$ such that $h_k^* = -h_k$ and $\psi_n(1) := \exp(-h_1)\psi(1)\exp(h_1)$, $\|\psi(s_j) - \psi_n(s_j)\| < \varepsilon$ and $\psi_n(s_j) = \exp(h_2)\psi(s_j)\exp(h_1)$ for $j = 1, 2$.*

Reorganize following proof:

Explain the relations between ``$\|1 - u\| < 1$ small'' and $u := \exp(h)$ for $h \in A$ with $h^* = -h$ and ``$\|h\|$ small''.

Start then (! 1st) the unital case with range projections in A_n for all n.

Do (2nd) the reduction from unital case where the range projections are not in A_n to the case where they are in all A_n

then (3rd) the reduction from most general to the unital case.

PROOF. Let $p_k := \psi(s_k s_k^*)$ for $k = 1, 2$. We consider first the C^*-morphism $\psi_0\colon \mathbb{C} \oplus \mathbb{C} \to A$ defined by $\psi_0(\xi_1, \xi_2) := \xi_1 p_1 + \xi_2 p_2$.

Let $y := p_1 - p_2$. It has spectrum $\{-1, 1\} \subseteq \mathrm{Spec}_A(y) \subseteq \{-1, 0, 1\}$. We find a sequence of selfadjoint contractions $y_n \in A_n$ such that $y = \lim y_n$. It follows that there exists n_0 such that $\|y_n - y\| < 1/8$ for all $n \geq n_0$. Thus, $\mathrm{Spec}(y_n)$ is in $[-1, -3/4] \cup [-1/4, 1/4] \cup [3/4, 1]$ for all $n \geq n_0$. Let $\gamma(t)$ the continuos pice-wise linear function with (only) break points $\{-3/4, -1/4, 1/4, 3/4\}$, values $\gamma(t) := -1$ on $[-1, -3/4]$, $\gamma(t) := 0$ on $[-1/4, 1/4]$, $\gamma(t) := 1$ on $[3/4, 1]$ and $\gamma(t)$ linear on $[-3/4, -1/4] \cup [1/4, 3/4]$.

Then $\mathrm{Spec}(\gamma(y_n)) \subseteq \{-1, 0, 1\}$ for all $n \geq n_0$, and $p_{1,n} := \gamma(y_n)_+$, $p_{2,n} := \gamma(y_n)_-$ are projections for $n \geq n_0$ and $\psi_{0,n}(\xi_1, \xi_2) := \xi_1 p_{1,n} + \xi_2 p_{2,n}$ are C^*-morphisms from $\mathbb{C} \oplus \mathbb{C}$ into A_n $(n \geq n_0)$ that satisfy $\lim_n \psi_{0,n}(\xi_1, \xi_2) = \psi_0(\xi_1, \xi_2)$.

More precisely, there exist $h_{1,n} \in A$ with $h_{1,n}^* = -h_{1,n}$ and $\|h_{1,n}\| \leq \arcsin????$, such that

$$\psi_{0,n}(1, 1) = \exp(-h_{1,n})(p_1 + p_2)\exp(h_{1,n})$$

for all $n \geq n_0$.

Let $z_j := \psi(s_j)$, $P := z_1^* z_1 = z_2^* z_2$, $p_j := z_j z_j^* \leq P$ $(j = 1, 2)$. Notice that $p_1 + p_2 \leq P$ (implies $p_1 p_2 = 0$).

Since the self-adjoint contractions in the algebraic *-algebra $\bigcup_n A_n$ are dense in the self-adjoint contractions of A, we can start with a sequence $x_n^* = x_n \in A_n$ with $\|x_n\| \leq 1$ and $\lim \|x_n - P\| = 0$. Let $\gamma_n := \|x_n - P\|$. Then the spectrum $\mathrm{Spec}(x_n)$ of x_n is contained in $[-\gamma_n, \gamma_n] \cup [1 - \gamma_n, 1]$. Thus, $P_n := \varphi(x_n) \in A_n$ is a projection with $\|x_n - P_n\| \leq \gamma_n$ for all n with $\gamma_n < 1/4$ where

$$\varphi(t) := \min(1, 2\max(0, 2t - 1)) = 4[(t - 1/2)_+ - (t - 3/4)_+] .$$

We get the existence of n_0 such that there are projections $P_n \in A_n$ with $\|P_n - P\| \leq 1/2$ for $n \geq n_0$ and that $\lim_n \|P_n - P\| = 0$.

Let $\lambda(t)$ a "suitable" continuous strictly increasing functions on $[0, 2]$ with $\lambda(0) = 0$.

By ????

`Check Ref's for changes!!`

Part (v) of Lemma 4.1.3

there exist $h_n \in A_+$ with $\|h_n\| \leq \arcsin \|P_n - P\|$ such that $e^{-ih_n} P e^{ih_n} = P_n$. Notice that here e^{ih_n} is build in $A + \mathbb{C}1$ after adjoining a unit to A and that $|e^{it} - 1| \leq |t|$ (for $t \in [-\pi, \pi]$) implies

$$\|1 - e^{ih_n}\| \leq \|h_n\| \leq \arcsin \|P_n - P\| .$$

An opposite estimate follows from $2|\sin(t/2)| = |\exp(-it/2) - \exp(it/2)| = |1 - \exp(it)|$ for $t \in [-\pi, \pi]$ and gives $\|h\| \leq 2\arcsin(\|1 - \exp(ih)\|/2)$ for $h^* = h$ with $\|h\| \leq \pi/2$.

Notice also that $\|1 - u\| < 1$ implies for unitary u that $s := \log(u) = \log(1 - (1 - u))$ exists, satisfies $s^* = -s$, $\|s\| \leq \pi/3$ and $\exp(s) = u$. (One can consider $C^*(u)$ as a quotient of $\mathrm{C}(S^1)$ and reformulate it as properties of characters of $\mathrm{C}(S^1)$ i.e., as conditions on points of $S^1 \subseteq \mathbb{C}$.) Using that $|\log(1 - t)| \leq -\log(1 - |t|) \leq |t|/(1 - |t|)$ for $|t| < 1$, we get also the estimate $\|s\| \leq -\log(1 - \|1 - u\|) \leq \|1 - u\|/(1 - \|1 - u\|)$ if u is a unitary with $\|1 - u\| < 1$. Let $h := -is$, then $u = \exp(ih)$ and

$$\|h\| \leq \|1 - u\|/(1 - \|1 - u\|) .$$

If we take some suitable $\ell > n_0$ such that $\|h_\ell\| < \lambda(\varepsilon)$, then we can replace A by $P_\ell A P_\ell$, ψ by the then unital C^*-morphism $\psi' \colon \mathcal{E}_2 \to P_\ell A P_\ell$ $b \in \mathcal{E}_2 \to A$ given by $\psi'(b) := e^{-ih_\ell} \psi(b) e^{ih_\ell}$ and consider only the $P_\ell A_n P_\ell$ with $n \geq \ell > n_0$. We store n_0, n_ℓ and $H_0 := h_\ell$ in our bookkeeping.

This reduces the considerations to unital A and a unital C^*-morphism $\psi \colon \mathcal{E}_2 \to A$, i.e., now $z_j^* z_k = \delta_{j,k} 1$. We proceed in the same way as above with the projections $p_j = z_j z_j^*$ and find self-adjoint $h_1 \in A$, $n_1 < n_2$ in $\mathbb{N}$ and self-adjoint $h_2 \in (1 - q_1)A(1 - q_1)$ both with $\|h_1\|, \|h_2\| \leq \lambda(\varepsilon)$, such that $e^{-ih_1} p_1 e^{ih_1} =: q_1 \in A_{n_1}$

and $e^{-ih_2}e^{-ih_1}p_2e^{ih_1}e^{ih_2} =: q_2 \in A_{n_2}$. Notice that also $e^{-ih_2}e^{-ih_1}p_1e^{ih_1}e^{ih_2} = q_1$, because $q_1e^{ih_2} = e^{ih_2}q_1 = q_1$. Again store $n_1 < n_2$ and $H_1 := h_1$ and $H_2 := h_2$ to our list.

In this way we have reduced the consideration to the case where we can start with the more comfortable assumptions $z_j^*z_k = \delta_{jk}1$ and $p_j = z_jz_j^* \in A_n$ for all $n \in \mathbb{N}$. Let S_n denote the closed unit-ball of A_n and S the closed unit-ball of A. Since $(p_jS_n)_n$ is an increasing sequence of closed convex subsets of p_jS and p_jS is the closure of $\bigcap_n p_jS_n$ there exists for given $\varepsilon > 0$ and $m \in \mathbb{N}$ an $n := n(\varepsilon, m) \in \mathbb{N}$ with $n > m$ and $\mathrm{dist}(z_j, p_jS_n) < \lambda(\varepsilon)$ for $j = 1, 2$. It means that we can find $w_j \in p_jS_n$ with $\|w_j - z_j\| < \lambda(\varepsilon)$ $(j = 1, 2)$. It implies that $w_jw_j^* \leq p_j$, $1-2\varepsilon \leq w_j^*w_j \leq 1$ and $\|w_jw_j^* - p_j\| < 2\lambda(\varepsilon)$. Thus, $(w_j^*w_j)^{-1/2}$ exists and satisfies

$$1 \leq (w_j^*w_j)^{-1/2} \leq (1 - 2\lambda(\varepsilon))^{-1/2} .$$

Let $u_j := w_j(w_j^*w_j)^{-1/2}$. Then u_j is an isometry with $p_ju_j = u_j$ and

$$\|u_ju_j^* - p_j\| \leq 2\lambda(\varepsilon) + [(1 - 2\lambda(\varepsilon))^{-1/2} - 1] < 1 ,$$

i.e., with $u_ju_j^* = p_j$ and

$$\|u_j - z_j\| \leq \lambda(\varepsilon) + [(1 - 2\lambda(\varepsilon))^{-1/2} - 1] .$$

The functions $\lambda(t)$ should be chosen such that $\lambda(\varepsilon) + [(1 - 2\lambda(\varepsilon))^{-1/2} - 1)] < \varepsilon/3$, and that $|e^{it} - 1| \leq 2\lambda(\varepsilon) + 2[(1 - 2\lambda(\varepsilon))^{-1/2} - 1]$ implies $|t| \leq \varepsilon/2$.

It follows that $U := u_1z_1^* + u_2z_2^* + (1 - p_1 - p_2)$ is a unitary with $Uz_j = u_j$ and

$$\|U - 1\| \leq \|u_1 - z_1\| + \|u_2 - z_2\| \leq 2\lambda(\varepsilon) + 2[(1 - 2\lambda(\varepsilon))^{-1/2} - 1] .$$

Then $u_j = Uz_j$ with unitary U such that $\|U - 1\|$ is sufficiently small.

Summing up we get that that $u_j = UV^*z_jV$ with $V := e^{iH_0}e^{iH_1}e^{iH_2}$ and $\|1 - V\|$????? and $\|1 - UV\| \leq \|1 - U\| + \|1 - V\|$.

Since $|1 - \exp(it)|^2 = 2(1 - \cos(t))$ the norm $\|H\| \leq \pi/2$ of $H^* = H$ approaches zero if $\|1 - \exp(iH)\|$ goes to zero. This allows to show that products of unitaries sufficiently near to 1 are exponentials $\exp(iH)$ with $H^* = H$ of small norm. □

3. On the Jiang-Su algebra $\mathcal{Z}$

Let $m, n \in \mathbb{N} = \{1, 2, \ldots\}$ natural numbers with g.c.d.$(n, m) = 1$, the dimension-drop C^*-algebra $\mathcal{E}(M_m, M_n)$ is defined as the C^*-subalgebra of $\mathrm{C}([0, 1], M_m \otimes M_n)$ consisting of the maps $f\colon [0, 1] \to M_m \otimes M_n$ with $f(0) \in M_m \otimes 1_n$ and $f(1) \in 1_m \otimes M_n$.

(We call it also “winding around” algebra ... build by a construction on pairs of algebras similar to the construction of a “Join” polyhedron in $\mathbb{R}^m \times \mathbb{R}^n$ from two polyhedra in $\mathbb{R}^m$ and $\mathbb{R}^n$ ...)

Need: Suitable central sequences, ...

There exists a trace-collapsing unital endomorphism from $\mathcal{E}(M_{2^\infty}\,,\ M_{3^\infty})$ into $\mathcal{E}(M_{2^\infty}\,,\ M_{3^\infty})$.

Definition A.3.1. The **Jiang-Su algebra** is isomorphic to the inductive limit of this endomorphism ...

There are several other definitions. See original Jiang-Su paper ... Needed properties of the Jiang-Su algebra...

Containment of Jiang-Su algebra in other algebras, e.g. infinite tensor products of suitable amenable unital C^*-algebras.

Need:
Special Central sequences of the JS algebra that allow to apply p.i. and s.p.i. criteria.

Each tensorial self-absorbing C^*-algebra absorbs the Jiang-Su algebra. (Winter)

Compare with my homotopy criterium ...

Something lost??

4. Fix-point algebras of compact group actions

Suppose that G is a compact group and $\alpha\colon G \to \mathrm{Aut}(A)$ a point-norm continuous group homomorphism from G into the group $\mathrm{Aut}(A)$ of automorphisms of A. It is not difficult to see, that the map

$$a \mapsto P^G(a) := \int_G \alpha(g)(a)\,\mathrm{d}(g)$$

defines a *faithful* conditional expectation P^G from A onto the fix-point algebra A^G of G. Here "faithful" means that $P^G(a) \neq 0$ for all non-zero $a \in A_+$.

Notice that one can not conclude similar properties for A from the corresponding property of the fix-point C^*-subalgebra of a $\mathbb{Z}$-action of A (by an automorphism of A).

Proposition A.4.1. *Suppose that a compact group G acts continuous in point-norm topology on a C^*-algebra A.*
The fix-point subalgebra A^G of A is nuclear (respectively is exact, weakly injective, QWEP, has the local lifting property), if and only if, A is nuclear (respectively is exact, weakly injective, QWEP, has the local lifting property).

Moreover, if the conditional expectation P_G can be approximated point-wise by inner c.p. maps

$$V_\tau(a) := \sum_{k=1}^{n(\tau)} d_{k,\tau}^* a d_{k,\tau}\,,$$

then each non-zero closed ideal of A has non-zero intersection with A^G.

It is interesting that the question if P_G respects also *local reflexivity* – as defined for operator spaces, which is different from the well-known (and almost trivial) local reflexivity of Banach spaces – remains open even in case of circle actions!

It could be that the new operator exact sequences criteria for left-ideals of (stable) locally reflexive C^*-algebras implies now a positive answer for "local reflexivity" ... ???

But this requires to check what happens with the the fixed points under compact actions?

Question: What about "relative" properties? In particular, "relative weak injectivity" could be a candidate ...

Equivalent formulation of r.w.i. is given by: $A \subseteq B$ r.w.i. in B if and only if $A \otimes^{\max} C^*(F_\infty) \subseteq B \otimes^{\max} C^*(F_\infty)$.

If G acts on B by $\rho\colon g \in G \mapsto \rho(g) \in \mathrm{Aut}(B)$ and $\rho(g)(A) = A$ for all $g \in G$, then $B^G \cap A$ is r.w.i. in B^G?

Here B^G denotes the fix-point algebra of the G-action on B. Seems to work for compact G.

Proof. Wa adapt an idea of A. Grothendieck for the study of locally convex vector spaces with help of tensor product functors. A simple variant of his idea transferred to the study of analytic properties of C^*-algebras is to express this properties with help of tensor product functors and use the automatic G-invariance of the functors. We use this proof to say something more general about the applications of this method and its limitation.

Let (at the moment) C denote a fixed C^*-algebra. Let $\alpha\colon G \to \mathrm{Aut}(A)$ denote the G-action on A, and let

$$(B, C) \to B \otimes_\mu C \quad \text{and} \quad (B, C) \to B \otimes_\nu C$$

denote C^*-algebra tensor product "functors" that satisfy $\|\cdot\|_\mu \geq \|\cdot\|_\nu$ on the algebraic tensor product $B \odot C$ for all C^*-algebras B, i.e., the closed ideals $J_\mu(B)$ and $J_\nu(B)$ of maximal C^*-algebra tensor product $B \otimes^{\max} C$ given as kernels of the natural *-epimorphisms $B \otimes^{\max} C \to B \otimes_\mu C$ and $B \otimes^{\max} C \to B \otimes_\nu C$ satisfy $J_\mu(B) \subseteq J_\nu(B)$. (In fact, a suitable functorial selection of those "kernels" contains all necessary information on the tensor product functors!)

They are defined by a B-functorial choice of C^*-norms $\|\cdot\|_\mu \geq \|\cdot\|_\nu$ on the algebraic tensor products $B \odot C$ and are the corresponding topological tensor-products are the completions of $B \odot C$ with this norms. The functoriality means that for each C^*-morphism $h\colon A \to B$ and $x \in A \odot C$ in the algebraic tensor product holds that $\|h \otimes \mathrm{id}(x)\|_\mu \leq \|x\|_\mu$ and similar for $\|\cdot\|_\nu$. Or, equivalently, $(h \otimes^{\max} \mathrm{id})(J_\mu(A)) \subseteq J_\mu(B)$ for each C^*-morphism $h\colon A \to B$ and fixed C.

With other words, we allow only "natural" functor transformations

$$\varphi_B \colon B \otimes^\mu C \to B \otimes^\nu C$$

that satisfy

$$\varphi_B \circ (h \otimes^\mu \mathrm{id}) = (h \otimes^\nu \mathrm{id}) \circ \varphi_A$$

for $h\colon A \to B$.

In addition, we suppose, that $V\otimes_\mu$id and $W\otimes_\nu$id remain contractions, whenever V and W are c.p. contractions. It is not difficult to see, – with help of Kasparov-Stinespring dilations of V and using the outer-unital extension $\widetilde{V}\colon \widetilde{A}\to\widetilde{B}$ –, that this property is equivalent to the property of $\otimes_\mu$ (and similar of $\otimes_\nu$) that $B\otimes_\mu C\subseteq \widetilde{B}\otimes_\mu C$ and $pBp\otimes_\mu C\subset B\otimes_\mu C$ for all C, and all full projections $p\in B$. (We let it to reader to check this.)

Let ???????

Thus, A^G is nuclear (respectively, weakly injective, QWEP, locally liftable) if A is so.
Exactness always passes to C^*-subalgebras.

The conditional expectations P^G are faithful for compact G. Indeed, if $a\geq 0$ and χ is a positive functional on A with $\chi(a)>0$, then $\chi(P^G(a))>0$, because it is the integral over the non-zero, non-negative, and continuous function $g\mapsto \chi(\alpha(g)(a))$.

The maps $\eta\otimes_\mu\mathrm{id}\colon A^G\otimes_\mu C\to A\otimes_\mu C$ and $V\otimes_\mu\mathrm{id}\colon A\otimes_\mu C\to A^G\otimes_\mu C$ satisfy $(V\otimes_\mu\mathrm{id})(\eta\otimes_\mu\mathrm{id})=\mathrm{id}$. Thus, $A^G\otimes_\mu C$ is naturally isomorphic to the closure of the subspace $A^G\odot C$ in $A\otimes_\mu C$, i.e., $A^G\otimes_\mu C\subset A\otimes_\mu C$.

Now let the inclusion $A\subset B$ be G-equivariant, for some (point-norm) continuous G-action $\beta\colon G\to \mathrm{Aut}(B)$, i.e., $\alpha_g(a)=\beta_g(a)$ for $a\in A$ and $g\in G$. Then it holds:
If $A^G\otimes_\mu C\subset B^G\otimes_\nu C$, then $A\otimes_\mu C\subset B\otimes_\nu C$.

Indeed, let J denote the kernel of the natural C^*-morphism $\varphi\colon A\otimes_\mu C\to B\otimes_\nu C$. The functoriality of $\otimes_\mu$ and $\otimes_\nu$ implies

$$\varphi\circ(\alpha(g)\otimes_\mu \mathrm{id}_C)=(\beta(g)\otimes_\mu\mathrm{id}_C)\circ\varphi\,.$$

Thus, $\alpha(g)\otimes_\mu\mathrm{id}_C(J)=J$ for all $g\in G$.

One can see, with help of elementary tensors $a\otimes c$, that $g\mapsto(\alpha(g)\otimes_\mu\mathrm{id}_C)$ and $g\mapsto(\beta(g)\otimes_\nu\mathrm{id}_C)$ are point-norm continuous, and that the corresponding faithful conditional expectations $P_1:=P^G_X\colon x\mapsto\int(\alpha(g)\otimes\mathrm{id})(x)\,\mathrm{d}g$ and $P_2:=P^G_Y\colon y\mapsto\int(\alpha(g)\otimes\mathrm{id})(x)\,\mathrm{d}g$ map $X:=A\otimes_\mu C$ onto the closure of $A^G\odot C$ in $A\otimes_\mu C$, respectively, maps $Y:=B\otimes_\nu C$ onto the closure of $B^G\odot C$ in $B\otimes_\nu C$ and satisfy $\varphi\circ P_1=P_2\circ\varphi$. for $\varphi\colon A\otimes_\mu C\to B\otimes_\nu C$. It follows, that $P_1(J)\subset J\cap\overline{A^G\otimes C}$

Since $A^G\otimes_\mu C\subset A\otimes_\mu C$ and $B^G\otimes_\nu C\subset B\otimes_\nu C$ are complemented subspaces, we get that $P_G(J)$ is in the kernel of the monomorphism $A^G\otimes_\mu C\to B^G\otimes_\nu C$ (after natural identifications of $A^G\otimes_\mu C$ and $B^G\otimes_\nu C$ with its images). Thus $P_G(J)=\{0\}$, and $J=0$.

Now we apply the latter to our cases:

One obtains that A is nuclear if A^G is nuclear if one uses above $\otimes_\mu:=\otimes^{\max}$, $\otimes_\nu:=\otimes^{\min}$, $B:=A$ and C arbitrary.

It has been shown in [**431**, prop.1.1] that B is weakly injective, if an only if, $B\otimes^{\max}C^*(F)=B\otimes^{\min}C^*(F)$, where F is the free group on countably many generators. Thus, we obtain that A is weakly injective if A^G is weakly injective, if we let $\otimes_\mu := \otimes^{\max}$, $\otimes_\nu := \otimes^{\min}$, $A = B$ and $C := C^*(F)$.

By [**431**, prop.1.1], B has the local lifting property, if and only if, $B \otimes^{\max} \mathcal{L}(\ell_2) = B \otimes^{\min} \mathcal{L}(\ell_2)$. We get that A has the local lifting property if A^G has the local lifting property, if we take $\otimes_\mu := \otimes^{\max}$, $\otimes_\nu := \otimes^{\min}$, $A = B$ and $C := C^*(F)$

To see that A has the QWEP if A^G has the QWEP, one can take $\otimes_\mu := \otimes^{\max}$, $\otimes_\nu := \otimes^\ell$, $B := A$, $C := C^*(F)$, because B has QWEP, if and only if, $B \otimes^{max} C^*(F) = B \otimes^\ell C^*(F)$.

Here (generally) $B \otimes_\ell C$ – "the minimal left-exact C^*-tensor-product functor" – is defined by the completion of $B \odot C$ with respect to the C^*-norms

$$\| \sum_k b_k \otimes c_k \|_\ell := \sup_{F,\pi} N_F(\sum_k b_k \otimes c_k)\,,$$

given by (sufficiently many) C^*-algebras F and epimorphisms $\pi\colon F \to B$ and,

$$N_F(\sum_k b_k \otimes c_k) := \operatorname{dist}(\sum_k f_k \otimes c_k, I \otimes^{\min} C)\,,$$

where $\pi(f_k) = b_k$ and $I := \ker(\pi)$, and with distance taken in $F \otimes^{\min} C$.

That the *exactness* of A follows from the exactness of A^G, can be seen by putting $\otimes_\nu := \otimes^{\min}$, $\otimes_\mu := \otimes_r$, $B := A$ and consider arbitrary C.

Here we define the functor $(B, D) \mapsto B \otimes^r D$ – "the minimal right exact C^*-tensor-product functor" – from $D \otimes_\ell B$ by

$$\| \sum_k b_k \otimes d_k \|_r := \| \sum_k d_k \otimes b_k \|_\ell ?????\,.$$

??? `More` ????

If P_G can be approximated point-wise by inner c.p. maps

$$V_\tau(a) := \sum_{k=1}^{n(\tau)} d_{k,\tau}^* a d_{k,\tau}\,,$$

then $P_G(J) \subset J \cap A^G$.

Since P_G is faithful on positive elements, each non-zero closed ideal of A has non-zero intersection with A^G. □

QUESTION A.4.2. Is the class of locally reflexive C^*-algebras is invariant under crossed product by abelian *compact* groups G?

(Could this follows from Takai Duality: $A \otimes \mathbb{K} \cong (A \rtimes G) \rtimes \widehat{G}$. For discrete groups H acting on B – e.g. for $H := \widehat{G}$ and

????

holds $B \subseteq B \rtimes H$. Now take $B := A \rtimes G$ and $H := \widehat{G}$.)

The Question is:

Can we deduce from the local reflexivity of the crossed product $A \rtimes G$ (respectively of the fixed point algebra A^G) of A by a continuous action of a compact group G on A that A itself is locally reflexive?

Even in the case of circle actions $G := T$ $(= S^1)$ the answer is not known.

5. Comparison of elements in C^*-algebras

HERE is some collection of observations on $\approx$ and $\precsim$ and some easy consequences:

Notice $a \approx a^*a \sim_{MvN} aa^*$ in A.

It holds $a \otimes b \approx (a+b) \otimes 0$ in $M_2(A)$ if $a^*b = 0 = ba^*$. Indeed: It implies $b^*a = 0$, $a^*ab^*b = 0$ and Thus $(a+b) \approx (a+b)^*(a+b) = a^*a + b^*b$,

It follows that the $\approx$-classes $[\mathbb{K}(\mathcal{H})]_{approx}$ for all (non-zero) Hilbert spaces $\mathcal{H}$ is isomorphic to $\{0, 1, \ldots, \mathrm{Dim}(\mathcal{H})\}$ if $\mathcal{H}$ has finite dimension and $\{0, 1, 2, \ldots\} \cup \{+\infty\}$ if $\mathcal{H} \cong \ell_2(\mathbb{N})$.

$S, T \in \mathbb{K}(\ell_2(\mathbb{N}))$ satisfy $S \approx T$ if an only if the ranks (= dimension of image) of S^*S and T^*T are the same.

The positive operators $g(\alpha) := (\alpha, \alpha^2, \alpha^3, \ldots) \in \mathbb{K}(\ell_2(\mathbb{N}))$ for $\alpha \in (0,1)$ are properly infinite in $\mathbb{K}(\ell_2(\mathbb{N}))$ with trace $= \alpha/(1-\alpha)$, because $g(\alpha) \precsim g(\alpha^2) = (\alpha^2, \alpha^4, \alpha^6, \ldots)$, and $g(\alpha) \precsim \alpha \cdot g(\alpha^2) = (\alpha^3, \alpha^5, \alpha^7, \ldots)$ imply $g(\alpha) \oplus g(\alpha) \precsim g(\alpha)$, because $\alpha g(\alpha) \sim_{MvN} g(\alpha^2) \oplus \alpha \cdot g(\alpha^2)$ in $\mathbb{K}(\ell_2(\mathbb{N}))$ and $\sim_{MvN}$ implies $\approx$. But $\alpha g(\alpha) \approx g(\alpha)$.

Notice also that inside the diagonal operators in $\mathbb{K}(\ell_2(\mathbb{N}))$ it holds $g(\alpha)^2 = g(\alpha^2)$. It gives $g(\alpha) \oplus g(\alpha) \precsim g(\alpha)^2 \oplus \alpha g(\alpha)^2 \approx \alpha \cdot g(\alpha)$.

The $g(\alpha) \in \mathbb{K}_+$ are all properly infinite and $\lim_{n\to\infty} \|g(1/n)\| \leq 1/n$ with traces $\mathrm{Tr}(g(\alpha)) = \alpha/(1-\alpha)$.

Asymptotic: $2\alpha/(1-\alpha)$ versus $(1+\alpha)\alpha^2/(1-\alpha^2)$ on $\alpha \in (0,1)$ behave similar/different for $\alpha \nearrow 1$.

A flexible almost "topological" version of comparison has been introduced in special cases in the papers [**170, 171**] and was later generalized e.g. by M. Rørdam in [**690**] and others to the following definition.

Definition A.5.1. The **Cuntz comparison** between elements $a, b \in A$ is defined as follows:

We say that b **majorizes** a (in A and in the sense of J. Cuntz [**170, 171**]), and write it as $a \precsim b$ or $b \succsim a$), if there are sequences $c_1, c_2, \ldots; d_1, d_2, \ldots \in A$ such that $a := \lim_n c_n b d_n$.

Below it is shown that $a \precsim b$ is a transitive order relation, i.e., $a \precsim b$ and $b \precsim c$ imply $a \precsim c$. Obviously always $a \precsim a$.

Thus, we can define an equivalence relation $a \approx b$ by $a \precsim b$ and $b \precsim a$. It has the obvious property $a \approx a$ for all $a \in A$.

`move to/ or see one of the below given lemmas:`

It is evident that $a \precsim b$ is a transitive relation: $a \precsim a$ because e.g. always $a = \lim_n (aa^*)^{1/n} a (a^*a)^{1/n}$, and $a = \lim_n g_n c h_n$ for suitable choices $g_n := c_{k_n} e_{\ell_n}$ and $h_n := f_{\ell_n} d_{k_n}$ if $e_1, e_2, \ldots ; f_1, f_2, \ldots \in A$ satisfies $b = \lim_n e_n c f_n$.

Elements $a, b \in A$ are **Cuntz equivalent** (notation: $a \approx b$) if $a \precsim b$ and $b \precsim a$. Since $a \precsim a$ and $\precsim$ is transitive, $\approx$ is an equivalence relation in the usual sense. The $a \approx b$–equivalence classes of $a \in A \otimes \mathbb{K}$ in $A \otimes \mathbb{K}$ will be denoted sometimes by $[a]_\approx$ or simply by $[a]$ for elements a in the *algebraic* inductive limit

$$\operatorname{indlim}_n M_n(A) \;=\; \operatorname{indlim}_n A \otimes M_n \subseteq\; A \otimes \mathbb{K}$$

(but sometimes even for $a \in A \otimes \mathbb{K}$). The corresponding semigroup of this classes with Cuntz-addition has later been written as $W(A)$ by M. Rørdam, cf. [**690**]. We denote by $\mathrm{Cu}(A)$ the classes in $A \otimes \mathbb{K}$, and call it the large Cuntz semi-group.

Since $\mathcal{M}(A \otimes \mathbb{K})$ contains a copy of $\mathcal{E}_2 := C^*(S_1, S_2;\, S_j^* S_k = \delta_{j,k} \cdot 1)$ unitally (It contains also a copy of $\mathcal{O}_2$, but that is for the definitions here not of interest), we can define a (Cuntz-)addition of elements by $a \oplus b := S_1 a S_1^* + S_2 b S_2^*$ for $a, b \in A \otimes \mathbb{K}$, it induces an addition of the $\approx$ classes, and allow to define the "general" and the "local" Cuntz semigroups, namely the "general" for all elements of $A \otimes \mathbb{K}$ and the "local" for the Pedersen ideal $P(A \otimes \mathbb{K})$ of $A \otimes \mathbb{K}$. Notice here that $P(A \otimes \mathbb{K})$ is usually different from the – naturally in $P(A \otimes \mathbb{K})$ as inductive limit contained – union (respective inductive limit) $\bigcap_{n \in \mathbb{N}} M_n(P(A))$, but from the definition of the Pedersen ideals $P(A)$ of A and $P(\mathbb{K} \otimes A)$ of $\mathbb{K} \otimes A$ as "the minimal dense algebraic ideals" it is easy to see that each element $x \in P(A \otimes \mathbb{K})_+$ is in the stronger sense of Murray–von-Neumann equivalent (see below) to some element in $y \in M_n(P(A))_+$ for some $n := n(x) \in \mathbb{N}$.

The semigroup $W(A)$ for elements in $\bigcup_n M_n(A)$ as introduced by M. Rørdam, [**690**], is in general strictly between the "large" and the "small" Cuntz semi-groups $\mathrm{Cu}(A)$ and $\mathrm{CS}(A)$.

It is often considered as the algebraic inductive limit

$$M_n \otimes A = M_n(A) \to M_{n+1}(A) = M_{n+1} \otimes A$$

via the embedding $M_n \oplus \{0\} \subseteq M_{n+1}$. But this is inessential because $\precsim$ and $\approx$ are weaker than $\leq$ and $\sim_{\mathrm{MvN}}$ combined, but this requires some care.

A stronger equivalence relation $\sim$ is the *Murray–von-Neumann equivalence*: Elements $a, b \in A_+$ are **MvN-equivalent** (denoted by $a \sim b$ or $a \sim_{\mathrm{MvN}} b$), if they are equivalent in sense of *Murray* and *von Neumann*, i.e., if there exists $d \in A$ with $d^*d = a$ and $dd^* = b$. Indeed, $a \approx b$ because one can take $d_n := d((d^*d)^{1/2} + 1/n)^{-1}$ and $c_n := d_n^*$ to get $a := \lim d_n^* b d_n$ and $b := \lim d_n a d_n^*$.

We define n**-step majorization** (denoted $b \succ_n a$) by

$$a \oplus 0_{n-1} \cong a \otimes p_{11} \precsim b \otimes 1_n\,.$$

?? Check all chapters for closed ideals: $J(b)$, J_b, $I(b)$ generated by an element or subset of B.
Decide which of them is the best and change others!!!

Definition A.5.2. Let B a C^*-algebra. A non-zero *contraction* $c \in B$ will be called a **scaling element** if $c^*cc = c$. We call a scaling element $c \in B$ "strictly scaling" if in addition $c^*c \neq cc^*$.

A positive contraction $b \in B_+$ is a **scale generator** if there exists $d \in B$ and $0 < \delta < \varepsilon < 1$ such that $d^*(b-\varepsilon)_+d = (b-\delta)_+$

In particular then, $(b-\delta)_+$ is in the closed ideal generated by $(b-\varepsilon)_+$.

A positive element $b \in B_+$ is a **compactly supported** element in B if there exist $\delta \in (0, \|b\|)$ such that b is contained in the closed ideal generated by $(b-\delta)_+$. (In particular each projection $p \in B$ is compactly supported.)

The element $b \in B$ is called **compactly n-supported** if there exists $\delta > 0$ such that $b \otimes p_{11} \precsim (b-\delta)_+ \otimes 1_n$.

Remark A.5.3. An equivalent definition of a scaling element $c \in B$ is that $e := c^*c$ is a positive contraction in B with $ecc^* = cc^* = cc^*e$.

A scaling element $c \in B$ that is not *strictly* scaling in sense of our Definition A.5.2 is simply a normal element in B with the property that $\operatorname{Spec}(c) \subseteq \{0\} \cup S^1$.

Notice that B. Blackadar and J. Cuntz call elements $c \in B$ in [**78**, def. 1.1] "scaling" only if they are *strictly* scaling elements in sense of our Definition A.5.2.

Remark A.5.4. The usual definition of compactness implies for Hausdorff spaces X that compact subsets of X are closed. But notice that for non-Hausdorff spaces this is not the case if we take the usual definition of a "compact" subset $Y \subseteq X$ that we find in every family $\mathcal{V} \subseteq \mathbb{O}(X)$ with $Y \subseteq \bigcup_{U \in \mathcal{V}} U$ a finite collection $U_1, \ldots, U_n \in \mathcal{V}$ with $Y \subseteq U_1 \cup \ldots \cup U_n$. This kind of subsets Y of X has been called in the Bourbaki monographs "quasi-compact" for non-Hausdorff spaces.

We have to consider sometimes the T_0 spaces $X := \operatorname{Prim}(A)$ for separable C^*-algebras A – or in cases where A is non-separable its "point" completions $X := \operatorname{prime}(A)$ ([4]). *We write often "compact" instead of "quasi-compact" in our considerations.*

Moreover this kind of ("quasi -") compact subsets K of X are even not "*saturated*", i.e., are not the intersections of all open subsets of X that contain K. Only the very special "coherent" spaces X defined by the property that each (quasi-) compact subset of X is saturated in this sense.

The class of saturated spaces does not contain $\operatorname{Prim}(A_0)$ for

$$A_0 := \{ f \in C([0,1], M_2) \, ; \; f(0) \in \mathbb{C} \oplus \mathbb{C} = \operatorname{diag}(M_2) \} .$$

[4] Such "adding" of all prime closed subsets of a T_0 space X to the set of points in X also called a "sobrification" of X, in a sense it is a kind of completion of X that does not change its lattice of open subsets.

The notions of Definition A.5.2 will be justified by the following Lemma:

LEMMA A.5.5. *Let $b \in B_+$, $c \in I((b-\gamma)_+)_+$ for some $\gamma > 0$.*

(i) *For each $\varepsilon > 0$ there exists $n := n(\varepsilon) \in \mathbb{N}$ such that $(b-\varepsilon)_+ \otimes p_{11} \precsim c \otimes 1_n$ in $A \otimes M_n$, if and only if, b is in the closed ideal generated by c. In particular, then $b \in I((b-\gamma)_+)$.*

(ii) *If b is contained in the closed ideal $I((b-\gamma)_+)$, then the Dini function $f_b \colon J \in \mathrm{Prim}(B) \mapsto \|\pi_J(b)\|$ on $\mathrm{Prim}(B)$ has an open and compact subset U_b of $\mathrm{Prim}(B)$ as its support, and $f_b(J) \geq \gamma$ for all $J \in U_b$. In particular, the closed ideal $I(b) = \overline{\mathrm{span}(BbB)}$ has (quasi-) compact primitive ideal space $\mathrm{Prim}(I(b))$.*

(iii) *If the closed ideal $I(b)$ of B generated by $b \in B_+$ has compact primitive ideal space, then there exists $\gamma > 0$ such that b is in the closed ideal generated by $(b-\gamma)_+$.*

In particular, for each $\varepsilon > 0$ there exists $n := n(\varepsilon) \in \mathbb{N}$ and $d_1, \ldots, d_n \in B$ such that $(b-\varepsilon)_+ = \sum_{k=1}^n d_k^*(b-\gamma)_+ d_k$.

(iv) *Let $c \in B$ a* scaling element, *i.e., $\|c\| \leq 1$ and $c^*cc = c$. The element $V(c) := c + i(1-c^*c)^{1/2}$ is an isometry in $B + \mathbb{C}\cdot 1$, and the projection*

$$p := p(c) := 1 - V(c)V(c)^* = (c^*c - cc^*) + i(c(1-c^*c)^{1/2} - (1-c^*c)^{1/2}c^*)$$

is a projection in the closed ideal $I(c)$ of B.

The ideal $I(p)$ generated by p contains a sequence of mutually orthogonal Murray–von-Neumann equivalent projections $p = p(c) =: p_1, p_2, \ldots$.

(v) *The closed ideal $I(p) \subseteq I(c)$ given by the projection $p \in I(c)$ of part (iv) is generated as a closed ideal by $c^*c - cc^* \in I(c)$.*

The ideal $I(p)$ contains $c^*c(1-c^*c)$ and each $d \in B$ that satisfies $dc = 0$ and $dc^*c = d$.

(vi) *If b and γ satisfy* (iii) *and that $(b-\gamma)_+$ is properly infinite, then for each $\varepsilon \in (0,\gamma)$ there exists $d_k := d_k(\varepsilon) \in B$ $(k = 1,2)$ such that*

$$d_j^*(b-\gamma)_+ d_k = \delta_{jk} \min(1, \varepsilon^{-1}(b-\varepsilon)_+) = \delta_{jk}\varepsilon^{-1}\big((b-\varepsilon)_+ - (b-(1+\varepsilon))_+\big).$$

In particular, the elements $c_k := (b-\gamma)_+^{1/2} d_k$ are "scaling" elements in B with

$$c_j^*c_k = \delta_{jk} c_1^* c_1\,, \;\; c_k^* c_k c_k = c_k \;\; \text{and } \|c_k\| = 1$$

that generates the closed ideal $I(b) := \overline{\mathrm{span}(BbB)}$ of B.

(vii) *The closed ideal $I(p_1)$ of B generated by $p_1 := 1 - V(c_1)V(c_1)^*$ with scaling elements $c_1, c_2 \in B$ as in Part (vi) coincides with $I(b)$. In particular, $I(b)$ is generated by a hereditary stable C^*-subalgebra D that is generated by a sequence of mutually orthogonal and mutually equivalent projections $p_1, p_2, \ldots$.*

PROOF. (i): Let $b \in B_+$, and $c \in I((b-\gamma)_+)_+$ for fixed $\gamma > 0$.

If b is contained in the closed ideal $I(c)$ generated by c then for each $\varepsilon > 0$ there exists $n \in \mathbb{N}$ and $d_1, \ldots, d_n \in B$ with $\|b - \sum_k d_k^* c d_k\| < \varepsilon/2$. By norm-continuity of $\delta \mapsto (c-\delta)_+$ and by Lemma 2.1.9, there exists a contraction $e \in B$ such that

$$(b-\varepsilon)_+ \;=\; \sum_{1\leq k\leq n} (d_k e)^*(c-\delta)_+(d_k e)\,.$$

We can this equation express by $(b-\varepsilon)_+ \otimes p_{11} = D^*((c-\delta)_+ \otimes 1_n)D$ in $B \otimes M_n$ with column $D := \sum_k (d_k e) \otimes p_{k1} \in M_{n,1}(B)$.

In particular, for each $\varepsilon > 0$ there exists $n := n(\varepsilon) \in \mathbb{N}$ such that $(b-\varepsilon)_+ \otimes p_{11} \precsim c \otimes 1_n$ in $A \otimes M_n$.

Suppose now that for each $\varepsilon > 0$ there exists $n := n(\varepsilon) \in \mathbb{N}$ such that $(b-\varepsilon)_+ \otimes p_{11} \precsim c \otimes 1_n$ in $A \otimes M_n$. It says that there exists a sequence of column matrices $D_1, D_2, \ldots \in M_{n,1}(B) \subseteq M_n(B)$ with $(b-\varepsilon)_+ \otimes p_{11} = \lim_n D_n^*(c \otimes 1_n)D_n$ in $M_n(B)$. It follows that $(b-\varepsilon)_+ \otimes p_{11} \in M_n(I(c))$ with $I(c) \lhd B$ the ideal generated by c. It follows that $(b-\varepsilon)_+ \in I(c) \subseteq I((b-\gamma)_+)$ for each $\varepsilon > 0$. Thus, b is in the closed ideal $I(c)$ generated by c, in particular, $b \in I((b-\gamma)_+)$.

(ii): Recall here that $f_b^{-1}[\gamma, \infty) \subseteq \mathrm{Prim}(A)$ is (quasi-) compact for every $\gamma > 0$, cf. [**213**, prop. 3.3.7], where we consider here the Dini function f_b on $\mathrm{Prim}(A)$ defined by $f_b(J) := \|\pi_J(b)\|$ for $b \in B$ and $J \in \mathrm{Prim}(B)$.

If b is contained in the closed ideal

$$I((b-\gamma)_+) \;=\; \bigcap \{ J \in \mathrm{Prim}(B)\,;\; \|\pi_J(b)\| \leq \gamma \}\,,$$

then the Dini function $f_b \colon J \in \mathrm{Prim}(B) \mapsto \|\pi_J(b)\| \in [0, \infty)$ on $\mathrm{Prim}(B)$ has support

$$U_b := \; f_b^{-1}(0, \infty) = \{ J \in \mathrm{Prim}(B)\,;\; f_b(J) > 0 \}\,.$$

This set U_b is identical with the (quasi-) compact subset

$$f_b^{-1}[\gamma, \infty) = \{ J \in \mathrm{Prim}(B)\,;\; f_b(J) \geq \gamma \}\,.$$

Indeed: The inequality $f_b(J) = \|\pi_J(b)\| < \gamma$ for $J \in \mathrm{Prim}(A)$ implies that there are $\varepsilon > 0$ and $\delta \in [f_b(J), \gamma)$ such that $\pi_J((b-\delta)_+) = 0$ and, – by assumption $b \in I((b-\gamma)_+)$ –, that there exist $d_1, \ldots, d_n \in B$ with $(b-\varepsilon)_+ = \sum_k d_k^*(b-\delta)_+ d_k$. If we apply to this π_J, we see that

$$(f_b(J) - \varepsilon)_+ = \|\pi_J((b-\varepsilon)_+)\| \leq \sum_k \|d_k\|^2 \|\pi_J((b-\delta)_+)\| = 0\,.$$

Thus, $f_b(J) \leq \varepsilon$ for all $\varepsilon > 0$, i.e., $f_b(J) = 0$ if $f_b(J) < \gamma$. It means $U_b := f_b^{-1}(0, \infty) = f_b^{-1}[\gamma, \infty)$.

Since the set $f_b(J) = \|\pi_J(b)\| \geq \gamma$ is a compact subset of $\mathrm{Prim}(B)$, the closed ideal $I(b) = \overline{\mathrm{span}(BbB)} = \bigcap \{ J \in \mathrm{Prim}(B)\,;\; f_b(J) = 0 \}$ has compact primitive ideal space $\mathrm{Prim}(I(b)) = f_b^{-1}[\gamma, \infty)$.

(iii): Suppose that $I(b)$ has compact primitive ideal space $\mathrm{Prim}(I(b)) \subseteq \mathrm{Prim}(B)$. The corresponding open subset of $\mathrm{Prim}(B)$ is given by $f_b^{-1}(0, \infty)$. The family of open subsets $f_b^{-1}(\delta, \infty)$ of $f_b^{-1}(0, \infty)$ with $\delta > 0$ covers the compact space $f_b^{-1}(0, \infty)$. Thus, there exists $\gamma > 0$ such that $f_b^{-1}(\gamma, \infty) = f_b^{-1}(0, \infty)$. It is easy to see that $f_b^{-1}(\gamma, \infty) = f_c^{-1}(0, \infty)$ for $c = (b-\gamma)_+$. It follows that $(b-\gamma)_+$ and b generate the same closed ideal of B.

This implies that for each $\varepsilon > 0$ there exists $n := n(\varepsilon) \in N$ and $d_1, \ldots, d_n \in B$ such that $(b-\varepsilon)_+ = \sum_{k=1}^n d_k^* \, (b-\gamma)_+ \, d_k$.

(iv,v): Let $c \in B$ a contraction with $cc^*c^*c = cc^*$. The element $V := V(c) := c + i(1-c^*c)^{1/2}$ of $B + \mathbb{C} \cdot 1$ is an isometry, because $cc^*(1-c^*c) = 0$ implies $c^*(1-c^*c) = 0$, $c^*(1-c^*c)^{1/2} = 0$ and $(1-c^*c)^{1/2}c = 0$.

The projection $p := p(c) := 1 - V(c)V(c)^*$, is in $I(c) \subseteq B$. The projections

$$p_n := V^{n-1}(V^*)^{n-1} - V^n(V^*)^n$$

are mutually orthogonal, where we let $p_1 := p(c)$. If $m < n$ then $p_m \sim_{MvN} p_n$ by $Z = V^{n-m}p_m$, i.e., $Zp_mZ^* = p_n$. In particular, $p_n \in I(p(c))$ for all $n \in \mathbb{N}$.

The equations $c^*(1-c^*c)^{1/2} = 0$ and $(1-c^*c)^{1/2}c = 0$ imply $p := 1 - V(c)V(c)^* = (c^*c - cc^*) + i(c(1-c^*c)^{1/2} - (1-c^*c)^{1/2}c^*)$ and that $(1-c^*c)^{1/2}p(1-c^*c)^{1/2} = c^*c(1-c^*c)$. Thus, $J := I(c^*c(1-c^*c)) \subseteq I(p)$. Since $c(1-c^*c) \in J$, we get $c(1-c^*c)^{1/2} \in J$ and that $\pi_J(p) = \pi_J(c^*c - cc^*)$, i.e., $p - (c^*c - cc^*) \in J$. The epimorphism π_J maps $I(p) \supseteq J$ onto $I(p)/J$ and has kernel $J \subseteq I(p)$. We get that the positive element $c^*c - cc^*$ must be in $I(p)$.

Let $d \in B$ with $d^*c = 0$ and $dc^*c = d$. Then $dd^*V(c) = 0$, because $d(1-c^*c)^{1/2} = 0$. It follows $dd^* \leq \|d\|^2 p$, which implies $d \in I(p)$.

(vi): Suppose that $b \in B_+$ and γ satisfy (iii) and that $(b-\gamma)_+$ is properly infinite.

It implies that for each $\tau > \gamma$ and $n \in \mathbb{N}$ the existence of $e_1, \ldots, e_n \in B$ such that $e_j^*(b-\gamma)_+ e_k = \delta_{ij}(b-\tau)_+$.

Indeed, for each $\mu > 0$ and $n \in \mathbb{N}$ there exists a matrix $R \in M_n(B)$ that satisfies $R^*((b-\gamma)_+ \otimes p_{11})R = ((b-\gamma)_+ - \mu)_+ \otimes 1_n$. Here we use again Lemma 2.1.9 in $M_n(B)$ to obtain equality. Define $\mu := \tau - \gamma$ and $e_1, \ldots, e_n$ by $[e_1, \ldots, e_n] := R$ with R for μ. The $e_1, \ldots, e_n$ have the desired property.

Let $\varepsilon \in (0, \gamma)$. There exists $\tau > \gamma$ and $m := m(\varepsilon, \tau) \in \mathbb{N}$ $g_\ell := g_\ell(\varepsilon, \tau) \in B$ ($\ell = 1, \ldots, m$) such that

$$\sum_{1 \leq \ell \leq m} g_\ell^*(b-\tau)_+ g_\ell = \min(1, \varepsilon^{-1}(b-\varepsilon)_+) = \varepsilon^{-1}\big((b-\varepsilon)_+ - (b-(1+\varepsilon))_+\big)\,,$$

because we find $f_\ell \in B$ with

$$\| \sum_\ell f_\ell^*(b-\gamma)_+ f_\ell - (b-\varepsilon/3)_+ \| < \varepsilon/3$$

and can apply the continuity of $\tau \mapsto (b-\tau)_+$ and the Lemma 2.1.9 to get the equation proper by multiplying the f_ℓ with a suitable contraction e from the right to reach the equality

$$\sum_{1 \leq \ell \leq m} (f_\ell e)^*(b-\tau)_+(f_\ell e) = (b - 2\varepsilon/3)_+ \,.$$

Finally we let $g_\ell := f_\ell e h(b)$ where

$$h(t) := \min(\varepsilon, (t-\varepsilon)_+)/(\varepsilon(t-2\varepsilon/3)_+)\,.$$

We take $n := 2m$ in the above given construction of the e_k and let $d_1 := \sum_{1\leq \ell\leq m} e_\ell g_\ell$ and $d_2 := \sum_{1\leq \ell\leq m} e_{m+\ell} g_\ell$. Then

$$d_j^*(b-\gamma)_+ d_k \;=\; \delta_{jk}\min(1, \varepsilon^{-1}(b-\varepsilon)_+)\,.$$

In particular, the $c_k := (b-\gamma)_+^{1/2} d_k$ are "scaling" elements in B with $c_j^* c_k = \delta_{jk} c_1^* c_1$, $c_k c_k^* c_k^* c_k = c_k c_k^*$, such that $I(c_k) = I(b)$ for the the closed ideals $I(c_k) := \overline{\mathrm{span}(Bc_kB)}$ and $I(b) := \overline{\mathrm{span}(BbB)}$ of B. □

We have sometimes to deduce estimates for the infimum $\gamma(n,a,b,\varepsilon)$ of the norms $\|\sum d_k^* d_k\|$ for $d_1,\ldots,d_n \in A$ with $\|b - \sum_k d_k^* a d_k\| < \varepsilon$. Notice that then there are *contractions* $e_1,\ldots,e_m \in A$ such that $\|b - \sum_j e_j^* a e_j\| < \varepsilon$ and $m \leq n(\gamma(n,a,b,\varepsilon)+1)$.

Lemma A.5.6. *Let $X = [b_{k\ell}] \in M_n(B)_+$, $d_1,\ldots,d_n \in B$, and let $\mathrm{diag}(X) \in M_n(B)$ denote the diagonal matrix with entries $b_{11},\ldots,b_{nn}$ in the diagonal of X.*

(i) *The linear map $X \mapsto n\,\mathrm{diag}(X) - X$ on $M_n(B)$ is completely positive. In particular, $X \leq n\,\mathrm{diag}(X)$ for all $X \in M_n(B)_+$.*
(ii) *Let $\mathrm{Tr}_n([\alpha_{jk}]) := (\alpha_{11}+\cdots+\alpha_{nn})\cdot 1_n$ for $[\alpha_{jk}] \in M_n$. The map $X \mapsto n(\mathrm{id}_B \otimes \mathrm{Tr}_n)(X) - X$ on $M_n(B)$ is completely positive.*
In particular, $X \leq n(\mathrm{id}_B\otimes \mathrm{Tr}_n)(X) = n(b_{11}+\ldots+b_{nn})\otimes 1_n$ for all $X = [b_{k,\ell}] \in M_n(B)_+$.
(iii) *$0 \leq \sum_{k,\ell=1}^n b_{k\ell} \leq n(b_{11}+\ldots+b_{nn})$ for all $X = [b_{k,\ell}] \in M_n(B)_+$.*
(iv) *For every $b \in B_+$ and $d_1,\ldots,d_n \in B$,*

$$(d_1+\cdots+d_n)^* b (d_1+\cdots+d_n) \leq n\,(d_1^* b d_1 + \cdots + d_n^* b d_n)\;.$$

Proof. (i): We identify $M_n(\mathcal{M}(B))$ naturally with $\mathcal{M}(B)\otimes M_n$, and M_n with $1\otimes M_n$. Let $z := \exp((2\pi i)/n)$ and $U := \mathrm{diag}(1, z, \ldots, z^{n-1}) \in M_n \subseteq M_n(\mathcal{M}(B))$. Then, for $a \in \mathcal{M}(B)$,

$$\sum_{k=0}^{n-1} (U^k)^*(a\otimes e_{ij})U^k = a\otimes (\sum_k z^{(j-i)k}) e_{ij} = n\delta_{ij}(a\otimes e_{ij})\,.$$

Thus, $X = (U^0)^* X U^0 \leq \sum_{k=0}^{n-1} (U^k)^* X U^k = n\,\mathrm{diag}(X)$, and the map

$$X \mapsto n\,\mathrm{diag}(X) - X = \sum_{k=1}^{n-1} (U^k)^* X U^k$$

is completely positive, because is a sum of c.p. maps.

(ii): The map $n(\mathrm{id}_B\otimes \mathrm{Tr}_n)(X) - X = (\mathrm{id}_B \otimes (n\,\mathrm{Tr}_n - \mathrm{id}))(X)$, id_B is c.p. on B and we show tat $n\,\mathrm{Tr}_n - \mathrm{id}$ is c.p. on M_n, where we define $\mathrm{Tr}([\alpha_{jk}]) := (\sum_k \alpha_{kk})\cdot 1_n$.

The complete positivity of $n\,\mathrm{Tr}_n - \mathrm{id}$ on M_n can be seen from the formula

$$n^{-1}(\sum_k \alpha_{kk})\cdot 1_n = n^{-2}\sum_{g\in G} g^{-1}[\alpha_{jk}]g\,,$$

because this implies $n(\sum_k \alpha_{kk})\cdot 1_n - [\alpha_{jk}]$ is the sum of n^2-1 inner *-automorphisms $g^{-1}[\alpha_{jk}]g$ of M_n.

Here $G := G(U,V) \subseteq \mathcal{U}(n) = \mathcal{U}(M_n)$ is the irreducible finite subgroup G of $\mathcal{U}(M_n)$ with n^2 unitary elements that is generated by the unitary $U := \mathrm{diag}(z^0, z^1, \ldots, z^{n-1})$ with $z := \exp(2\pi i)/n$ and by the cyclic permutation $V \in \mathcal{U}(M_n)$ of the canonical basis $\{e_1, \ldots, e_n\}$ of $\mathbb{C}^n$, i.e., $V(e_k) = e_{k+1}$ $(k = 1, \ldots, n-1)$ and $V(e_n) = e_1$. To see $|G| = n^2$, notice that $U^jV^k = z^{jk}V^kU^j$ for $j, k \in \{0, \ldots, n-1\}$.

`Alternative proof:`

The map

$$S\colon X \mapsto \mathrm{diag}(X) = (b_{11}, \ldots, b_{nn}) \in B^n = B \oplus \cdots \oplus B \cong \mathrm{diag}(M_n(B)) \subseteq M_n(B)$$

is a c.p. map, because it is a conditional expectation and

$$\mathrm{diag}(X) = n^{-1}(n\,\mathrm{diag}(X) - X) + n^{-1}X\,.$$

It is clear that the maps $T_j(b_1, \ldots, b_n) := \sum_{k\neq j} b_k$ are completely positive, because they are sums of c.p. maps.

The map $(b_1, \ldots, b_n) \mapsto (b_1 + \ldots + b_n) \otimes 1_n - \mathrm{diag}(b_1, \ldots, b_n) \in M_n(B)$ is completely positive in $B^n \cong \mathrm{diag}(M_n(B))$, because it is the orthogonal sum of the c.p. maps T_j.

It follows the positivity of

$$X \mapsto [n(b_{11}+\ldots+b_{nn})]\otimes 1_n - X = n((\mathrm{id}_B \otimes \mathrm{Tr}_n)(X) - \mathrm{diag}(X)) + (n\,\mathrm{diag}(X) - X)\,.$$

(iii): Let C the column $C := [1, 1, \ldots, 1]^\top \in M_{n,1}(\mathcal{M}(B))$. Apply the c.p. map $Y \mapsto C^*YC$ to $Y := n\,\mathrm{diag}(X) - X$. Since $Y \geq 0$ by part (i), we get

$$\sum_{k,\ell=1}^{n} b_{k\ell} = C^*XC \leq nC^*\,\mathrm{diag}(X)C = n(b_{11} + \ldots + b_{nn})\,.$$

(iv): Take $X := [b_{jk}]$ in part (iii) with $b_{j,k} := d_j^* b d_k$, i.e., $X = D^*D$ for the row matrix $D := [b^{1/2}d_1, \cdots, b^{1/2}d_n] \in M_{n,1}(B)$. □

Next remark considers the equivalence given by polar decomposition of a of the hereditary C^*-subalgebras generated by a^*a and by aa^*.

`Next appears also before proof of THM.E. ??`

Remark A.5.7. Let $a \in A$ non-zero and $a := v(a^*a)^{1/2}$ its polar decomposition in the W*-algebra A^{**}, let $D := \overline{a^*aAa^*a}$ and $E := \overline{aa^*Aaa^*}$ the hereditary C^*-subalgebras of A generated by a^*a, respectively by aa^*.

Then $D = \overline{a^*Aa}$, $E = \overline{aAa^*}$, and the map $\varphi\colon d \in D \to vd\,v^* \in A^{**}$ has image in E and defines a C^*-algebra isomorphism from D onto E. The inverse isomorphism φ^{-1} is given by $e \in E \mapsto v^*ev \in D$.

It holds $\varphi(D \cap I) = E \cap I$ for every closed ideal $I \triangleleft A$ of A. In particular, if D is a full hereditary C^*-subalgebra of A, i.e., if $\overline{\mathrm{span}(ADA)} = A$, then also E is full in A.

In particular, D is simple if and only if E is simple.

PROOF. Let $a \in A$ and $a = v(a^*a)^{1/2} = (aa^*)^{1/2}v$ its unique (right) polar decomposition of a in A^{**}. Then $vx \in A$ for every x in the norm-closed right-ideal $R := \overline{a^*aA} = \overline{a^*A}$ of A that is generated by $(a^*a)^{1/2}$.

The map $x \mapsto vx$ is an isometric right-module isomorphism from R onto the closed right-ideal $\overline{aA} = \overline{aa^*A}$. The inverse map from $\overline{aA}$ onto R is given by $y \mapsto v^*y$, because $a^* = v^*(aa^*)^{1/2}$ is the polar decomposition of a^* in A^{**}.

This follows from $vf(a^*a) = f(aa^*)v$ for each non-negative continuous function $f \in \mathrm{C}_0(0, \|a\|^2]$, and can be easily seen in A^{**}.

easily seen: more details?

In particular, $y := vz^\alpha \in A$ and $y^*y = z^{2\alpha}$ for all $z \in A_+$ with $z \leq a^*a$ and all $\alpha > 0$. □

REMARK A.5.8. Let D a closed hereditary C^*-subalgebra of A.

Each closed ideal J of D is the intersection $J = D \cap I$ with D of the closed ideal $I := I(J) := \overline{\mathrm{span}(AJA)}$ of A.

For $I_1, I_2 \in \mathcal{I}(A)$ holds $I_1 \cap D = I_2 \cap D$ if and only if $I_1 \cap I(D) = I_2 \cap I(D)$, where $I(D) := \overline{\mathrm{span}(ADA)}$.

If $I(D) = A$ then the map $I \in \mathcal{I}(A) \mapsto J := I \cap D \in \mathcal{I}(D)$ is a lattice isomorphism from the lattice $\mathcal{I}(A)$ of closed ideals of A onto the lattice $\mathcal{D}$. The inverse of this map is given by $J \mapsto I := \overline{\mathrm{span}(AJA)}$.

6. Basic properties of Cuntz semigroups

Compare also with W-vN equivalence ??

Let A a C^*-algebra. Recall that $a \precsim b$ (with more precise notation $a \precsim_A b$) for $a, b \in A$ is defined by the existence of sequences of elements $d_n, e_n \in A$ with $a = \lim_n d_n b e_n$.

In particular, always $a \precsim a^*a \precsim aa^* \precsim a^*$.

The relation depends from A and passes in general not to C^*-subalgebras: Let $a, b \in A_+$ non-zero with $ab = 0$ and $a \precsim_A b$ define $D \subseteq A$ as $D := \overline{aAa + bAb}$ then $a \not\precsim b$ in D.

Notice that for $A \neq 0$, ?????

It follows that $a, b \in (A \otimes \mathbb{K})_+$ then $a \precsim b$ is equivalent to the existence of $c_1, c_2, \ldots \in A \otimes \mathbb{K}$ with $a = \lim_n c_n^* b c_n$. Moreover, if $a \neq 0$, the c_n can be replaced here by $(b-\delta_n)_+^{1/k_n} c_n (a-\delta_n)_+^{1/k_n}$ with suitable choices $k_n \in \mathbb{N}, < \delta_n < \min(\|a\|, \|b\|)$ with $k_n \to \infty$ and $\delta_n \to 0$, depending on the norms $\|c_n\|$, $\|a\|$ and $\|b\|$ in an "universal" way. (The explicit formula should be an exercise.) Thus, if a, b are in the Pedersen ideal $P(A)$ of A – which is by definition the minimal dense ideal of A denoted by $P(A)$ – then $a, b \in P(A)$ and $a \approx_A b$ implies $a \approx_{P(A)} b$. Recall also that $a \approx b$ means $a \precsim b$ and $b \precsim a$.

LEMMA A.6.1. *The relation $a \precsim_A b$ has following properties:*

(i) *The relation $\precsim$ is transitive:*

Always $a \precsim a$ in $C^*(a) \subseteq A$ itself. The relations $a \precsim_A b$ and $b \precsim_A c$ imply $a \precsim_A c$.

The relation $a \approx b$, i.e., $a \precsim b$ and $b \precsim a$ together, is an equivalence relation on A, and it satisfies that $a \precsim b$, $a \approx c$ and $b \approx d$ together imply that $c \precsim d$.

(ii) *The relations $\approx$ and $\precsim$ are compatible with $\oplus$, e.g. $a \oplus c \precsim b \oplus d$ in $M_2(A)$ if $a \precsim b$ and $c \precsim d$ in A. If, moreover, $b, d \in A$ are "orthogonal" in the sense that $bd^* = 0$ and $b^*d = 0$, then $a \precsim b$ and $c \precsim d$ imply $a \oplus c \precsim (b + d) \oplus 0 \approx b \oplus d$ in $M_2(A)$.*

(iii) *The relation $\precsim$ is compatible with *-morphisms: If $\psi \colon A \to B$ is a *-morphism, and $a \precsim_A b$ in A, then $\psi(a) \precsim_B \psi(b)$ in B.*

(iv) *The set $\xi(b)$ of $a \in A$ with $a \precsim b$ is* closed *in A and satisfies $c\xi(b)d \subseteq \xi(b)$ for $c, d \in \mathcal{M}(A)$.*

More precisely, $\xi(b)$ is the closure in A of the set *of all elements $cbd \in A$ with $c, d \in \mathcal{M}(A)$.*

(v) *It holds $aa^* \approx a^*a \approx a^* \approx a$, and $g(a^*a) \precsim a$ for all continuous functions g on $\mathrm{Spec}(a^*a)$ with $g(0) = 0$.*

If, in addition, $g(t) > 0$ for $t > 0$, then $g(a^*a) \approx a$.

(vi) *If $a, b \in A_+$, then $a \precsim b$, if and only if, for every $\varepsilon > 0$, there are $\delta = \delta(\varepsilon) > 0$ and $d = d(\varepsilon) \in A_+$ such that $d^*(b - \delta)_+ d = (a - \varepsilon)_+$. In particular, $a \precsim b$ if $a \sim_{MvN} c$ for some $0 \leq c \leq b$.*

If p and q are projections in A, then $p \precsim q$, if and only if, there is a projection $r \in A$ with $p \sim r \leq q$.

(vii) *If $a \in A_+$ then $a \precsim b$ if and only if $(a - \varepsilon)_+ \precsim b$ for all $\varepsilon > 0$.*

(viii) *If D is a hereditary C^*-subalgebra of A, and $a, b \in D \subseteq A$, then $a \precsim_D b$ in D, if and only if $a \precsim_A b$ in A.*

Particular cases are:

Always $a \precsim_D b$ for $a \in D := \overline{b^*Ab}$ and $b \in A$.

$x \oplus 0_n \precsim_B y \oplus 0_n$ in $B := M_{n+1}(A)$, if and only if, $a \precsim_A y$ (i.e., in A itself).

If $a, b \in A$, then $a \precsim_A b$ in A, if and only if, $a \precsim_{\mathcal{M}(A)} b$ in the multiplier algebra $\mathcal{M}(A)$.

(ix) *$(x \oplus y) \approx (y \oplus x)$ in $M_2(A)$ and $((x \oplus y) \oplus z) \approx (x \oplus (y \oplus z))$ in $M_3(A)$ for all $x, y, z \in A$.*

(x) *$(x + y) \oplus 0 \precsim x \oplus y$ in $M_2(A)$ for all $x, y \in A$.*

(xi) *If $a, b \in A_+$, $\pi_J(a) \precsim \pi_J(b)$ for $J \lhd A$, then, there is $c \in J_+$ with $a \precsim b \oplus c$.*

In particular, there exists $c \in J_+ \cap \overline{bAb}$ such that $(b \oplus b) \precsim (b \oplus c)$ if $\pi_J(b) \oplus \pi_J(b) \precsim \pi_J(b)$.

(xii) *Suppose that $a \in A_+$ and that there is $b \in \mathrm{Ann}(a, A)_+$ such that $a \in \overline{\mathrm{span}(AbA)}$.*

Then, for each closed ideal $J \triangleleft A$, each $\delta > 0$, each $c \in J_+$, and every $\varepsilon > 0$ there is $d = d(\varepsilon) \in J_+ \cap \mathrm{Ann}((a-\delta)_+, A)$ and $n = n(\delta, \varepsilon) \in \mathbb{N}$ such that

$$(a-\delta)_+ + (c-\varepsilon)_+ \precsim a \oplus (d \otimes 1_n)\,.$$

(xiii) *Parts (xiii) and (xiv) should be separated*

Suppose that A is an AW-algebra, $p_n, q \in A$ projections with $p_1 \leq p_2 \leq \cdots$ and with $p_n \precsim q$ for each $n \in \mathbb{N}$. Then $p \precsim q$ for $p := \sup_n p_n$.*

(xiv) *If A is an AW*-algebra, and if $a, b \in A_+$ with $a \precsim b$, then $p_a \precsim p_b$ for the support projections $p_a, p_b \in A$ of a and b, and $az \precsim bz$ for each $z \in A_+$ in the center of A.*

(xv) *Suppose that $a_n, b_n \in A$, $a = \lim a_n$, $b = \lim b_n$. If there is a continuous function $\psi \in \mathrm{C}[0,1]_+$ with $\psi(\delta) > 0$ for $\delta > 0$, such that $(a_n^* a_n - \delta)_+ \precsim (b_n^* b_n - \psi(\delta))_+$ for all $n \in \mathbb{N}$ and all rational $\delta > 0$. Then $a \precsim b$.*

(xvi) *Suppose that $C \subseteq B \subseteq A$ are C*-subalgebras of A, and that $S \subseteq C$ is a set of positive contractions with the property that, for each $c_1, c_2 \in S$ and each positive rational numbers r_1, r_2 with property $(c_1 - r_1)_+ \precsim_A (c_2 - r_2)_+$ in A holds also $(c_1 - r_1)_+ \precsim_B (c_2 - r_2)_+$ in B.*

If $S \subseteq C \subseteq B$ satisfy the following condition (D), then for all $a, b \in C$,

$$a \precsim_A b \quad \textit{if and only if} \quad a \precsim_B b\,.$$

(D) *For each positive contraction $a \in C_+$ and $\delta > 0$, there exists $c \in S$ and rational $r > 0$ with $(a-\delta)_+ \precsim_B (c-r)_+ \precsim_B a$.*

Condition (D) *is satisfied, if S is dense in the set of contractions in C_+.*

(xvii) *Let $a, b \in A$ and $B := A_\omega$ or $B := \mathrm{C_b}(X, A)/\,\mathrm{C_0}(X, A)$ with any locally compact Hausdorff space X, and $A \subseteq B$ the natural embedding. Then $a \precsim_A b$, if and only if, $a \precsim_B b$.*

Proof. The properties (i) and (iii) come straight form the definition.

(ii): $a \oplus c = \lim_n (e_n \oplus g_n)(b \oplus d)(f_n \oplus h_n)$ if $a = \lim_n e_n b f_n$ and $c = \lim_n g_n d h_n$.

If (moreover) $b, d \in A$ satisfy $bd^* = 0$ and $b^*d = 0$, then $(b+d) \oplus 0 \approx b \oplus d$ in $M_2(A)$ by part (v), because $(b+d)(b+d)^* \oplus 0 = [b,d][b,d]^*$ and $[b,d]^*[b,d] = (b \oplus d)^*(b \oplus d)$ for the row matrix $[b,d] \in M_{1,2}(A)$.

(iv): If $a = \lim_n f_n b e_n$ then $cad = \lim_n (cf_n) b (e_n d)$. Thus, $cad \in \xi(b)$ if $a \in \xi(b)$ for all $c, d \in \mathcal{M}(A)$.

Let $a := \lim a_n$ with $a_n \precsim b$ for each $n \in \mathbb{N}$, and let $\varepsilon > 0$. Put $\delta := \varepsilon/2$. There are $n = n(\delta) \in \mathbb{N}$ with $\|a - a_n\| < \delta$ and elements $f, g \in A$ with $\|a_n - fbg\| < \delta$. Thus $\|a - fbg\| < \varepsilon$ for suitable $f, g \in A$. It implies that $a \precsim b$. Thus, $a \in \xi(b)$ if $a \in \overline{\xi(b)}$.

The closed set $\xi(b)$ is the closure in A of the *set* of all elements $cbd \in A$ with $c, d \in \mathcal{M}(A)$, because $cbd \precsim b$, i.e., $cbd \in \xi(b)$, for all elements $c, d \in \mathcal{M}(A)$, and if $a \in \xi(b)$, i.e., if $a \precsim b$, then the there exist sequences (c_n) (d_n) in $A \subseteq \mathcal{M}(A)$ such that $a = \lim_n c_n b d_n$.

(v): The relations $g(b) \precsim_A b$ for $b \in A_+$ and continuous $g\colon \mathrm{Spec}(b) \to \mathbb{R}_+$ with $g(0) = 0$ can be seen in $C^*(b) \cong \mathrm{C}_0(\mathrm{Spec}(b) \setminus \{0\})$, using later part (iii). In this way one can also see that $g(b) \approx b$ if $g(t) > 0$ for all $0 < t \in \mathrm{Spec}(b)$.

In particular, $b \approx b^2$, thus $a(a^*a)a^* = (aa^*)^2 \approx aa^*$. It implies $aa^* \precsim a^*a$. If we replace a by a^*, then we get $aa^* \approx aa^*$.

Hence $b \approx c$ if $b, c \in A_+$ and $b \sim_{\mathrm{MvN}} c$.

The definition of $\precsim$ shows that $a \precsim b$ implies $a^* \precsim b^*$. Thus, $a \approx b$ if and only if $a^* \approx b^*$.

We have $a^*a = \lim_n c_n a d_n$ with $c_n = a^*$ and $d_n = (a^*a)^{1/n}$. On the other hand, $a = \lim_n e_n a^*a f_n$ for $e_n = a$, $f_n := g_n(a^*a)$, where $g_n(t) = (t + 1/n)^{-1} t^{1/n}$. It follows $a \approx a^*a$, and then $a^* \approx (a^*a)^* = a^*a$.

(vi): If $a, b \in A_+$ and $a \precsim b$, then $a \approx a^{1/2} \precsim b^{1/2} \approx b$ by parts (i) and (v). Thus, there are sequences $c_n, d_n \in A$ with $\lim_n c_n b^{1/2} d_n = a^{1/2}$. Let $\varepsilon > 0$. There is $n \in \mathbb{N}$ with $\|c_n b^{1/2} d_n d_n^* b^{1/2} c_n^* - a\| < \varepsilon/3$.

Thus, $\varepsilon/3 + \|d_n\|^2 c_n b (c_n)^* \geq a$, and Lemma 2.1.9 gives the existence of a contraction $e \in A$ with $f^*bf = e^*b_1e = (a - \varepsilon/2)_+$ for $b_1 := \|d_n\|^2 c_n b (c_n)^*$ and $f := \|d_n\| c_n^* e$. It follows $\|f^*(b-\delta)_+ f - a\| < \varepsilon$ for $\delta = \varepsilon/(4(\|f\|^2 + 1)) > 0$. Now again Lemma 2.1.9 applies and gives the existence of $g \in A$ with $d^*(b-\delta)_+ d = g^*(f^*(b-\delta)_+ f)g = (a-\varepsilon)_+$ where $d := fg$.

Conversely, if there are $\delta = \delta(\varepsilon) > 0$ and $d = d_\varepsilon \in A_+$ such that $d^*(b-\delta)_+ d = (a-\varepsilon)_+$ for every $\varepsilon > 0$, then $(a-\varepsilon)_+ \precsim (b-\delta)_+$. Since $(b-\delta)_+ \precsim b$ by part (v), then $(a - 1/n)_+ \precsim b$ for all $n \in \mathbb{N}$. It implies $a \precsim b$ by part (iv).

By part (v), $a \sim c$ implies $a \approx c$. If $0 \leq c \leq b$, then there are contractions $d_n \in A$ with $d_n^* b d_n = (c - 1/n)_+$ by Lemma 2.1.9. Thus $c \approx a \precsim b$.

It follows, that the existence of $r \leq p = p^* = p^2$ with $r \sim p$ implies $p \precsim q$, if p and q are projections in A.

If $p \precsim q$ then there are $\delta > 0$ and $d \in A$ with $(1-\delta)d^*qd = d^*(q-\delta)_+ d = (p - 1/2)_+ = (1/2)p$. It follows that $z := (2(1-\delta))^{1/2} qd$ satisfies $z^*z = p$ and $r := zz^* \leq q$.

(vii): It follows from parts (v) and (iv), because

$$(a-\varepsilon)_+ \precsim a \quad \text{and} \quad a = \lim (a - (1/n))_+ \,.$$

(viii): Use an approximate unit of D.

(ix); Part (viii) allows to use suitable (unitary) permutation matrices in $M_2(\mathcal{M}(A))$ respectively $M_3(\mathcal{M}(A))$.

(x): $d^*(x \oplus y)d = (x+y) \oplus 0$ for $d \in M_2 \subseteq M_2(\mathcal{M}(A))$ with matrix entries $d_{11} = d_{21} = 1$, $d_{12} = d_{22} = 0$.

(xi): Let $a, b \in A_+$, $\pi_J(a) \precsim \pi_J(b)$ and $\varepsilon > 0$. Then Part (vi) shows that there are $\delta = \delta(\varepsilon) > 0$ and $d = d(\varepsilon) \in A$, such that $x_\varepsilon := d^*(b-\delta)_+ d - (a-\varepsilon)_+ \in J$. It follows $(a-\varepsilon)_+ \leq b \oplus |x_\varepsilon|$. If we take here $\varepsilon \in \{1/n\,;\ n \in \mathbb{N}\}$ and let $c :=$

$\sum_n 2^{-n}(1+\|x_{1/n}\|)^{-1}|x_{1/n}|$, then $c \in J_+$, $\|c\| \leq 1$, $|x_{1/n}| \precsim c$ and $(a-1/n)_+ \precsim b \oplus c$ for all $n \in \mathbb{N}$. Thus $a \precsim (b \oplus c)$ by (vii).

(xii): Let $a \in A_+$ and $b \in \mathrm{Ann}(a, A)_+ := \{c \in A\,;\ ca = 0 = ac\}$ such that $a \in \overline{\mathrm{span}(AbA)}$. Let $\delta > 0$ and let K denote the closed ideal, that is generated by $\mathrm{Ann}((a-\delta)_+, A)$. Then $b \in \mathrm{Ann}(a, A) \subset \mathrm{Ann}((a-\delta)_+, A)$. It follows that $a \in K$. On the other hand, $\pi_K(a)$ is invertible in A/K, because K contains $(1 - f_\delta(a))a$, i.e., $\mathrm{Spec}(\pi_K(a)) \subseteq [\delta, \|a\|]$. Thus $K = A$, which means that $D := \mathrm{Ann}((a-\delta)_+, A)$ is a full hereditary C^*-subalgebra of A. Then $J \cap D$ is full in J for each $J \triangleleft A$.

Thus, for every $\varepsilon > 0$ and $c \in J_+$, there are $e_1, \ldots e_n \in (J \cap D)_+$ and $f_1, \ldots, f_n \in J$ such that $(c-\varepsilon)_+ = \sum_k f_k^* e_k f_k$. Thus $(c-\varepsilon)_+ \precsim d \otimes 1_n$ for $d := \sum_k e_k$. Now $(a-\delta)_+ + c \precsim a \oplus (d \otimes 1_n)$ follows from Parts (ii), (vi) and (x).

`Put (xiii) and (xiv) on extra place` (xiii): There is a projection $y \in qAq$ such that y is central in qAq, $y = yq$ is finite (or zero) and $(q-y)$ is properly infinite (or zero). There exist a central projection z of A such that $zq = y$. Notice that the projection $p := \sup_n p_n \in A_+$ exists, because A is an AW*-algebra. If $a \in A$ is a contraction, then the left and right support projections $p_{aa^*} := \sup_n (aa^*)^{1/n}$ and $p_{a^*a} := \sup_n (a^*a)^{1/n}$ of a are Murray–von-Neumann equivalent in A by the partial isometry $v \in A$ of the polar decomposition $a = v(a^*a)^{1/2}$ of a in A, cf. [**64**].

By Part (vi), there exist $q_n \leq q$ such that $p_n \sim q_n$ for $n \in \mathbb{N}$. It implies $zp_n \sim zq_n \subseteq zq = y$ and $(1-z)p_n \sim (1-z)q_n \subseteq (1-z)q = q-y$.

If $q \neq y$ then $q - y$ is properly infinite, i.e., there are $s, t \in A$ with $s^*s = t^*t = q - y$ and $s^*t = 0$ and $ss^* + tt^* \leq q - y$. Then there exist a sequence $s_1, s_2, \ldots \in (q-y)A(q-y)$ with $s_m^* s_n = \delta_{m,n}(q-y)$. Let $w_n \in A$ with $(1-z)p_n = w_n^* w_n$ and $w_n(w_n)^* \leq q - y$. Now we define

$$a := s_1 w_1 + \sum_{n=1} 2^{-n} s_{n+1} w_{n+1} (1-z)(p_{n+1} - p_n)\,.$$

Then $\|a\| \leq 1$, $(1-z)p = \sup_n (a^*a)^{1/n}$ and $aa^* \leq (q-y)$. Thus $p_{aa^*} = \sup_n (aa^*)^{1/n} \leq (1-z)q = q - y$ and $(1-z)p = p_{a^*a} \sim p_{aa^*} \leq (1-z)q\,.$

The AW*-algebra yAy is finite. Let v_0 a partial isometry with $v_0^* v_0 = zp_1$ and $v_0(v_0)^* \leq y = zq$. By induction, we find partial isometries $v_2, v_3, \ldots \in A$ with $v_n^* v_n = z(p_{n+1} - p_n)$, $v_n(v_n)^* \leq zq = y$ and $v_n^* v_k = 0$ for $k < n$. Indeed:
The partial isometry $w_n := v_0 + \cdots + v_{n-1}$ satisfies $w_n^* w_n = zp_n$ and $w_n(w_n)^* \leq y$. By Part (vi), there is a partial isometry $x \in A$ with $x^*x = zp_{n+1}$ and $xx^* \leq y$, because $zp_{n+1} \precsim y$. Then $xzp_n x^* \sim w_n(w_n)^*$ in the finite AW*-algebra yAy. We find a unitary $u \in yAy$ with $uxzp_n x^* u^* = (w_n w_n)^*$, because Murray–von-Neumann equivalent projections in finite AW*-algebras are unitarily equivalent, cf. [**64**, chap. 6]. Let $v_n := uxz(p_{n+1} - p_n)$, then $v_n^* w_n = 0$ and $v_n^* v_n = z(p_{n+1} - p)$ and $v_n v_n^* \leq zq$.

Now let $b := \sum 2^{-n} v_n$. Then $\|b\| \leq 1$, $bb^* \leq zq$, $zp = \sup_n (b^*b)^{1/n}$. Thus $zp = p_{b^*b} \sim p_{bb^*} \leq zq$.

It follows $p = p_{a^*a} + p_{b^*b} \sim p_{aa^*} + p_{bb^*} \leq q\,.$

(xiv): If $z \in A_+$ is in the center of A, and if (d_n), $(e_n) \subseteq A$ satisfy $\lim e_n b d_n = a$, then $\lim e_n(zb)d_n = za$, i.e., $a \precsim b$ implies $za \precsim zb$.

Let $a, b \in A_+$ with $a \precsim b$, then $(1/n)p_n \leq a \precsim b \leq \|b\| q$, $p_1 \leq p_2 \leq \cdots$ and $p = \sup_n p_n$ for the support projections $p := p_a$, $p_n := p_{a_n}$ and $q := p_b$ of a, $a_n := (a - (1/n))_+$ and b respectively. In particular, $p_n \precsim q$ for all $n \in \mathbb{N}$. Thus, Part (xiii) implies $p_a \precsim p_b$.

(xv): Suppose that $a = \lim a_n$, $b = \lim b_n$, and that ψ is a continuous function $\psi(\delta) > 0$ such that $(a_n^* a_n - \delta)_+ \precsim (b_n^* b_n - \psi(\delta))_+$ for all $n \in \mathbb{N}$ and all rational $\delta > 0$. Let $\varepsilon > 0$, and $\delta \in (0, \varepsilon/2)$ rational. There is $n_0 \in \mathbb{N}$ with $\|a^*a - a_n^* a_n\| < \delta$ and $\|b^*b - b_n^* b_n\| < \psi(\delta)/2$ for all $n \geq n_0$. This implies $a^*a \leq (a_n^* a_n - \delta)_+ + 2\delta$ and $b_n^* b_n \leq b^*b + \psi(\delta)/2$. By Lemma 2.1.9, we find $d_1, d_2 \in A$ with $(a^*a - \varepsilon)_+ = d_1^*(a_n^* a_n - \delta)_+ d_1$ and $(b_n^* b_n - \psi(\delta))_+ = d_2^* b^* b d_2$. It follows $(a^*a - \varepsilon)_+ \precsim b^*b$ (for all $\varepsilon < 0$), and (finally) $a \approx a^*a \precsim b^*b \approx b$ by Parts (i), (vii) and (v).

(xvi): Let $a_1, b_1 \in C \setminus \{0\}$ with $a_1 \precsim_A b_1$, then $a \approx_C a_1$, $b \approx_C b_1$ and $a \precsim_A b$ for the contractions $a := \|a_1\|^{-2} a_1^* a_1 \in C_+$ and $b := \|b_1\|^{-2} b_1^* b_1 \in C_+$. By Part (vi) there exist $0 < \delta_n \leq \varepsilon_n < 1/4$ with $\lim_n \varepsilon_n = 0$ such that $(a - \varepsilon_n)_+ \precsim_A (b - \delta_n)_+$. For each $n \in \mathbb{N}$ there are $c_n, d_n \in C_+$ and rational $r_n, s_n > 0$ with $(a - 2\varepsilon_n)_+ \precsim_B (c_n - r_n)_+ \precsim_B (a - \varepsilon_n)_+$ and $(b - \delta_n)_+ \precsim_B (d_n - s_n)_+ \precsim_B b$.

It follows $(c_n - r_n)_+ \precsim_A (d_n - s_n)_+$. Then $(c_n - r_n)_+ \precsim_B (d_n - s_n)_+$ by assumptions on S. It yields $(a - 2\varepsilon_n)_+ \precsim_B b$ for all $n \in \mathbb{N}$, by Part (i). Thus, $a \precsim_B b$ and $a_1 \precsim_B b_1$ by Parts (vii) and (i).

Condition *(D)* is satisfied, if S is dense in the set of contractions in C_+, because $\|c - a\| < \delta/3$ implies the existence of contractions $d_1, d_2 \in C$ and rational $r \in (\delta/3, \delta/2]$ with $(a - \delta)_+ = d_1^*(c - r)_+ d_1$ and $(c - r)_+ = d_2^* a d_2$, by Lemma 2.1.9.

proofs complete ??

(xvii): Let $a, b \in A$ and $B := A_\omega$ or $B := \mathrm{C_b}(X, A)/\mathrm{C_0}(X, A)$, and consider the natural embedding $a \mapsto \pi_\omega(a, a, \ldots) \in A_\omega$, respectively $a \mapsto f_a + \mathrm{C_0}(X, A)$ for $f_a(x) := a$. Then $a \precsim_A b$ implies $a \precsim_B b$ by Part (iii). We use $a \approx a^*a$ for the opposite direction, cf. Part (v). Let $a, b \in A_+$ with $a \precsim_B b$ and $\delta > 0$, then Part (v) says that there is $d = (d_1, d_2, \ldots) \in \ell_\infty(A)$ with $\lim_n d_n^* b d_n = (a - \delta)_+$ (respectively $d \in \mathrm{C_b}(X, A)$ with $g \in \mathrm{C_0}(X, A)$ for $g(x) := d(x)^* b d(x) - (a - \delta)_+$). Thus $(a - \delta)_+ \precsim_A b$ in both cases (since X is not compact). It follows $a \precsim_A b$ by Part (vii). □

We call a C^*-subalgebra B of A **$\precsim$-preserving** if $a, b \in B$ and $a \precsim_A b$ imply that $a \precsim_B b$.

Lemma A.6.2. *Let $C \subseteq A$ a separable C^*-subalgebra and $B_1 \subseteq B_2 \subseteq \cdots \subseteq A$ a sequence of $\precsim$-preserving C^*-subalgebras of a C^*-algebra A.*

(o) *Each hereditary C^*-subalgebra $D \subseteq A$ is $\precsim$-preserving.*
(i) *The closure B of $\bigcup_n B_n$ is $\precsim$-preserving.*

(ii) *There exists a separable $\precsim$-preserving C^*-subalgebra B of A with $C \subseteq B \subseteq A$.*

(iii) *Consider a C^*-algebra E naturally as a C^*-sub-algebra of $A := E_\omega$, (respectively of $A := \mathrm{C_b}(X, E)/\mathrm{C_0}(X, E)$ for a locally compact Hausdorff space X). Then E is a $\precsim$-preserving C^*-subalgebra of A.*

PROOF. (o): See Lemma A.6.1(viii).

(i): We prove a stronger result: Suppose that $a \precsim_A b$ and $a, b \in B_n$ imply $a \precsim_{B_{n+1}} b$. Then, obviously, the relation $a \precsim_A b$ for $a, b \in \bigcup_n B_n$ implies $a \precsim_B b$. Let $C := B$ and let $S \subseteq C_+$ denote the set of positive contractions in $\bigcup_n B_n$. Then S, C, B and A satisfy the assumptions of Lemma A.6.1(xvi). Thus, for all $a, b \in B$, $a \precsim_A b$ if and only if $a \precsim_B b$.

(ii): Since C is separable, there exists a countable dense subset S in the set of positive contractions in C_+.

If $c, d \in S$ and $r, t \in [0, 1]$ are rational with $(c - r)_+ \precsim_A (d - t)_+$, then there is a sequence $d_1, d_2, \ldots \in A$ with $(c - r)_+ = \lim_n d_n^*(d - t)_+ d_n$.

The set $S \times S \times ([0, 1] \cap \mathbb{Q}) \times ([0, 1] \cap \mathbb{Q})$ is at most countable. It follows, that there is a separable C^*-subalgebra $C \subseteq B_1 \subseteq A$ such that $(c - r)_+ \precsim_A (d - t)_+$ implies $(c - r)_+ \precsim_{B_1} (d - t)_+$ for $c, d \in S$ and $r, t \in [0, 1]$. By Lemma A.6.1(xvi), for each $a, b \in C$, $a \precsim_A b$ is equivalent to $a \precsim_{B_1} b$.

We can repeat this argument for B_1 in place of C, and get a separable C^*-subalgebra $B_1 \subseteq B_2 \subseteq A$ such that, for each $a, b \in B_1$, $a \precsim_A b$ is equivalent to $a \precsim_{B_2} b$. Going on this way, we can find a sequence $B_1, B_2, \ldots$ of separable C^*-subalgebras $B_n \subseteq B_{n+1} \subseteq A$ such that $B_0 := C \subseteq B_1$ and, for each $a, b \in B_n$, $a \precsim_A b$ is equivalent to $a \precsim_{B_{n+1}} b$. Then the closure B of $\bigcup_n B_n$ is a $\precsim$-preserving separable C^*-subalgebra of A that contains C.

(iii): The cases $E \subseteq E_\omega$ and $E \subseteq \mathrm{C_b}(X, E)/\mathrm{C_0}(X, E)$ follow from Lemma A.6.1(xvii). □

REMARK A.6.3. Suppose that $B \subseteq A$ is a C^*-subalgebra. Let $a \in A_+$, $b \in B_+$ and let $J_A(b) := \overline{\mathrm{span}(AbA)}$ (respectively $J_B(b) := \overline{\mathrm{span}(BbB)}$) the closed ideal of A (respectively of B) generated by b.

Notation $I(a)$ was in conflict with absorption ideal

$$I_A(a) = \{b \in A\,;\ [b] + [a] \leq [a]\}$$

The following observation (o) is trivial, and the implications (o)⇒(i)⇒(ii) are straight-forward:

(o) The smallest number $t \geq 0$ with $(a - t)_+ \in J_A(b)$ is given by

$$\mathrm{dist}(a, J_A(b)) = \|a + J_A(b)\| = \|\pi_{J_A(b)}(a)\|\,.$$

(i) For each $\delta > 0$ there exists $n = n(\delta) \in \mathbb{N}$ such that $(a - (t+\delta))_+ \precsim b \otimes 1_n$, if and only if, $t \geq \operatorname{dist}(a, J_A(b))$.

(ii) $\operatorname{dist}(a, J_A(b)) = \operatorname{dist}(a, J_B(b))$ for all $b \in B_+$ if $B \otimes \mathbb{K} \subseteq A \otimes \mathbb{K}$ is $\precsim$-preserving.

Let $B \subseteq A$ a C^*-sub-algebra of A and $a, b \in A$ positive contractions, and let $d_1, d_2 \in A$ contractions. We define

$$\rho(a, b;\, d_1, d_2) := \|a^2 - d_1^* a^2 d_1\| + \|b^2 - d_2^* b^2 d_2\| + \|d_1^* a b d_2\|\,,$$

and denote by $\rho(a, b; B)$ the infimum of the non-negative numbers

$$\{\rho(a, b; d_1, d_2)\,;\; d_1, d_2 \in B,\, \|d_1\| \leq 1,\, \|d_2\| \leq 1,\,\}\,.$$

The following Lemma establishes the continuity of the property s.p.i. in the category of C^*-algebras with respect to inductive limits.

LEMMA A.6.4. *Let $C \subseteq A$ and $B_1 \subseteq B_2 \subseteq \ldots \subseteq A$ separable C^*-subalgebras. Let B denote the closure $\bigcup_n B_n$. Then:*

(i) *For contractions $a, b, a', b' \in A_+$ holds*

$$|\,\rho(a', b'; A) - \rho(a, b; A)\,| \leq 5\|a' - a\| \,+\, 5\|b' - b\|$$

and $\rho(a, b; C) \geq \rho(a, b; A)$ if $a, b \in C$.

(ii) *$\rho(a, b; A) = \rho(a, b; A_\omega)$ for all contractions $a, b \in A_+$.*

(iii) *If $\rho(a, b; B_{n+1}) = \rho(a, b; A)$ for all positive contractions $a, b \in B_n$ for $n = 1, 2, \ldots,$ then $\rho(a, b; B) = \rho(a, b; A)$ for all positive contractions $a, b \in B$.*

(iv) *There exists a separable C^*-subalgebra B of A with $C \subseteq B \subseteq A$, such that $\rho(a, b; B) = \rho(a, b; A)$ for all contractions $a, b \in B_+$.*

PROOF. (i): The inequality $\rho(a, b; C) \geq \rho(a, b; A)$ is immediate from the definition. Straight calculation shows

$$|\,\rho(a', b'; d_1, d_2) - \rho(a, b; d_1, d_2)\,| \leq 5\|a' - a\| \,+\, 5\|b' - b\|\,.$$

(ii): By Part (i), $\rho(a, b; A) \geq \rho(a, b; A_\omega)$. Here we have identified $a \in A$ with $\pi_\omega(a, a, \ldots) = \Delta(a) + c_\omega(A)$ in A_ω.

Let $a, b \in A_+$ contractions and $\delta > 0$. There are sequences of contraction $e_1, e_2, \ldots; f_1, f_2, \ldots \in A$ such that, for $e := \pi_\omega(e_1, e_2, \ldots)$ and $f := \pi_\omega(f_1, f_2, \ldots)$,

$$\rho(a, b; A_\omega) + \delta > \rho(a, b; e, f) = \lim_\omega \rho(a, b; e_n, f_n) \geq \inf_n \rho(a, b; e_n, f_n)\,.$$

Clearly, $\inf_n \rho(a, b; e_n, f_n) \,\geq\, \rho(a, b; A)\,.$

(iii): By assumptions and Part (i), we have $\rho(a, b; B) = \rho(a, b; A)$ for all positive contractions $a, b \in \bigcup_n B_n$. It implies $\rho(a, b; B) = \rho(a, b; A)$ for all positive contractions $a, b \in B$, because $(a, b) \mapsto \rho(a, b; B) - \rho(a, b; A)$ is continuous.

(iv): Let $X \subseteq C_+$ a countable subset of contractions, that is dense in the set of all positive contractions in C. For each $a, b \in X$ there are sequences of contractions

$e_1, e_2, \ldots ; f_1, f_2, \ldots \in A$, such that $\lim_n \rho(a,b;e_n,f_n) = \rho(a,b;A)$. Thus, there is a countable subset $X \subseteq Y \subseteq A$ of the contractions in A, such that

$$\inf\{\, \rho(a,b;d_1,d_2)\,;\; d_1,d_2 \in Y \,\} = \rho(a,b;A) \quad \forall\, a,b \in X\,.$$

Let $C \subseteq B_1 \subseteq A$ denote the separable C^*-subalgebra that is generated by Y. Then $\rho(a,b;B_1) = \rho(a,b;A)$ for all $a,b \in X$. This is true also for all positive contractions $a,b \in C$, because $(a,b) \mapsto \rho(a,b;B) - \rho(a,b;A)$ is continuous.

Now we can repeat the argument with B_1 in place of C, and get a separable C^*-subalgebra $B_1 \subseteq B_2 \subseteq A$ with $\rho(a,b;B_2) = \rho(a,b;A)$ for all $a,b \in B_1$. Thus, we find a sequence $B_1 \subseteq B_2 \subseteq \cdots \subseteq A$ that satisfies the assumptions of Part (iii). Then the closure B of $\bigcup_n B_n$ is a separable C^*-subalgebra of A with $C \subseteq B$ and $\rho(a,b;B) = \rho(a,b;A)$ for all $a,b \in B$. □

LEMMA A.6.5. *Let M a W^*-algebra, $a \in M_+$ with $\|a\| = 1$, let $P_b \in M$ denote the support projection of $b \in M_+$, and let $d_1, \ldots, d_m \in M$ with $\sum d_j^* d_j \leq 1$.*

Suppose that the support projections of $z(a-t)_+$ and of $z(1-a-t)_+(a-s)_+$ are either zero or infinite for all $t,s \in (0,1)$ and for all central projections $z \in M$. Then:

(i) *The support projections of $(a-t)_+$ and $(1-a-t)_+ \cdot (a-s)_+$ are properly infinite or zero for every $t,s \in [0,1]$.*
(ii) *For each $\delta > 0$, there exists mutually orthogonal projections $p_1, \ldots, p_n \in \{a\}' \cap M$ and $0 \leq \alpha_1 \leq \cdots \leq \alpha_n \leq 1$ such that p_k is properly infinite in M for $k = 1, \ldots, n$, $\sum_k p_k = P_a$ and $(a-\delta)_+ \leq \sum_k \alpha_k p_k \leq a$.*
(iii) *For each $\delta > 0$ and $m \in \mathbb{N}$ there exists partial isometries $v_1, \ldots v_m \in P_a M P_a$ with $v_j^* v_k = \delta_{jk} P_a$ and $\|\, v_j\, a - a v_j \,\| < \delta$ for $j,k = 1, \ldots, m$.*
(iv) *For each $\varepsilon > 0$ there exist self-adjoint $h_k \in M$ with $\|h_k\| \leq \pi$ $(1 \leq k \leq 4)$ such that $h_2 = -h_1$, $h_4 = -h_3$ and*
`next ok ?? ??`

$$\Big(\big(\sum_j d_j^* a d_j\big) - \varepsilon\Big)_+ \;\leq\; \sum_{k=1}^{4} \exp(ih_k)\, a \exp(-ih_k)$$

PROOF. `check proof of (i) again` (i): Suppose that the support projections of $z(a-t)_+$ and of $z(1-a-t)_+(a-s)_+$ are either zero or infinite for all $t \in (0,1)$ and for all central projections $z \in M$.

Let $b \in M_+$ such that the support projection $P_b \in M$ of b is infinite. Then there exists a central projection $z \in M$ such that zP_b is finite (or is zero) and that $(1-z)P_b$ is properly infinite (or is zero). The support projection of zb is given by zP_b. Thus, if the support projection of zb is not finite, then $zP_b = 0$ and $P_b = (1-z)P_b$ is properly infinite.

Thus, all support projections $P_{(a-t)_+}$ and and $P_{(1-a-t)_+(a-s)_+}$ of the elements $(a-t)_+$ respectively $(1-a-t)_+(a-s)_+$ are properly infinite ore zero in M.

If follows that $(a-t)_+$ and $(1-a-t)_+(a-s)_+$ are zero or are properly infinite elements of M for each $s,t \in [0,1]$, by Lemma 2.5.3(xv).

(ii): By Lemma A.6.2(ii), there exists a separable C^*-subalgebra $B \subseteq M$ with $a \in B$, such that $c \precsim_B d$ if and only if $c \precsim_M d$ for all $c, d \in B$. Let $M_0 \subseteq M$ the $\sigma(M, M_*)$-closure (i.e., ultra-weak closure) of B in M.

Then M_0 is a direct sum $M_0 \cong \prod_\alpha N_\alpha$ of W*-algebras N_α *with separable predual*, and the elements $(a-t)_+$ and $(1-a-t)_+(a-s)_+$ are properly infinite or zero in M_0 for all $s,t \in [0,1]$. It follows, that the image a_α of $a = \{a_\alpha\}_\alpha \in \prod_\alpha N_\alpha$ have the properties that the elements $(a_\alpha - t)_+$ and $(1-a_\alpha-t)_+(a_\alpha-s)_+$ are properly infinite or zero.

Fix some of the α. Let $b := a_\alpha \in N_\alpha =: N$. Then $0 \leq b \leq 1$ and the elements $(b-t)_+$ and $(t-b)_+(b-s)_+$ are properly infinite for all $s,t \geq 0$. Let $E := P_b \in N$ the support projection of b in N. By 2.5.3(xv), the support projections $P(t) := P_{(b-t)_+}$ of $(b-t)_+$ and the support projections $Q(t) := P_{(t-b)_+ b}$ of $(t-b)_+ b$ are properly infinite projections in N (but, clearly, they can't be properly infinite in $\{b\}'' \subseteq N$, and they are not necessarily properly infinite in $\{b\}' \cap N$). It holds $Q(t), P(t) \in \{b\}''$, $Q(t)P(t) = 0$, $Q(s) \leq Q(t)$, $P(s) \geq P(t)$ for $s < t$ $Q(t) + P(t) \leq E$. The projection $R(t) := E - Q(t) - P(t)$ satisfies $bR(t) = tR(t)$ for each $t \in [0,1]$. In particular, $R(t)R(s) = 0$ for $s \neq t$. Since N has separable pre-dual, there is a faithful normal state ρ on N. It follows $\rho(R(t)) > 0$ if $R(t) \neq 0$, and that $\{t \in [0,1]\,;\, \rho(R(t)) \geq 1/n\}$ contains at most n points. It implies, that the set $S = \{t \in [0,1]\,;\, R(t) \neq 0\}$ is countable. We have $0 \notin S$, because $P(0) = E$.

If $s < t$ and $R(t) = 0$, then $P(s) - P(t) = P(s)Q(t)$. But $P(s)Q(t)$ is the support projection of $(t-b)_+(b-s)_+$, and $(t-b)_+(b-s)_+$ is zero or properly infinite properly infinite. Now, Lemma 2.5.3(xv) implies that the support projection $P(s) - P(t) = P(s)Q(t)$ of $(t-b)_+(b-s)_+$ is properly infinite if $P(s) \neq P(t)$ and $t \notin S$.

Since $b = \sup_+ tP(t)$ (in the lattice $(\{b\}'')_+$), we can approximate b from below in norm by $\sum t_k(P(t_k) - P(t_{k+1})) = \sup_k t_k P(t_k)$ with $0 = t_1 < t_2 < \ldots < t_n < 1$, $t_{k+1} \notin S$ and where $t_k \in ((k-1)/n, k/n]$.

It follows that each $R_k = P(t_k) - P(t_{k+1})$ (with $P(t_{n+1}) := 0 = P(1)$) is a properly infinite projection in N_α or is zero, $R_k \in \{b\}''_+$, $b - 1/n \leq \sum(k-1)/nR_k \sum t_k R_k \leq b$.

If we do this for each summand N_α of M_0, then we get projections $p_k = (R_k^\alpha)_\alpha \in M_0$, $k = 1, \ldots, n$, such that the p_k commute with a, are mutually orthogonal, are properly infinite or zero, have sum $\sum p_k = P_a$, and $a - (2/n) \leq \sum(k-1)/np_k \leq a$.

(iii): Let $\delta > 0$ and $m \in \mathbb{N}$. Let $n = [2/\delta] + 1$. We find $p_k \in \{a\} \cap M$, $k = 1, \ldots, n$, with the properties in (ii). It follows, that, for each $j \in \{1, \ldots, n\}$,

$$\|p_j T p_j b - b p_j T p_j\| \leq \|b - \sum_k (k-1)/n) p_k\| \|p_j T p_j\| \leq (2/n)\|p_j T p_j\|\,.$$

Since the projections p_k are properly infinite, we find $z_{\ell,j} \in p_j M p_j$, $\ell = 1, \ldots, m$ with $z_{\ell,j}^* z_{k,j} = \delta_{\ell,k} p_j$.

Let $v_\ell = \sum_j z_{\ell,j}$. Then $v_1, \ldots v_m \in P_a M P_a$ and $v_\ell^* v_k = \delta_{\ell,k} P_a$. Since the p_j commute with a and v_ℓ, we have that $v_\ell\, a - a\, v_\ell = \sum_j p_j (z_{\ell,j}\, a - a z_{\ell,j}) p_j$. Thus, the above estimate gives $\| v_\ell\, a - a\, v_\ell \| < \delta$ for $\ell, k = 1, \ldots, m$,

end above? more?

(vi): Given $d_1, \ldots, d_m \in M$ with $\sum d_j^* d_j \leq 1$, and $\varepsilon > 0$, we let $\delta := \varepsilon/(1 + \sqrt{m})$. We find the $v_1, \ldots, v_m$ with the properties of (iii), and define a contraction $d \in M$ by $\sum_{\ell=1}^m v_\ell d_\ell$. Then $d^* a d - \sum_\ell d_\ell^* a d_\ell = CBC^*$ for the row $C = [d_1, \ldots, d_m] \in M_{1,m}(M)$ and the matrix $B = [b_{\ell,k}] \in M_m(M)$ with entries

$$b_{\ell,k} = \delta_{\ell,k} a - v_\ell^* a v_k = v_\ell^* (v_k a - a v_k)\,.$$

Thus, $B = V^* D$ for the rows $V := [v_1, \ldots, v_m]$ and $D = [v_1 a - a v_1, \ldots, v_m a - a v_m]$ in $M_{1,m}(M)$. Since $\|C\| \leq 1$, $V^* V \leq P_a \otimes 1_n$, and $\|D\| \leq \delta\sqrt{m}$, it follows $\|CBC^*\| \leq \|B\| \leq \|D\| < \varepsilon$. Hence,

$$\sum_\ell d_\ell^* a d_\ell - \varepsilon \leq d^* a d\,.$$

Let $e := (d + d^*)/2$, $f := (d - d^*)/2i$, $h_1 := \arcsin(e)$, $h_2 := -h_1$, $h_3 := \arcsin(f)$ and $h_4 := -h_3$, then $\|e\| \leq 1$, $\|f\| \leq 1$, and $\|h_k\| \leq \pi$ for $k = 1, 2, 3, 4$.

$$\begin{aligned} d^* a d \leq d^* a d + d a d^* = 2(eae + faf) &\leq \\ 2(eae + faf) + 2(\cos(h_1) a \cos(h_1) + \cos(h_3) a \cos(h_3)) &= \\ 4 \sum_k \exp(ih_k) a \exp(-ih_k)\,. & \end{aligned}$$

□

Lemma A.6.6. *For every $a \in A$ and every unitary $u \in \mathcal{M}(A)$, the element $u^* a u$ is in the norm-closed convex hull of the set $\{\exp(ih) a \exp(-ih)\,;\ h^* = h \in A, \|h\| < \pi\}$.*

In particular, if $C \subseteq A_+$ is a hereditary closed convex sub-cone of A_+, then

$$K := \{a \in A_+\,;\ \exp(ih) a \exp(-ih) \in C \quad \textit{for all} \quad h^* = h \in A \quad \textit{with} \quad \|h\| < \pi\}$$

is the positive part $I_+ := K$ of a closed ideal I of A.

The closed ideal I is the largest ideal of A with $I_+ := I \cap A_+ \subseteq C$.

Proof. Recall that $\mathcal{M}(A) \subseteq A^{**}$. The set $\{\exp(ih)\,;\ h^* = h \in A, \|h\| < \pi\}$ is *-ultra-strongly dense in the unitaries of A^{**}, because $\exp\colon A^{**} \to A^{**}$ is *-ultra-strongly continuous on bounded parts, and because every unitary V of a W*-algebra is of the form $V = \exp(ih)$ for some self-adjoint $h \in A^{**}$ with $\|h\| \leq \pi$.

Use Hahn-Banach separation from the closed convex hull of

$$\{\exp(ih) a \exp(-ih)\,;\ h^* = h \in A, \|h\| < \pi\}\,.$$

If $\exp(ih)a\exp(-ih) \in C$ for all $h^* = h \in A$ with $\|h\| < \pi$ and if C is closed and convex, then $u^*au \in C$ for all unitaries $u \in \mathcal{M}(A)$, i.e.,

$$a \in K := \bigcap_{u\in\mathcal{U}(\mathcal{M}(A))} u^*Cu\,.$$

If C is a hereditary closed convex sub-cone of A_+, then $K := \bigcap_{u\in\mathcal{U}(\mathcal{M}(A))} u^*Cu$ is a hereditary closed convex sub-cone of A_+ that is invariant under "inner" automorphisms $\mathrm{Ad}(u)$ of A.

Thus, the hereditary C^*-subalgebra $I := \overline{KAK}$ of A is a closed ideal of A with $I_+ = K$.

If $J \lhd A$ is a closed ideal with $J_+ \subseteq C$, then $u^*au \in C$ for all $a \in J_+$ and $u = \exp(-ih)$ with $h^* = h \in A$. Thus, $J \subseteq I$. □

Lemma A.6.7. *Suppose that A is a C^*-algebra with the property that every* additive *lower semi-continuous trace $\tau\colon A_+ \to [0,\infty]$ takes only the values 0 and ∞.*

Let $\mathcal{S}_{in}$ denote the set of approximately inner completely positive contractions, and let $\mathcal{S}_u$ denote the point-norm closed convex hull of the (exponential) inner automorphisms

$$a \mapsto \exp(ih)a\exp(-ih)$$

with $h^* = h$ of norm $< \pi$.

Then, for each contraction $a \in A_+$, $V \in \mathcal{S}_{in}$ and $\varepsilon > 0$, there exists $T \in \mathcal{S}_u$ with

$$V(a) - \varepsilon \leq 4T(a)\,.$$

Proof. to be filled in ?? □

Lemma A.6.8. *Let $a \in A_+$, and suppose that there is $m \in \mathbb{N}$ such that, for every* contraction *$b \in A_+$ in the (algebraic) ideal generated by $\{a\}$ there are $d_1, \ldots, d_m \in A$ (depending on b) with $\sum_{k=1}^m d_k^* a d_k = (b - 1/2)_+$.*
We denote by $m(a)$ the smallest $m \in \mathbb{N}$ with this property.

Let $I(a)$ denote the closed ideal of A generated by $a \in A_+$. Then:

(i) *For every $c \in I(a)_+$ and $\varepsilon > 0$ there are $\delta > 0$ and $d_1, \ldots, d_{m(a)} \in aAc$ with $\sum_k d_k^*(a-\delta)_+ d_k = (c-\varepsilon)_+$ and $\|\sum_k d_k^* d_k\| \leq 2\delta^{-1}\|c\|$.*
check above estimate
(ii) *If $A_1, A_2, \ldots$ is a sequence of C^*-algebras, such that there is $\mu \in \mathbb{N}$ with $m(a) \leq \mu$ for each $n \in \mathbb{N}$ and $a \in (A_n)_+$ then $m(b) \leq \mu$ for every positive $b \in \prod_n A_n$.*
(iii) *If $m(a) \leq m_0$ for all $a \in A_+$, and if J is a closed ideal of A, then $m(b) \leq m_0$ for every positive $b \in (A/J)_+$.*
(iv) *Suppose that, for each $b \in (A_\omega)_+$ and $\varepsilon > 0$, there exists $m = m(b,\varepsilon) \in \mathbb{N}$ such that $(b-\varepsilon)_+ \otimes 1_{2m} \precsim b \otimes 1_m$.*
Then there exists $n \in \mathbb{N}$ such that $a \otimes 1_{2n} \precsim a \otimes 1_n$ for all $a \in A_+$.

PROOF. (i): Let $c \in I(a)_+$ and $\varepsilon > 0$. There are $n \in \mathbb{N}$ and $f_1, \ldots, f_n \in A$ with $\|c - \sum_k f_k^* a f_k\| < \varepsilon/2$.

Question:

Are there $\delta > 0$ and $d_1, \ldots, d_m \in aAc$ with $\sum_k d_k^*(a-\delta)_+ d_k = (c-\varepsilon)_+$ and $\|\sum d_k^* d_k\| \leq 2\delta^{-1}\|c\|$?

(If it does not work in A^{**} then not in A!)

`check above estimates`

`to be filled in` ?? □

QUESTION A.6.9. If $0 \leq a \leq b$ and $\|b\| \leq 1$, then, for every $\varepsilon > 0$ there is a contraction $d \in C^*(a,b) \subseteq A$ with $d^*bd = (a-\varepsilon)_+$ and $\|db - bd\| \leq f(\|ab - ba\|, \varepsilon)$, where

$$f(t,\varepsilon) := \sup\{\mu(a,b;\varepsilon)\,;\ \ a,b \in \mathcal{L}(\ell_2)_+\,,\ 0 \leq a \leq b \leq 1\,,\ \|ab - ba\| \leq t\,\}$$

for $t > 0$ and

$$\mu(a,b;\varepsilon) := \inf\{\|db - bd\|\,;\ d \in C^*(a,b),\ \|d\| \leq 1,\ d^*bd = (a-\varepsilon)_+\,\}\,.$$

Is $\lim_{t\to 0} f(t,\varepsilon) = 0$ for each (fixed) $\varepsilon > 0$?

That is "in the limit" (i.e., in $\mathcal{L}(\ell_2)_\omega$) the case of commuting $0 \leq a \leq b$ and

$$d := \lim_{\delta\to 0}(b+\delta)^{-1/2}(a-\varepsilon)_+^{1/2}\,.$$

The question has to do with the study of images in $\mathrm{Q}(X,B)|\omega$ of the fibers $F(X;A,B)|\omega$ of the unital $\mathrm{C}(\gamma X)$-algebra

$$F(X\,;\,A,B) := (A' \cap \mathrm{Q}(X,B))/\operatorname{Ann}(A, \mathrm{Q}(X,B))$$

for separable C^*-subalgebra $A \subseteq \mathrm{Q}(X,B)$.

QUESTION A.6.10. Is there a universal continuous function $\rho\colon \mathbb{R}_+ \to \mathbb{R}_+$ with $\rho(0) = 0$, such that ρ is increasing and has the following property (*)?

(*) If $a, b \in A_+$, $0 \leq \gamma < \varepsilon$ satisfy $b \leq a + \gamma$, then there is a contraction $d := d(a,b;\gamma,\varepsilon) \in A$ with $d^*ad = (b-\varepsilon)_+$ and

$$\|da - ad\| \leq \rho\big(\sup_{\gamma\leq\delta\leq\varepsilon}\|a(b-\delta)_+ - (b-\delta)_+ a\|\big)\,.$$

What about using ultrapowers here?

7. Basics on Quasi-traces

`Is only collection/list of topics now`

DEFINITION A.7.1. `To be defined:`

Dimension function d, **dimension function**

Rank function = subadditive local rank function, local rank function r, quasi-trace τ, 2-quasi-trace bounded, unbounded, l.s.c. traces = additive q-traces, ...

For every compact Hausdorff space X of dimension ≥ 2 there exists a compact Hausdorff space Y of dimension $\leq \mathrm{Dim}(X)+1$, a continuous injective map $\varphi\colon X \to Y$ (with adjoint epimorphism $\widehat{\varphi}\colon \mathrm{C}(Y) \to \mathrm{C}(X)$ given by $\widehat{\varphi}(f)(x) := f(\varphi(x))$ for $x \in X$) and a unital extension

$$0 \to \mathbb{K} \otimes c_0 \to A \to \mathrm{C}(Y) \to 0$$

(– with fixed canonical epimorphism $\pi\colon A \to \mathrm{C}(Y)$ –) such that for each quasi-measure μ on X (in the sense of Aarnes [**3**]) with $\mu(X) = 1$ the composition $\tau_\mu := \nu_\mu \circ \widehat{\varphi} \circ \pi$ is a unital quasi-trace on A_+, where $\nu_\mu\colon \mathrm{C}(X)_+ \to [0, \infty)$ is the *local* quasi-trace defined by the quasi-measure μ. It is then easy to see that τ_μ can't be 2-sub-additive on the positive part A_+ of the type-I C^*-algebra A_+ if ν_μ is not additive on $\mathrm{C}(X)_+$, because otherwise the (again) 2-sub-additive class map $[\tau_\mu]$ on $\mathrm{C}(X)_+$ coincides with ν_μ, but the quasi-state ν_μ on $\mathrm{C}(X)_+$ can't be 2-sub-additive if the quasi-measure μ is not a (then finite) Borel measure on X.

Recall here that a quasi-trace τ is 2-*sub-additive* if it has the property $\tau(a+b) \leq 2(\tau(a) + \tau(b))$ for $a, b \in A_+$. This property is equivalent to both of $\tau(a+b)^{1/2} \leq \tau(a)^{1/2} + \tau(b)^{1/2}$ (U. Haagerup) and the existence of a quasi-trace τ_2 on $M_2(A)_+$ with $\tau_2(a \otimes p_{11}) = \tau(a)$,

Aarnes has defined in [**3**] a quasi-state on $\mathrm{C}([0,1]^2)$ that is not additive, therefore it can not be 2-sub-additive. Thus, *there are bounded quasi-traces that are not* 2-*quasi-traces on unital type-I* C^*-*algebras.*

Haagerup [**342**] (cf. also [**348**]) has shown that every bounded 2-quasi-trace on an exact unital C^*-algebra is additive (i.e., is a bounded trace). One can technically improve the arguments of Haagerup [**342**] and Blackadar/Handelman [**79**] to get this result also for all (not necessarily bounded !) lower semi-continuous 2-quasi-traces $\tau\colon A_+ \to [0, \infty]$.

REMARK A.7.2. The lower semi-continuous dimension functions $d\colon M_\infty(A) \to [0, \infty]$, where $M_\infty(A) := \bigcup_n M_n(A)$, are in one-to-one correspondence to lower semi-continuous 2-quasi-traces $\tau\colon A_+ \to [0, \infty]$ by :

$$\tau_d(a) := \lim_{\varepsilon \searrow 0} \int_\varepsilon^\infty d((a-t)_+)\, \mathrm{d}t$$

and $d_\tau(b)$ for $b \in M_n(A)$ and given τ – extended to $\tau_n\colon M_n(A)_+ \to [0, +\infty]$, by

$$d_\tau(b) := \limsup_m \tau_n((b^*b)^{1/m})\,.$$

Check last definition!
Is here $((b^*b)^{1/m} - 1/m)_+$ better??

The local quasi-trace τ (respectively rank function d) is on A_+ lower semi-continuous, if and only if, for every $a \in A_+$: $\tau(a) = \sup_{\delta > 0} \tau((a-\delta)_+)$ (respectively $d(a) = \sup_{\delta>0} d((a-\delta)_+)$). All on $A_+^1 := \{a \in A_+ \,;\, \|a\| \leq 1\}$ bounded local quasi-traces are lower semi-continuous.

An l.s.c. quasi-trace $\tau\colon A_+ \to [0, \infty]$ is a 2-quasi-trace, if and only if, $\tau(a+b) \leq 2(\tau(a) + \tau(b))$ for all $a, b \in A_+$, if and only if, $\tau(a+b)^{1/2} \leq \tau(a)^{1/2} + \tau(b)^{1/2}$ for all

$a, b \in A_+$. It is equivalent to the original definition of J. Cuntz that proposes the existence of a quasi-trace τ_2 on $M_2(A)_+$ with $\tau(a) = \tau_2(\mathrm{diag}(a, 0))$ for all $a \in A_+$.

The dimension functions $d \colon M_\infty(A) \to [0, \infty]$ are in one-to-one correspondence to the *monotone* additive maps $\lambda \colon \mathrm{CS}(A \otimes \mathbb{K}) \to \mathbb{R}_+ \cup \{+\infty\}$.

Need definitions of $\mathrm{Cu}(A)$, $\mathrm{CS}(A)$ and $M_\infty(A)$ given in Chp. 2 ! Or move them to here? ??? Or only remind them here? ???

If $d \colon M_\infty(A) \to [0, \infty]$ is a dimension function (respectively a rank function $r \colon A \to [0, \infty]$, respectively $\tau \colon A_+ \to [0, \infty]$ a quasi-trace) then $d_*(b) := \sup_{\varepsilon > 0} d((b^*b - \varepsilon)_+)$ for $b \in M_\infty(A)$ (respectively $r_*(b) := \sup_{\varepsilon>0} r((b^*b - \varepsilon)_+)$ for $b \in A$, $\tau_*(a) := \sup_{\varepsilon>0} \tau((a - \varepsilon)_+)$ for $a \in A_+$) is a lower semi-continuous dimension function on $M_\infty(A)$ (respectively, lower semi-continuous rank function, lower semi-continuous quasi-trace). r_* is sub-additive on A if r is sub-additive. (τ_* is a 2-quasi-trace if τ is a 2-quasi-trace.

It holds $\tau_* = \tau_{d_\tau}$ and $d_* = d_{\tau_d}$.

Let $a \in A_+$ and denote by S the semigroup of $x \in \mathrm{CS}(A \otimes \mathbb{K})$ with the property that there is $n \in \mathbb{N}$ with $x \leq n[a] = [a \otimes 1_n]$, i.e., $b \precsim a \otimes 1_n$ for $[b] = x$.

????

then $(S, \leq, [a])$ is a scaled abelian semigroup (with the induced preorder $\leq$ and order unit $[a]$). Every monotone and additive map $\lambda \colon S \to [0, \infty]$ extends to a monotone and additive map $\lambda_e \colon \mathrm{CS}(A \otimes \mathbb{K}) \to [0, \infty]$ by $\lambda_e(x) := \lambda(x)$ for $x \in S$ and by $\lambda_e(x) := +\infty$ for $x \notin S$.

Proof. If $x \leq y$ and $\lambda_e(y) < \infty$, then $x, y \in S$, in case that $\lambda_e(x) \leq \lambda_e(y)$. If $\lambda_e(x + y) < \infty$ then $x + y \in S$. Since $0 \leq y$ and $0 \leq x$ in $\mathrm{CS}(A \otimes \mathbb{K})$ it follows that $x = 0 + x \leq x + y \leq n[a]$.

and ?????

If $\lambda_e(x) + \lambda_e(y) < \infty$, then $\lambda_e(x) < \infty$ and $\lambda_e(y) < \infty$, i.e., $x, y \in S$. □

Proof. `to be filled in ??` □

Corollary A.7.3. *Let A denote a C^*-algebra, and $a \in A_+$ with the property that $d(a) = 0$ for every lower semi-continuous dimension function d on $M_\infty(A) := \bigcup_n M_n(A)$ with $d(a) < \infty$, then, for every $\varepsilon > 0$, there is $n(a, \varepsilon) \in \mathbb{N}$ (depending on ε) such that $(a - \varepsilon)_+ \otimes 1_{2n} \precsim a \otimes 1_n$ in $M_{2n}(A)$ for all $n \geq n(a, \varepsilon)$.*

Proof. Let I denote the algebraic ideal of A generated by a. It contains the minimal dense ideal (Pedersen ideal) of the hereditary C^*-subalgebra $\overline{aAa}$, in particular, $(a - \varepsilon)_+ \in I$ for all $\varepsilon > 0$. Consider the sub-semigroup S of classes $[c] \in \mathrm{CS}(\overline{aAa})$ with the property that there is $n \in \mathbb{N}$ with $[c] \leq n[a]$, i.e., $c \precsim a \otimes 1_n$. Then $(S, \leq, [a])$ is a "scaled" semigroup with the preorder induced from $\mathrm{CS}(\overline{aAa})$.

Since every monotone additive map $\lambda \colon S \to \mathbb{R}_+$ extends to monotone additive map $\lambda_e \colon \mathrm{CS}(A) \to [0, \infty]$, and $D(x) := \lambda_e([x])$ is a dimension function on $M_\infty(a)$, and since $D_*(x) := \sup_{\varepsilon>0} D(((x^*x)^{1/2} - \varepsilon)_+)$ is a lower semi-continuous dimension function on A, we have $D_*(a) = 0$. Thus, $\lambda((a-\varepsilon)_+) = 0$ for all $\varepsilon > 0$.

By A.13.10, for every $\varepsilon > 0$, there is $n_0 = n_0(\varepsilon) \in \mathbb{N}$ with $2n[(a-\varepsilon)_+] \leq n[a]$ in $\mathrm{CS}(\overline{aAa})$ for all $n \geq n_0$, i.e., $(a-\varepsilon)_+ \otimes 1_{2n} \precsim a \otimes 1_n$ for all $n \geq n_0$. □

Lemma A.7.4. *Suppose that $\tau \colon A_+ \to [0, \infty]$ is a lower semi-continuous quasi-trace.*

(i) *If τ is a 2-quasi-trace, and if $e \in A_+$ satisfies $\tau(e) < \infty$ and $\|e\| = 1$, then there is a bounded quasi-trace $\rho \colon M_2(\widetilde{D})_+ \to \mathbb{R}_+$ with $\rho(d \oplus 0) = \tau(d)$ for $d \in D_+$, where $D := \{d \in A\,;\ ed = de = d\}$.*

(ii) *The l.s.c. quasi-trace τ is* additive *on A_+, if $\tau|D_+$ is* sub-additive *for every hereditary C^*-subalgebra $D \subseteq A$ with the property that there is $e \in A_+$ with $\tau(e) < \infty$, $\|e\| = 1$ and $de = ed = d$ for all $d \in D$.*

Proof. (i): We have $\tau(d) \leq \|d\|\tau(e)$ for all $d \in D$. By [**79**, cor.II.2.5], the bounded 2-quasi-trace $\tau' := \tau|D_+$ on D extends to a bounded 2-quasi-trace $\tau''|\widetilde{D}_+$ on the unitization $\widetilde{D}$ of D with

$$\tau''(1) = \sup\{\tau(d)\,;\ d \in D_+,\ \|d\| \leq 1\} \ \leq\ \tau(e)\,.$$

The proof of [**79**, cor.II.2.5] is based on the technically engaged theorem [**79**, thm.I.4.1]. A *detailed and elementary* proof of Part (i) goes as follows:

It follows that $f := 2(e - 1/2)_+$ satisfies $df = fd = d$ for all $d \in D$ and $f^{1/n} \leq 2e$ for all $n \in \mathbb{N}$. In particular, f is a strictly positive contraction in the center of the C^*-subalgebra $C^*(D, f)$ of A, because $h(f)d = h(1)d$ for $h \in \mathrm{C}_0(0,1]$ and d, which implies $C^*(D, f) = D + C^*(f)$ and $DC^*(f) = D$.

The restriction of τ to $C^*(D, f)_+$ is bounded, because, for $c \in C^*(D, f)_+$,

$$\tau(c) \leq \|c\| \sup_n \tau(f^{1/n}) \leq 2\|c\|\tau(e)\,.$$

The element $f(1-f)$ is orthogonal to D and is a strictly positive element of an ideal I of $C^*(D, f)$, with $\widetilde{D} \cong C^*(D, f)/I$. The isomorphism is defined by the epimorphism $\phi \colon C^*(D, f) \to \widetilde{D}$ with kernel $C^*(f(1-f))$, given by $\phi(f) = 1$ and $\phi(d) = d$.

Then we have $M_2(D) = \{b \in M_2(A)\,;\ b(e \oplus e) = (e \oplus e)b = b\}$. Thus $M_2(C^*(D, f))$ is generated by $M_2(D)$ and $M_2(C^*(f))$, $f \oplus f = f \otimes 1_2$ is in the center of $M_2(C^*(D, f))$, and the ideal $M_2(C^*(f(1-f)))$ is the hereditary C^*-subalgebra of $M_2(C^*(D, f))$ that is generated by $g := (f(1-f)) \otimes 1_2 = (f - f^2) \oplus (f - f^2)$.

Use the identification $M_2(A) = A \otimes M_2$, then $e \oplus e = e \otimes 1_2$, $f \oplus f = f \otimes 1_2$, $M_2(C^*(D, f)) = C^*(M_2(D), M_2(C^*(f))$, $M_2(C^*(f(1-f))) = C^*(f(1-f)) \otimes M_2$, $f \oplus f$ is in the center of $M_2(C^*(D, f))$.

`check again!::`

We define on the unital C^*-algebra $M_2(\widetilde{D}) \cong M_2(C^*(D, f))/M_2(I)$ a function $\nu(a + s) := \inf_n \tau_2((1 - g^{1/n})(a + f \otimes s)(1 - g^{1/n})$ for selfadjoint $a^* = a \in M_2(D)$

and $s^* = s \in M_2$ with ???????? $\leq a + s \geq 0$. It is obvious that $\nu(d \oplus 0) = \tau(d)$ for all $a \in D_+$, and it is not hard to see, that $\nu|C_+$ is additive for every commutative C^*-subalgebra $C \subseteq M_2(\widetilde{D})$, because $C^*(C \cdot (f \otimes 1_2), g) \subseteq M_2(C^*(D, f))$ is a commutative C^*-subalgebra of $M_2(C^*(D, f))$.

Thus $\nu_1(d + t) = \nu((d + t) \oplus 0)$ (for $d^* = d \in D$ and $t \in \mathbb{R}_+$ with $d + t \geq 0$) is a bounded 2-quasi-trace on $\widetilde{D}_+$ with $\nu_1(d) = \tau(d)$ for $d \in D_+$.

(ii): Let $a, b \in A_+$. Since τ is in particular a lower s.c. 2-quasi-trace, one has $\tau(a + b) \leq 2(\tau(a) + \tau(b))$ and $\max(\tau(a), \tau(b)) \leq \tau(a + b)$. Thus $\tau(a) + \tau(b) = +\infty$, if and only if, $\tau(a + b) = +\infty$. Hence, we may suppose that $\tau(a + b) < \infty$.

Let $g_\delta(t) := \min((2/\delta)\max(t - \delta/2, 0), 1)$ for $t \in \mathbb{R}_+$ and $\delta \in (0, 1]$, and notice that $g_\delta g_\varepsilon = g_\varepsilon$ for $\delta \leq \varepsilon/2$.

If $\tau(a+b) < \infty$ and $\delta > 0$, let $e := g_\delta(a+b)$ and $D := \{x \in A;\ xe = ex = x\}$. The elements $c := g_{4\delta}(a+d)^{1/2}$ and $d := \|a+b\| g_{2\delta}(a+d)^{1/2}$ are in D_+, d commutes with all elements in cAc and $d \geq c(a+b)c$. In particular, $\tau(d-cac)+\tau(cac) = \tau(d)$, $\tau(d - cbc) + \tau(cbc) = \tau(d)$, and

$$2\tau(d) - \tau(c(a + b)c) = \tau(2d - c(a + b)c) = \tau((d - cac) + (d - cbc))$$

The sub-additivity of τ implies $\tau(c(a + b)c) \leq \tau(cac) + \tau(cbc)$, and

$$2\tau(d) - \tau(c(a + b)c) \leq \tau(d - cac) + \tau(d - cbc) = 2\tau(d) - (\tau(cac) + \tau(cbc)).$$

Hence, $\tau(c(a + b)c) = \tau(cac) + \tau(cbc)$.

The elements a, b, $a + b$ are in $E := \overline{(a + b)A(a + b)}$. Since

$$\tau(y^{1/2} g_{2\delta}(a + b) y^{1/2}) = \tau(g_{2\delta}(a + b)^{1/2} y g_{2\delta}(a + b)^{1/2})$$

and

$$\tau(y) = \lim_{\delta \searrow 0} \tau(y^{1/2} g_{2\delta}(a + b) y^{1/2})$$

for all $y \in E_+$ by monotony and lower semi-continuity of τ, it follows $\tau(a + b) = \tau(a) + \tau(b)$. □

REMARK A.7.5. Similar arguments show:
A lower s.c. local *quasi-trace* $\tau\colon A_+ \to [0, \infty]$ *is* 2-subadditive*,*
i.e., $\tau(a + b) \leq 2(\tau(a) + \tau(b))$ *for all* $a, b \in A_+$*, if and only if*
$\tau(a + b) = \infty$ *implies* $\tau(a) + \tau(b) = \infty$*, and, for every* $e \in A_+$ *with* $\tau(e) < \infty$ *and* $\|e\| = 1$*,* $\tau|D_+$ *is* 2*-subadditive, where* D *is the the hereditary* C^**-subalgebra* $D := \{a \in A;\ ae = ea = a\}$.

COROLLARY A.7.6. *Let* A *an exact* C^**-algebra. Then every lower semi-continuous* 2*-quasi-trace* $\tau\colon A_+ \to [0, \infty]$ *is an additive trace.*

PROOF. If A is exact, unital and $\tau(1) < \infty$, then this was shown by U. Haagerup in [**342**] (see also [**348**]).

It suffices to show in the non-unital case that $\tau|D_+$ is sub-additive for every hereditary C^*-subalgebra $D \subseteq A$ with the property that there is $e \in A_+$ with $\tau(e) < \infty$, $\|e\| = 1$ and $de = ed = d$ for all $d \in D$, cf. Lemma A.7.4(ii). But then there is an extension $\widetilde{\tau}\colon \widetilde{D}_+ \to [0,\infty)$ of $\tau|D_+$ by Lemma A.7.4(i). Where we use that the unitization $\widetilde{D}$ of $D \subseteq A$ is exact if A is exact. □

REMARK A.7.7. There exist unital quasi-traces that are not 2-quasi-traces on the unital C^*-algebra $A := \mathrm{C}([0,1]) * \mathrm{C}([0,1])$, i.e., on the unital free product of two copies of $\mathrm{C}([0,1])$, and on a type-I C^*-algebra A that is a unital extension

$$0 \to c_0(\mathbb{K}) \to A \to \mathrm{C}([0,1]^2) \to 0\,.$$

`Cite! place of exact definition.`

8. Projectivity of some C^*-algebras

DEFINITION A.8.1. A C^*-algebra B is **projective** if for every C^*-algebra A, closed ideal $J \triangleleft A$ of A and C^*-morphism $\psi\colon B \to A/J$ there exists a C^*-morphism $\phi\colon B \to A$ with $\psi = \pi_J \circ \phi$ (ϕ is a **lift** of ψ).

Obvious examples of projective C^*-algebras are the free algebras generated by a finite, countable or uncountable number of contractions. (The latter by using the Axiom of Choice.)

Here we display a proof of the projectivity of the cones $CF := \mathrm{C}_0((0,1],F)$ over finite-dimensional C^*-algebras F.

The following Lemma A.8.2 reformulates [**540**, thm. 3.3]. We use a variant of [**616**, prop. 1.5.10] for a proof.

LEMMA A.8.2. *Let $J \triangleleft A$, $a,b \in A_+$ and $d \in A/J$ with $d^*d \leq \pi_J(a)$ and $dd^* \leq \pi_J(b)$. Then there exists $g \in A$ with $g^*g \leq a$, $gg^* \leq b$ and $\pi_J(g) = d$.*

REMARK A.8.3. Lemma A.8.2 is a two-sided version of an order lifting theorem of Combes [**155**], cf. also [**616**, prop. 1.5.10]:

Let $\rho\colon B \to C$ a C^*-algebra epimorphism. If $x \in B_+$ and $y \in C$ satisfy $y^*y \leq \rho(x)$ then there exists some $z \in B$ with $\rho(z) = y$ and $z^*z \leq x$.

Inspection of the proof of [**616**, prop. 1.5.10] allows to see moreover the following:

For each $b \in B$ with $\rho(b) = y$ there exists $z \in B$ with $\rho(z) = y$, $z^*z \leq x$ and (in addition) $zz^* \leq bb^*$.

Indeed: Let $b \in B$ with $\rho(b) = y$ and $J := \rho^{-1}(0)$. Then $(x - b^*b)_- \in J_+$, and $c = (x - b^*b)_- + x$ satisfies $\rho(c) = \rho(x)$, $b^*b \leq c$ and $x \leq c$.

Let $z := \lim_{n\to\infty} b(n^{-1}1 + c)^{-1/2}x^{1/2}$. This limit exists because the elements $t_n := b(n^{-1}1+c)^{-1/2}x^{1/2}$ satisfy via monotony and centrality of C^*-algebra norms the inequalities

$$\|t_m - t_n\|^2 \;\leq\; \|\,\big((m^{-1}1 + c)^{-1/2} - (n^{-1}1 + c)^{-1/2}\big)c\,\|\,.$$

The equation $\pi_J(x) = \pi_J(c)$ implies $\pi_J(z) = \pi_J(b)$. The additional inequality $zz^* \leq bb^*$ comes from $\|(n^{-1}1 + c)^{-1/2}x^{1/2}\|^2 \leq 1$ via $x \leq c$.

Proof of Lemma A.8.2: Let $J \triangleleft A$, $a, b \in A_+$ and $d \in A/J$ with

$$d^*d \leq \pi_J(a) \quad \text{and} \quad dd^* \leq \pi_J(b)\,.$$

We find some $e \in A$ with $\pi_J(e) = d$ by surjectivity of π_J. There exists $f \in A$ with $f^*f \leq a$ and $\pi_J(f) = d$, by Remark A.8.3.

We can apply again Remark A.8.3, but this time with (d^*, f^*, b) in place of (y, b, x), because $\pi_J(f) = d$ and $dd^* \leq \pi_J(b)$. Get $z \in A$ with $\pi_J(z) = d^*$, $z^*z \leq b$ and $zz^* \leq f^*f$.

The element $g := z^*$ has the desired properties: $g^*g \leq f^*f \leq a$, $gg^* = z^*z \leq b$ and $\pi_J(g) = \pi_J(z)^* = d$. □

Proposition A.8.4. [**540**, cor. 3.8] *For each C^*-algebra F of finite dimension, the cone $CF := \mathrm{C}_0((0,1], F)$ of F is projective in sense of Definition A.8.1.*

Proof. The following simple observation works only for σ-unital C^*-algebras B_1 and B_2. This is necessary to observe because the (free) universal C^*-algebra generated by un-countably many contractions is projective (by using the Axiom of Choice) but is not σ-unital.

If B_1 and B_2 are projective σ-unital C^*-algebras, then $B_1 \oplus B_2$ is projective.

Indeed: Let $\psi\colon B_1 \oplus B_2 \to A/J$ a C^*-morphism, $e_1 \in B_1$ and $e_2 \in B_2$ strictly positive contractions, and let $a \in A$ with $\pi_J(a) = \psi(e_1 \oplus (-e_2))$. The elements $a_1 := (a^* + a)_+$, $a_2 := (a^* + a)_- \in A_+$ and hereditary C^*-subalgebras $D_k := \overline{a_k A a_k}$ $(k \in \{1,2\})$ satisfy $D_1 D_2 = \{0\}$, $\psi(B_1 \oplus \{0\}) \subseteq \pi_J(D_1) \cong D_1/(J \cap D_1)$ and $\psi(\{0\} \oplus B_2) \subseteq \pi_J(D_2) \cong D_2/(J \cap D_2)$. Then $\psi_1(b_1) := \psi(b_1 \oplus 0)$ $(b_1 \in B_1)$ and $\psi_2(b_1) := \psi(0 \oplus b_2)$ $(b_2 \in B_2)$ are C^*-morphisms into $D_1/(J \cap D_1)$ respectively $D_2/(J \cap D_2)$. By projectivity of B_1 and B_2 there are C^*-morphisms $\phi_k\colon B_k \to D_k$ with $\pi_J(\phi_k(b_k)) = \psi_k(b_k)$ for $b_k \in B_k$ $(k \in \{1,2\})$. The map $\phi(b_1 \oplus b_2) := \phi_1(b_1) + \phi_2(b_2)$ $(b_k \in B_k)$ is a linear lift of ψ. It is a C^*-morphism, because $D_1 D_2 = \{0\}$.

This shows that finite orthogonal direct sums of σ-unital projective C^*-algebras are projective.

Let $k_1, k_2, \ldots, k_n \in \mathbb{N}$ and $F := M_{k_1} \oplus \cdots \oplus M_{k_n}$. It is easy to see that

$$CF := \mathrm{C}_0((0,1], F) \cong \mathrm{C}_0((0,1], M_{k_1}) \oplus \cdots \oplus \mathrm{C}_0((0,1], M_{k_n})\,.$$

The additive invariance of the class of σ-unital projective C^*-algebras shows that it is enough to prove the projectivity of CF only in the cases $F := \mathbb{C}$ and of $F := M_n$ for $n > 1$.

If $F := \mathbb{C}$ then $CF \cong \mathrm{C}_0(0,1]$ and has the generator f_0 defined by $f_0(t) = t$ $(t \in [0,1])$. $\psi\colon CF \to A/J$ is determined by the positive contraction $b := \psi(f_0)$. Let $d \in A$ with $\pi_J(d) = b^{1/2}$. Then $\pi_J(f(a_0)) = \psi(f)$ for $f \in \mathrm{C}_0(0,1]$ and $a_0 := d^*d - (d^*d - 1)_+$. Thus $\phi\colon f \mapsto f(a_0)$ is a lift of ψ.

Since projectivity is invariant under direct sums we get that CF is projective for $F = \mathbb{C}^n = \mathbb{C} \oplus \cdots \oplus \mathbb{C}$.

If $F := M_n$ with $n > 1$ then the C^*-algebra $CF = CM_n := \mathrm{C}_0((0,1], M_n)$ is isomorphic to the universal C^*-algebra $\mathcal{A}_n := C^*(x_2, \ldots, x_n; R_n)$ with conditions and relations R_n given by $\|x_2\| \leq 1$, $x_j^* x_k = \delta_{jk} x_2^* x_2$ and $x_j x_k = 0$ for $j, k \in \{2, \ldots, n\}$.

Indeed (by using arguments in the proof [**538**, prop. 2.7]): It is easy to see that the elements $\gamma_n(x_k) := f_0 \otimes p_{k,1} \in \mathrm{C}_0((0,1], M_n)$ – with the canonical matrix units $p_{j,k} \in M_n$ – generate $\mathrm{C}_0(0,1] \otimes M_n = \mathrm{C}_0((0,1], M_n)$ and satisfy the norm-condition and relations R_n and therefore define a *-epimorphism onto $\mathrm{C}_0((0,1], M_n)$. Moreover, it is not difficult to check that the positive element

$$Z_n := (x_{1,2} x_{1,2}^* + x_{1,2}^* x_{1,2} + \ldots + x_{1,n}^* x_{1,n})^{1/2}$$

is a contraction in the center of $\mathcal{A}_n$ and $\gamma_n(Z_n) = f_0 \otimes 1_n$. Since it is in the center, it must be strictly positive in $\mathcal{A}_n$ (by the defining relations). Thus, every irreducible *-representation ρ of $\mathcal{A}_n$ maps Z_n to a scalar $\rho(z_n) = \alpha 1$ for some $\alpha \in (0,1]$ and that $\rho(\mathcal{A}_n) \cong M_n$ with $\rho(x_{1,k}) = \alpha p_{1,k}$.

Use now that $\gamma_n(Z_n) = f_0 \otimes 1_n$ to get that the natural C^*-morphism γ_n from $\mathcal{A}_n$ onto $\mathrm{C}_0((0,1], M_n)$ is an isomorphism, because any irreducible representation of A is the compositions of γ_n with the irreducible representations of $\mathrm{C}_0((0,1], M_n)$ and those exhaust all the corresponding $\alpha \in (0,1]$.

The relations R_n (or its realization in $CM_n = \mathrm{C}_0(0,1] \otimes M_n$) show the existence of canonical C^*-morphisms from $\mathcal{A}_n$ into $\mathcal{A}_{n+1}$ that agrees with the natural C^*-morphisms from CM_n into CM_{n+1} given by the inclusion $M_n \subseteq M_{n+1}$ (as left upper corner). Moreover the natural inclusion $CF \subset \mathrm{C}_0((0,1], M_n)$ for $F := \mathbb{C}^n$ defines an isomorphism from CF onto

$$C^*((x_2 x_2^*)^{1/2}, (x_2^* x_2)^{1/2}, \ldots, (x_n^* x_n)^{1/2}) \subseteq \mathcal{A}_n\,,$$

in a way such that $f_0 \otimes 1_n \in CF$ corresponds to Z_n, $f_0 \otimes p_{11}$ to $(x_2^* x_2)^{1/2}$ and the $f_0 \otimes p_{kk}$ map to $(x_k\, x_k^*)^{1/2}$ for $k = 2, \ldots, n$.

Let $\psi \colon \mathcal{A}_n \to A/J$ a C^*-morphism. The projectivity of $CF \cong \mathrm{C}_0((0,1], \mathbb{C}^n)$ for $F := \mathbb{C}^n$ shows that there is a C^*-morphism $\phi_1 \colon \ell_n(\mathrm{C}_0(0,1]) = C\mathbb{C}^n \to A$ that is always given by mutually orthogonal positive contractions $a_1, \ldots, a_n \in A_+$ with $\phi_1((x_2^* x_2)^{1/2}) = a_1$ and $\phi_1((x_k x_k^*)^{1/2}) = a_k$ for $k = 2, \ldots, n$, and satisfies the equations

$$\pi_J(a_1)^2 \;=\; \psi(x_2^* x_2) \quad \text{and} \quad \pi_J(a_k)^2 \;=\; \psi(x_k x_k^*) \quad \text{for} \quad k \geq 2\,. \tag{8.1}$$

Let $a_1, \ldots, a_n \in A$ mutually orthogonal positive contractions, and suppose that there are given C^*-morphism $\psi \colon \mathcal{A}_n \to A/J$ with $\psi(x_2^* x_2) \leq \pi_J(a_1^2)$ and $\psi(x_k\, x_k^*) \leq \pi_J(a_k^2)$ for $k \geq 2$. We show that there exists a C^*-morphism $\phi \colon \mathcal{A}_n \to A$ with $\pi_J \circ \phi = \psi$.

In addition we show that we can find the ϕ with $\phi(x_2^* x_2) \leq a_1^2$ and $\phi(x_k\, x_k^*) \leq a_k^2$ for $k \geq 2$.

We proceed by induction over $k \geq 2$ and produce from above defined $\phi_1 \colon C\mathbb{C}^n \to A$, given by mutually orthogonal positive contractions $a_1, \ldots, a_n \in A_+$, inductively C^*-morphisms $\phi_k\colon \mathcal{A}_k \to A$ with $\phi_k(x_2)^*\phi_k(x_2) \le a_1^2$, $\phi_k(x_j)\phi_k(x_j)^* \le a_j^2$ and $\pi_J(\phi_k(x_j)) = \psi(x_j)$ for $j = 2, \ldots, k$.

If $k = 2$ then this follows immediately from Lemma A.8.2 with $a := a_1^2$, $b := a_2^2$, $d := \psi(x_2)$.

Let $2 < k < n$ and suppose that we have a C^*-morphism $\phi_k\colon \mathcal{A}_k \to A$ with the above listed properties. We apply Lemma A.8.2 to $a := \phi_k(x_2)^*\phi_k(x_2) \le a_1^2$, $b := a_{k+1}^2$ and $d := \psi(x_{k+1})$, and obtain $g \in A$ with $g^*g \le \phi_k(x_2)^*\phi_k(x_2)$, $gg^* \le a_{k+1}^2$ and $\pi_J(g) = \psi(x_{k+1})$.

We use ϕ_k and g to define a C^*-morphism $\phi_{k+1}\colon \mathcal{A}_{k+1} \to A$ with $\pi_J \circ \phi_{k+1} = \psi|\mathcal{A}_{k+1}$, $\phi_{k+1}(x_2^*x_2) \le a_1^2$ and $\phi_{k+1}(x_jx_j^*) \le a_j^2$.

Recall that $\phi_k(x_i)^*\phi_k(x_j) = \delta_{ij}\phi_k(x_2)^*\phi_k(x_2)$ for $i, j \in \{2, \ldots, k\}$ and let $S := (\phi_k(x_2)^*\phi_k(x_2))^{1/2}$. Then $\phi_k(x_j) := v_jS$ is the polar decomposition of $\phi_k(x_j)$ with the partial isometries $v_j \in A^{**}$ given by $v_j = \lim_n \phi_k(x_j)(n^{-1}1 + S)^{-1}$. It follows that $v_j^*v_i = \delta_{ij}v_2^*v_2$. Since $g^*g \le S^2$, we can define $y_j := v_j(g^*g)^{1/2} = \lim_n \phi_k(x_j)(n^{-1}1 + S)^{-1}(g^*g)^{1/2}$ $(j = 2, \ldots, k)$ and $y_{k+1} := g$.

The y_j satisfy $y_jy_j^* \le \phi_k(x_j)\phi_k(x_j)^* \le a_j^2$, $y_i^*y_j = \delta_{ij}y_2^*y_2 = \delta_{ij}g^*g$. for $2 \le i, j \le k$, and $y_{k+1}^*y_j = g^*y_j = 0$ for $j \le k$ because $gg^* \le a_{k+1}^2$ and $y_jy_j^* \le a_j^2$.

Moreover, $y_iy_j = 0$ because $y_i^*y_i \le g^*g \le a_1^2$ and $y_jy_j^* \le a_j^2$ and $a_1a_j = 0$ for $j = 2, \ldots, n$. $\|y_2\| = \|g\| \le \|\phi_k(x_2)\| \le 1$

Thus, the elements $\{y_2, \ldots, y_{k+1}\} \subset A$ satisfy the condition and relations R_{k+1} of $\mathcal{A}_{k+1}$. Moreover, they satisfy $y_2^*y_2 \le a_1^2$ and $y_jy_j^* \le a_j^2$ for $j = 2, \ldots, k+1$. Let $\phi_{k+1}\colon \mathcal{A}_{k+1} \to A$ the corresponding C^*-morphism.

We check that $\pi_J \circ \phi_{k+1}$ is the restriction of $\psi\colon \mathcal{A}_n \to A/J$ to $\mathcal{A}_{k+1}$:

Recall that $\pi_J(y_{k+1}) = \pi_J(g) = \psi(x_{k+1})$ by construction of g, and $\pi_J(\phi_k(x_j)) = \psi(x_j)$ for $2 \le j \le k$ by assumption on ϕ_k. In particular $\pi_J((g^*g)^{1/2}) = (\psi(x_2)^*\psi(x_2))^{1/2}$, and $\pi_J(S) = (\psi(x_2)^*\psi(x_2))^{1/2}$ by definition of $S := (\phi_k(x_2)^*\phi_k(x_2))^{1/2}$. Let $T := (\psi(x_2)^*\psi(x_2))^{1/2}$. It satisfies $\psi(x_j)^*\psi(x_j) = T^2$. Then the definition of the y_j for $j = 2, \ldots k$ show the norm convergence

$$\pi_J(y_j) = \lim_n \psi(x_j)(n^{-1}1 + T)^{-1}T = \psi(x_j)\,.$$

It says that ϕ_{k+1}, – defined by $\phi_{k+1}(x_j) := y_j$ –, satisfies $\pi_J \circ \phi_{k+1} = \psi|\mathcal{A}_{k+1}$. □

Corollary A.8.5. *For each $n \in \mathbb{N}$ the universal C^*-algebra A generated by n contractions $t_1, \ldots, t_n$ with mutually orthogonal ranges is projective.*

Proof. Notice that A is given by universal C^*-algebra with relations

$$A := C^*(t_1, \ldots, t_n\,;\ \|t_k\| \le 1, t_k^*t_\ell = 0 \text{ for } k \ne \ell\,, k, \ell \in \{1, \ldots, n\}\,)$$

with contractions t_k. The relations imply the additional relation $t_1t_1^* + \cdots + t_nt_n^* \le 1$. Let B a C^*-algebra, $J \subseteq B$ a closed ideal of B and $\rho\colon A \to B/J$ a C^*-morphism. We let $s_k := \rho(t_k)$. All we need is to find contractions $c_1, \ldots, c_n \in B$ with $c_j^*c_k = 0$

for $j \neq k$ and $\pi_J(c_k) = s_k := \rho(t_k)$, because then there is a C^*-morphism $\psi\colon A \to B$ with $\psi(t_k) = c_k$, which implies $\pi_J \circ \psi = \rho$.

The C^*-subalgebra of A generated by $(t_k t_k^*)^{1/4}$ $(k = 1, \dots, n)$ is the image of a unique C^*-morphism $\gamma\colon CF \to A$ for $F := \mathbb{C}^n$ and

$$CF \cong C^*(y_1, \dots, y_n\, ;\ 0 \leq y_k \leq 1,\, y_k y_\ell = 0, \text{ for } k \neq \ell\,)$$

with $\gamma(y_k) = (t_k t_k^*)^{1/4}$. By the projectivity of CF there exists a C^*-morphism λ from CF into B that is a lift of $\rho \circ \gamma\colon CF \to B/J$. The C^*-morphism λ satisfies the equations

$$\pi_J(\lambda(y_k)) = \rho((t_k t_k^*)^{1/4}) = (s_k s_k^*)^{1/4}\,.$$

The polar decomposition $s_k = v_k(s_k^* s_k)^{1/2} = (s_k s_k^*)^{1/2} v_k$ of s_k in $(B/J)^{**}$ has the property that $(s_k s_k^*)^{1/4} v_k = v_k (s_k^* s_k)^{1/4} \in B/J$. Let $x_k \in B$ elements with $\pi_J(x_k) = (s_k s_k^*)^{1/4} v_k$. Then the elements $b_k := \lambda(y_k) x_k$ satisfy $b_\ell^* b_k = 0$ for $k \neq \ell$ and $\pi_J(b_k) = s_k$ for $k = 1, \dots, n$. We define elements $c_k \in B$ by $c_k := b_k f(b_k^* b_k) = \lim_{p\to\infty} b_k f(1/p + b_k^* b_k)$ for the continuous function $f(t) := \max(1,t)^{-1/2}$ on $[0,\infty)$. Use here that the element $f(b_k^* b_k)$ is a multiplier of $C^*(b_k^* b_k)$. The elements $c_1, \dots, c_n$ are contractions in B with $c_k^* c_j = 0$ for $j \neq k$ (i.e., with orthogonal ranges) and $\pi_J(c_k) = \rho(t_k)$. □

REMARK A.8.6. The projectivity of CF can be equivalent expressed by the following formulation:

If F is a C^*-algebra of finite linear dimension then every extension

$$0 \to J \to E \to \mathrm{C}_0((0,1], F) \to 0$$

of $\mathrm{C}_0((0,1], F)$ by a C^*-algebra J is a split extension.

9. Projectivity and c.p.c. order zero maps

Elements $a, b \in A$ of a C^*-algebra A are *orthogonal* if $(aa^* + a^*a)(bb^* + b^*b) = 0$. We denote this by $a \perp b$. It is equivalent to the 4 equations $ab = 0$, $ba = 0$, $a^*b = 0$ and $ab^* = 0$. And it says equivalently that $h_{1,j} h_{2,k} = 0$ for $j, k \in \{1, 2\}$, where $h_{1,1}, h_{1,2}, h_{2,1}, h_{2,2} \in A$ are the selfadjoint elements with $a = h_{1,1} + i h_{1,2}$ and

$b = h_{2,1} + ih_{2,2}$. In particular, for self-adjoint $a, b \in A$ holds $a \perp b$ if and only if $ab = 0$.

DEFINITION A.9.1. Let A and B C^*-algebras and $\psi\colon A \to B$ a bounded linear map that is invariant under passage to adjoint elements, i.e., $\psi(a^*) = \psi(a)^*$ for all $a \in A$ ([5]). We call a map ψ with this property *orthogonality preserving* if ψ has the additional property that $\psi(h)\psi(k) = 0$ for selfadjoint $h, k \in A$ with $hk = 0$. ([6])

If ψ is moreover a completely positive contraction, then ψ is called an "order-zero map" by W. Winter and J. Zacharias in [**836**, def. 1.3].
(We call it here sometimes "*order-zero morphism*".)

If $\varphi\colon \mathrm{C}_0((0,1], A) \to B$ is a C^*-algebra homomorphism then $\psi_\varphi(a) := \varphi(f_0 \otimes a)$ is the contractive completely positive order-zero map defined by φ.

It turns out that there exists a natural decomposition of ψ_φ into element-wise commuting C^*-morphisms $\lambda\colon \mathrm{C}_0(0,1] \to \mathcal{M}(D)$ and $\rho\colon A \to \mathcal{M}(D)$ with $\psi_\varphi(f \otimes a) = \lambda(f)\rho(a)$ for all $f \in \mathrm{C}_0(0,1]$ and $a \in A$, where D denotes the hereditary C^*-subalgebra B generated by $\psi_\varphi(A)$ ...

We use in this book only the C^*-morphisms $\varphi\colon \mathrm{C}_0((0,1], A) \to B$ instead of order-zero morphisms, because by our

Lemmata ??, ??, ??, and Proposition ??

there is a natural bijective relation between *contractive, 2-positive and orthogonality preserving* maps $\psi\colon A \to B$ and the usual C^*-morphisms $\varphi\colon \mathrm{C}_0((0,1], A) \to B$ that is given by $\psi(a) = \varphi(f_0 \otimes a)$ for all $a \in A$. It is a bijective relation because the 2-positive contraction ψ determines φ uniquely by the following obvious equations for all $n \in \mathbb{N}$ and $a \in A_+$:

$$\varphi(f_0^n \otimes a) = \varphi(f_0 \otimes a^{1/n})^n = \psi(a^{1/n})^n .$$

In particular, this implies that all 2-positive *and* orthogonality preserving maps $\psi\colon A \to B$ are automatically completely positive!

The following Proposition A.9.2 should be moved below general observations!
One application of the projectivity of $\mathrm{C}_0((0,1], F)$ for a finite-dimensional C^*-algebra F and the characterization of 2-positive order-zero maps $\varphi\colon F \to A/J$ is the following proposition.

PROPOSITION A.9.2. *Let F a C^*-algebra of finite dimension and $\varphi\colon F \to A/J$ a 2-positive order-zero map, then there exists a completely positive order zero map $\psi\colon F \to A$ with $\pi_J \circ \psi = \varphi$.*

PROOF. For each 2-positive order-zero map φ from F into the C^*-algebra $B := A/J$ there exists a C^*-morphism $\lambda_0\colon \mathrm{C}_0((0,1], F) \to B$ and $f \in \mathrm{C}_0(0,1]_+$

[5] Such maps ψ are sometimes called "symmetric".

[6] Equivalently, $a_1 \perp a_2$ implies $\psi(a_1) \perp \psi(a_2)$, because $\psi(a^*) = \psi(a)^*$ on A. M. Wolff calls our "orthogonality preserving" maps "*disjointness preserving*" in [**838**].

with $\varphi(b) = \lambda_0(f \otimes b)$ for all $b \in B$. By Proposition A.8.4, the algebra $\mathrm{C}_0((0,1], F)$ is projective. Thus, there exists a C^*-morphism $\lambda_1 \colon \mathrm{C}_0((0,1], F) \to A$ with $\pi_J \circ \lambda_1 = \lambda_0$. Then $\psi(b) := \lambda_1(f \otimes b)$ defines a completely positive order-zero from F into A with $\pi_J \circ \psi = \varphi$. □

Here are some citations from the paper [**836**] of W. Winter and J. Zacharias.

Erase them or replace them by my own version (with citations).

Corollary 3.1 of WILHELM WINTER AND JOACHIM ZACHARIAS in COMPLETELY POSITIVE MAPS OF ORDER ZERO:

[**836**, cor. 3.1]

Let A and B be C^*-algebras, and $\varphi\colon A \to B$ a c.p.c. order zero map. Then, the map given by $\rho_\varphi(f_0 \otimes a) := \varphi(a)$ (for $a \in A$) induces a *-homomorphism $\rho_\varphi\colon \mathrm{C}_0((0,1], A) \to B$.

Conversely, any *-homomorphism $\rho\colon \mathrm{C}_0(0,1] \otimes A \to B$ induces a c.p.c. order zero map $\varphi_\rho\colon A \to B$ via $\varphi_\rho(a) := \rho(f_0 \otimes a)$. These mutual assignments yield a canonical bijection between the point-norm closed set of c.p.c. order zero maps from A to B and the *-homomorphisms from $\mathrm{C}_0(0,1] \otimes A$ to B.

My Remarks:

The positive case:

If A is abelian and $\varphi\colon A \to B$ *positive*, then φ is completely positive, because the second conjugate $\varphi^{**}\colon A^{**} \to B^{**}$ is again positive. Then φ and φ^{**} are moreover a *completely* positive map because each finite subset of A^{**} can be approximated (in norm) by the linear span of finitely many projections in A^{**}.

Thus, then there are unique (!) C^*-morphisms $\rho_C\colon \mathrm{C}(0,1] \otimes C \to B$ with $\rho_C(f_0 \otimes c) = \varphi(c)$ for each commutative $C \subseteq A$ ...

Check if it is on intersections of different abelian $C \subseteq A$ the same. (Seems to be ...)

But the PROBLEM (!) is, that general elements of $(\mathrm{C}(0,1] \otimes A)_+$ are not contained in some $\mathrm{C}(0,1] \otimes C$ ... Thus, this old idea of proof don't work.

The following theorem reformulates the theorem [**838**, thm.2.3] of M. Wolff on Jordan algebras for the more special case of C^*-algebras, where he calls the above defined "symmetric" and "orthogonality preserving" maps "*disjointness preserving*".

Theorem A.9.3. *Let A and B be C^*-algebras, with unital A, and let $\varphi\colon A \to B$ be a disjointness preserving map. Define $D := \{\varphi(1_A)\}' \cap B \subseteq B$ and*

$$C := \overline{\varphi(1_A) \cdot D}\,.$$

*Then, $\varphi(A) \subseteq C$ and there is a Jordan *-homomorphism $\psi\colon A \to \mathcal{M}(C)$ from A into the multiplier algebra of C satisfying $\varphi(a) = \varphi(1_A)\psi(a)$ for all $a \in A$.*

The ideas of his proof are related to some study of Lamperti operators by W. Arendt in [**41**].

Notice that $\varphi(1_A)$ is selfadjoint, but is here not required to be positive. The proof of Theorem A.9.3 reduces to the case where $A = \mathrm{C}[0,1]$, but is not obvious.

We use the below given Lemma **??** and consider then a slightly more general case where A is not necessarily unital, $\varphi \colon A \to B$ is a bounded linear map with the properties that φ is "symmetric" – in the sense that $\varphi(a^*) = \varphi(a)^*$ for all $a \in A$ – and is "orthogonality preserving" – in the sense that $\varphi(a_1)\varphi(a_2) = 0$ if $a_1 a_2 = 0$ for orthogonal selfadjoint elements $a_1 = a_1^*$, $a_2 = a_2^*$ (i.e., with $a_1 a_2 = 0$).

REMARK A.9.4. `First (see below explained): Banach case for` $V \colon Y^* \to X^*$.
`Then` V `is` $\sigma(Y^*, Y)$-$\sigma(X^*, X)$ `continuous`
`if and only if`
`there exists bounded linear map` $U \colon X \to Y$ `such that` $V = U^*$.
`But look to the notations!! Chaos there???`

The continuity properties for $S \colon A^{**} \to B^{**}$ and $T \colon A^{**} \to B^{**}$ with respect to $\sigma(A^{**}, A^*)$ and $\sigma(B^{**}, B^*)$ (... play role of $V := U^* \colon Y^* \to X^*$, e.g. with suitable $S_* \colon B^* \to A^*$ in the role of $U \colon X \to Y$ with continuity of V with respect to $\sigma(Y^*, Y)$ and $\sigma(X^*, X)$.)

Because then, for example, the linear functional given by $a \in A^{**} \mapsto \varphi(T(a))$ where $\varphi \in B^*$ is equal the linear functional $V(\varphi) \in A^*$. This proves the continuity properties for $T = V^*$.

$V \colon Y^* \to X^*$.
Then V is $\sigma(Y^*, Y)$-$\sigma(X^*, X)$ continuous
if and only if
there exists bounded linear map $U \colon X \to Y$ such that $V = U^*$.

Conversely, the quoted continuity properties e.g. for T on A^{**} implies that for each $\varphi \in B^*$ the map $\varphi \circ T$ is in A^* and has norm $\leq \|\varphi\| \cdot \|T\|$. Thus, $V(\varphi) := \varphi \circ T$ defines a bounded linear map $V \colon B^* \to A^*$.

Compare notational chaos with above:

From Banach space theory it follows that a continuous linear map $V \colon X \to Y$ (here $U := V^* = T_*$) for Banach spaces X and Y (here in our case $X := B^*$ and $Y := A^*$) has an adjoint $T := L^* \colon Y^* = A^{**} \to X^* = B^{**}$ that is $\sigma(A^{**}, A^*)$ – $\sigma(B^{**}, B^*)$ continuous, i.e., is continuous with respect to the topologies $\sigma(A^{**}, A^*)$ on A^{**} and $\sigma(B^{**}, B^*)$ on B^{**}, because this means that $L(\varphi) = \varphi \circ T$ is in A^* for each $\varphi \in B^*$.

In particular, then ????

Indeed, we can consider $\varphi\colon B \to \mathbb{C}$ as linear operator. Then $\varphi^{**}\colon B^{**} \to \mathbb{C}$ is in $B^* \subseteq (B^{**})^*$ and $(\varphi \circ V)^{**} = \varphi^{**} \circ T$. But this says that $T\colon A^{**} \to B^{**}$ is continuous with respect to $\sigma(A^{**}, A^*)$ and $\sigma(B^{**}, B^*)$.

In the special case of ???????? we have to require in addition also that $U(a^*) = U(a)^*$ and $V(a^*) = V(a)^*$ for all $a \in A$, such that $S := U^{**}$ and $T := V^{**}$ map selfadjoint elements to selfadjoint elements.

REMARK A.9.5. We consider on the class of C^*-algebras only "symmetric" Jordan morphisms $T\colon A \to B$ for C^*-algebras A and B, i.e., linear maps with the properties that $T(a^*) = T(a)^*$ for all $a \in A$ and $T(h^2) = T(h)^2$ for $h^* = h \in A$.

It follows then that $T(a^*b + b^*a) = T(a)^*T(b) + T(b)^*T(a)$ for all $a, b \in A$.

The second conjugate $T^{**}\colon A^{**} \to B^{**}$ of a C^*-Jordan morphism is again a C^*-Jordan morphism.

`PROOF of this ??:`

At first T and T^{**} are positive linear contractions on $A_{s.a.}$ and $(A^{**})_{s.a.}$, because $T(a) = T(a^{1'/2})T(a^{1/2}) \geq 0$ for $a \in A_+$ and $\chi(T(\cdot)) \in (A^*)_+$ for positive $\chi \in B^*$ gives that its natural extensions is the positive functional $\chi(T^{**}(\cdot)) \in A^*$ and is again positive on A^{**}_+ and T^{**} is $\sigma(A^{**}, A^*) - \sigma(B^{**}, B^*)$ continuous.

Let $0 \geq c \in A^{**}$ with $\|c\| = 1$. Then there exists a net of self-adjoint contractions $\{a_\lambda\} \subseteq A_+$ that converges to c *-ultra-strongly in A^{**}. Then $T(a_\lambda^2) \to T(c^2)$???????

If $\rho \in B^*$ is a state then $\rho(T(a_\lambda)T(a_\lambda)) \to$???

LEMMA A.9.6. *Let A and B C^*-algebras and $T\colon A \to B$ a C^*-Jordan morphism. Then the following properties of T are equivalent:*

(i) *T is 2-positive, i.e., $T \otimes \mathrm{id}_{M_2}\colon A \otimes M_2 \to B \otimes M_2$ is positive.*
(ii) *The linear map $T_2 := T \otimes \mathrm{id}_{M_2}\colon A \otimes M_2 \to B \otimes M_2$ is contractive, i.e., has norm ≤ 1.*
(iii) *T is C^*-algebra morphism.*

PROOF. It is somewhere calculated (further down?).

It holds $(T_2)^{**} = T_2^{**}$. Thus one can restrict the considerations to W*-algebras. □

REMARK A.9.7. Let A denote a C^*-algebra.

The open support projection $p_t \in A^{**}$ of $(a-t)_+ \in A_+$ is the unit element of $D_t^{**} \subseteq A^{**}$, where $D_t := \overline{(a-t)_+ A (a-t)_+}$ with $t \in [0, \|a\|]$. The projection p_t is contained in $C * (a)^{**} \subseteq A^{**}$ and is the unit element of $C * ((a-t)_+)^{**} \subseteq A^{**}$.

We can here replace A by $C^*(a)$ and A^{**} by the second conjugate $(C^*(a))^{**} \subseteq A^{**}$ of $C^*(a)$.

We denote the projection $p_0 \in A^{**}$ – respectively more generally the p_0 for a positive contraction in any W*-algebra M –, for $a \in A_+$ also by p_a, respectively by p_b for $b \in A_+$ (or $b \in M$), to distinguish the support projections of different elements $a, b \in A_+$.

If $a \neq 0$ and $t \in [0, \|a\|]$ then the projection p_t is a projection that is the smallest positive contraction $q \in A^{**}$ with the property

$$(\|(a-t)_+\|^{-1}(a-t)_+)^{1/n} \leq q \text{ for all } n \in \mathbb{N}\,.$$

This remains true for every W^*-algebra M (in place of the special case $M := A^{**}$):

The "support projection" $p_a \in M$ for some positive contraction $a \in M_+$ is the smallest positive contraction in M with $a^{1/n} \leq p_a$ for all $n \in \mathbb{N}$; i.e.:

Let $0 \leq x \leq 1$ in M with $a^{1/n} \leq x$ for all $n \in \mathbb{N}$ then $p_a \leq x$.

In particular, if N is another W*-algebra and $\psi \colon M \to N$ is an injective unital C^*-algebra mono-morphism from M into N and $E \colon N \to \psi(M) \subseteq N$ is a conditional expectation of N onto a C^*-subalgebra $\psi(M)$ of N, then $E(p_\psi(a)) = \psi(p_a)$, where $p_\psi(a)$ the support projection in N of $\psi(a) \in N$ and p_a the support projection in N of a positive contraction $a \in N$.

This applies to the natural unital conditional expectation from $N := M^{**}$ onto $M \subseteq M^{**}$, where ψ denotes here the canonical embedding of the W*-algebra M in its second conjugate N.

Let $0 \leq s < t \leq 1$, $a \in A_+$ with $\|a\| \leq 1$ and $p_s, p_t \in A^{**}$ the open support projection of $(a-s)_+$ and $(a-t)_+$ then $(a-t)_+ \leq (a-s)_+$, $p_s p_t = p_t$ and $(a-t)_+ = ((a-s)_+ - (t-s))_+ \leq (t-s) \cdot p_s + (a-t)_+$. It follows that $(a-s)_+ - (a-t)_+ \leq (t-s)p_s$. Moreover, $p_t((a-s)_+ - (a-t)_+) = (t-s)p_t \leq (a-s)_+ - (a-t)_+$.

Thus, $(t-s)p_t \leq (a-s)_+ - (a-t)_+ \leq (t-s)p_s$ for the support projections p_t for $(a-t)_+$ and p_s for $(a-s)_+$ and $0 \leq s \leq t \leq 0$.

LEMMA A.9.8. *Let A a C^*-algebra.*

(i) *Every $a \in A_+$ is contained in the norm closure of the convex set generated by the open support projections $p_t := p_{(a-t)_+} \in A^{**}$ of $(a-t)_+ \in A_+$ with $t \in (0, \|a\|)$.*
(ii) *All elements of A are contained in the (norm-)closed linear span of the open support projections $p_a \in A^{**}$ of elements $a \in A_+$.*
(iii) *Let $T \colon A \to M$ a bounded linear map into a W^*-algebra M, and let $\widetilde{T} \colon A^{**} \to M$ denote its unique natural extension to a $\sigma(A^{**}, A^*)$–$\sigma(M, M_*)$ continuous linear map (i.e., the normal extension of T).*

The point is:
It uses the natural conditional expectation from M^{**} onto M,
where M is considered as C- subalgebra of M^{**}.*

The linear map T is a Jordan morphism (cf. Remark A.9.5) if and only if, $\widetilde{T}(p_a)$ is an orthogonal projection in M for the open support projections $p_a \in A^{**}$ of each elements $a \in A_+$.

PROOF. (i): Let $a \in A_+$ with $\|a\| = 1$ and $p_{n,k} \in C*(a)^{**} \subseteq A^{**}$ the open support projection of $a_k := (a-(k-1)/n)_+ \in C*(a) \subseteq A$ for $k \in \{1, \ldots, n+1\}$. Then $a_\ell \leq a_k$ for $k \leq \ell$, and

$$a_{k+\ell}(a_k - a_{k+\ell}) = \|a_k - a_{k+\ell}\| a_{k+\ell} \,.$$

Then $a_1 = a$, $a_2 = (a-1/n)_+$, ..., $a_k = (a-(k-1)/n)_+$, ..., $a_n = (a-(n-1)/n)_+$, $a_{n+1} = 0$. Thus, $a = \sum_{k=1}^{n}(a_k - a_{k+1})$. Notice that $a_k \geq a_\ell$ for $\ell > k$.

We denote hereby $p_{n,k}$ the open support projection of a_k, $k = 1, \ldots, n+1$. Then $p_{n,n+1} = 0$. Thus

$$1/np_{n,k+1} \leq a_k - a_{k+1} \leq 1/np_{n,k} \,.$$

It follows that

$$(\sum_{k=1}^{n} p_{n,k+1}) \leq n \cdot a \leq (\sum_{k=1}^{n} p_{n,k}) \,.$$

Since $p_{n,n+1} = 0$, the difference of the left and right estimates is $= p_{n,1}$. It shows that $a \in A_+$ can be approximated arbitrarily well by scalar multiples of sums of open projections in A^{**}.

(ii): Each element $a \in A$ is the (complex) linear combination of at most 4 elements in A_+.

(iii): If $T\colon A \to M$ is a C^*-Jordan morphism and $a \in A_+$ is a positive contraction then $T(a) = T(a^{1/n})^n$ for all $n \in \mathbb{N}$. Thus, $T(a)^{1/n} = T(a^{1/n})$ for $n \in \mathbb{N}$.

Is $T^{**}\colon A^{**} \to M^{**}$ again C^*-Jordan???

Is the "natural" map $M^{**} \to M$ multiplicative?

The increasing sequence $T(a)^{1/n}$ converges in M to the support projection of $T(a)$ with respect to the $\tau(M, M_*)$-topology, that is stronger than the $\sigma(M, M_*)$-topology.

The increasing sequence of elements $a^{1/n}$ converge $\tau(A^{**}, A^*)$-strongly in A^{**} to the support projection $p_a \in A^{**}$ of a. Here $p_a A^{**} p_a$ is the $\tau(A^{**}, A^*)$ closure of the hereditary C^*-subalgebra $\overline{aAa}$

of ??????

In general the map $\widetilde{T}\colon A^{**} \to M$ is continuous with respect to the topologies $\sigma(A^{**}, A^*)$ and $\sigma(M, M_*)$, because $\widetilde{T} = P_M \circ T^{**}$ where $T^{**}\colon A^{**} \to M^{**}$ is the weakly continuous bi-dual map from T and $P_M\colon M^{**} \to M$

together τ-continuous ???

normal (!!! ???) W*-algebra epimorphism from M^{**} onto M.

Is this correct ????

$T\colon A \to M$ (positive because Jordan)

$T^{**}\colon A^{**} \to M^{**}$ σ-continuous.

(One could also use an orthogonality argument,

Or reduction to abelian case?

Take maximal commutative C^*-subalgebra C of A that contains the given element $a \in A_+$.

Then $C^{**} \subseteq A^{**}$ $T|C$ is a C^*-algebra morphism from C into M.

Second conjugate $T^{**}|C = (T|C)^{**} \colon C^{**} \to M^{**}$ The algebra $T(C) \subseteq M$ is commutative.

in particular $p_a \in A^{**} \to \widetilde{T}(p_a) \in M$

□

LEMMA A.9.9. *Let A and B denote C^*-algebras and suppose that $S, T \colon A^{**} \to B^{**}$ are $\sigma(A^{**}, A^*)$-$\sigma(B^{**}, B^*)$ continuous "symmetric" linear maps in the sense that $S(a^*) = S(a)^*$ and $T(a^*) = T(a)^*$ for all $a \in A$.*

(i) *Let $a, b \in A_+$ positive contractions with $a \in D := \overline{bAb}$ and $p, q \in A^{**}$ the open projection $p = pq \leq q$ corresponding to the hereditary C^*-subalgebras D and $E := \overline{aAa} \subseteq D$ of A.*

Then $S(p)T(1-q) \in A^{**}$ is contained in the $\sigma(A^{**}, A^*)$-closure of the set of elements $S(e)T(1-d)$ with positive contractions $e \in E_+$, $d \in D_+$ with $de = e$.

Moreover, each element $S(e)T(1-d)$ with positive contractions $d \in D_+$ and $e \in E_+$ and $de = e$ is in the $\sigma(A^{**}, A^*)$-closure of the set of elements $S(e)T(g)$ with positive contractions $g \in \overline{(1-d)A(1-d)}$.

(ii) *In particular, $S(p)T(1-q) = 0$ if $p, q \in A^{**}$ are open projections with the properties that $qp = q$ and for each contractions $a, b, c \in A_+$ with $cb = b$ and $ca = a$. holds $S(a)T(c-b) = 0$ for all positive contractions $a, b, c \in A_+$ with the properties that $a \leq p$ and $b \leq q$ and $cb = b$ $a(c-b) = 0$.*

?????????????????

$S((a - 1/n)_+)T(1 - f_m(b)) = 0$ for all $a \in A_+$ with $0 \leq a \leq p$ and $n, m \in \mathbb{N}$ with $(a - 1/n)_+(1 - f_m(a)) = 0$.

REMARKS A.9.10. Notice that Part (iii????) of Lemma A.9.9 contains the case $a = b$ and $D = E$.

The continuity properties of S and T are equivalent to the existence bounded linear maps $U, V \colon A \to B$ with $S := U^{**}$ and $T := V^{**}$. Because in general Banach space theory one has that a continuos map $V \colon A \to B$ from

In our case $U(a^*) = U(a)^*$ and $V(a^*) = V(a)^*$ for all $a \in A$, such that $S := U^{**}$ and $T := V^{**}$.

Proofs not ready, because of the partial continuity of ??? !!!

Ad(iii):

TEXT: Let $a, b \in A_+$ positive contractions with $a \in D := \overline{bAb}$ and $p, q \in A^{**}$ the open projection $p = pq \leq q$ corresponding to the hereditary C^*-subalgebras D and $E := \overline{aAa} \subseteq D$ of A.

Then $S(p)T(1-q) \in A^{**}$ is contained in the $\sigma(A^{**}, A^*)$-closure of the set of elements $S(e)T(1-d)$ with positive contractions $e \in E_+$, $d \in D_+$ with $de = e$.

We use the piece-wise linear continuous functions $\varphi_n(t)$ on $[0,1]$ given by $\varphi_n(t) := 2^{n+1}((t - 2^{-(n+1)})_+ - (t - 2^{-n})_+)$ for $n = 1, 2, \ldots$. This continuous functions are non-negative, $\varphi_n(0) = 0$, $\|\varphi_n\| = 1$, $\varphi_{n+1}\varphi_n = \varphi_n$ and φ_n converges on each interval $[s, 1] \subseteq (0, 1]$ uniformly to 1. For every $n \in \mathbb{N}$ and protection $P^* = P = P^2$ holds $\varphi_n(P) = P$.

Let $e_n := \varphi_n(a) \in E_+$, where a is a strictly positive contraction in E. Then the e_n are positive contractions that satisfy $e_m e_n = e_m$ for $m < n$ and the sequence $e_1, e_2, \ldots$ converges to the support projection $p \in A^{**}$ of a in the $\tau(A^{**}, A^*)$ topology, that is stronger than the $\sigma(A^{**}, A^*)$ topology on A^{**}. By our assumption that $S\colon A^{**} \to A^{**}$ is $\sigma(A^{**}, A^*)$-continuous shows that the sequence $S(e_1), S(e_2), \ldots$ converges to the element $S(p) \in A^{**}$ in the $\sigma(A^{**}, A^*)$ topology.

Let $p \leq q \in A^{**}$ denote the open support projection $E = \overline{aAa} \subseteq D = \overline{bAb}$. Since $e_n \leq p \leq q$, we get that $e_n + (1-e_n)^{1/2} q (1-e_n)^{1/2} = q$ for each $n \in \mathbb{N}$, i.e., $q - e_n = (1-e_n)^{1/2} q (1-e_n)^{1/2}$.

Let $f_n := \varphi_n(a) \in D_+$. This positive contractions satisfy $f_m f_n = f_m$ for $m < n$, and the increasing sequence $f_1, f_2, \ldots$ converges to the support p of a

Need to find contractions $d_n \in D_+$ (for $D = \overline{bAb}$) with $d_n e_n = e_n$ and $d_n \to q$ in A^{**}.

$d_{n-1} = e_n + (1-e_n)^{1/2} f_n (1-e_n)^{1/2}$

for suitable contractions $f_n \in D_+$ with $f_n \to q$ in A^{**} and $f_n^{1/2} e_n^{1/2} - e_n^{1/2} f_n$ and $e_n - f_n e_n$ small ...

Since $e_n \leq p \leq q$, we get $e_n + (1-e_n)^{1/2} q (1-e_n)^{1/2} = q$????

We call a projection $p \in A^{**}$ *open* in the following Lemma A.9.11 if $pA^{**}p$ is the $\sigma(A^{**}, A^*)$-closure of a hereditary C^*-subalgebra D of A. We say that p is a σ-unital open projection if the corresponding $D \subseteq A$ is σ-unital, i.e., if $D = \overline{dAd}$ for some $d \in A_+$. The following Lemma A.9.11 considers special cases of orthogonally preserving pairs of symmetric maps $V, W\colon A \to B$.

(It seem that the general theory of such pairs, without assuming the additional equivalent conditions (i)–(ix) in Lemma A.9.11 has to do with approximately inner gradings on C^*-algebras and questions of different nature.)

Lemma A.9.11. *Let A and B C^*-algebras and let $V\colon A \to B$ and $W\colon A \to B$ linear maps that are "symmetric" in the sense that $V(a^*) = V(a)^*$ and $W(b^*) = V(b^*)$. and are relatively orthogonality preversing that satisfy*

(1) $T := V^{**}(1_{A^{**}}) = W^{**}(1_{A^{**}}) \in B^{**}$ *and*

(2) $V(a_1)W(a_2) = 0$ *for all* $a_1, a_2 \in A_+$ *with* $a_1a_2 = 0$.

Then the following properties (i)–(ix) of V *and* W*, respectively of its bi-adjoints* V^{**} *and* W^{**}*, are equivalent:*

(i) $TV(a) = V(a)T$ *for all* $a \in A$.
(ii) $TW(a) = W(a)T$ *for all* $a \in A$.
(iii) $TV^{**}(p) = V^{**}(p)T$ *for all open projections* $p \in A^{**}$.
(iv) $TW^{**}(p) = W^{**}(p)T$ *for all open projections* $p \in A^{**}$.
(v) $TV^{**}(p) = V^{**}(p)T$ *for all* σ*-unital open projections* $p \in A^{**}$.
(vi) $TW^{**}(p) = W^{**}(p)T$ *for all* σ*-unital open projections* $p \in A^{**}$.
(vii) $V = W$.
(viii) $V(a)V(b) = 0$ *for all* $a, b \in A_+$ *with* $ab = 0$.
(ix) $W(a)W(b) = 0$ *for all* $a, b \in A_+$ *with* $ab = 0$.

Proof. □

Proposition A.9.12. *If* $V\colon A \to B$ *is symmetric and orthogonality preserving and has norm* $\|V\| \le 1$*, then there are two uniquely defined symmetric Jordan morphisms* $\psi_k\colon \mathrm{C}_0((0,1], A) \to B$ *(*$k \in \{1, 2\}$ *with the following properties:*

(i) $\psi_1(\mathrm{C}_0((0,1], A)) \cdot \psi_2(\mathrm{C}_0((0,1], A)) = \{0\}$ *and*
(ii) $V(a) = \psi_1(f_0 \otimes a) - \psi_2(f_0 \otimes a)$ *for all* $a \in A_+$.

Proof. Next proof wrong here?

By Lemma A.9.9 we get with $W = V$ that $W^{**}(1-p)V^{**}(p) = 0 = V^{**}(1-p)W^{**}(p)$

Thus $TW^{**}(p) = V^{**}(p)W^{**}(p)$, $V^{**}(p)T = V^{**}(p)W^{**}(p)$ and $TV^{**}(p) = W^{**}(p)V^{**}(p)$. Thus $TW^{**}(p) = V^{**}(p)T$. It follow that $TW(a) = V(a)T$ for all $a \in A$.

□

Lemma A.9.13. *Let* $\varphi\colon A \to B$ *an orthogonality preserving map in sense of Definition A.9.1. Then the restriction* $\psi\colon C^*(A, 1_{A^{**}}) \to B^{**}$ *of* $\varphi^{**}\colon A^{**} \to B^{**}$ *is again an* orthogonality preserving *map from* $C^*(A, 1_{A^{**}}) = A + \mathbb{C}\cdot 1_{A^{**}}$ *into* B^{**}.

Proof. We write here 1 for the unit element $1_{A^{**}}$ of A^{**}. If A is unital then nothing is to prove. If A is not unital then $A + \mathbb{C}\cdot 1 = C^*(A, 1) \subseteq A^{**}$ is natural isomorphic to the standard unification of A.

It implies: If $x^* = x$ and $y^* = y$ elements of A and $\alpha, \beta \in \mathbb{R}$ such that $(x + \alpha 1)(y + \beta 1) = 0$, then necessarily $\alpha\beta = 0$, and $xy = yx$.

If $\alpha = \beta = 0$ then $xy = 0$ and $\psi(x)\psi(y) = \varphi^{**}(x)\varphi^{**}(y) = \varphi(x)\varphi(y) = 0$, because φ preserves orthogonality.

By symmetry of the cases $\alpha \neq 0$ and $\beta \neq 0$ for $\alpha\beta = 0$, it suffices to consider the case $\alpha = 0$:
Let $z := -\beta^{-1}y$. It gives $zx = x = xz$, i.e., $(1-z)x = 0$.

If $\varphi^{**}(1-z)\varphi^{**}(x) = 0$, then $\varphi(x)(\varphi(y) + \beta\varphi^{**}(1)) = 0$, because $\beta\varphi^{**}(1 + \beta^{-1}y) = \varphi(y) + \beta\varphi^{**}(1)$ is equivalent to $\varphi^{**}(x)\varphi^{**}(1 + \beta^{-1}y) = 0$.

Suppose that $zx = x$, $x^* = x$ and $z^* = z$. Then also $xz = x$, $x_+ = zx_+$ and $x_- = zx_-$, because for example $x(x_+^{1/n}) \to x_+$, and, in the same way, $x_- = zx_-$.

A similar argument shows that $z_+x_+ - z_-x_+ = zx_+ = x_+$ implies $z_-x_+ = 0$ and $z_+x_+ = x_+$. If we take here x_- in place of x_+, then we get $z_-x_- = 0$ and $z_+x_- = x_-$.

It follows that $(z_+ - 1)_+x_+ = 0$ from $(z_+ - 1)x_+ = 0$, because $(z_+ - 1)$ and x_+ commute. (In general, if a selfadjoint element is orthogonal to a positive element, then its positive and negative parts are also orthogonal to the positive element.)

$z_+x = x$, $(z_+ - (z_+ - 1)_+)x = x$, $0 \geq v := 2(z_+ - (z_+ - 1/2)_+) \leq 1$ satisfies $v(z_+ - (z_+ - 1)_+) = (z_+ - (z_+ - 1)_+)$, $vx = x$ and $(1-v)^{1/2}x = 0$ in A^{**}

...

Positive contraction $e_\tau \in A_+$ suitably chosen ...

Need: $v + (1-v)^{1/2}e_\tau(1-v)^{1/2} \in A_+$ converges in A^{**} to 1 in $\sigma(A^{**}, A^*)$ topology.

Since ψ is linear, ...

□

Corollary A.9.14. *Let A and B C^*-algebras, $\varphi\colon A \to B$ an* orthogonality preserving

My blue Remarks:

Let $\varphi\colon A \to B$ a 2-positive and orthogonality preserving map.

Question:
Does there exists a C^*-algebra morphism $h\colon \mathrm{C}_0(0,1] \otimes A \to B$ and an element $g_\varphi \in \mathrm{C}_0(0,1]_+$ such that $\varphi(a) = h(g \otimes a)$ for all $a \in A$.

(Is there a certain uniqueness for such h and g?)

If A is not unital or B is not unital, then take $\varphi^{**}\colon A^{**} \to B^{**}$.

(It is here not clear if φ^{**} is still orthogonality preserving, – except for "open" projections in A^{**} corresponding to hereditary C^*-subalgebras of A. But φ^{**} maps selfadjoint elements to selfadjoint elements, respectively is positive, 2-positive or c.p. if φ has this properties.)

One has now to check if the (again 2-positive) restriction $\varphi^{**}|C^*(A \cup \{1_{A^{**}}\})$ of φ^{**} is again orthogonality preserving:

Let $a_1, a_2 \in A$ selfadjoint, $\alpha_1, \alpha_2 \in \mathbb{R}$ and suppose that A is not unital. If $x := a_1 + \alpha_1 \cdot 1_{A^{**}}$ and $y := a_2 + \alpha_2 \cdot 1_{A^{**}}$ are "orthogonal" in the sense $xy = 0$, then at least one of α_1 and α_2 is equal to 0. Therefore, up to change of indices and multiplication by a non-zero real number, this reduces all to the cases where $a_1a_2 = 0$ and $a_1a_2+a_1 = a_1(a_2+1) = 0$. Then $a_1a_2 = 0$ leads to $\varphi(a_1)\varphi(a_2) = 0$ by using the assumption that φ preserves orthogonality of selfadjoint elements. The case $a_1a_2 = -a_1$ induces that a_1 and a_2 are commuting selfadjoint elements and that $e^* = e := -a_2$ is a local unit for a_1.

Reduces to the case of $A_0 := C^*(a, e)$ with $ae = a$, $a^* = a$, $e^* = e$, $\varphi_0 \colon A_0 \to B$ linear, bounded, involution and orthogonality preserving. $C := A_0 + \mathbb{C} \cdot 1 \subseteq A^{**}$ (where 1 denotes here the unit element $1_{A^{**}}$ of A_0^{**}).

NEED that $\varphi_0(a)(\varphi^{**}(1_C)) = (\varphi^{**}(1_C))\varphi_0(a)$ and

??????????????????????

Let $T := \varphi^{**}(1_{A^{**}}) \in B^{**}$.

Does T commute element-wise with $\varphi(A)$?

Suppose (!!!) we have found a C^*-Jordan morphism $\psi \colon A \to \{T\}' \cap B^{**}$ with $\varphi(a) = T \cdot \psi(a)$, and suppose that φ is 2-positive on A.

Can we deduce that $\psi \colon A \to B^{**}$ is 2-positive if φ is 2-positive?

It would be enough to show that

$$\psi_\delta(a) := T_\delta\varphi(a)T_\delta$$

for $T_\delta := (T + \delta 1_{B^{**}})^{-1/2}$ is 2-positive for all $\delta \in (0, \|T\|/2)$.

(THIS ARE THE KEY QUESTION!)

Since $\psi(A)$ commutes ???????

It should reduce to the study of the images of the support projection $P \in A^{**}$ of positive elements in the Pedersen ideals of A:

They should have the important property $\varphi^{**}(1-P)\varphi^{**}(P) = 0$. It is then the key for all other study!

(Seems to be OK at least in case of positive maps φ, because if $a, b \in \mathrm{Ped}(A)_+$ are contractions with $ab = a$ and $b \le P$, then $(1-b)a = 0$ and $a \le P$, $(1-P) \le 1-b$. ...)

To obtains that $\varphi^{**}(1-b)\varphi^{**}(a) = 0$ we have to check if $(1-b)$ the $\sigma(A^{**}, A^*)$ - limit of elements $(1-b)^{1/2}c(1-b)^{1/2}$, where $c \in \mathrm{Ped}(A)_+$ with $\|c\| \le 1$.

All this should work also in case of self-adjoint non-positive case of $\varphi \colon A \to B$.

Precise estimates in self-adjoint case?

This could give that $\varphi^{**}(P) = T \cdot \Phi(P)$ with $\Phi(P)^2 = \Phi(P) = \Phi(P)^*$, where $T := \varphi^{**}(1_{A^{**}}) \in B^{**}$ is a *-preserving map (self-adjoint maps).

It seems that the Φ can be integrated to to a C^*-Jordan morphism from A to B^{**}.

It is not clear if $\Phi(A)B \subseteq B$ ...(likely not!)

Is this new bounded linear map again orthogonality preserving on self-adjoint elements?

(Seems to be by the above outlined decomposition for the images of the "compact" projections!)

General observations:
A C^*-Jordan morphism $\psi\colon A \to C$ is a linear map with $\psi(a^*) = \psi(a)^*$ for all $a \in A$, and satisfies $\psi(ib) = i\psi(b)$ and $\psi(b^2) = \psi(b)^2$ for all $b \in A_+$. In particular, ψ is a *positive* linear map: $\psi(A_+) \subseteq C_+$.

Then $\psi(b^2) = \psi(b)^2$ for all $b^* = b \in A_{s.a.}$. $A_{s.a.}$ is a real Jordan algebra with $[a, b] := (1/2) \cdot (ab + ba)$ for $a, b \in A_{s.a.}$, and $\psi|A_{s.a.}$ is a real Jordan algebra morphism from $A_{s.a.}$ into $C_{s.a.}$, because $ab + ba = (a + b)^2 - (a^2 + b^2)$. Clearly ψ is determined by its restriction to $A_{s.a.} = A_+ - A_+$.

Lemma A.9.15. *If $\psi\colon A \to C$ is a C^*-Jordan morphism then properties (i), (ii) and (iii) are equivalent:*

(i) *ψ is a C^*-morphism.*
(ii) *$\psi(a^*a) = \psi(a)^*\psi(a)$ for all $a \in A$.*
(iii) *$\psi(a^*a) \geq \psi(a)^*\psi(a)$ for all $a \in A$.*

Proof. The implications (i)⇒(ii)⇒(iii) are obvious.

(iii)⇒(ii): Always $\psi(a^*) = \psi(a)^*$ for C^*-Jordan morphisms ψ and

$$\psi(a)^*\psi(a) + \psi(a)\psi(a)^* = \psi(a^*a + aa^*) = \psi(a^*a) + \psi(aa^*)$$

Suppose $\psi(a^*a) \geq \psi(a)^*\psi(a)$ and $\psi(aa^*) \geq \psi(a)\psi(a)^*$, then this all together implies that the sum of the two positive elements $\psi(a^*a) - \psi(a)^*\psi(a)$ and $\psi(aa^*) - \psi(a)\psi(a)^*$ is zero. Thus, $\psi(a^*a) = \psi(a)^*\psi(a)$ and $\psi(aa^*) = \psi(a)\psi(a)^*$.

(ii) ⇒ (i): For C^*-Jordan morphisms ψ holds in general

$$\psi(h)\psi(k) + \psi(k)\psi(h) = \psi(hk + kh) = \psi(hk) + \psi(kh)$$

by using the equations $\psi((h + k)^2) = (\psi(h) + \psi(k))^2$, $\psi(h^2) = \psi(h)^2$ and $\psi(k^2) = \psi(k)^2$. It delivers the general formula:
$\psi(h)\psi(k) + \psi(k)\psi(h) = \psi(hk) + \psi(kh)$.

Now use $\psi(a^*a) = \psi(h)^2 + \psi(k)^2 + i(\psi(hk - kh))$ and
$\psi(a)^*\psi(a) = \psi(h)^2 + \psi(k)^2 + i(\psi(h)\psi(k) - \psi(k)\psi(h))$

The property $\psi(a^*a) = \psi(a)^*\psi(a)$ and that $\psi(hk - kh) = \psi(hk) - \psi(kh)$ imply the equation

$$\psi(h)\psi(k) - \psi(k)\psi(h) = \psi(hk) - \psi(kh)\,.$$

Add this to the general formula for C^*-Jordan morphisms (obtained by pentagon rule): $\psi(h)\psi(k) + \psi(k)\psi(h) = \psi(hk) + \psi(kh)$ and get $2\psi(h)\psi(k) = 2\psi(hk)$.

It says that ψ is multiplicative. Thus $\psi\colon A \to C$ is a C^*-algebras morphism. □

Remark: Let $T\colon A \to C$ a $\mathbb{C}$-linear map with $\|T\| \leq 1$, $T^{**}(1_{A^{**}}) = 1_{C^{**}}$ then T is positive.

LEMMA A.9.16. *Let A and C C^*-algebras, $T: A \to C$ a positive linear map (i.e., T is linear and $T(A_+) \subseteq C_+$).*

Then $\|T\| = \|T^{**}(1_{A^{**}})\|$ and $T(a)^2 \leq \|T\| \cdot T(a^2)$ for all $a^* = a \in A$.

If, moreover, T is 2-positive, in the sense that

$$T_2 := T \otimes \mathrm{Id}_{M_2} : A \otimes M_2 \to C \otimes M_2$$

is positive, then, for each $a \in A$,

$$T(a)^* T(a) \leq \|T\| \cdot T(a^* a) .$$

If T is positive and unital and $T \otimes \mathrm{id}_{M_2}$ has norm ≤ 1 on $A \otimes M_2$, then $T \otimes \mathrm{id}_{M_2}$ is positive.

Is generally a unital hermitian contraction T automatically positive:

Restrict T to $C^*(1, a)$ for $a \in A_+$, $\|a\| \leq 1$. Take pure state ρ on C with $\rho(T(a)) = \min\{t \in \mathrm{Spec}(T(a))\}$. Then $\rho \cdot T$ is a unital linear functional on A with norm ≤ 1.

(Is equivalent for positive T^{**}, to decompose T^{**} as $T^{**} = GS(\cdot)G$ with $G := T^{**}(1_{A^{**}})^{1/2}$ for some suitable positive $S: A^{**} \to C^{**}$ with $S(1) =$ support projection of G. Then require (!) that $S_2 := S \otimes \mathrm{id}_{M_2}$ has norm $= 1$. This requirement is equivalent to the 2-positivity of T.)

(The 2-positivity for positive T could be also equivalent to

$$Z \cdot \mathrm{diag}(T(a_{1,2}), T(a_{2,1})) \leq \mathrm{diag}(T(a_{11}), T(a_{22})) .$$

Here $Z \in M_2(\mathcal{M}(A))$ has entries $[1 - \delta_{j,k}]$, and $[a_{j,k}] \in M_2(A)_+$.

This should be equivalent to $\|(1/n + T(a_{1,1}))^{-1} T(a_{1,2})(1/n + T(a_{2,2}))^{-1}\| \leq 1$ and $\|(1/n + T(a_{2,2}))^{-1} T(a_{2,1})(1/n + T(a_{1,1}))^{-1}\| \leq 1$ ...

PROOF. Consider in place of A the commutative C^*-algebra $C^*(a)$. Then $T|C^*(a)$ is the restriction of the completely positive map $S := (T|C^*(a))^{**}$ from $C^*(a)^{**} \subseteq A^{**}$. Let $P \leq 1_{A^{**}}$ denote the unit-element of $C^*(a)^{**}$. Passage to linear sums of projections show that S is c.p. with norm $\|S\| = \|S(P)\| \leq \|T^{**}(1_{A^{**}})\| \leq \|T\|$ and therefore $T(a)^2 = S(a)^2 \leq \|S(P)\| S(a^2) \leq \|T\| T(a^2)$.

The map $T_2 := T \otimes \mathrm{id}_{M_2}$ has norm $\|T_2\| = \|T \otimes 1_2\| = \|T\|$ if T_2 is again positive (by the additional assumption). We can build for $a \in A$ the selfadjoint element $b^* = b := [a_{jk}]$ in $M_2(A) \cong A \otimes M_2$ with zero diagonal entries $b_{11} = b_{22} = 0$ and off-diagonal entries $b_{12} := a$ and $b_{21} := a^*$.

Can now apply the general formula for positive maps and self-adjoint elements: Get $T_2(b)^2 \leq \|T\| T_2(b^2)$ by positivity of T_2 and $\|T_2\| = \|T\|$. The upper left entries show that $T(a^*)T(a) \leq \|T\| \cdot T(a^* a)$. □

The following Proposition is a straight conclusion of above Lemmata A.9.15 and A.9.16.

Proposition A.9.17. *Let A and C C^*-algebras and $\psi\colon A \to C$ a C^*-Jordan morphism.*

Then ψ is a C^*-algebra morphism, if and only if, ψ is a 2-positive contraction, i.e., the algebraic tensor product

$$\psi_2 := \psi \otimes \mathrm{id}_{M_2}\colon A \otimes M_2 \to C \otimes M_2$$

is a positive contraction.

Suppose we have a C^*-Jordan morphism (or a C^*-morphism) $\pi\colon A \to B^{**}$ and $T \geq 0$ in B^{**} such that $\pi(A) \in \{T\}' \cap B^{**}$ and $T \cdot \pi(a) = \varphi(a) \in B$.

The C^*-Jordan morphism π is 2-positive (and therefore is a C^*-algebra morphism) if φ is 2-positive, because $\pi(\cdot)$ is point-wise limit of $(T + 1/n)^{-1/2}\varphi(\cdot)(T + 1/n)^{-1/2}$ for $n \to \infty$, and the maps $b \in B \mapsto (T + 1/n)^{-1/2}b(T + 1/n)^{-1/2}$ are completely positive.

(Is important to know, for my version of a complete proof!).

??? Let $D \subseteq B$ the hereditary C^*-subalgebra generated by $\varphi(A)$, i.e., $D := \overline{\varphi(A)B\varphi(A)}$, then it is likely that $T \in \mathcal{M}(D)$ (modulo annihilator of D?) and $\pi(a) \in \mathcal{M}(D)$ for all $a \in A$. ?????

10. The "socle" of a C^*-algebra.

Recall that the "socle" of Banach algebra A is the (algebraic) ideal of A generated by all elements $a \in A$ with aAa of finite linear dimension. In case of C^*-algebras A the socle(A) it is an algebraic *-ideal generated by all projections $p^* = p^2 = p \in A$ with pAp of finite dimension.

The closure of the socle of a C^*-algebra A is the largest closed ideal of A that is a c_0-sum of "elementary" C^*-algebras $\cong \mathbb{K}(\mathcal{H})$ with $\mathcal{H}$ of finite or infinite dimensions.

Lemma A.10.1. *Let ρ a pure state on A with $\rho(\mathrm{socle}(A)) = \{0\}$ and $a \in A_+$ with $\|a\| = 1 = \rho(a)$, then, for every $\delta > 0$ and $n \in \mathbb{N}$, in the commutant of $(a-(1-\delta))_+$ in $(a-(1-\delta))_+A(a-(1-\delta))_+$ contains pairwise orthogonal positive elements $a_1, \ldots, a_n$ with $\|a_i\| = 1$.*

Notice that the element $a \in A_+$ could be a projection $a = p$ and that then $(a - (1 - \delta))_+ = \delta p$ for all $\delta \in [0, 1]$.

Proof. If 1 is not isolated in the spectrum of a, then $a_1, \ldots, a_n$ exist by functional calculus applied to $(a - (1 - \delta/2))_+$. If 1 is isolated, then there are $\gamma > 0$, $b \in A_+$ and a projection $q \in A$ with $bq = 0$, $a = b + q$, $\|b\| = 1 - \gamma$. Then $(a - (1 - \delta))_+A(a - (1 - \delta))_+ = qAq$ for $0 < \delta < \gamma$. Since also $\rho(a^2) = 1$, we get $\rho(b(1 - b)) = \rho(a - a^2) = 0$, $\rho(b) = 0$ and $\rho(q) = 1$. It follows that $q \notin \mathrm{socle}(A)$. Thus any maximal commutative C^*-subalgebra C of qAq is infinite-dimensional, i.e., for every $n \in \mathbb{N}$ we find non-zero orthogonal $a_1, \ldots, a_n \in C_+$. □

REMARK A.10.2. Let $J := \overline{\mathrm{socle}(A)}$ and D a hereditary C^*-algebra of A, then $D \cap \mathrm{socle}(A) = \mathrm{socle}(D)$ and $D \cap J = \overline{\mathrm{socle}(D)}$.

Indeed: The elements $a \in \mathrm{socle}(A)$ are characterized by the property that a^*Aa is finite-dimensional. It implies $D\,\mathrm{socle}(A)D \subseteq D \cap \mathrm{socle}(A) = \mathrm{socle}(D)$. And it follows $\overline{\mathrm{socle}(D)} \subseteq DJD = J \cap D$ and $DJD \subseteq \overline{D\,\mathrm{socle}(A)D} \subset \overline{\mathrm{socle}(D)}$.

LEMMA A.10.3. *Let $J := \overline{\mathrm{socle}(A)}$, and $\psi\colon \mathrm{C}_0((0,1], M_n) \to A$ a C^*-morphism with $\|\pi_J \circ \psi(f_0 \otimes e_{1,1})\| = 1$, D the hereditary C^*-subalgebra of A generated by $\psi(f_0 \otimes 1)$, where $f_0(t) = t$ for $t \in [0,1]$.*

Then there exist an increasing continuous map $\lambda\colon [0,1] \to [0,1]$ with $\lambda(0) = 0$ and $\lambda(1) = 1$, and a C^*-morphism $\varphi\colon \mathrm{C}_0((0,1], M_n) \to D$ with $\varphi(f \circ \lambda) = \psi(f)$ for $f \in \mathrm{C}_0((0,1], M_n)$, such that 1 is not isolated *in the spectrum of $\varphi(f_0 \otimes 1)$ and $\psi(f_0(1 - f_0) \otimes 1_n)$ is contained in the hereditary C^*-subalgebra E generated by $\varphi((f_0(1 - f_0) \otimes 1_n)$. Moreover $\varphi(g - (g \circ \lambda)) \in E$ for $g \in \mathrm{C}_0((0,1], M_n)$.*

PROOF. We take $\varphi := \psi$ and $\lambda := f_0$ if 1 is not isolated in $\mathrm{Spec}(\varphi(f_0 \otimes 1))$. Thus we may suppose that 1 is isolated in $\mathrm{Spec}(\varphi(f_0 \otimes 1_n))$.

First we consider the case where $n = 1$ and where $e := \psi(f_0)$ is a strictly positive element of A:
Then there is $\mu \in (0,1)$ such that the hereditary C^*-algebra F of A generated by $(e - \mu)_+$ is unital with unit $p := 1_F = (1 - \mu)^{-1}(e - \mu)_+$. Then $pe = p = pe$ and $\|(1 - p)e\| \le \mu$. Since $\|\pi_J(e)\| = 1$, it follows that p is not in J. Let $C \subseteq F$ a maximal commutative C^*-subalgebra of F. The compact Hausdorff space $X := \mathrm{Prim}(C)$ can't be finite, because $p \in C \setminus J$ and the minimal idempotents of C are in the *socle* of $F = pAp$ and, therefore, are in J. Moreover, by the same argument, if the open subset U of $X := \mathrm{Prim}(C)$ corresponding to the ideal $C \cap J$ of C is closed in X, then the open and closed set $Y := X \setminus U$ (that is homeomorphic to $\mathrm{Prim}(C/J \cap C)$) is not finite. Thus, in any of this cases, there is a point $x_0 \in Y$ that is not isolated in X. It allows to find a function $h\colon \mathrm{Prim}(C) \to [0, (1 - \mu)/2]$ with $h(x_0) = 0$ such that there is a sequence $x_n \in X$ with $0 < h(x_n)$ and $h(x_n) \to 0$. This means that $0 \in \mathrm{Spec}(\pi_J(g))$, and that 0 is not isolated in $\mathrm{Spec}(g) \subseteq [0, (1 - \mu)/2]$ if $g \in C_+$ has Gelfand transform $\widehat{g} = h$.

Now let $a := e(1 - p) + (p - g) = e - g \in A_+$. Then $\mu e \le a \le e$, $\|\pi_J(a)\| = \|\pi_J(p) - \pi_J(g)\| = 1$, and 1 is not isolated in $\mathrm{Spec}(a)$. Moreover, $e(1 - e) = (1 - p)(e - e^2) \le e(1 - e) + (p - g) - (p - g)^2 = a(1 - a)$, i.e., $e(1 - e)$ is contained in the hereditary C^*-subalgebra that is generated by $a(1 - a)$. We denote by φ the (unique) C^*-morphism $\varphi\colon \mathrm{C}_0(0,1] \to A$ with $\varphi(f_0) = a$ and define a pice-wise linear *continuous* function $\lambda\colon [0,1] \to [0,1]$ by $\lambda(t) := t$ for $t \in [0, \mu]$, $\lambda(t) := 1$ for $t \in [(\mu + 1)/2, 1]$ and $\lambda|[\mu, (\mu + 1)/2]$ linear. Then $\varphi(\lambda) = \lambda(a) = e = \psi(f_0)$, and $\varphi(f \circ \lambda) = f \circ \lambda(a) = f(e) = \psi(f)$ for all $f \in \mathrm{C}_0(0,1]$.

In the *general case* we let D denote the hereditary C^*-subalgebra D of A that is generated by $\psi(f_0 \otimes 1_n) \in A_+$, and let $A_1 \subseteq D$ denote the hereditary C^*-subalgebra of A that is generated by $\psi(f_0 \otimes e_{1,1})$. Then $\psi_1(f) := \psi(f \otimes e_{1,1})$

defines a C^*-morphism from $\mathrm{C}_0(0,1]$ into A. There is a natural isomorphism θ from $A_1 \otimes M_n$ onto D such that $\theta(\psi_1(f) \otimes \alpha) = \psi(f \otimes \alpha)$ for all $f \in \mathrm{C}_0(0,1]$ and $\theta(a \otimes e_{1,1}) = a$ for all $a \in A_1$. Since $D \cap J = \overline{\mathrm{socle}(D)}$ and $A_1 \cap J = \overline{\mathrm{socle}(A_1)}$, the C^*-morphism $\psi_1\colon \mathrm{C}_0(0,1] \to A_1$ satisfies the assumptions for the case $n = 1$. With $\varphi_1\colon \mathrm{C}_0(0,1] \to A_1$ and $\lambda\colon [0,1] \to [0,1]$ constructed as above, we have that $\varphi := \theta \circ (\varphi_1 \otimes \mathrm{id}_n)$ and λ have the required properties. (Notice here that $\lambda(1) = 1$ and $\lambda(0) = 0$ implies $g - (g \circ \lambda) \in \mathrm{C}_0(0,1) \otimes M_n$ for all $g \in \mathrm{C}_0((0,1], M_n)$.) □

11. C^*-version of Cohen factorization

The following theorem is a C^*-version of the Cohen factorization theorem, given by G.K. Pedersen in [**621**, Thm. 4.1] with a proof on 13 lines. We give a more detailed proof. Only elementary knowledge on functional calculus and approximate units of C^*-algebras is used.

THEOREM A.11.1. *Suppose that a C^*-algebra A acts on the Banach space X from left with $\|a \cdot x\| \le \|a\|\|x\|$ and* $\mathrm{span}(A \cdot X)$ *dense in X.*

Then for given $\varepsilon > 0$ and $x \in X$, there exist $y \in \overline{\{a \cdot x\,;\ a \in A_+\}}$ and $e \in A_+$ with $e \cdot y = x$, $\|e\| \le 1$ and $\|y - x\| < \varepsilon$.

PROOF. Since the span of $A \cdot X$ is dense in X, any approximate unit (u_λ) for A will converge strongly to the operator 1 in $\mathcal{L}(X)$. We let $\widetilde{A} := A + \mathbb{C}1$ be the unitized C^*-algebra acting on X, and by induction (setting $a_0 := 1$ and $x_0 := x$) we define sequences (a_n) and (x_n) in $\widetilde{A}_+$ and X, respectively, by

$$a_n := a_{n-1} - 2^{-n}(1 - u_n)\,, \quad x_n := a_n^{-1} \cdot x\,.$$

It is easy to verify (by induction) that $a_n \ge 2^{-n}1$ (so that $\|2^{-n}a_n^{-1}\| \le 1$), and that $\mathrm{dist}(a_n, A) = 2^{-n}$.

Moreover

$$x_n - x_{n-1} = a_n^{-1}(a_{n-1} - a_n)a_{n-1}^{-1} \cdot x = 2^{-n}a_n^{-1}(1 - u_n) \cdot x_{n-1}\,.$$

Having chosen the u_n's properly we can therefore assume that $\|x_n - x_{n-1}\| < 2^{-n}\varepsilon$ for all n.

Let $e := \lim a_n$ and $y := \lim x_n$. Since $a_n \cdot x_n = x$ for all n, we have $ey = x$. Moreover, $\|x - y\| < \varepsilon$ by construction. Finally, $e \in A_+$ and $\|e\| \le 1$. In fact, $e = \sum_{n \ge 1} 2^{-n} u_n$. □

The additional condition $y \in \overline{\{a \cdot x\,;\ a \in A_+\}}$ is not mentioned in the original formulation of [**621**, Thm. 4.1], but can be seen from its proof, or can be shown from the decomposition of $x = e \cdot y$ and combination with the corresponding decomposition $e'f = e$ of e with $f \in \overline{C^*(e)_+ e}$ and a contraction $e' \in C^*(e)_+$.

Of course, Theorem A.11.1 works also for non-degenerate right-actions: Consider the left multiplication $a \cdot_\ell x := a \cdot x$ by $a \in A^{op}$, where A^{op} denotes the opposite C^*-algebra of A, i.e., A with opposite multiplication.

An easy separation argument and the fact that $\{e \in A_+ \,;\, \|e\| < 1\}$ is an approximate unit for A show that the non-degeneracy condition $\overline{\mathrm{span}(A \cdot X)} = X$ implies that each $x \in X$ is contained in the closure of $\{a \cdot x \,;\ a \in A_+, \|a\| < 1\}$.

In particular, $A \cdot x = \{0\}$ implies $x = 0$ if X is a non-degenerate Banach A-module.

It allows to extend the left-multiplication $(a, x) \in A \times X \mapsto a \cdot x \in X$ uniquely to a left multiplication $(b, x) \in \mathcal{M}(A) \times X \to X$ that is strictly continuous with respect to $b \in \mathcal{M}(A)$.

Since one can replace the Banach module X by $c_0(X)$ in Theorem A.11.1, this Theorem implies the following formally stronger result:

For every finite sequence $x_1, \ldots, x_n$ in X and $\varepsilon > 0$ there exists a positive contraction $e \in A_+$ and $y_1, \ldots, y_n \in X$ with $y_k \in \overline{\{a \cdot x_k \,;\ a \in A_+\}}$ such that $e \cdot y_k = x_k$, $\|y_k - x_k\| < \varepsilon$ and $\|e\| \leq 1$.

12. On centralizers in asymptotic coronas

The discrete version of asymptotic coronas for a C^*-algebra A is $A_\infty := \ell_\infty(A)/c_0(A)$.

LEMMA A.12.1. *The algebra $F_\infty(C, A) := (C' \cap A_\infty)/\operatorname{Ann}(C, A_\infty)$ is a unital C^*-algebra if C is any σ-unital C^*-subalgebra of A_∞.*

For a better understanding what is going on, notice here that an arguments in [**448**] can be modified to obtain the stronger result for *separable* C^*-subalgebras $C \subseteq A_\infty$ and $D := \overline{C(A_\infty)C}$ that there exists a natural isomorphism

$$(C' \cap A_\infty)/\operatorname{Ann}(C, A_\infty) \cong C' \cap \mathcal{M}(D)\,.$$

PROOF. If $e \in C_+$ is a strictly positive contraction then obviously $C \subseteq D := \overline{e \cdot A_\infty \cdot e} = \overline{C \cdot A_\infty \cdot C}$,

$$D' \cap A_\infty \subseteq C' \cap A_\infty \subseteq \{e\}' \cap A_\infty$$

and $\operatorname{Ann}(\{e\}, A_\infty) = \operatorname{Ann}(D, A_\infty) = \operatorname{Ann}(C, A_\infty)$. (We can suppose that $\|e\| = 1$, but this is not important.) Then $e = (e_1, e_2, \ldots) + c_0(A)$ with contractions $e_n \in A_+$.

Let $(g_1, g_2, \ldots)$ a sequence of positive contractions with $g_n \in C^*(e_n)$ and $\|e_n - g_n e_n\| < 1/n$.

Then $g := (g_1, g_2, \ldots) + c_0(A)$ satisfies $0 \leq g \leq 1$, $g - g^2 \in \operatorname{Ann}(\{e\}, A_\infty)_+$ and $g \in D' \cap A_\infty$. The latter because $gd = d = dg$ for all $d \in D$, i.e., the positive contraction d is a "local" unit for all elements in $D \supseteq C$. It follows that $g + \operatorname{Ann}(\{e\}, A_\infty)$ is a projection in $(D' \cap A_\infty)/\operatorname{Ann}(D, A_\infty)$.

Thus, g is a positive contraction in $D' \cap A_\infty \subseteq C' \cap A_\infty$ with $gc = c = cg$ for all $c \in C$ and $g + \operatorname{Ann}(C, A_\infty)$ is a projection in $(C' \cap A_\infty)_+/\operatorname{Ann}(C, A_\infty)$.

If $h \in C' \cap A_\infty$ and $c \in C$ then $(h - gh)c = 0 = c(h - gh)$ because $ghc = gch = ch = hc$ and $cgh = ch$, i.e., $(h - gh) \in \operatorname{Ann}(C, A_\infty)$.

We obtain $gh, hg \in C' \cap A_\infty$ for $h \in C' \cap A_\infty$ and $h - gh, h - hg, g - g^2 \in \operatorname{Ann}(C, A_\infty)$ in a similar way. It implies that $g + \operatorname{Ann}(C, A_\infty)$ is the unit element of $(C' \cap A_\infty)/\operatorname{Ann}(C, A_\infty)$. □

REMARK A.12.2. Let X a Polish l.c. space, that is not compact, and let $\omega \in \gamma X := \beta X \setminus X$ a point of the corona γX of X.

Recall that $\mathrm{C_b}(X, B)$ and $\mathrm{Q}(X, B) := \mathrm{C_b}(X, B)/\mathrm{C_0}(X, B)$ are C^*-bundles over βX respectively $\gamma X := \beta X \setminus X$, i.e., are algebras of continuous section of continuous fields of C^*-algebras B_ω (if $\omega \in \gamma X$) and $B_x = B$ (if $x \in X$).

In particular, $\mathrm{C_b}(X) \cong \mathrm{C}(\beta X)$ and $\mathrm{C_b}(X)/\mathrm{C_0}(X) \cong \mathrm{C}(\gamma X)$. $\mathrm{C_b}(X, B)$ is a $\mathrm{C}(\beta X)$-algebra, and $\mathrm{Q}(X, B)$ is a $\mathrm{C}(\gamma X)$-algebra. This explains the notations $\mathrm{C_b}(X, B)|Y$ and $\mathrm{Q}(X, B)|Z$ for closed subsets $Y \subseteq \beta X$ and $Z \subseteq \gamma Y$. We write also B_ω for $\mathrm{Q}(X, B)|\{\omega\}$ if $\omega \in \gamma X$.

Let $A \subseteq \mathrm{Q}(X, B)$ a *separable* C^*-subalgebra. We define

$$F(X;\, A, B) := \, (A' \cap \mathrm{Q}(X, B))/\operatorname{Ann}(A, \mathrm{Q}(X, B))\,.$$

It is always a *unital* algebra that contains a copy of $\mathrm{C}(\gamma X)$ in its center.

(*Indeed*: Clearly, $A' \cap \mathrm{Q}(X, B)$ is a $\mathrm{C}(\gamma X)$-algebra. Since $\operatorname{Ann}(A, \mathrm{Q}(X, B))$ is a hereditary C^*-subalgebraof $\mathrm{Q}(X, B)$, it is a $\mathrm{C}(\gamma X)$-algebra. An approximate unit of a separable C^*-subalgebra $C \subseteq \mathrm{C_b}(X, B)$ with $C|\gamma X = A$ allows to construct a positive contraction $f \in \mathrm{C_b}(X, B)_+$ with $\|f(x)\| = 1$ for each $x \in X$ and $ea = a = ae$ for all $a \in A$, where $e := f|\gamma X$.)

Let $D_A := \overline{A\, \mathrm{Q}(X, B) A}$ denote the σ-unital C^*-subalgebra of $\mathrm{Q}(X, B)$ that is generated by A, and let

$$\mathcal{N}(D_A) := \{\, f \in \mathrm{Q}(X, B)\, ;\; fD_A \cup D_A f \subseteq D_A \,\}\,.$$

Then (obviously) $A' \cap \mathrm{Q}(X, B) \subseteq \mathcal{N}(D_A)$, and the natural C^*-morphism from $A' \cap \mathrm{Q}(X, B)$ into $\mathcal{M}(D_A)$ has kernel $\operatorname{Ann}(A, \mathrm{Q}(X, B)) = \operatorname{Ann}(D_A, \mathrm{Q}(X, B))$. The image is contained in $A' \cap \mathcal{M}(D_A)$. It is not hard to show that it is really all of $A' \cap \mathcal{M}(D_A)$, because $\operatorname{Ann}(A, \mathrm{Q}(X, B)) \subseteq A' \cap \mathrm{Q}(X, B)$ and the natural *-monomorphism

$$\mathcal{N}(D_A)/\operatorname{Ann}(A, \mathrm{Q}(X, B)) \to \mathcal{M}(D_A)$$

is surjective. The latter can be deduced from the facts that A contains a strictly positive contraction e of D_A, and each element of $\mathcal{M}(D_A)_+$ is the sum $T + S + a$, where $a \in A$, and $T, S \in \mathcal{M}(D_A)_+$ are in $\mathcal{M}(D_A)$ strictly convergent sequences of mutually orthogonal positive elements of A.

Thus, the natural *-isomorphism from $\mathcal{N}(D_A)/\operatorname{Ann}(A, \mathrm{Q}(X, B)) \to \mathcal{M}(D_A)$ defines a natural $C(\gamma X)$-algebra isomorphism

$$F(X;\, A, B) \cong A' \cap \mathcal{M}(D_A)\,.$$

This isomorphism allows to see, that $F(X;\, \cdot, \cdot)$ is a "stable" invariant, i.e., $F(X;\, A \otimes \mathbb{K}, B \otimes \mathbb{K})$ is naturally $\mathrm{C}(\gamma X)$-module isomorphic to $F(X;\, A, B)$. In fact this follows easily from the natural $\mathrm{C}(\gamma X)$-module isomorphisms

$$(D_A) \otimes \mathbb{K} \cong D_{(A \otimes \mathbb{K})}$$

and

$$(A \otimes \mathbb{K})' \cap \mathcal{M}(D_A \otimes \mathbb{K}) \cong A' \cap \mathcal{M}(D_A)\,.$$

Let $\pi_Y \colon \mathrm{Q}(X,B) \to \mathrm{Q}(X,B)|Y = \mathrm{C_b}(X,B)|Y$ denote the natural $\mathrm{C}(\gamma X)$-modular epimorphism, and denote by $D|Y$ the image $\pi_Y(D) \subseteq \mathrm{Q}(X,B)|Y$ of a subset $D \subseteq \mathrm{Q}(X,B)$, in particular, $f|Y := \pi_Y(f)$.

We generalize $F(X;\, A,B)$ to closed subsets $Y \subseteq \gamma X$:

$$F(X,Y;\, A,B) := ((A|Y)' \cap (\mathrm{Q}(X,B)|Y)) / \operatorname{Ann}((A|Y),(\mathrm{Q}(X,B)|Y))\,.$$

Again one can show that $F(X,Y;\, A,B)$ is a stable invariant in the above considered sense. Our old definition of $F(X;\, A,B)$ becomes $F(X,\gamma X;\, A,B)$ in the new terminology.

The map π_Y maps $\operatorname{Ann}(A,\mathrm{Q}(X,B))$ into $\operatorname{Ann}((A|Y),(\mathrm{Q}(X,B)|Y))$, and maps $A' \cap \mathrm{Q}(X,B)$ into $(A|Y)' \cap (\mathrm{Q}(X,B)|Y)$.

It is not clear, for which Y one has $(A' \cap \mathrm{Q}(X,B))|Y = (A|Y)' \cap (\mathrm{Q}(X,B)|Y)$ see Questions A.12.3.

We have $\operatorname{Ann}(A,\mathrm{Q}(\mathbb{N},B))|Y \neq \operatorname{Ann}((A|Y),(\mathrm{Q}(\mathbb{N},B)|Y))$ for $B := \mathbb{C}$ and $Y = \{\omega\} \subseteq \gamma\mathbb{N}$ a suitable free ultrafilter and $A = C^*(f)$ for non-zero non-negative $f \in \mathrm{Q}(\mathbb{C}) = \ell_\infty(\mathbb{N})/c_0(\mathbb{N})$ with $0 \in \operatorname{Spec}(f)$ not isolated and $\omega \in \gamma\mathbb{N}$ a boundary point of the support of f.

It follows, that π_Y does *not* necessarily define an isomorphism from $F(X;\, A,B)|Y$ onto $F(X,Y;\, A,B)$. In particular, the fibers $F(X;\, A,B)|\omega$ of the $\mathrm{C}(\gamma X)$-algebra can not be identified with $F(X,\{\omega\};A,B)$.

The situation is less complicate if $A \subseteq B$. In particular, the algebras $F(X,Y;\, A,A)$ are stable invariants that have fibers $F(X,\{\omega\};A,B)$ with $\omega \in Y$.

Questions A.12.3. Let $A' \cap \mathrm{Q}(X,B)$ and $F(X;A,B)$ as in Remark A.12.2.

Here are some questions related to a possible or impossible reduction of properties of asymptotic invariants $F(X;A,B)$ to properties of its fibers $F(\omega;A,B)$:

When $(A' \cap \mathrm{Q}(X,B))|Y = (A|Y)' \cap (\mathrm{Q}(X,B)|Y)$?

What are the fibers $F(X;A,B)_\omega$ of $F(X;A,B)$?

Is it clear from the definition of $F(X;A,B)$ that $F(\{\omega\};A,B)$ is a quotient of $F(X;A,B)|\{\omega\}$?

Let $a,b \in \mathrm{Q}(X,B)$ self-adjoint contractions with commuting $\pi_\omega(a)$ and $\pi_\omega(b)$. Does there exist commuting self-adjoint $a',b' \in \mathrm{Q}(X,B)$ with $\pi_\omega(a') = \pi_\omega(a)$ and $\pi_\omega(b') = \pi_\omega(b)$?

Let $f,g \in \mathrm{C_b}(X,B)$ self-adjoint contractions with $a = f + \mathrm{C}_0(X,B)$ and $b = g + \mathrm{C}_0(X,B)$. When we can find self-adjoint $f_0 \in \mathrm{C}_0(X,B)$ and a continuous function $\mu\colon X \to [1, \infty)$ such that, for $f_1 = f + f_0$,

$$h(x) := (2\mu(x))^{-1} \int_{-\mu(x)}^{\mu(x)} e^{itf_1(x)} g(x) e^{-itf_1(x)}\, \mathrm{d}t$$

has the property $\pi_\omega(b') = \pi_\omega(b)$ and $ab' = b'a$ for $b' := h + \mathrm{C}_0(X, B)$?

Is there a "universal" continuous function $\tau\colon \mathbb{R}_+ \to \mathbb{R}_+$ with $\tau(0) = 0$, such that τ is increasing and has the following property?

If $a, b \in C_+$ are contractions with $\|ab\| < \varepsilon$, then, for every $\delta > 0$, there is a contraction $d \in C$ with $d(a - \delta)_+ = 0$ and $\|db - bd\| + \|d^*bd - b\| \leq \tau(\varepsilon)$.

Continuous maps into canonical commutation relations could give counterexamples?

Remark A.12.4. Let $\omega \in \beta(\mathbb{N})$, $f \in \ell_\infty(\mathbb{N})_+$ with $f(\omega) = 0$. It is not difficult to see that there is a sequence $S = \{n_1, n_2, \ldots\} \subseteq \mathbb{N}$ (where $n_k < n_{k+1}$), such that $\lim_k f(n_k) = 0$, i.e., $f|S \in c_0(S)$.

(On finds a sequence $n_1 < n_2 < \ldots$ in $\mathbb{N}$ with $n_k \in X_k := f^{-1}[0, 1/k] \subseteq \mathbb{N}$, because each X_k is an *infinite* subset of $\mathbb{N}$.)

A subset S with $f|S \in c_0(S)$ can be found in the ultrafilter defined by ω, i.e., with $\chi(S)(\omega) = 1$, if and only if, $\omega \in \gamma\mathbb{N}$ is in the interior of $\beta\mathbb{N} \cap f^{-1}(0)$.

Remark A.12.5. Suppose that X and Y are non-compact σ-compact locally compact spaces, that X is finite-dimensional, and that $\psi\colon X \to Y$ is a proper continuous map.

Then ψ extends naturally to a continuous map $\beta\psi\colon \beta X \to \beta Y$ with $\beta\psi(\gamma X) = \beta\psi(\beta X) \cap \gamma Y$. Take $\omega \in \gamma X := \beta X \setminus X$ and let $\omega' := \beta\psi(\omega)$.

Now let B a C^*-algebra, and $\mathcal{S} \subseteq \mathrm{CP}_{\mathrm{in}}(B)$ a convex set of approximately inner completely positive contractions, such that $\mathcal{S}$ is closed in point-norm topology.

If, for each (point-norm) continuous map $x \in X \mapsto V_x \in \mathcal{S}$, the map $V_\omega\colon B_\omega \to B_\omega$ is ideal preserving, then, for each (point-norm) continuous map $y \in Y \mapsto W_y \in \mathcal{S}$, the map $W_{\omega'}\colon B_{\omega'} \to B_{\omega'}$ is ideal preserving.

Notice that every σ-compact non-compact l.c. space Y has a proper continuous map $\psi\colon Y \to \mathbb{R}_+$. This leads to the following question.

Question A.12.6. Let $\omega \in \beta(\mathbb{R}_+) \setminus \mathbb{R}_+$, and B a C^*-algebra.

Suppose that $V_\omega\colon B_\omega \to B_\omega$ is ideal preserving for every bounded (point-norm) continuous map $t \in \mathbb{R}_+ \mapsto V_t \in \mathrm{CP}_{\mathrm{in}}(B)$.

Does B satisfy the condition (i) of Definition 2.0.4 ?

The problem here is the following: Let $n \in \mathbb{N} \mapsto V_n \in \mathrm{CP}_{\mathrm{in}}(B)$ is a given sequence of approximately inner c.p. contractions. Can it be extended to $t \in \mathbb{R}_+ \mapsto V_t \in \mathrm{CP}_{\mathrm{in}}(B)$ point-norm continuous, with same properties of V_ω on B_ω for $\omega \in \gamma(\mathbb{R}_+)$ as for V_ω with $\omega \in \gamma(\mathbb{N})$?

13. Order unit spaces and pre-ordered semigroups

Order-unit spaces are the spaces of continuous affine functions on compact convex subsets of locally convex *real* vector spaces. We use them to derive some results on the extension of states of pre-ordered abelian semigroups with order unit. We denote by $\mathbb{Q}$ the rational numbers (and not the quaternions) during Section 13. The results are basic, but they are also known and proved with other or similar methods a long time ago.

DEFINITION A.13.1. An **order unit space** is a triple (B, B_+, e), where B is a *real* Banach space, B_+ is a closed convex cone in B and $e \in B_+$ is a distinguished element of the cone B_+, such that $-e \notin B_+$ and for every $x \in B$ holds:
The vectors $te + x$ and $te - x$ are both in B_+, if and only if, $t \geq \|x\|$.

B is partially ordered by

$$x \leq y \ \Leftrightarrow y - x \in B_+ \,.$$

A **state** of B is a *monotone* (i.e., order preserving) $\mathbb{R}$-linear map $\lambda\colon B \to \mathbb{R}$ from B into $\mathbb{R}$ with $\lambda(e) = 1$.

We denote by $E(B) \subseteq B^*$ the set of states of B equipped with the $\sigma(B^*, B)$-topology. Then $E(B)$ is a compact convex set with this topology (cf. Part (ii) of Proposition A.13.2).

PROPOSITION A.13.2. *Let $\mathbf{B} = (B, B_+, e)$ and $\mathbf{B_1} = (B_1, (B_1)_+, e_1)$ order unit spaces (in particular real Banach spaces), and let $Y \subseteq B$ denote an additive subgroup of B with $e \in Y$.*

(i) *Closed linear subspaces L of B with $e \in L$ are again order unit spaces, if we let $L_+ := B_+ \cap L$.*
(ii) *An additive map $\lambda\colon B \to \mathbb{R}$ is positive (i.e., $\lambda(B_+) \subseteq \mathbb{R}_+$), if and only if, λ is $\mathbb{R}$-linear and bounded with $\|\lambda\| = \lambda(e)$.*

*In particular, the positive states functionals $\lambda \in B^*$ with $\lambda(e) = 1$ and $\|\lambda\| \leq 1$, and $E(B)$ is a compact convex subset of B^* with *weak topology (i.e., $\sigma(B^*, B)$-topology).*
(iii) *For each $x \in B$ there is a state λ with $|\lambda(x)| = \|x\|$. In particular, B is in a natural way an order unit subspace of* $\mathrm{C}(E(B))$.
(iv) *For every continuous linear functional $f \in B^*$ there are (not necessarily unique) states $\lambda_1, \lambda_2 \in E(B)$ and $\alpha, \beta \in \mathbb{R}_+$ with $f = \alpha\lambda_1 - \beta\lambda_2$ and $\alpha + \beta = \|f\|$.*
(v) *An element $x \in B$ is in the interior $(B_+)^\circ$ of B_+, if and only if, there is $n \in \mathbb{N}$ with $e \leq nx$.*
(vi) *An additive subgroup Y of B with $e \in Y$ separates the* states *of B, if and only if, $\bigcup_n (1/n)Y = \{(1/n)x\,;\ x \in Y\}$ is dense in B.*
(vii) *Suppose that $\phi\colon B \to B_1$ is a unital additive map, (i.e., $\phi(e) = e_1$ and $\phi(x + y) = \phi(x) + \phi(y)$ for all $x, y \in B$), and let $Y \subseteq B$ an additive subgroup such that $\{(1/n)x\,;\ x \in Y\}$ is dense in B.*

The following properties (1)–(5) *are equivalent and imply that* ϕ *is* $\mathbb{R}$-*linear.*

(1) ϕ *is monotone (i.e., is order preserving:* $\phi(B_+) \subseteq (B_1)_+$ *).*
(2) $\rho \circ \phi \in E(B)$ *for every state* $\rho \in E(B_1)$.
(3) ϕ *is a contraction.*
(4) ϕ *is continuous, and, for* $x \in Y$, *the existence of* $n \in \mathbb{N}$ *with* $e \leq nx$ implies *the existence of* $m \in \mathbb{N}$ *with* $e_1 \leq m\phi(x)$.
(5) $\phi((B_+)^\circ) \subseteq (B_1)_+$.

(viii) *If* Y *is as in* (vii), *and the unital additive map* $\phi\colon B \to B_1$ *is monotone, then the following properties are equivalent:*
(a) $B_+ = \phi^{-1}(\phi(B) \cap (B_1)_+)$.
(b) *For every* $\lambda \in E(B)$ *exists* ρ *of* B_1 *with* $\lambda = \rho \circ \phi$.
(c) ϕ *is* isometric.
(d) *For* $x \in Y$, *the existence of* $m \in \mathbb{N}$ *with* $e_1 \leq m\phi(x)$ implies *the existence of* $n \in \mathbb{N}$ *with* $e \leq nx$.
(e) $b \in (B_+)^\circ$, *if and only if,* $\phi(b) \in ((B_1)_+)^\circ$.

(ix) *Suppose that a subset* $F \subseteq E(B)$ *is* norming *for* B *(or that* F *is* norming *on a rationally dense additive subgroup* Y *of* B *in the sense that* $\|y\| = \sup_{f\in F} |f(y)|$ *for each* $y \in Y$*).*

Then the convex hull of F *is* $\sigma(B^*, B)$*-dense in* $E(B)$.

In particular, this implies: If K *is a compact convex subset of a locally convex real vector space* V, *then the space* $\mathrm{Aff}_c(K) \subseteq \mathrm{C}(K)$ *of all continuous* affine *functions* $f\colon K \to \mathbb{R}$ *is an order unit space, and* $E(\mathrm{Aff}_c(K))$ *is naturally isomorphic to* K.

(x) (B, B_+, e) *is naturally isomorphic to the ordered space* $\mathrm{Aff}_c(E(B)) \subseteq \mathrm{C}(E(B))$ *of all real-valued continuous affine functions on the (*weakly) compact convex subset* $E(B) \subseteq B^*$.

Proof. (i): $(L, L_+ := B_+ \cap L, e)$ satisfies the axioms of an order unit space, because the definition is "local", i.e., requires only the (norm-)completeness of the space and the cone, and that any (at most) two-dimensional subspace $\mathbb{R}e + \mathbb{R}x$ is an order unit space.

(ii): Since $-e \notin B_+$ and $e \in B_+$, it follows that $te - e, te + e \in B_+$, if and only if, $t \geq 1$. Thus, $\|e\| = 1$.

Let $U := \{x \in B\,;\ \|x\| < 1\}$ denote the open unit ball of B. The sets $\delta e + B_+$ ($\delta > 0$) are contained in the interior of B_+, because $e + U \subseteq B_+$ and $\delta e + B_+ \subseteq \delta(e + U) + B_+$.

Let $\lambda\colon B \to \mathbb{R}$ an additive map with $\lambda((B_+)^\circ) \subseteq [0, \infty)$. Then λ is $\mathbb{Q}$-linear. Since $re \pm x = (r - \|x\|)e + (\|x\|e - x) \in (B_+)^\circ$ for rational $r > \|x\|$, we get $0 \leq \lambda(re + x) = r\lambda(e) \pm \lambda(x)$ for all rational numbers $r > \|x\|$. Thus, $\|\lambda\| < \infty$ and $\lambda(e) \geq \|\lambda\|$. On the other hand, $\|\lambda\| = \|\lambda\| \cdot \|e\| \geq \lambda(e)$.

Let $b \in B$, then $b \in B_+$, if and only if, $\|(\|b\|e) - b\| \le \|b\|$. Indeed: If $b \neq 0$, then $a := \|b\|^{-1}b \in B_+$, if and only if, $e - (e-a) = a \in B_+$ and $e + (e-a) \in B_+$, if and only if, $\|e - a\| \le 1$.

Let $\lambda \in B^*$ with $\|\lambda\| = \lambda(e)$. Then $|\,\lambda(e)\|b\| - \lambda(b)\,| \le \lambda(e)\|b\|$ for all $b \in B_+$, which implies that $\lambda(b) \ge 0$.

Since $\|e\| = 1$, there exists $\lambda \in B^*$ with $\lambda(e) = 1$, by Hahn-Banach extension, i.e., $E(B) \neq \emptyset$.

The subset $E(B)$ of $\lambda \in B^*$ with $\|\lambda\| \le 1$ and $\lambda(e) = 1$ is a *weakly closed subset of the unit ball $(B^*)_{\le 1}$ of B^*. The latter is compact in the *weak topology ($:= \sigma(B^*, B)$-topology).

(iii): It suffices to consider the case $\|b\| = 1$.
Let $\delta := 2 - \max(\|e-b\|, \|e+b\|) \ge 0$. Then $(1-\delta)e \pm b = (2-\delta)e - (e \mp b) \in B_+$, which implies $(1-\delta) \ge \|b\| = 1$ and $\delta = 0$. It follows that $\|e - b\| = 2$ or $\|e + b\| = 2$. We may suppose $\|e+b\| = 2$, because we can replace b by $(-b)$. By Hahn-Banach extension, there is $\lambda \in B^*$ with $\|\lambda\| = 1$ and $\lambda(e+b) = 2$. It follows that $\|\lambda\| = \lambda(e) = 1 = \lambda(b)$. Thus, $\lambda \in E(B)$ by Part (ii), and $\|b\| = |\lambda(b)|$.

(iv): It suffices to consider the case of $f \in B^*$ with $\|f\| = 1$. Let $T(\lambda_1, \lambda_2, \alpha) := \alpha\lambda_1 - (1-\alpha)\lambda_2$ for $\lambda_1, \lambda_2 \in E(B)$ and $\alpha \in [0,1]$. Then T is a (*weakly) continuous map from the compact set $K := E(B) \times E(B) \times [0,1]$ into the (*weakly) compact set $B^*_{\le 1} := \{g \in B^*\,;\ \|g\| \le 1\}$. In particular, the image $T(K)$ of T is closed. Straight calculation shows that $T(K)$ is also convex and $T(K) = -T(K)$. Since the subset $E(B) = T(E(B) \times E(B) \times \{1\})$ is norming for B, a standard Hahn-Banach separation argument shows that $T(K) = (B^*)_{\le 1}$. In particular, there are $\alpha, \beta \in [0, \infty)$ and $\lambda_1, \lambda_2 \in E(B)$ with $\alpha + \beta = \|f\| = 1$ and $\alpha\lambda_1 - \beta\lambda_2 = f$.

(v): If $x \in (B_+)^\circ$ then $x - (1/n)e \in (B_+)^\circ$ for sufficiently big $n \in \mathbb{N}$, in particular $nx - e \in B_+$. Conversely, if $nx - e \in B_+$, then $x = (1/n)e + y$ with $y := x - (1/n)e \in B_+$. Thus, $x \in y + (1/n)(e + U) \subseteq B_+$ for the open unit ball U of B, cf. proof of Part (ii). Hence, $x \in (B_+)^\circ$.

(vi): Let $\lambda_1, \lambda_2 \in E(B)$. $\lambda_1(x) = \lambda_2(x)$ for all $x \in Y$, if and and only if, $Z := \{(1/n)x\,;\ x \in Y\}$ is in the kernel of $\lambda_1 - \lambda_2$. If Z is dense in B, then $\lambda_1 = \lambda_2$, and the elements of Y separate the states.

Now let Y an additive subgroup of B with $e \in Y$. Then $Z := \{(1/n)x\,;\ x \in Y\} = \mathrm{span}_{\mathbb{Q}}(Y)$ is norm-dense in $\mathrm{span}_{\mathbb{R}}(Y)$. Thus, if Z is not dense in B, then there exists $f \in B^*$ with $\|f\| = 1$ and $f(x) = 0$ for all $x \in Y$. By Part (iv), there are states $\lambda_1, \lambda_2 \in E(B)$ and $\alpha \in [0,1]$ with $f = \alpha\lambda_1 - (1-\alpha)\lambda_2$. Since $e \in Y$, it follows that $0 = f(e) = 1 - 2\alpha$. Hence, $\lambda_1(x) = \lambda_2(x)$ for $x \in Y$ and $\lambda_1 \neq \lambda_2$.

It follows, that Z must be dense in B if Y separates the states.

(vii): The additivity of ϕ implies that $\phi(rb) = r\phi(b)$ for all rational numbers $r \in \mathbb{Q}$. Thus, if ϕ satisfies (3), then ϕ is $\mathbb{R}$-linear. The implications (1)$\Rightarrow$(5) is obvious.

(5)⇒(2): The map $\rho \circ \phi\colon B \to \mathbb{R}$ is additive and $\rho \circ \phi(e) = \rho(e_1) = 1$ for $\rho \in E(B_1)$. If $\phi((B_+)^\circ) \subseteq (B_1)_+$, then $\rho \circ \phi$ is an additive map from B to $\mathbb{R}$ that is not negative on $(B_+)^\circ$. It follows that $\rho \circ \phi$ is continuous by an argument in the proof of Part (ii). Then $\rho \circ \phi(B_+) \subseteq [0, \infty)$, and Part (ii) shows $\rho \circ \phi \in E(B)$.

(2)⇒(3): If $\rho \circ \phi \in E(B)$ for every state $\rho \in E(B_1)$, then $\|\phi(b)\| = \sup_{\rho \in E(B_1)} |\rho \circ \phi(b)| \leq \|b\|$ by Parts (ii) and (iii).

(3)⇒(1): Let $x \in B_+$ and $m, n \in \mathbb{N}$ with $m/n > \|x\|$. Then $me \pm (me - nx) \in B_+$ and, thus, $\|me - nx\| \leq m$. It follows $\|me_1 - n\phi(x)\| \leq m$. Thus $n\phi(x) = me_1 - (me_1 - n\phi(x)) \in (B_1)_+$.

(1)⇒(4): Let $x \in Y$ and $n \in \mathbb{N}$ with $nx - e \in B_+$, then $n\phi(x) - e_1 \in (B_1)_+$. The map ϕ is continuous, because (1) implies (3).

(4)⇒(5): Let $Z := \bigcap_n (1/n)Y = \operatorname{span}_{\mathbb{Q}}(Y)$. If $z = (1/k)y \in Z \cap (B_+)^\circ$ with $y \in Y$ and $k \in \mathbb{N}$, then $y \in Y \cap (B_+)^\circ$. By Part (v), there is $n \in \mathbb{N}$ with $ny - e \in B_+$. By assumptions, it follows that there is $m \in \mathbb{N}$ with $m\phi(y) - e_1 \in (B_1)_+$. In particular, $\phi(z) = (1/(mk))((m\phi(y) - e_1) + e_1) \in (B_1)_+$. Hence, $\phi(\,(B_+)^\circ \cap Z\,) \subseteq (B_1)_+$.

Since ϕ is continuous by assumptions, ϕ maps the closure M of $(B_+)^\circ \cap Z$ into $(B_1)_+$. By assumption, Z is dense in B. Thus Z is dense in each open subset of B, in particular $(B_+)^\circ \subseteq M$.

(viii): Since ϕ is unital and increasing (i.e., $\phi(B_+) \subseteq (B_1)_+$), ϕ is a unital contraction by Part (vii). By (v), $x \in (B_+)^\circ$, if and only if, there is $n \in \mathbb{N}$ with $nx - e \in B_+$. Thus $n\phi(x) - e_1 \in (B_1)_+$, and $\phi(x) \in ((B_1)_+)^\circ$, if $x \in (B_+)^\circ$. It shows that, under our assumptions, the properties (a), (c) and (e) are equivalent to:

(a') $\phi(B_+) \supset (B_1)_+ \cap \phi(B)$.
(c') $\|\psi(x)\| \geq \|x\|$ for all $x \in B$.
(e') $\phi((B_+)^\circ) \supset ((B_1)_+)^\circ$.

(c)⇒(e): Let $x \in B$ with $\phi(x) \in ((B_1)_+)^\circ$. There is $m \in \mathbb{N}$ with $\phi(b) := m\phi(x) - e_1 \in (B_1)_+$ for $b := mx - e \in B$, cf. Part (v). In the proof of Part (ii) we have seen that $\phi(b) \in (B_1)_+$ implies $\|te_1 - \phi(b)\| \leq t$ for $t := \|\phi(b)\| = \|b\|$. Thus $\|\|b\|e - b\| = \|te_1 - \phi(b)\| \leq \|b\|$, which implies $b = nx - e \in B_+$, as shown in proof of Part (ii). Thus, $x \in (B_+)^\circ$ by Part (v).

(e)⇒(a): Let $\phi(x) \in (B_1)_+$, then $\phi(x) + \delta e_1 \in ((B_1)_+)^\circ$ for each $\delta > 0$, by Part (v). It follows $x + \delta e \in B_+$ for each $\delta > 0$, i.e., $x \in B_+$.

(a)⇒(c): If $B_+ = \phi^{-1}(\phi(B) \cap (B_1)_+)$, then we get from $\|\phi(b)\|e_1 \pm \phi(x) \in (B_1)_+$, that $\|\phi(b)\|e \pm x \in B_+$. Thus $\|x\| \leq \|\phi(x)\|$ for all $x \in B$, and ϕ is isometric.

(c)⇒(b): The map ϕ defines an isometric unital isomorphism from B onto the closed subspace $L := \phi(B)$ with $e_1 \in L$. If $\lambda \in E(B)$, then $\rho' := \lambda \circ \phi^{-1}\colon L \to \mathbb{R}$ is in $E(L)$. There is an extension $\rho \in (B_1)^*$ of ρ' with $\|\rho\| = \|\rho'\| = 1$. Thus, $\rho \in E(B_1)$ by Part (ii), and $\lambda \circ \phi = \lambda' \circ \phi = \rho$.

(b)⇒(c): By Part (iii), for $b \in B$,

$$\|b\| = \sup_{\lambda \in E(B)} |\lambda(b)| = \sup_{\rho \in E(B_1)} |\rho(\phi(b))| = \|\phi(b)\| \,.$$

(e)⇒(d): Suppose that $x \in Y$ and $m \in \mathbb{N}$ satisfy $e_1 \leq m\phi(x)$. Then $\phi(x) \in ((B_1)_+)^\circ$ by Part (v), and (e) implies that $x \in (B_+)^\circ$. Again, Part (v) implies that there is $n \in \mathbb{N}$ with $e \leq nx$.

(d)⇒(c): Let $y \in Y$ and $p, q \in \mathbb{N}$ with $(p/q) > \|\phi(y)\|$. Then $pe_1 \pm q\phi(y) \in (B_1)_+$. Thus $\phi(x_k) - e_1 \in (B_1)_+$ for $x_k := (p+1)e + (-1)^k qy \in Y \,,\ k \in \{1, 2\}$. By assumption (d), there are $n_1, n_2 \in \mathbb{N}$ with $n_k x_k - e \in B_+$. Since $(n_k(p+1) - 1)/(n_k q) \leq (p+1)/q$, we get Thus $((p+1)/q)e \pm y \in B_+$, and $(p+1)/q \leq \|y\|$. Since $\inf\{(p+1)/q\,;\ p/q > t\} = t$ for each $t \in \mathbb{R}_+$, we obtain $\|\phi(y)\| \geq \|y\|$ for all $y \in Y$. This carries over to all $z \in Z = \bigcup_n (1/n)Y$, i.e., $\|z\| \leq \|\phi(z)\|$ for all $z \in Z$. It follows $\|b\| = \|\phi(b)\|$ for all $b \in B$, because Z is dense in B and $\|\phi\| \leq 1$.

(ix): Suppose that $Y \subseteq B$ is an additive subgroup such that $\mathrm{span}_{\mathbb{R}}(Y)$ is dense in B, and that $F \subseteq E(B)$ satisfies $\|y\| = \sup_{f \in F} |f(y)|$ for each $y \in Y$. Let $M(b) := \sup_{f \in F} |f(b)|$ for $b \in B$. Then $M(b)$ is a semi-norm on B with $M(b) \leq \|b\|$, the set $Z := \{(1/n)x\,;\ x \in Y\} = \mathrm{span}_{\mathbb{Q}}(Y)$ is norm-dense in B, and $M(z) = \|z\|$ for all $z \in Z$. Thus, $M(b) = \|b\|$ on all $b \in B$, i.e., F is norming for B.

Suppose now that F is norming on B. Let $G \subseteq E(B)$ denote the *weak closure of the the convex hull of F. Then G is convex, compact, and is norming on B.

Suppose that $G \neq E(B)$. Then, by Hahn-Banach separation, there exist $b \in B$ and $f \in E(B)$ such that $f(b) \notin \{g(b)\,;\ g \in G\}$. Since G is compact and convex, there are $\alpha, \beta \in \mathbb{R}$ with $\{g(b)\,;\ g \in G\} = [\alpha, \beta]$. Let $c := 2b - (\alpha + \beta)e$, then $f(c) \notin \{g(c)\,;\ g \in G\} = [\alpha - \beta, \beta - \alpha]$. Thus, $\|c\| = \sup_{g \in G} |g(c)| = \beta - \alpha$ and $|f(c)| > \|c\|$, which contradicts $f \in E(B)$.

Let K a compact convex subset of a locally convex vector space V. Then the continuous linear functionals $f \in V^*$ separate the point of K and $f|K \in \mathrm{Aff}_c(K)$. The set $\mathrm{Aff}_c(K)$ of continuous affine functions on K is a closed subspace of $\mathrm{C}(K)$ that contains 1.

The natural map $k \in K \mapsto \delta_k E(\mathrm{C}(K)) \subseteq \mathrm{C}(K)^*$ is continuous. The restrictions $\widehat{k}$ of δ_k to the elements of $\mathrm{Aff}_c(K)$ are in the state space $E(\mathrm{Aff}_c(K))$ of $\mathrm{Aff}_c(K)$. The map $k \mapsto \widehat{k}$ is continuous, affine (= convex) and injective. Thus, $\widehat{K}$ is a norming closed convex subset of the state space of $\mathrm{Aff}_c(K)$. Thus, $k \mapsto \widehat{k}$ is surjective. It follows that $k \mapsto \widehat{k}$ is an affine topological isomorphism from K onto $E(\mathrm{Aff}_c(K))$.

(x): The natural map $B \ni b \mapsto \widehat{b} \in \mathrm{Aff}_c(E(B)) \subseteq \mathrm{C}(E(B))$ with $\widehat{b}(\lambda) := \lambda(b)$. Is unital and isometric by Part (iii). By Part (ix), the natural map from $E(B)$ into $E(\mathrm{Aff}_c(E(B)))$ is bijective. It follows that $\widehat{B} \subseteq \mathrm{Aff}_c(E(B))$ separates the states of $\mathrm{Aff}_c(E(B))$. Now Part (vi) shows that $\widehat{B} = \mathrm{Aff}_c(E(B))$. Thus, $b \mapsto \widehat{b}$ defines a natural unital isometric isomphism from (B, B_+, e) onto the order unit space $\mathrm{Aff}_c(E(B)) \subseteq \mathrm{C}(E(B))$. □

Lemma A.13.3. *Let V be a real vector space, $K \subseteq V$ a convex cone in V and $u \in K$ such that $-u \notin K$ and that, for every $x \in V$ there exists $n = n(x) \in \mathbb{N}$ with $nu - x \in K$.*
Define $P(x) := \inf\{m/n\,;\ m, n \in \mathbb{N},\ mu \pm nx \in K\}$.

Then P is a seminorm on V.

Let V_0 the space of $v \in V$ with $P(v) = 0$, let $\pi(x) := x + V_0$ the quotient map $\pi\colon V \to V/V_0$ and define a Norm $\|\cdot\|$ on V/V_0 by $\|\pi(x)\| = P(x)$.

(i) *The completion B of the normed space V/V_0 becomes an order unit space with order unit $e := \pi(u) = u + V_0$ and $B_+ := \overline{\pi(K)}$.*
(ii) *(B, B_+, e) is naturally order-unit isomorphic to the space of affine functions on the $\sigma(V', V)$-compact convex set of linear maps $\lambda\colon V \to \mathbb{R}$ with $\lambda(K) \subseteq \mathbb{R}_+$ and $\lambda(u) = 1$.*
(iii) *$\pi(x)$ is in the interior of B_+, if and only if, there is $n \in \mathbb{N}$ with $nx-u \in K$.*
(iv) *Suppose that X is an additive subgroup of of V, such that $u \in X$ and V is the real linear span of X, and that $\psi\colon X \to B_1$ is an additive map from X into an order unit space $(B_1, (B_1)_+, e_1)$ with $\psi(u) = e_1$.*

 If the existence of $n \in \mathbb{N}$ with $nx - e \in K$ implies the existence of $m \in \mathbb{N}$ with $m\psi(x) - e_1 \in (B_1)_+$, then there is a unique unital linear contraction $\eta\colon B \to B_1$ with $\eta(\pi(x)) = \psi(x)$ for all $x \in X$.

 This is in particular the case, if the map $\psi\colon X \to B_1$ is order preserving, i.e., if $\psi(x) \le \psi(y)$ if $y - x \in K$.
(v) *The map $\eta\colon B \to B_1$ in (iv) is isometric, if and only if, for each $x \in X$, the existence of $n \in \mathbb{N}$ with $nx - e \in K$ is equivalent to the existence of $m \in \mathbb{N}$ with $m\psi(x) - e_1 \in (B_1)_+$.*

Proof. Clearly $P(x) = P(-x)$, $P(u) = 1$ (by $-u \notin K$) and $P(0) = 0$. If $t \in \mathbb{R}_+$ satisfies $tu \pm x \in K$, then $su \pm x = (tu \pm x) + (s - t)u \in K$ for all $s \ge t$. Thus, $P(x) = \inf\{t \ge 0\,;\ tu \pm x \in K\}$. Since, for $t, s > 0$, $tu \pm x \in K \quad \Leftrightarrow (st)u \pm sx \in K$, we get $P(sx) = sP(x)$ for $s > 0$ and $x \in V$.
If $t_1, t_2 \ge 0$ and $t_1u \pm x, t_2u \pm y \in K$ implies $(t_1 + t_2)u \pm (x + y) \in K$. Thus $P(x + y) \le P(x) + P(y)$. Thus, P is a semi-norm on V.

(i): Since $(P(x)+\varepsilon)u \pm x \in K$ for all $\varepsilon > 0$, we have $(\|\pi(x)\|+\varepsilon)e \pm \pi(x) \in B_+$ for all $x \in V$. The map $y \mapsto (\|y\| + \varepsilon)e - y$ is continuous on B and takes values in B_+ for all $y \in \pi(V) = V/V_0$. Since B_+ is closed, we get $\|y\|e - y \in B_+$ for all $y \in B$. It follows $te - y = (\|y\|e - y) + \in B_+$ for all $y \in B$ and $t \ge \|y\|$. In particular, $e + U \subseteq B_+$ for the open unit ball U of B, and e is contained in the interior of B_+.

If $y \in B$ and $s \ge 0$ satisfies $se \pm y \in B_+$ then for every $\varepsilon > 0$, there are $x_1, x_2 \in K$ and $z \in V$ with $\|se + y - \pi(x_1)\| < \varepsilon$, $\|se - y - \pi(x_2)\| < \varepsilon$ and $\|y-\pi(z)\| < \varepsilon$. It implies $P(su+z-x_1) < 2\varepsilon$, $P(se-z-x_2) < 2\varepsilon$ and $\|y\| \le P(z)+\varepsilon$.

It follows $(2\varepsilon)u + (su + z - x_1) \in K$ and $(2\varepsilon)u + (su - z - x_2) \in K$. Since $x_1, x_2 \in K$, we get $(2\varepsilon) + s \geq P(z)$ and, finally, $s \geq \|y\| - 3\varepsilon$. Thus, $se \pm y \in B_+$ and $s \geq 0$ imply $s \geq \|y\|$, and (B, B_+, e) is an order unit space.

(ii): We have $(P(x)+\varepsilon)u \pm x \in K$ for $x \in V$ and all $\varepsilon > 0$. Thus, $|\lambda(x)| \leq P(x)$ for all linear maps $\lambda\colon V \to \mathbb{R}$ with $\lambda(u) = 1$ and $\lambda(K) \subseteq \mathbb{R}_+$. Since V/V_0 is dense in B, there is a unique linear functional $\rho\colon B \to \mathbb{R}$ with $\rho \circ \pi = \lambda$ and $\|\rho\| \leq 1$. The functional ρ is positive and unital, because $\pi(K)$ is dense in B_+ and $\rho(e) = \lambda(u) = 1$.
Clearly, $\lambda := \rho \circ \pi$ is a linear map from V to $\mathbb{R}$ with $\lambda(K) \subseteq \mathbb{R}_+$ and $\lambda(u) = 1$, if $\rho\colon B \to \mathbb{R}$ is a positive linear functional on B with $\rho(e) = 1$.
The $\sigma(\mathrm{Lin}(V, \mathbb{R}), V)$-topology on the convex set of linear maps $\lambda\colon V \to \mathbb{R}$ with $\lambda(K) \subseteq \mathbb{R}_+$ and $\lambda(u) = 1$ gives it a structure of a compact convex set $E(V, K, u)$. The (algebraic and affine) isomorphism $E(B) \to E(V, K, u)$, given by $\rho \mapsto \rho \circ \pi$, is is an affine homeomorphism, because $\pi(V)$ is dense in B. By Proposition A.13.2(ix), the order unit space (B, B_+, e) is naturally order-unit isomorphic to the space of real-valued continuous affine functions on the compact convex set $E(B)$ of states on B.

(iii): If $nx - u \in K$, then $n\pi(x) - e \in B_+$, which implies that $\pi(x)$ is in the interior of B_+ by Proposition A.13.2(v).

Suppose that $\pi(x)$ is in the interior of B_+, then there is $n \in \mathbb{N}$ with $\pi(x) - (2/n)e \in B_+$, i.e., $\pi(nx - 2u) \in B_+$. Since B_+ is the closure of $\pi(K)$, there exists $y \in V$ and $k \in K$ with $nx - 2u = y + k$ and $P(y) = \|\pi(y)\| < 1$. It follows that $u + y \in K$ (by definition of $P(y)$). Hence $nx - u = (y + u) + k \in K$.

(iv): Suppose that $\psi\colon X \to B_1$ is an additive map with $\psi(u) = e_1$, and suppose that, for each $x \in X$, the existence of $n \in \mathbb{N}$ with $nx - u \in K$ implies the existence of $m \in \mathbb{N}$ with $m\psi(x) - e_1 \in (B_1)_+$.

Let $p, n \in \mathbb{N}$ with $p/n > P(x) = \|\pi(x)\|$, then $pu \pm nx \in K$, and $((p+1)u \pm nx) - e \in K$. Thus, there is $m \in \mathbb{N}$ with $m((p+1)e_1 \pm n\psi(x)) - e_1 \in (B_1)_+$. It follows, that $(m(p+1) - 1)e_1 \pm mn\psi(x) \in (B_1)_+$. Hence $\|\psi(x)\| \leq (p+1-1/m)/n \leq p/n + 1/n$. Since we can approximate $P(x) \geq 0$ from above by rational p/n with arbitrary large denominator n, we get $\|\psi(x)\| \leq P(x)$ for all $x \in X$.

The $\mathbb{Q}$-linear hull of X is given by $W := \bigcup_n (1/n)X$. The map $\psi\colon X \to B_1$ naturally extends to W by $\psi_0((1/n)x) := (1/n)\psi(x)$. The extension is well-defined and $\mathbb{Q}$-linear, because $(nm)^{-1}(mpx \pm nqy) = (1/n)(px) \pm (1/m)(qy)$ maps to $(nm)^{-1}(mp\psi(x) \pm nq\psi(y)) = (1/n)(p\psi(x)) \pm (1/m)(q\psi(y))$. We have $P(w) \geq \|\psi_0(w)\|$ for all $w \in W$, because this holds for $w \in X$. In particular, $\psi_0(w) = 0$ if $w \in V_0$.

Consider the set $Y := \pi(X) \subseteq B$. It satisfies the assumptions on Y of Parts (vi, vii, viii) of Proposition A.13.2, because V is the real span of X. In particular, the rational span $Z := \bigcup_n (1/n)\pi(X)$. of Y is dense in the real span of X, hence is dense in B. Let $z = (1/n)\pi(x) \in Z$.

We define $\eta_0(z) := \psi_0(w)$ for $z \in Z$ and $w \in W$ with $\pi(w) = z$. The definition is correct, because $\pi(w') = \pi(w)$ is equivalent to $P(w' - w) = 0$ by definition of V_0 and $\pi\colon V \to B$. Thus $\|\psi_0(w' - w)\| \leq P(w' - w) = 0$ and $\psi_0(w') = \psi_0(w)$. We have $\|z\| = P(w) \geq \|\psi_0(w)\| = \|\eta_0(z)\|$.

The map $\eta_0\colon Z \to B_1$ satisfies $\eta_0 \circ \pi = \psi_0$. It follows that η_0 is $\mathbb{Q}$-linear and contractive.

Since V is the real span of X, and since $\pi(V)$ is dense in B, the rational span Z of Y is dense in B. Thus, the unital contractive $\mathbb{Q}$-linear map $\eta_0\colon Z \to B_1$ uniquely extends to a unital contractive $\mathbb{R}$-linear map $\eta\colon B \to B_1$. This map satisfies $\eta \circ \pi(x) = \psi(x)$.

Since $\eta\colon B \to B_1$ is a unital linear contraction, the map η is increasing.

(v): Let $\eta\colon B \to B_1$ an isometric linear map with $\eta(\pi(x)) = \psi(x)$ for all $x \in X$. Then $\eta(e) = \eta(\pi(u)) = \psi(u) = u_1$. Since η unital and contractive, $\eta(B_+) \subseteq (B_1)_+$, by Proposition A.13.2(vii). If $nx - u \in K$, then $n\pi(x) - e \in B_+$ and $\eta(n\pi(x) - e) = n\psi(x) - e_1 \in (B_1)_+$. If there is $m \in \mathbb{N}$ with $\eta(m\pi(x) - e) = m\psi(x) - e_1 \in (B_1)_+$, then $m\pi(x) - e \in B_+$ by Proposition A.13.2(viii,a).

Conversely, suppose that $\psi\colon X \to B_1$ is additive and unital, and suppose that, for each $x \in X$, the existence of $n \in \mathbb{N}$ with $nx - u \in K$ is equivalent to the existence of $m \in \mathbb{N}$ with $m\psi(x) - e_1 \in (B_1)_+$. Then, by part (iv), there is a unique unital linear contraction $\eta\colon B \to B_1$ with $\eta(\pi(x)) = \psi(x)$ for all $x \in X$.

The set $Y := \pi(X)$ satisfies the assumptions of Proposition A.13.2(viii,d): $Z = \bigcup_n (1/n)Y$ is dense in B, and for $y \in Y$,the existence of $m \in \mathbb{N}$ with $e_1 \leq m\eta(y)$ implies the existence of $n \in \mathbb{N}$ with $e \leq ny$. Indeed: If $e_1 \leq m\eta(y)$ and $x \in X$ with $y = \pi(x)$, then $m\psi(x) - e_1 = m\eta(y) - e_1 \in (B_1)_+$, which implies, by assumption on X, the existence of $n \in \mathbb{N}$ with $nx - u \in K$, i.e., $ny - e = \pi(nx - u) \in B_+$. Thus, the unital linear contraction η is isometric by the equivalence of properties (viii,c) and (viii,d) in Proposition A.13.2(viii). □

Now we use the above elementary material on order-unit spaces for a study of scaled abelian semigroups.

Definition A.13.4. Let S denote an abelian semigroup. S is **preordered** by the relation $x <_S y$ if the relation is transitive and invariant under addition, i.e., $x <_S z$ if $x <_S y$ and $y <_S z$, $x + w <_S y + w$ for all $w \in S$. We do not require that $x <_S x$, therefore we write $x \leq_S y$ if $x <_S y$ *or* $x = y$. The preordered semigroup $(S, <_S)$ is **partially ordered** if $x \leq_S y$ and $y \leq_S x$ imply $x = y$. (If it is clear, which S and preorder $<_S$ is ment, we simply write $<$ and $\leq$ for $<_S$ respectively $\leq_S$.)

An element $u \in S$ is an **order unit** in the preordered abelian semigroup $(S, <_S)$ if $x \leq x + u$ for all $x \in S$, and, for every $y \in S$, there is $n = n(y) \in \mathbb{N}$ such that $y \leq nu$ and $u \leq y + nu$ ([7]). Usually there are many different order units in S.

[7]The properties $x \leq x + u$ and that $u \leq y + nu$ follow automatically, if S has a zero element 0 with $0 \leq x$ for all $x \in S$.

An abelian preordered semigroup $(S\,,\,<_S\,,\,u)$ with a *distinguished* order unit $u \in S$ will be called a **scaled** (abelian) semigroup.

A **state** on S is an order preserving additive map $\lambda\colon S \to \mathbb{R}$ with $\lambda(u) = 1$.

LEMMA A.13.5. *Suppose that V and W are vector spaces over the* rational numbers $\mathbb{Q}$.

(i) *The natural $\mathbb{Z}$-modul morphism $V \otimes_{\mathbb{Z}} W \to V \otimes_{\mathbb{Q}} W$ is an isomorphism.*
(ii) *$\eta\colon v \mapsto v \otimes_{\mathbb{Z}} 1$ is a natural $\mathbb{Q}$-linear monomorphism from V into the real vector space $V \otimes_{\mathbb{Z}} \mathbb{R} = V \otimes_{\mathbb{Q}} \mathbb{R}$.*
(We identify V with its image in $V \otimes_{\mathbb{Q}} \mathbb{R}$.)
(iii) *Let $U \subseteq V \otimes_{\mathbb{Z}} \mathbb{R}$ an open subset with respect to an locally convex topology $\mathbb{O}$ on $V \otimes_{\mathbb{Z}} \mathbb{R}$. Then $V \cap U$ is dense in U with respect to $\mathbb{O}$.*
(iv) *For every subset $X \subseteq V$, and for every (not necessarily separated) locally convex topology on $V \otimes_{\mathbb{Z}} \mathbb{R}$, the rational convex hull* $\mathrm{conv}_{\mathbb{Q}}(X)$ *of X in V is dense in the real convex hull* $\mathrm{conv}_{\mathbb{R}}(X)$ *of X in $V \otimes_{\mathbb{Z}} \mathbb{R}$.*
(v) $\mathrm{conv}_{\mathbb{R}}(X) \cap V = \mathrm{conv}_{\mathbb{Q}}(X)$ *holds in $V \otimes_{\mathbb{Z}} \mathbb{R}$.*

The observations (i)-(v) imply the following observation:

Suppose that $T\colon V \to W$ is an additive map, $\nu\colon W \to [0,\infty)$ is a semi-norm on $W \otimes_{\mathbb{Z}} \mathbb{R}$, $X \subseteq W$ is a subset of W, and that there exists $v_1 \in V \otimes_{\mathbb{Z}} \mathbb{R}$, such that $(T \otimes_{\mathbb{Z}} \mathrm{id}_{\mathbb{R}})(v_1)$ is in the interior of $\mathrm{conv}_{\mathbb{R}}(X) \subseteq W \otimes_{\mathbb{Z}} \mathbb{R}$ *with respect to the topology on $W \otimes_{\mathbb{Z}} \mathbb{R}$ defined by ν.*

Then there exists $v_2 \in V$ such that $T(v_2) \in W$ is in the interior of $\mathrm{conv}_{\mathbb{Q}}(X)$ *with respect to ν.*

PROOF. Since the tensor products are the *algebraic* tensor products, the statements reduces to V, W of finite dimension (over $\mathbb{Q}$, i.e., $V \cong \mathbb{Q}^n$ and $W \cong \mathbb{Q}^m$ as vector spaces over $\mathbb{Q}$), and to finite subsets X of $V \cong \mathbb{Q}^n$.

Then the proofs automatically reduce to the following easy observations:

(i): There are natural isomorphisms $\mathbb{Q} \otimes_{\mathbb{Z}} \mathbb{Q} \cong \mathbb{Q}$, and, therefore, also natural isomorphisms

$$\mathbb{Q}^n \otimes_{\mathbb{Z}} \mathbb{Q}^m \cong \mathbb{Q}^{nm} \cong \mathbb{Q}^n \otimes_{\mathbb{Q}} \mathbb{Q}^m\,.$$

(ii): By Part (i), there is a natural isomorphism $V \otimes_{\mathbb{Z}} \mathbb{R} \cong V \otimes_{\mathbb{Q}} \mathbb{R}$, because $\mathbb{R}$ is a $\mathbb{Q}$-vector space. In case $V = \mathbb{Q}^m$, the natural isomorphism induces the natural embedding of $\mathbb{Q}^m$ in $\mathbb{R}^m$. The injectivity of $\eta\colon v \mapsto v \otimes_{\mathbb{Z}} 1$ then follows from the injectivity of natural embedding $\mathbb{Q}^n \to \mathbb{R}^m = \mathbb{Q}^m \otimes_{\mathbb{Z}} \mathbb{R}$.

(iii): The finest locally convex topology on $\mathbb{R}^n$ is identical with the topology induced by the norm $\|(x_1,\ldots,x_n)\|_\infty := \max_j |x_j|$. Thus, every open subset U of $\mathbb{R}^n$ with respect to any (not necessarily separated) locally convex topology $\mathbb{O}$ of $\mathbb{R}^n$ is the union of products $I_1 \times \cdots \times I_n$ of open intervals $I_k \subseteq \mathbb{R}$. It follows that the vectors with rational coordinates are dense U with respect to to the topology $\mathbb{O}$, because $U_1 \cap U = \emptyset$ if $U_1 \in \mathbb{O}$ and $U_1 \cap U$ does not contain a vector with rational coordinates.

(iv): Any $\mathbb{R}$-convex combination $\sum_{j=1}^{m} \alpha_j v_j = p \in \mathbb{R}^n$ of $v_1, \ldots, v_m \in \mathbb{Q}^n$ can be approximated by a convex combination of the $v_1, \ldots, v_m$ with rational $\alpha_j \geq 0$ with $\sum_j \alpha_j = 1$, because the rational points are dense in the $(m-1)$-dimensional standard simplex $S \in \mathbb{R}^m$ (by part (iii) applied to the inverse $T^{-1}(S)$ of a suitable affine injective map $T\colon \mathbb{R}^{m-1} \to \mathbb{R}^m$ with $T(0) = (1/m, \ldots, 1/m)$ and rational entries in its coefficient matrix).

(v): $\mathrm{conv}_{\mathbb{R}}(X) \cap V = \mathrm{conv}_{\mathbb{Q}}(X)$ comes from the case where $V \cong \mathbb{Q}^n$. Let $X = \{v_1, \ldots, v_m\} \subseteq \mathbb{Q}^n$ is a finite subset, and $\sum_j \alpha_j v_j = v_0 \in \mathbb{Q}^n$, with $\alpha_j \in (0, \infty)$, $\sum \alpha_j = 1$. Then we can form the matrix $A \in M_{m,n+1}(\mathbb{Q})$ with columns $a_j = (v_j, 1)^\top$, and let $b \in M_{n+1,1}(\mathbb{Q})$ the column $b = (v_0, 1)$. Then $A \cdot x_0 = b$ with $x_0 = [\alpha_1, \ldots, \alpha_n]^\top \in M_{n,1}(\mathbb{R})$. It follows that the matrices A and the extended matrix (A, b) have same rank (calculated in $\mathbb{R}$). Since both matrices have rational entries, the ranks are also equal if calculated in Q. Thus there is a solution of $A \cdot x_1 = b$ with $x_1 = [\beta_1, \ldots, \beta_n]^\top \in M_{n,1}(\mathbb{Q})$. If $B \in M_{n+1,m}(\mathbb{Q})$ is a generalized inverse of A then $T\colon y \in M_{m,1}(\mathbb{R}) \mapsto (1_m - BA)y + Bb$ is an affine map from $\mathbb{R}^m \cong M_{m,1}(\mathbb{R})$ onto the set of all solutions $x \in M^{(}_{m,1}\mathbb{R})$ of $Ax = b$. The set $T^{-1}(0, \infty)^m$ is an open convex subset of $\mathbb{R}^m$ that is not empty, because $(0, \infty)^m$ is open in $\mathbb{R}^m$ and $x_0 \in (0, \infty)^m$ by assumption. By part (ii), we get that $\mathbb{Q}^m \cap T^{-1}(0, \infty)^m$ is not empty, i.e., there is $x_2 \in (0, \infty)^m \cap \mathbb{Q}^m$ with $Ax_2 = b$. This means that v_0 is a rationally-convex combination of $v_1, \ldots, v_m$. □

The following key lemma is an observation of B. Blackadar and M. Rørdam [**86**]. It provided a useful "almost" cancellation property.

LEMMA A.13.6. *If $(S, <_S, u)$ is a scaled abelian semigroup, then, for $x, y \in S$, there exists $m, p \in \mathbb{N}$ with $mx + (p+1)u \leq my + pu$, if and only if, there are $n \in \mathbb{N}$ and $z \in S$ with $nx + u + z \leq ny + z$.*

PROOF. If $mx + (p+1)u \leq my + pu$, then we let $n := m$ and $z := pu$. To show the non-trivial direction, it suffices to show that $x + u + z \leq y + z$ implies the existence of $m, p \in \mathbb{N}$ with $mx + (p+1)u \leq my + pu$, because we can rename nx and ny by x and y in the statement.

If $x_j, y_j, z \in S$ satisfy $x_j + z \leq y_j + z$ $(j = 1, 2)$, then

$$x_1 + x_2 + z \leq x_1 + y_2 + z \leq y_1 + y_2 + z\,.$$

Induction gives that $nx + z \leq ny + z$ for all $n \in \mathbb{N}$ if $x + z \leq y + z$.

If $x_1, x_2 \in S$, then there is $n \in \mathbb{N}$ with $x_1 \leq x_2 + nu$: Indeed, there are $n_1, n_2 \in \mathbb{N}$ with $a \leq n_1 u$, $b \leq n_2 u$ and $u \leq b + n_2 u$. It follows $n_1 b \leq b + (n_1 - 1) n_2 u$ and $a \leq b + nu$ for $n := (2n_1 - 1)n_2$.

Let $x, y, z \in S$ with $x + u + z \leq y + z$. There are $k, \ell \in \mathbb{N}$ such that $u \leq z + ku$ and $z \leq ku$, $u \leq y + \ell u$, $y \leq \ell u$. It follows $z \leq k(y + \ell u)$. Let $x' = x + \ell u$, $y' = y + \ell u$. Then $z \leq ky'$, $x' + u + z \leq y' + z$, thus $nx' + nu + z \leq ny' + z$ for all $n \in \mathbb{N}$. Take above $a := kx' + u$ and $b := z$, then there is $n \in \mathbb{N}$ with $kx' + u \leq nu + z$. We get

$$(n + k)x' + u = nx' + kx' + u \leq nx' + nu + z \leq ny' + z \leq (n + k)y'\,.$$

It implies $mx + (p+1)u \leq my + pu$ for $m := n + k$, $p := (n+k)\ell$. □

PROPOSITION A.13.7. *Suppose that $(S, <, u)$ is a scaled abelian semigroup such that $m, n \in \mathbb{N}$ and $mu \leq nu$ imply $m \leq n$.*

Then there is an order unit space $B(S) = (B, B_+, e)$ and a unital additive map $\gamma\colon S \to B$ with $\gamma(u) = e$, such that, for every state λ on $(S, <, u)$, there is exactly one state ρ on B with $\lambda = \rho \circ \gamma$. Furthermore:

- (i) *Natural universality: If B_1 is an oder unit space, and $\psi\colon S \to B_1$ is monotone, unital and additive, then there is a unique monotone unital linear map $T\colon B(S) \to B_1$ with $T \circ \gamma = \psi$.*
- (ii) *There are equivalent:*
  - (ii.1) *$\gamma(y) - \gamma(x)$ is in the interior of B_+.*
  - (ii.2) *There exist $m, p \in \mathbb{N}$ such that $mx + (1+p)u \leq my + pu$.*
  - (ii.3) *$\lambda(x) < \lambda(y)$ for all states λ of S.*
- (iii) *An additive unital map ψ from S to an order unit space $(B_1, (B_1)_+, e_1)$ is monotone, if and only if, the inequality $x+u \leq y$ in S implies $\psi(x) \leq \psi(y)$ for $x, y \in S$ ([8]).*
- (iv) *For a* monotone *additive unital map $\psi\colon S \to B_1$ are equivalent:*
  - (iv.1) *There is an isometric unital map $I\colon B \to B_1$ with $I(\gamma(x)) = \psi(x)$ for $x \in S$.*
  - (iv.2) *If there is $n \in \mathbb{N}$ with $n\psi(x) + e_1 \leq n\psi(y)$, then there exist $m, p \in \mathbb{N}$ with $mx + (p+1)e \leq my + pe$ (i.e., $\gamma(y) - \gamma(x)$ is in the interior of B_+ by (ii)).*
  - (iv.3) *For every state λ on S there exists a state ρ on B_1 with $\lambda = \rho \circ \psi$.*

PROOF. Let $\mathrm{Gr}(S)$ denote the Grothendieck group of S, and let

$$\mathrm{Gr}(S)_+ := \{[y] - [x]\,;\ x, y \in S,\ x \leq_S y\}\,.$$

Then for each $g \in \mathrm{Gr}(S)$ there are $s, t \in S$ with $g = [s] - [t]$.

By Definition A.13.4, there are $m, n \in \mathbb{N}$ with $s \leq nu$, $u \leq t + nu$ and $t \leq nu$. We get $g = ([nu] - [t]) - ([nu] - [s]) \in \mathrm{Gr}(S)_+ - \mathrm{Gr}(S)_+$ and $g \leq g + ([nu] - [s]) = [nu] - [t] \leq 2n[u]$. Thus, $(\mathrm{Gr}(S), \mathrm{Gr}(S)_+, [u])$ is a scaled abelian group with order $g \leq h \Leftrightarrow g - h \in \mathrm{Gr}(S)_+$ and order unit $[u]$.

It turns out for $x, y \in S$ that $[x] \leq [y]$ in $\mathrm{Gr}(S)$, if and only if, there is $z \in S$ with $x + z \leq y + z$. Indeed, $x + z \leq y + z$ implies $[y] - [x] \in \mathrm{Gr}(S)_+$. If $[y] - [x] \in \mathrm{Gr}(S)_+$ then there are $x_1, x_2, s \in S$ with $x_1 \leq x_2$ and $y + x_1 + s = x + x_2 + s =: t$. Thus $x + z = t + x_1 \leq t + x_2 = y + z$ for $z := x_1 + x_2 + s$.

By Lemma A.13.6 it follows that there is $n \in \mathbb{N}$ with $n[x] + [u] \leq n[y]$ in $\mathrm{Gr}(S)$ (i.e., that there exists $z \in S$ with $nx + z + u \leq ny + z$), if and only if, there are $m, p \in \mathbb{N}$ with $mx + (p+1)u \leq my + pu$ in S.

We define a pre-ordered $\mathbb{R}$-vector space (V, K, w) by $V := \mathrm{Gr}(S) \otimes_Z \mathbb{R}$, $w := [u] \otimes_{\mathbb{Z}} 1$ and K is the convex cone of $V := \mathrm{Gr}(S) \otimes_Z \mathbb{R}$ generated by $\mathrm{Gr}(S)_+ \otimes_{\mathbb{Z}} 1$.

[8] It implies then that $\phi(y) - \phi(x)$ is in the interior of the positive cone $(B_1)_+$.

Since $\mathbb{Q}\otimes_Z\mathbb{R} = \mathbb{Q}\otimes_\mathbb{Q}\mathbb{R} = \mathbb{R}$, we get from Lemma A.13.5, that $\mathrm{Gr}(S)\otimes_Z\mathbb{Q} \to V$ is injective and that $(\mathrm{Gr}(S)\otimes_Z\mathbb{Q})\cap K = \bigcup_n(\mathrm{Gr}(S)_+\otimes_\mathbb{Z} 1/n)$. Hence, $(g\otimes 1) \in K$, if and only if, there exists $n \in \mathbb{N}$ with $ng \in \mathrm{Gr}(S)_+$. In particular, $([y]-[x])\otimes 1 \in K$, if and only if, there are $m \in \mathbb{N}$ and $z \in S$ with $mx + z \leq my + z$.

Suppose $-w = ([u] - [2u]) \otimes 1 \in K$, then there is $m \in \mathbb{N}$ (w.l.o.g.) with $2mu + z \leq mu + z$ in S. By LemmaA.13.6, there are $n, q \in \mathbb{N}$ with $n((2m-1)u) + (q+1)u \leq nmu + qu$, i.e., $ku \leq_S \ell u$ with $mn + q =: \ell < k := n(2m-1) + q + 1$. This contradicts our assumption that $ku \leq \ell u$ implies $k \leq \ell$.

Since $-w \notin K$, (V, K, w) is a scaled $\mathbb{R}$-vector space, as considered in Lemma A.13.3. We define, $B(S) := (B, B_+, e)$ as the order unit space that is obtained from the scaled $\mathbb{R}$-vector space (V, K, w) in Lemma A.13.3, and let $\gamma(x) := \pi([x] \otimes_\mathbb{Z} 1)$, where $\pi\colon V \to B$ is the quotient map $v \in V \mapsto v + V_0 \in V/V_0 \subseteq B$ as considered in Lemma A.13.3.

Since $g \in G \mapsto g \otimes_\mathbb{Z} 1 \in V$ and π are monotone and unital, we get that $\gamma\colon S \to B$ is a monotone, unital additive map. Thus $\lambda := \rho \circ \gamma$ is a monotone additive unital map, if ρ is a state of $B(S)$.

It is obvious, that every state $\lambda\colon S \to \mathbb{R}$ uniquely factorizes through $\mathrm{Gr}(S)$ and then through (V, K, w), i.e., for every state λ of S there is a unique state ρ' on (V, K, w) and then a unique state ρ on (B, B_+, e) (by Lemma A.13.3(iv) with $(B_1, (B_1)_+, u_1) := (\mathbb{R}, \mathbb{R}_+, 1))$ with $\rho(\gamma(x)) = \rho'([x] \otimes 1) = \lambda(x)$ for all $\lambda \in E(S)$. It follows from Lemma A.13.3(ii), that there is a unique isometric unital order isomorphism ι from B onto $\mathrm{Aff}_c(E(S))$ with $\iota(\gamma(x)) = \iota(\pi([x] \otimes 1))(\lambda) = \lambda(x)$ for all $x \in S$.

(i): Suppose that $\psi\colon S \to B_1$ is monotone, unital and additive map into an order unit space B_1. Since B_1 is an $\mathbb{R}$-vector space, the map factorizes through a linear map $[\varphi]\colon V = \mathrm{Gr}(S) \otimes_\mathbb{Z} \mathbb{R} \to B_1$ with $\psi(x) = [\psi]([x])$ for $x \in S$.

The map $[\psi]$ is unital and order preserving, and $X := \mathrm{Gr}(S) \otimes_Z \mathbb{Q}$ satisfies the assumptions of Lemma A.13.3(iv).

Have to show:

There is a unique monotone unital linear map $T\colon B(S) \to B_1$ with $T \circ \gamma = \psi$.

That means: Existence by construction ... and proof of uniqueness ... e.g. by use of separating states on B_1.

If $x \leq y$ then $mx + u \leq (mx + u)$ for any $m \in \mathbb{N}$. It follows that there are $n, q \in \mathbb{N}$ with $n(m\phi(x)) + (q+1)v \leq n(m\phi(x) + v) + qv$. Thus $nm\lambda(\phi(x)) \leq (n-1) + nm\lambda(\phi(x))$ and $\lambda(\phi(x)) \leq \lambda(\phi(x)) + (1/m)$ for all $m \in \mathbb{N}$ and all states λ on $(B_1, (B_1)_+, e_1)$.

`to be filled in` ?? □

Corollary A.13.8. *Let* $(S\,, <\,, u)$, $(T\,, <\,, v)$ *scaled abelian semigroups, and* $\phi\colon S \to T$ *an additive map with* $\phi(u) = v$.

If $mv \leq_T nv$ implies $m \leq n$ (for $n, m \in \mathbb{N}$), then ϕ has the following properties (i) and (ii).

(i) *$\lambda \circ \phi$ is a state of S for each state λ of T,*
if and only if,
for $x, y \in S$, the inequality $x + u \leq y$ implies the existence of $n, q \in \mathbb{N}$ with $n\phi(x) + (q+1)v \leq n\phi(y) + qv$.

(ii) *For every state ρ of S there is a state λ of T with $\rho = \lambda \circ \phi$,*
if and only if,
for $x, y \in S$, the existence of $m, p \in \mathbb{N}$ with $mx + (p+1)u \leq my + pu$ is equivalent to the existence of $n, q \in \mathbb{N}$ with $n\phi(x) + (q+1)v \leq n\phi(y) + qv$.

Proof. (i): Suppose that for each $x, y \in S$ with $x + u \leq y$ there are $n, q \in \mathbb{N}$ with $n\phi(x) + (q+1)v \leq n\phi(y) + qv$, then $1/n \leq \lambda(\phi(y)) - \lambda(\phi(x))$ for all states $\lambda \colon T \to \mathbb{R}$ on $(T, <_T, v)$. Thus $x + u \leq y$ implies $\lambda(\phi(x)) \leq \lambda(\phi(y))$. Since $(\mathbb{R}, \mathbb{R}_+, 1)$ is an order unit space, we get from Part(iii) of Proposition A.13.7, that the additive unital maps $\lambda \circ \phi \colon S \to \mathbb{R}$ are monotone, i.e., that the λ are states on $(S\, ,<_S\, ,u)$.

Suppose, conversely, that $\lambda \circ \phi$ is a state on $(S, <_S\, , u)$ for all states λ on $(T, <_T\, , v)$. If $x + u \leq y$ then $\lambda(\phi(y) - \phi(x)) \geq 1$ for all states λ on $(T, <_T\, , v)$. This implies the existence of $n, q \in \mathbb{N}$ such that $n\phi(x) + (l+q)v \leq n\phi(y) + qv$, by part (ii) of Proposition A.13.7,

(ii): By part (i) and by Proposition A.13.7, there is a unique unital monotone linear map $\psi \colon B(S) \to B_1 := \mathrm{Aff}_c(E(T)) \cong B(T)$ with $\psi(\gamma_S(x))(\lambda) = \lambda(\phi(x))$ for all $x \in S$ and $\lambda \in E(T)$.

Suppose that $n\phi(x) + (p+1)v \leq n\phi(xy) + pv$ in T implies the existence of $m, p \in \mathbb{N}$ with $mx + (p+1)e \leq my + pe$ in S. If there is $k \in \mathbb{N}$ with $k\psi(x) + e_1 \leq k\psi(y)$ in $(B(T), B(T)_+, e_T)$ then $1/k \leq \lambda(\phi(y)) - \lambda(\phi(x))$ for every state λ on T. If follows the existence of $n, q \in \mathbb{N}$ with $n\phi(x) + (p+1)v \leq n\phi(xy) + pv$ in T, by part (ii) of Proposition A.13.7. By assumption, there are $m, p \in \mathbb{N}$ with $mx + (p+1)e \leq my + pe$.

Thus, $\psi \colon B(S) \to \mathrm{Aff}_c(E(T))$ satisfies the condition in part (iv.2) of Proposition A.13.7(iv). It implies that for every state ρ on S there is a state ρ' on $\mathrm{Aff}_c(E(T))$ with $\rho(x) = \rho'(\psi(\gamma_S(x)))$ for $x \in S$. Since $E(T)$ is compact and convex, it follows that there is $\lambda \in E(T)$ with $\rho'(\gamma_T(y)) = \lambda(y)$ for all $y \in T$. Thus,

$$\rho(x) = \rho'(\psi(\gamma_S(x)) = \rho'(\gamma_T(\phi(x)) = \lambda(\phi(x))\,.$$

By Proposition A.13.7, there is a state λ on T such that $\rho'(\gamma_T(y)) = \lambda(y)$ for all $y \in T$.

$\gamma(y) - \gamma(x)$ is in the interior of $B(S)_+$, iff, there are $m, p \in \mathbb{N}$ with $mx + (p+1)u \leq my + pu$.

For every state λ on S there exists a state ρ on B_1 with $\lambda = \rho \circ \psi$.

Suppose that for every state ρ on S there is a state λ on T with $\lambda \circ \phi = \rho$, then ψ is isometric by

????????????? reference?

For every state ρ of S there is a state λ of T with $\rho = \lambda \circ \phi$, if and only if, for $x, y \in S$, the existence of $m, p \in \mathbb{N}$ with $mx + (p+1)u \leq my + pu$ is equivalent to the existence of $n, q \in \mathbb{N}$ with $n\phi(x) + (q+1)v \leq n\phi(y) + qv$.

Let $\eta \colon T \to B(T) \cong \mathrm{Aff}_c(E(T))$ denote the natural unital additive map from T into is universal order unit space $(B(T), B(T)_+, e_T)$ (cf. Proposition A.13.7), and let $\psi := \eta \circ \phi$.

By part (iii) of Proposition A.13.7, the additive unital map $\psi \colon S \to B(T)$ from S to the order unit space $(B(T), B(T)_+, e_T)$ is monotone, if and only if, the inequality $x + u \leq y$ in S implies $\phi(x) \leq \phi(y)$ for $x, y \in S$.

`to be filled in` ??

A.13.7 □

Corollary A.13.9. *If $(S_1, <, u)$ is a scaled subgroup of $(S, <, u)$ (with induced order), then $B(S_1) \to B(S)$ is isometric. In particular, every state of S_1 extends to a state of S.*

Proof. Consider the inclusion map $\phi \colon S_1 \ni x \mapsto x \in S$ and let $x, y \in S_1$. There are $n, p \in \mathbb{N}$ with $nx+(p+1)u \leq ny+pu$ in S_1, if and only if, $n\phi(x)+(p+1)u \leq n\phi(y) + pu$. Now apply part (ii) of Corollary A.13.8 and Proposition A.13.7. □

Corollary A.13.10. *Suppose that the scaled abelian semigroup $(S, <, u)$ has a zero element 0 with $0 \leq x$ for all $x \in S$.*

If $a \in S$ satisfies $\lambda(a) = 0$ for all states λ of S, then there exists $n(a, u) \in \mathbb{N}$ such that

$$2na \leq nu \quad \text{for all } n \geq n(a, u)\,.$$

Proof. The proof includes the case, that $\phi \equiv 0$ is the only monotone additive map $\phi \colon S \to \mathbb{R}$.

If $\phi(x) \equiv 0$ is the only monotone linear map $\phi \colon S \to \mathbb{R}$, then there is no state on the sub-semigroup $T = \mathbb{N} \cdot u$ of S with induced preorder and order-unit u (by Corollary A.13.9). It follows that there is $m \in \mathbb{N}$ with $(m+1)u \leq mu$, because otherwise there is a state on $(T, <_S |T, u)$ that extends to $(S, <_S, u)$ by Corollary A.13.9. We get $(n+\ell)u \leq nu$ for all $n \geq m$ and $\ell \in \mathbb{N}$ (by induction over ℓ). There is $k \in \mathbb{N}$ with $a \leq ku$. Thus, $2na \leq 2nku \leq nu$ for all $n \geq m$.

If $mu \leq nu$ always implies $m \leq n$, then, by Proposition A.13.7(ii), there are $m, p \in \mathbb{N}$ with $3ma + (p+1)u \leq (m-1)u + (p+1)u$, because $1 \leq \lambda(u) - \lambda(4a)$ for all states λ of S.

It implies $q3ma + (p+1)u \leq q(m-1)u + (p+1)u$ for all $q \in \mathbb{N}$ (by induction over q, cf. proof of Lemma A.13.6). There is $k \in \mathbb{N}$ with $a \leq ku$ and $k \geq p+1$. We get $(q3m+1)a \leq (q(m-1)+k)u$ for all $q \in \mathbb{N}$. If $n \in \mathbb{N} \cap [q(m-1)+k, (q3m+1)/2]$ then $2na \leq nu$. Let $q \geq (2m-3+2k)/(m+2)$ then $q3m+1 \geq 2((q+1)(m-1)+k)$.

It follows that

$$[n_0, \infty) \subseteq \bigcup_{q \in \mathbb{N}} [q(m-1)+k, (q3m+1)/2]$$

for $n_0 := q_0(m-1)+k$ with $q_0 := 1 + [(2m-3+2k)/(m+2)]$. □

14. Approximate intertwining of inductive limits

We have to work sometimes with C^*-systems that are inductive limits of completely positive contractions on non-unital C^*-algebras.

Some text missing? ??

We write $B_\infty := \ell_\infty(B)/c_0(B)$ for a Banach space B. Recall that B_∞ is a C^*-algebra in case that B is a C^*-algebra. Then B_∞ is the same as B_∞ in the terminology $\mathrm{Q}(X,B) := \mathrm{C_b}(X,B)/\,\mathrm{C}_0(X,B)$ used in Chapter 6 for locally compact spaces X (here $X := \mathbb{N}$). More generally, we define B_∞ for a sequence $B_1, B_2, \ldots$ of Banach algebras or C^*-algebras by

$$B_\infty := (\prod_n B_n)/(\bigoplus_n B_n) \;=\; \ell_\infty(B_1, B_2, \ldots)/c_0(B_1, B_2, \ldots).$$

A sequence of contractions $V_n \colon A_n \to B_n$ defines a contraction $V_\infty \colon A_\infty \to B_\infty$ by

$$V_\infty((a_1, a_2, \ldots) + c_0(A_1, A_2, \ldots) := (V_1(a_1), V_2(a_2), \ldots) + c_0(B_1, B_2, \ldots)$$

for $(a_1, a_2, \ldots) \in \ell_\infty(A_1, A_2, \ldots)$, a norm-bounded sequence with $a_n \in A_n$.

to be filled in: basics on $\mathrm{indlim}(T_n \colon B_n \to B_{n+1})$??

The following lemmata collect some basic facts on inductive limits of linear contractions on Banach spaces and c.p. contractions on C^*-algebras. We use notations $\oplus_n B_n = c_0(B_1, B_2, \ldots) \subseteq c_0(\mathcal{L}(\mathcal{H}))$ and $\Pi_n B_n = \ell_\infty(B_1, B_2, \ldots) \subseteq \ell_\infty(\mathcal{L}(\mathcal{H}))$ for closed subspaces of $\mathcal{L}(\mathcal{H})$ with sufficiently big Hilbert space $\mathcal{H}$ (which plays only an intermediate role).

Lemma A.14.1. *Suppose that $A_1, A_2, \ldots$ and $B_1, B_2, \ldots$ are Banach spaces, and that $S_n \colon A_n \to A_{n+1}$ and $T_n \colon B_n \to B_{n+1}$ are contractions.*

There is a natural isometric embedding $\mathrm{indlim}(T_n \colon B_n \to B_{n+1}) \subseteq B_\infty$ *given by the maps $\eta_n \colon B_n \to B_\infty$ defined by*

$$\eta_n(b) := (0, \cdots, 0, b, T_n(b), T_{n+1}T_n(b), \ldots) + (\oplus_n B_n)\,,$$

where $b \in B_n$ is on the n-th position. We write also $T_{n,\infty}$ instead of η_n.

Let $V_n \colon A_n \to B_n$, $W_n \colon B_n \to A_{n+1}$ contractions, *and let $S_n := W_n V_n$, $T_n := V_{n+1} W_n$.*

only up to small ε_n ?

Then there is a natural isometry

$$\mathrm{indlim}(S_n \colon A_n \to A_{n+1}) \cong \mathrm{indlim}(T_n \colon B_n \to B_{n+1})$$

given by $V_\infty|\operatorname{indlim}(S_n\colon A_n \to A_{n+1})$ *and* $W_\infty|\operatorname{indlim}(T_n\colon B_n \to B_{n+1})$*, where* $V_\infty\colon A_\infty \to B_\infty$ *and* $W_\infty\colon B_\infty \to A_\infty$ *are given on representatives of elements in* A_∞ *and* B_∞ *by*

$$(a_1, a_2, \ldots) \mapsto (V_1(a_1), V_2(a_2), \ldots)\,,$$

respectively

$$(b_1, b_2, \ldots) \mapsto (0, W_1(b_1), W_2(b_2), \ldots)\,.$$

Suppose now that the A_n *and* B_n *are operator spaces (respectively are* C^**-spaces or* C^**-algebras). The above given isomorphism is completely isometric (respectively completely positive, respective is a* C^**-algebra isomorphism), if, for every* $k \in \mathbb{N}$ *there is* $n(k) \in \mathbb{N}$ *such that* $V_n \otimes \mathrm{id}_k$ *and* $W_n \otimes \mathrm{id}_k$ *are contractive (respectively are positive, i.e., have positive second conjugates; respective the* V_n*,* W_n *are* C^**-morphisms).*

Proof. We have $T_{k,\infty}(V_k(a)) = V_\infty(S_{k,\infty}(a))$ for $a \in A_k$ because, for $n > k$ and $a \in A_k$,

$$V_n(W_{n-1}V_{n-1}(\cdots(W_kV_k(a))\cdots)) = T_{n-1}(\cdots(T_k(V_k(a))\cdots))\,.$$

Thus V_∞ maps $\operatorname{indlim}(S_n\colon A_n \to A_{n+1})$ into $\operatorname{indlim}(T_n\colon B_n \to B_{n+1})$.

A similar argument shows that W_∞ maps $\operatorname{indlim}(T_n\colon B_n \to B_{n+1})$ into $\operatorname{indlim}(S_n\colon A_n \to A_{n+1})$.

Straight calculation shows that $W_\infty \circ V_\infty = S_\infty$ and $V_\infty \circ W_\infty = T_\infty$, for the maps $S_\infty\colon A_\infty \to A_\infty$ and $T_\infty\colon B_\infty \to B_\infty$ given on representatives by

$$(a_1, a_2, \ldots, a_n, a_{n+1}\ldots) \mapsto (0, S_1(a_1), S_2(a_2), \ldots, S_{n-1}(a_{n-1}), S_n(a_n), \ldots)\,,$$

and

$$(b_1, b_2, \ldots, b_n, b_{n+1}\ldots) \mapsto (0, T_1(b_1), T_2(b_2), \ldots, T_{n-1}(b_{n-1}), T_n(b_n), \ldots)\,.$$

The operators S_∞ and T_∞ are contractions and fix the images of $\operatorname{indlim}(S_n\colon A_n \to A_{n+1}) \subseteq A_\infty$, respectively of $\operatorname{indlim}(T_n\colon B_n \to B_{n+1}) \subseteq B_\infty$. Indeed: On representatives one has $S_\infty(S_{n,\infty}(a_n)) = S_{n,\infty}(a_n)$ for $a_n \in A_n$.

Thus, the restriction of V_∞ defines an isometric linear isomorphism from $\operatorname{indlim}(S_n\colon A_n \to A_{n+1})$ onto $\operatorname{indlim}(T_n\colon B_n \to B_{n+1})$ with the restriction of W_∞ to $\operatorname{indlim}(T_n\colon B_n \to B_{n+1})$ as inverses.

Suppose now that the A_n and B_n are operator spaces, matrix operator systems, or C^*-spaces (all not necessarily unital). It follows, that this isomorphism is completely isometric (respectively are matrix-order isomorphisms) if V_∞ and W_∞ are completely contractive (respectively completely positive) on the images of the respective images of the inductive limits.

It suffices to suppose that for each $k \in \mathbb{N}$ there is $n(k) \in \mathbb{N}$ such that $V_n \otimes \mathrm{id}_k$ and $W_n \otimes \mathrm{id}_k$ are contractions (respectively are positive) for each $n \geq n(k)$. □

LEMMA A.14.2. *Suppose that* $B_1, B_2, \ldots$ *are separable Banach spaces and that* $\mathcal{G}_n \subseteq \mathcal{L}(B_n, B_{n+1})$ *are* subsets *of linear contractions from* B_n *into* B_{n+1}. *If, for each* $n \in \mathbb{N}$, *the operator* $T_n \colon B_n \to B_{n+1}$ *is in the point-norm closure of* $\mathcal{G}_n$ (= *closure of* $\mathcal{G}_n$ *in strong operator topology), then there exist* $g_1, g_2, \ldots \mathcal{G}$, *such that in* $\ell_\infty(B_1, B_2, \ldots)/c_0(B_1, B_2, \ldots)$ *the related inductive limits coincide:*

$$\text{indlim}(g_n \colon B_n \to B_{n+1}) = \text{indlim}(T_n \colon B_n \to B_{n+1}) .$$

We identify here the inductive limits with their canonical corresponding closed subspaces of $B_\infty := \ell_\infty(B_1, B_2, \ldots)/c_0(B_1, B_2, \ldots)$.

PROOF. There exist sequences $b_{1,n}, b_{2,n}, \ldots \in B_n$ that are dense in B_n, for each $n \in \mathbb{N}$.

We define $T_{m,n} \colon B_m \to B_n$ for $n \geq m$, by $T_{m,m} = \text{id}$ (identity map of B_m), $T_{n,n+1} := T_n$ $T_{m,n} := T_{n-1} \circ \cdots \circ T_{m+1} \circ T_m$ for $n > m$. We denote by

$$T_{m,\infty} \colon B_m \to X := \text{indlim}(T_n \colon B_n \to B_{n+1}) \subseteq B_\infty$$

the defining morphisms from B_m into X. Recall that for our realization $X \subseteq B_\infty$ of $\text{indlim}(T_n \colon B_n \to B_{n+1})$ holds

$$T_{m,\infty}(b) = (0, \ldots, 0, b, T_{m,m+1}(b), T_{m,m+2}(b), \ldots) + c_0(B_1, B_2, \ldots)$$

for $b \in B_m$. Then $T_{m,\infty} = T_{n,\infty} \circ T_{m,n}$.

The set $\{T_{m,\infty}(b_{k,m})\,;\ k, m \in \mathbb{N}\}$ is dense in $X := \text{indlim}(T_n \colon B_n \to B_{n+1})$, because X is the closure of $\bigcup_m T_{m,\infty}(B_m)$.

We find linear subspaces $L_n \subseteq B_n$ and $g_n \in \mathcal{G}_n$ of finite dimension, such that

(i) L_n contains the sets $T_{n-1}(L_{n-1}) \cup g_{n-1}(L_{n-1})$, $\{ b_{1,n}, b_{2,n}, \ldots, b_{n,n} \}$, and $\{T_{k,n}(b_{j,k})\,;\ 1 \leq k \leq n-1,\ j \leq n\}$, and $\{g_{k,n}(b_{j,k})\,;\ 1 \leq k < n-1,\ j \leq n\}$, where $g_{k,n} := g_{n-1} \circ \cdots \circ g_{k+1} \circ g_k$ for $1 \leq k < n-1$.
(ii) $\|T_n(b) - g_n(b)\| \leq 2^{-n}\|b\|$ for $b \in L_n$.

Then $T_n(L_n) \subseteq L_{n+1}$, $g_n(L_n) \subseteq L_{n+1}$, and $\text{indlim}(T_n \colon L_n \to L_{n+1})$ and $\text{indlim}(g_n \colon L_n \to L_{n+1})$ are the same closed subspaces of $(\prod_n L_n)/(\bigoplus_n L_n) \subseteq B_\infty$, because, $T_{m,\infty}(L_m) \subseteq T_{n,\infty}(L_n)$ and $g_{m,\infty}(L_m) \subseteq g_{n,\infty}(L_n)$ for $n \geq m$, and because, for $b \in L_m$,

$$\|T_{m,\infty}(b) - g_{m,\infty}(b)\| \leq \|b\| \cdot \sum_{n \geq m} \|(T_n - g_n)|L_n\| \ \leq\ \|b\| \cdot 2^{1-m} .$$

The set $\{T_{m,\infty}(b_{k,m})\,;\ m, k \in \mathbb{N}\}$ is dense in $\text{indlim}(T_n \colon B_n \to B_{n+1})$. The element $T_{m,n}(b_{k,m})$ is in L_n for $n > \max(k,m)$. Thus, $T_{m,\infty}(b_{k,m}) = T_{n,\infty}(T_{m,n}(b_{k,m})) \in T_{n+1,\infty}(L_{n+1})$. It shows that $\text{indlim}(T_n \colon L_n \to L_{n+1})$ is the same closed subspace of B_∞ as $\text{indlim}(T_n \colon B_n \to B_{n+1})$. Since also $g_{m,n}(b_{k,m})$ is in L_n for $n > \max(k,m)$, a similar argument shows that

$$\text{indlim}(g_n \colon L_n \to L_{n+1}) = \text{indlim}(g_n \colon B_n \to B_{n+1}) .$$

It is obvious that the resulting isomorphisms are, e.g. , C^*-algebra isomorphisms if the intertwining maps are e.g. C^*-morphisms. □

15. Intersection with sums of left and right ideals

The following Remark allows to circumvent in some cases the rather engaged general (semi-constructive) reduction to relatively weakly injective separable subspaces of operator spaces given in Section 14.

REMARK A.15.1. The sum $L+R \subseteq B$ of a closed left ideal L and a closed right ideal R of a C^*-algebra B is always a closed subspace of B, see Proposition A.15.2.

Thus, if D is a C^*-subalgebra of B with the *property* that $(D \cap L) + (D \cap R)$ is *dense* in $D \cap (L + R)$ then automatically $(D \cap L) + (D \cap R) = D \cap (L + R)$.

Density of $(D \cap L) + (D \cap R)$ in $D \cap (L + R)$ is a very special situation. The following trivial example shows this:

Let $B = \mathbb{C} \oplus \mathbb{C}$, $L := \mathbb{C} \oplus 0$, $R := 0 \oplus \mathbb{C}$ and $D := \mathbb{C} \cdot (1, 1)$. Then $D \cap (L+R) = D$ but $D \cap L = \{0\}$ and $D \cap R = \{0\}$.

But in the very particular case of Lemma B.14.1 where B is a C^*-algebra, $G \subseteq B$ separable subset, X is a closed left ideal and Y is a closed right ideal of B, we need only Part (2) of Sublemma B.14.2 to get a separable C^*-algebra D with $G \subseteq D$ and $(D \cap X) + (D \cap Y)$ dense in $D \cap (X + Y)$.

Then the equality follows from next Proposition A.15.2.

PROPOSITION A.15.2. *Let L a closed left ideal and R a closed right ideal of a C^*-algebra A. Consider the intersections $D := L^* \cap L$ and $E := R^* \cap R$. Then*

(i) *D and E are hereditary C^*-subalgebras A that are identical with the sets of products $L^* \cdot L = \{a^*b\,;\ a, b \in L\} = D$, respectively $R \cdot R^* = E$.*
(ii) *L and R are the element-wise products $L = A \cdot D$ and $R = E \cdot A$, where, e.g. , $A \cdot D := \{\, a \cdot d\,;\ d \in D\,, a \in A \,\}$.*
(iii) *Let $\eta := \pi_{L \cap R} \colon a \mapsto a + (L \cap R)$ denotes the quotient map from A onto $A/(L \cap R)$. For any $x \in L$ and $y \in R$ holds*

$$\max\big(\|\eta(x)\|,\, \|\eta(y)\|\big) \;\leq\; \|\eta(x+y)\| \;\leq\; 2\max\big(\|\eta(x)\|,\, \|\eta(y)\|\big)\,.$$

(iv) *The algebraic sum $L + R$ is a closed linear subspace of A.*
(v) *The second conjugate operator space of $A/(L+R)$ is naturally isomorphic to the ternary algebra $(1-q)A^{**}(1-p)$, where p and q are the "open" support projections in A^{**} for the hereditary C^*-subalgebras $D = L^* \cap L$ and $E = R^* \cap R$ of A. In particular,*

$$\|\pi_{L+R}(a)\| = \|(1-q)a(1-p)\| \qquad \textit{for all } a \in A\,. \tag{15.1}$$

Here L^* (respectively R^*) mean the right ideal (respectively left ideal) given by $L^* := \{a^*\,;\ a \in L\}$ and $R^* := \{a^*\,;\ a \in R\}$, – not the dual spaces. Our approach here ignores the general theory of operator spaces, because we try to derive all from basic knowledge about Functional analysis, as e.g. the "Krein bi-polar theorem" for convex subsets in locally convex vector spaces ... All that we show here prove in the same way the corresponding results for the operator-matrix norms, because e.g. $M_n(A/L) \cong M_n(A)/M_n(L)$ and $M_n(A) \cong M_n \otimes A$, ... etc. The following proof is not minimal, because contains some additional observations.

Proof. Clearly, $D := L^* \cap L = D^2$ because D is a C^*-algebra and every element of a C^*-algebra is the product of two elements, e.g. by using polar decomposition and roots of positive elements.

The closed left ideal L is a non-degenerate right module for the C^*-algebra D. Thus $L = L \cdot D$ by the Cohen factorization theorem A.11.1.

Then $A \cdot D \subseteq L$, $L = L \cdot D$ and $L \subseteq A$ give that $A \cdot D = L$. Since D is a hereditary C^*-subalgebra, we get $D = D^3 \subseteq DAD \subseteq D$. It follows $D = D^2 \subseteq L^* \cdot L = DA^2D \subseteq D$.

Similar considerations, – or passage to the left ideal $R^* := \{a^*\,;\ a \in R\}$ –, show also the corresponding results for closed right ideals of A and $E := R^* \cap R$.

Since $(L \cap R) \cdot D \subseteq L \cap R$ and $E \cdot (L \cap R) \subseteq L \cap R$ we get that

$$\operatorname{dist}(f \cdot x, L \cap R) \le \|f\| \cdot \operatorname{dist}(x, L \cap R)$$

for $f \in E$ and $x \in A$, and

$$\operatorname{dist}(x \cdot g, L \cap R) \le \|g\| \cdot \operatorname{dist}(x, L \cap R)$$

for $g \in D$, and $x \in A$.

Let $\eta := \pi_{L\cap R}$. Then obviously $\|\eta(x+y)\| \le \|\eta(x)\| + \|\eta(y)\| \le 2\max(\,\|\eta(x)\|,\, \|\eta(y)\|\,)$.

We show that $\max(\|\eta(x)\|,\, \|\eta(y)\|) \le \|\eta(x+y)\|$:

Let $x \in L$ and $y \in R$. Then $\eta((x+y)(x^*x)^{1/n}) = \eta(x(x^*x)^{1/n})$, because $y(x^*x)^{1/n} \in L \cap R$. We get an estimate

$$\operatorname{dist}((x+y)(x^*x)^{1/n}, L \cap R) \le \|x\|^{2/n} \operatorname{dist}((x+y), L \cap R)\,,$$

because $(x^*x)^{1/n} \in D$.

It follows that for all $n \in \mathbb{N}$, $\|\eta(x(x^*x)^{1/n})\| = \|\eta((x+y)(x^*x)^{1/n})\| \le \|x\|^{2/n}\|\eta(x+y)\|$. On the other hand, $\|\eta(x)\| \le \|\eta(x(x^*x)^{1/n})\| + \|x - x(x^*x)^{1/n}\|$.

Since $\lim_{n\to\infty} \|x\|^{2/n} = 1$ and $\lim_{n\to\infty} \|x - x(x^*x)^{1/n}\| = 0$, we obtain that $\|\eta(x)\| \le \|\eta(x+y)\|$. In the same way we get that $\|\eta(y)\| \le \|\eta(x+y)\|$.

It follows that the natural linear map from $B := L/(L\cap R) \oplus_\infty R/(L \cap R)$ onto the image $C := \eta(L+R) \subseteq A/(L \cap R)$ of the sum $L + R \subseteq A$ is a bijective linear map that maps the Banach space B onto the normed vector space C. The above given estimates show now that the norm on B induced by this map is equivalent to the given complete norm on B. Thus, B is also a Banach space with this new norm, and C is a Banach space with respect to the norm on C induced from $A/(L \cap R)$. This implies that C is closed in $A/(L\cap R)$. It follows that $L+R = \eta^{-1}(C)$ is closed in A.

Therefore $A/(L+R)$ is a well-defined Banach space. It is in a natural way an operator space, because we can in above observations A, L and R replace by $M_n(A) \cong M_n \otimes A$, $M_n(L)$ and $M_n(R)$.

The general theory of Banach spaces A shows that for closed linear subspaces X of A the bi-dual space $(A/X)^{**}$ is naturally isomorphic to $A^{**}/\mathrm{wcl}(X)$, where $\mathrm{wcl}(X)$ is the $\sigma(A^{**}, A^*)$-closure of X. It is identical with the bi-polar X^{oo} of X in A^{**}. It holds $\mathrm{dist}(a, X) = \mathrm{dist}(a, X^{oo})$ measured with the norm in A^{**}. Thus $\|\pi_X(a)\| = \|\pi_{X^{oo}}(a)\|$ for all $a \in A$.

In case of (matrix-normed) operator spaces this carries over to the matrix spaces $M_n(A)$, $M_n(X)$ and $M_n(A/X) \cong M_n(A)/M_n(X)$.

The $\sigma(A^{**}, A^*)$ closure of $L+R$ in A^{**} is $A^{**}p + qA^{**}$, where $p, q \in A^{**}$ are the "open" projections corresponding to the hereditary C^*-subalgebras D and E respectively.

The second conjugate of $A/(L+R)$ is the quotient of A^{**} by the bi-polar of $L+R$ in A^{**}. The bi-polar of $L+R$ is just the $\sigma(A^{**}, A^*)$-closure of $L+R$ in A^{**}. It contains the sum of $A^{**}p \cong L^{**}$ and $qA^{**} \cong R^{**}$, and it is not difficult to see that the unit-ball of $A^{**}p + q\,A^{**}$ is $\sigma(A^{**}, A^*)$-compact. Here p and q are the open projections in A^{**} corresponding to the hereditary C^*-subalgebras $D = L^* \cap L$ and $E := R^* \cap R$ of A. Thus, $\big(A/(L+R)\big)^{**}$ is natural isomorphic to $A^{**}/(A^{**}p + q\,A^{**})$.

It is easy to check that the norm of $\pi_{(A^{**}p+q\,A^{**})}(a)$ for $a \in A^{**}$ is equal to $\|(1-q)a(1-p)\|$.

In particular, $\|\pi_{L+R}(a)\| = \|(1-q)a(1-p)\|$ for all $a \in A$.

In every W*-algebra M holds: If $p, q \in M$ are projections, then

$$\mathrm{dist}(a, Mp + qM) = \|(1-q)a(1-p)\| \quad \text{for all } a \in M\,.$$

This is the case because $(1-q)a(1-p) - a \in Mp + qM$ and the map $T\colon M \ni a \mapsto (1-q)a(1-p)$ is a linear contraction with $T^2 = T$ and kernel $= Mp + qM$.

It follows that $\|\pi_{L+R}(a)\| = \mathrm{dist}(a, A^{**}p + qA^{**}) = \|(1-q)a(1-p)\|$ for all $a \in A$. □

COROLLARY A.15.3. *If L and R are closed left and right ideals of a C^*-algebra A and $B \subseteq A$ a separable C^*-subalgebra of A then there exists a separable C^*-algebra $C \subseteq A$ such that $B \subseteq C$ and*

$$B \cap (L+R) \subseteq (C \cap L) + (C \cap R)\,.$$

PROOF. By Proposition A.15.2(iv,v), the linear subspace $L+R$ is closed in A. Thus $B \cap (L+R)$ is a closed separable subspace of $L+R$ and of B. We find a dense sequence $\{b_1, b_2, \ldots\}$ in the unit-ball of the separable Banach space $B \cap (L+R)$. In $L+R$ are elements $c_n \in L$ and $d_n \in R$ such that $b_n = c_n + d_n$. The separable C^*-algebra C of A generated by B and $\{c_1, c_2, \ldots; d_1, d_2, \ldots\}$ has the properties that $B \subseteq C$, and that $C \cap L$ and $C \cap R$ are closed left and right ideals of C, and, by

Proposition A.15.2, $(C \cap L) + (C + R)$ is a closed subspace of C that contains a dense subset of $B \cap (L+R) \subset C$. Thus, $B \subseteq C$ and $B \cap (L+R) \subseteq (C \cap L) + (C \cap R)$. □

16. Surjectivity and control of perturbations

Let E and F be Banach spaces and T a bounded linear map from E into F. If X and Y are subsets of E, then $\mathrm{cl}(X)$ means the (norm-) closure of X, $\mathrm{wcl}(X) \subseteq E^{**}$ is the $\sigma(E^{**}, E^*)$-closure of X in the second conjugate space E^{**} of E, and $\mathrm{dist}_H(X, Y)$ denotes the *Hausdorff distance* between subsets $X, Y \subseteq E$ (or $X, Y \subseteq E^{**}$ or – more generally – subsets of any metric space E) that is given by

$$\mathrm{dist}_H(X, Y) := \sup\{\, \mathrm{dist}(a, Y), \mathrm{dist}(b, X)\, ;\ a \in X,\ \ b \in Y\,\}.$$

We denote by S the *open* unit ball of E.

`Does def. of` $f(x,T)$ `fit the case of` $T := \pi(c(.)d)$`?`

Suppose that there exists a function $f(t)$ of $t \in (0, 2]$ with the properties that $\lim_{t \to 0} f(t) = 0$ and that if $a, b \in S$ and $\|T(a) - T(b)\| < x$ then $\mathrm{dist}(a, S \cap T^{-1}(T(b)) \leq f(x)$.

This allows to show that T maps the closed unit ball $\overline{S}$ of E *onto* the closure of $T(S)$:

Since T is bounded, $T(\overline{S})$ is contained in the closure of $T(S)$.

Let $g_1, g_2, \ldots \in T(S) \subseteq F$ a Cauchy sequence that converges to some $h_\infty \in F$.

Find a subsequence $h_1, h_2, \ldots$ of (g_n) such that for each $e \in T^{-1}(h_n) \cap S$ there exists $e' \in T^{-1}(h_{n+1}) \cap S$ with $\|e' - e\| \leq f(\|h_{n+1} - h_n\|)$ and $\sum_n f(\|h_{n+1} - h_n\|) < \infty$.

The latter requires only that $\lim_{x \to 0} f(x) = 0$ if we pass to a suitable subsequence of (h_n) of (g_n).

Then one finds step-wise $e_n \in T^{-1}(h_n)$ with $\sum_n \|e_n - e_{n+1}\| < \infty$. It follows that (e_n) converges to some $e_\infty \in \overline{S}$ and $T(e_\infty) = h_\infty$.

We define a function $f(x, T)$ for $x \in (0, \infty)$ by

Definition A.16.1.

$$f(x, T) := \sup\{\, \mathrm{dist}_H\big(S \cap T^{-1}(T(a)),\ S \cap T^{-1}(T(b))\big)\, ;\ a, b \in S,\ \|T(a-b)\| \leq x\,\}.$$

Clearly $f(x, T)$ is an increasing function of $x \in (0, \infty)$. The *perturbation constant* $\mathrm{per}(T)$ will be defined by $\mathrm{per}(T) := \lim_{x \to 0} f(x, T)$.

Proposition A.16.2. *Let $x \mapsto f(x, T)$ the above defined function.*

(i) *$f(x, T)$ is a continuous increasing function on* $]0, \infty[$.
(ii) *$per(T) = 0$ implies* $T(\mathrm{cl}(S)) = \mathrm{cl}(T(S))$.
(iii) *$f(x, T) = f(x, T^{**})$ for every $x > 0$.*

Here T^{**} means the second adjoint operator of T. $f(x,T)$ is the infimum of all numbers $y > 0$ such that given $b \in S$, $d \in T(S)$ with $\|T(b) - d\| \leq x$ there exists a perturbation $b + h$ of b *inside* S such that $\|h\| \leq y$ and $T(b+h) = d$. Thus, $per(T) = 0$ says that a small perturbation inside $T(S)$ can be realized by a small perturbation inside S. The proofs and further results will be given in

Section **??** (= in old A).

Now let A be a C^*-algebra and L, R closed left and right ideals with open support projections l and r in A^{**} respectively, i.e., l, r are the open projections in A^{**} satisfying $A^{**}l = \mathrm{wcl}(L)$ and $rA^{**} = \mathrm{wcl}(R)$, cf. [**767**, vol.I, chp.III.,def.6.19,cor.6.20], [**616**, thm.3.10.7, prop.3,11.9, rem.3.11.10].

Put $q = 1 - l$ and $p = 1 - r$. Let b, d be elements of A^{**} in the multiplier algebra $\mathcal{M}(A)$ of A such that pbb^*p is invertible in $pA^{**}p$ with inverse g and qd^*dq is invertible in $qA^{**}q$ with inverse h.

The algebraic sum $R + L$ is a closed linear subspace of A, $\mathrm{wcl}(L+R) = A^{**}l + rA^{**}$ and $\|\pi_{L+R}(a)\| = \|(1-r)a(1-l)\|$ for all $a \in\in A$ by Proposition A.15.2.

We denote by $\pi = \pi_{L,R}$ the quotient map $A \to A/(L+R)$ given by $c \to c + L + R$ and denote by $\pi(b(.)d)$ the map given by $c \to bcd + L + R$ for $c \in A$.

Proposition A.16.3. *$f(x,T) \leq x(\|g\| \ \|h\|)^{1/2} + (2x(\|g\| \ \|h\|)^{1/2})^{1/2}$, where $T := \pi(b(.)d)$.*

The Proof follows from Corollaries **??** (old cor.A.2.9 ???) and **??** (old cor.A.3.2 ???) (cf. Section **??** old A.4?).

We obtain from Propositions A.16.2(ii) and A.16.3 immediately the following corollary:

Corollary A.16.4. *Under the above assumptions concerning A, L, R, b and d the quotient map $A \to A/(L+R)$ maps $b(\mathrm{cl}(S))d$ onto a closed set.*

In particular the quotient map maps the closed unit ball of A onto the closed unit ball of $A/(L+R)$.

For every positive integer n, the map $[b_{j,k}]_n \to [pb_{j,k}q]_n$ from $M_n(A^{**}) \cong M_n(A)^{**}$ onto $M_n(pA^{**}q)$ is a contraction and has kernel $M_n(A^{**}l + rA^{**}) = M_n(\mathrm{wcl}(L+R)) \cong \mathrm{wcl}(M_n(L+R))$; passage to the quotient space defines an isometric M_n–bimodule isomorphism from $(M_n(A)/M_n(L+R))^{**} \cong M_n(A^{**})/M_n(\mathrm{wcl}(L+R))$ onto $M_n(pA^{**}q)$. On the other hand there is a natural M_n–bimodule isomorphism from $M_n(A/(L+R))$ onto $M_n(A)/M_n(L+R)$. The matrix norms induced by these isomorphisms give $A/(L+R)$ the structure of a *matrix normed space* in the sense of

Effros [EF2]

such that the second conjugate matrix normed space is completely isometrically isomorphic to $pA^{**}q$, an operator subspace of A^{**} and C^*-triple system,

cf. Section **??**.

If moreover A is unital and $L = \{b^*: b \in R\}$ then $p = q$ and, under the above identifications, $A/(L+R) = pAp \subseteq pA^{**}p$ becomes a matrix order unit space in the sense of [**235**] with matrix order unit $p \in A/(L+R)$ such that the second conjugate matrix order unit space is just the unital C^*-algebra $pA^{**}p$, thus then $A/(L+R)$ is an operator space in the sense of [**245**]. More generally we call a matrix order unit space X a *C^*-system* if its second conjugate matrix order unit space X^{**} is unitally matrix order isomorphic to a unital C^*-algebra. Then X is an operator system in the sense of

??? ??? [C/E2],

i.e., a closed unital and selfadjoint linear subspace of a C^*-algebra together with the matrix order inherited from the inclusion. The C^*-algebra structure on X^{**} is uniquely determined as the second conjugate matrix order unit structure of the given one on X and we can define the *left multiplier algebra* $\mathcal{M}_\ell(X)$, the *right multiplier algebra* $\mathcal{M}_r(X)$ and the *multiplier algebra* $\mathcal{M}(X)$ of X as follows: $\mathcal{M}_\ell(X) := \{b \in X^{**}: bX \subseteq X\}$, $\mathcal{M}_r(X) := \{b \in X^{**}: Xb \subseteq X\}$, $\mathcal{M}(X) := \mathcal{M}_\ell(X) \cap \mathcal{M}_r(X)$. Here we identify X with its canonical and isometric image in X^{**} by the evaluation map $\mathrm{ev}_X : X \to X^{**}$. The algebras $\mathcal{M}_\ell(X)$ and $\mathcal{M}_r(X)$ are closed subalgebras of X^{**} contained in X (more precisely: in the image of $\mathrm{ev}_X : X \to X^{**}$), $\mathcal{M}_\ell(X) = \{b^*: b \in \mathcal{M}_r(X)\}$ and the multiplier algebra $\mathcal{M}(X)$ of X is a unital C^*-algebra which is unitally completely positively and completely isometrically contained in the operator system X. In our special case $A/(L+R)$ is identified with $pAp (\subseteq pA^{**}p \subseteq A^{**})$ and $\mathcal{M}_r(A/(L+R)) = \{pbp;\ b \in A, pApbp \subseteq pAp\}$, $\mathcal{M}(A/(L+R)) = \{pbp;\ b \in A, pbpAp + pApbp \subseteq pAp\}$.

Let D be a hereditary C^*-subalgebra of A (i.e. D closed, selfadjoint and $DAD \subseteq D$). An element $b \in A$ that satisfies $Db \subseteq D$ (respectively $bD \subseteq D$, $bD + Db \subseteq D$) a *right normalizer* (respectively *left normalizer*, *normalizer*) of D in A. The right normalizers, left normalizers, normalizers obviously form closed operator algebras $\mathcal{N}_r(D)$, $\mathcal{N}_\ell(D)$ and $\mathcal{N}(D)$ respectively, $\mathcal{N}_r(D) = \{b^*: b \in \mathcal{N}_\ell(D)\}$ and $\mathcal{N}(D) = \mathcal{N}_\ell(D) \cap \mathcal{N}_r(D)$ is a C^*-subalgebra of A. Notice that $L = A \cdot D$ and $R = D \cdot A$ are closed left and right ideals of A, respectively, whose support projections in A^{**} are equal that of D (i.e., are equal to the unit element of $D^{**} = \mathrm{wcl}(D) \subseteq A^{**}$). From definitions we see that $L = \mathrm{cl}(AD) = A \cdot D \subseteq \mathcal{N}_r(D)$, $R = \mathrm{cl}(DA) \subseteq \mathcal{N}_\ell(D)$ and $D \subseteq \mathcal{N}(D)$ are closed ideals of $\mathcal{N}_r(D)$, $\mathcal{N}_\ell(D)$ and $\mathcal{N}(D)$ respectively.

We define $A//D := A/(\mathrm{cl}(AD) + \mathrm{cl}(DA))$, the (unital) *quotient–C^*-system* of the unital C^*-algebra A *with respect to the hereditary C^*-subalgebra* D of A. We denote again by $\pi_D : A \to A//D$ the quotient map $b \mapsto b + \mathrm{cl}(AD) + \mathrm{cl}(DA)$. Now we are in position to state the main result of this section.

Theorem A.16.5. *Let A be a unital C^*-algebra. D a hereditary C^*-subalgebra of A, $A//D := A/(AD + DA)$ the quotient–C^*-system of A with respect to D and $\pi_D : A \to A//D$ the quotient map.*

(i) *The restriction of* π_D *to* $\mathcal{N}_r(D)$ *(resp. to* $\mathcal{N}_\ell(D)$*) is a Banach algebra epimorphism onto* $\mathcal{M}_r(A//D)$ *(resp. onto* $\mathcal{M}_\ell(A//D)$*) with kernel* $\mathrm{cl}(AD)$ *(resp.* $\mathrm{cl}(DA)$*),*

(ii) *for every positive integer* n, $\pi_D \otimes \mathrm{id}_n$ *maps the closed unit ball of*

$$\mathcal{N}_r(M_n(D)) = M_n(\mathcal{N}_r(D)) \subseteq M_n(A)$$

onto the closed unit ball of

$$M_n(\mathcal{M}_r(A//D)) \subseteq M_n(A//D) \cong M_n(A)//M_n(D)\,,$$

(iii) $\pi_D|\mathcal{N}(D)$ *is a* C^**-algebra epimorphism from the (two-sided) normalizer algebra* $\mathcal{N}(D) \subseteq A$ *of* D *onto the multiplier algebra* $\mathcal{M}(A//D)$ *of* $A//D$ *with kernel ideal* $\ker(\pi_D|\mathcal{N}(D)) = D$.

As a corollary we get the following which can be seen as alternative formulation of

REFERENCE ?

Theorem **??** in view of Proposition **??**.

Corollary A.16.6. *Let* A *and* C *be unital* C^**-algebras,* B *a unital closed subalgebra of* C *and* $V\colon A//D \to C$ *a unital completely isometric map such that* $B \cup \{b^*b\colon b \in B\} \subseteq Im(V)$*. Then there exists a unital closed subalgebra* E *of* A *such that*

(i) $E \cap (\mathrm{cl}(AD) + \mathrm{cl}(DA)) = \mathrm{cl}(AD)$,

(ii) $V \circ \pi_D|E$ *is a Banach algebra epimorphism form* E *onto* B *with kernel* $\mathrm{cl}(AD)$ *and*

(iii) *the induced map* $[V \circ \pi_D]^0\colon E/\mathrm{cl}(AD) \to B$ *is completely isometric, where* B *is equipped with the matrix norms induced by* C *and* $E/\mathrm{cl}(AD)$ *is equipped with the matrix norms induced by the inclusion* $A/\mathrm{cl}(AD) \subseteq A^{**}p$.

If moreover B *is a* C^**-subalgebra of* C *then there exists a unital* C^**-subalgebra* F *of* A *such that*

(iv) $F \cap (\mathrm{cl}(DA) + \mathrm{cl}(AD)) = D$ *and*

(v) $V \circ \pi_D|F$ *is a* C^**-algebra epimorphism from* F *onto* B *with kernel* D.

With other words and under the assumptions of Corollary A.16.6: B is a C^*-quotient algebra of a C^*-subalgebra of A if B is a C^*-subalgebra of C. Theorem **??** and Corollary **??** are proven in Section **??**.

??? `Give ref. to suitable place` In a forthcoming paper we shall show:

The assumptions of Corollary **??** *are satisfied with the CAR-algebra* $A := M_{2^\infty}$ *and with* D,C *and* V *suitably chosen if and only if* B *is separable and exact in the sense of* [KI2], cf. [KI4].

Notice that all proofs work both in real and complex case. There are shorter proofs if one is interested only in the results of Theorem **??**(iii) and Corollary **??**(iv,v).

The results presented here are essentially reworking of material which has been circulating as preprint since 1989. Results similar to those of Corollary ???1.3??? and Theorem ???1.4(i)??? are also contained in preprints of L. Brown [BR], where he gives proofs using different methods and estimates.

17. On perturbation of unitaries

`Change here all signs to Halmos unitary !`

If b is a contraction on a Hilbert space we denote by $U(b) \in M_2(A)$ the "Halmos unitary" matrix defined in Remark 4.2.4, i.e., the matrix

$$\begin{bmatrix} b\,, & -(1-bb^*)^{1/2} \\ (1-b^*b)^{1/2}, & b^* \end{bmatrix}.$$

We are going to prove the following Proposition A.17.1 and its Corollary A.17.2.

Proposition A.17.1. *Let A denote a complex (or real) unital C^*-algebra, u a unitary in A and p,q a pair of projections in A such that $\|puq\| < 1$. Then for every contraction b in pAq there exists a unitary $\tilde{u}$ in A such that $p\tilde{u}q = b$ and $\|u - \tilde{u}\| = \|U(puq) - U(b)\|$.*

Corollary A.17.2. *Let A be a unital C^*-algebra (real or complex), p,q nonzero projections in A and T the natural map from A onto pAq given by $T(a) = paq$ (a in A). Then the perturbation function $f(x,T)$ of T, cf. Definition A.16.1, can be estimated by $f(x,T) \le x + (2x)^{1/2}$.*

We need some preliminary lemmata. To simplify notation, let $\operatorname{diag}(a,b,\ldots)$ denote the diagonal matrix with diagonal elements $a,b,\ldots$, let $M(c)$ be the matrix

$$\begin{bmatrix} c\,, & -(p-cc^*)^{1/2} \\ (q-c^*c)^{1/2}, & c^* \end{bmatrix}$$

if c is a contraction in pAq and let us denote by Z the matrix

$$\begin{bmatrix} 0, & 1 \\ 1, & 0 \end{bmatrix}.$$

Lemma A.17.3. *Let A be a C^*-algebra, p,q projections in A, a in pAq, d in qAp such that a and*

$$N := \begin{bmatrix} a\,, & -(p-aa^*)^{1/2} \\ (q-a^*a)^{1/2}, & d \end{bmatrix}$$

are contractions in $M_2(A)$.
Then $M(a)$ satisfies $M(a)^*M(a) = \operatorname{diag}(q,p)$, $M(a)M(a)^* = \operatorname{diag}(p,q)$.
If moreover $\|a\| < 1$ then $d = a^*$.

Proof. $(1-aa^*)^{1/2}p = p(1-aa^*)^{1/2} = (p-aa^*)^{1/2}$ and $q(1-a^*a)^{1/2} = (1-a^*a)^{1/2}q = (q-a^*a)^{1/2}$ because $aa^* \le p,\ \ aa^* \le q$ and $paq = a$. It follows that $a^*(p-aa^*)^{1/2} = (q-a^*a)^{1/2}a^*$, $(p-aa^*)^{1/2}a = a(q-a^*a)^{1/2}$, and $(q-a^*a)^{1/2}d = (1-a^*a)^{1/2}d$. Put $M := M(a)$. Using these identities straightforward computations show $M^*M = \operatorname{diag}(q,p)$ and $MM^* = \operatorname{diag}(p,q)$. Moreover

$$M^*N = \operatorname{diag}(q, p-aa^*-ad) + \operatorname{diag}(c,0)Z$$

where $c := a^*(p-aa^*)^{1/2} + (q-a^*a)^{1/2}d$. But $\|M^*N\| \le \|M^*\|\cdot\|N\| \le 1$ by the assumptions on N and the above observations concerning M. Looking to the $(1,1)$-element of $(M^*N)(M^*N)^*$ we obtain $\|q+cc^*\| \le 1$. On the other hand $c = qc$ by the above identities. Thus $q+cc^* = q(q+cc^*)q \le q$, i.e., $c=0$. It follows:

$$(1-a^*a)^{1/2}(-a^*) = -a^*(p-aa^*)^{1/2} = (q-a^*a)^{1/2}d = (1-a^*a)^{1/2}d\,.$$

If $\|a\|<1$ then $(1-a^*a)^{1/2}$ is invertible and $d=-a^*$. □

Lemma A.17.4. *Let be A, a, p and q as in Lemma A.17.3 and $\|a\|<1$. If the matrix*

$$V := \begin{bmatrix} a, & (p-aa^*)^{1/2}, & g \\ (q-a^*a)^{1/2}, & d, & h \\ f, & k, & e \end{bmatrix}$$

is a partial isometry in $M_3(A)$ such that $V^*V = \operatorname{diag}(q,p,s)$ and $VV^* = \operatorname{diag}(p,q,r)$ then $f=g=h=k=0$, $d=-a^*$, $e^*e=s$ and $ee^*=r$.

Proof. The upper left 2×2-sub-matrix of V must be a contraction in $M_2(A)$. By Lemma A.17.3, $d=-a^*$ because $\|a\|<1$. Using now the equality $VV^* = \operatorname{diag}(p,q,r)$ from $d=-a^*$ we get $gg^*=0$, $hh^*=0$, and using $V^*V = \operatorname{diag}(q,p,s)$, we obtain $f^*f=0$, $k^*k=0$. From $f=g=h=k=0$ it follows that $e^*e=s$ and $ee^*=r$. □

Lemma A.17.5. *Let p,q,r,s be projections in a unital C^*-algebra A and $v,w \in A$ such that $v^*v=q,\ \ ww^*=p,\ \ p+r+vv^*=1$ and $q+s+w^*w=1$. Put*

$$D := \begin{bmatrix} p, & v, & r \\ 0, & 0, & 0 \\ 0, & 0, & 0 \end{bmatrix},\ E := \begin{bmatrix} q, & w^*, & s \\ 0, & 0, & 0 \\ 0, & 0, & 0 \end{bmatrix},\ F(y) := \begin{bmatrix} y, & 0, & 0 \\ 0, & 0, & 0 \\ 0, & 0, & 0 \end{bmatrix}.$$

And $G(y) := D^*F(y)D$, $H(y) := E^*F(y)E$, $T(y) := D^*F(y)E$ if y is in A. Then, for each $y\in A$,

(i)

$$T(y) = \begin{bmatrix} pyq, & pyw^*, & pys \\ v^*yq, & v^*yw^*, & v^*ys \\ ryq, & ryw^*, & rys \end{bmatrix}.$$

(ii) *G and H are injective C^*-morphisms from A into $M_3(A)$ such that $G(1) = \operatorname{diag}(p,q,r)$ and $H(1) = \operatorname{diag}(q,p,s)$.*

(iii) *T is an isometry from A into $M_3(A)$ such that $T(y)T(y)^* = G(yy^*)$ and $T(y)^*T(y) = H(y^*y)$ for $y\in A$.*

(iv)

$$T(a + vb + cw + vdw + e) = \begin{bmatrix} a, & c, & 0 \\ b, & d, & 0 \\ 0, & 0, & e \end{bmatrix}$$

if $e \in rAs$, $a \in pAq$, $b \in qAq$, $c \in pAp$ *and* $d \in qAp$.

(v) *If* $y \in A$ *then the equality*

$$T(y) = \begin{bmatrix} a, & c, & 0 \\ b, & d, & 0 \\ 0, & 0, & e \end{bmatrix}$$

implies $y = a+vb+cw+vdw+e$ *with* $e \in rAs$, $a \in pAq$, $b \in qAq$, $c \in pAp$ *and* $d \in qAp$.

(vi) *An element* $y = a+vb+cw+vdw+e$ *satisfying the conditions of Part(iv) is a unitary of A if and only if the upper left* 2×2*–submatrix is a partial isometry (say* W*) in* $M_2(A)$ *with* $W^*W = \mathrm{diag}(q,p)$ *and* $WW^* = \mathrm{diag}(p,q)$ *and* e *is a partial isometry with* $e^*e = s$ *and* $ee^* = r$.

Proof. (i) is obvious.

(ii,iii): We denote $M_3(A)$ by B and the projection $\mathrm{diag}(1,0,0) = F(1)$ by P. Then F defines a unital C^*-algebra isomorphism from A onto PBP. By our assumptions $DD^* = P = EE^*$. Thus $z \to D^*zE$, $z \to D^*zD$ and $z \to E^*zE$ define linear isometries from PBP onto D^*DBE^*E, D^*DBD^*D and E^*EBE^*E respectively. Moreover the latter two are unital C^*-algebra isomorphisms.

$$T(y)T(y)^* = D^*F(y)EE^*F(y^*)D = D^*F(yy^*)D = G(yy^*)$$

and $T(y)^*T(y) = H(y^*y)$. Hence T is an isometry from A onto D^*DBE^*E and G, H are unital $*$-isomorphisms from A onto D^*DBD^*D and E^*EBE^*E respectively. Computations show that $G(1) = D^*D = \mathrm{diag}(p,q,r)$ and $H(1) = E^*E = \mathrm{diag}(q,p,s)$.

(iv): By the assumptions on p, q, r, s, w, v we have $ws = qs = rv = rp = pv = wq = 0$. Put $y := a + vb + cw + vdw + e$. Then by the assumptions on a, b, c, d, e we have $ry = e = ys = rys$. With $g = y - e$ by (i) it follows that

$$T(y) = \begin{bmatrix} pgq, & pgw^*, & 0 \\ v^*gq, & v^*gw^*, & 0 \\ 0, & 0, & e \end{bmatrix}.$$

Using $pv = wq = 0$ we get $pgq = paq = a$, $pgw^* = cww^* = cp = c$, $v^*gq = v^*vb = qb = b$ and $v^*gw^* = v^*vdww^* = qdp = d$.

(v): As we have seen in the proofs of (ii) and (iii), T defines an isometry from A onto $\mathrm{diag}(p,q,r)B\,\mathrm{diag}(q,p,s)$.

From $T(y) = \mathrm{diag}(p,q,r)T(y)\,\mathrm{diag}(q,p,s)$ we see that $a = paq$, $b = qbq$, etc. Put $z := a + vb + cw + vdw + e$. Then by (iv), $T(z) = T(y)$. But $\ker(T) = 0$, i.e. $y = z$.

(vi): By (ii), (iii) and (iv),

$$\begin{aligned}
&W^*W = \mathrm{diag}(q,p),\ \ WW^* = \mathrm{diag}(p,q),\ \ e^*e = s \ \text{ and } \ ee^* = r && \text{if and only if}\\
&T(y)^*T(y) = H(1) \ \text{ and } \ T(y)T(y)^* = G(1) && \text{if and only if}\\
&H(1-y^*y) = 0 \ \text{ and } \ G(1-yy^*) = 0 && \text{if and only if}\\
&y^*y = 1 = yy^* .
\end{aligned}$$

□

Proof of Proposition A.17.1. :
We put $a = puq$. Then $\|a\| < 1$, $(1-a^*a)^{-1/2}$ and $(1-aa^*)^{-1/2}$ exist. Let $v = (1-p)uq(1-a^*a)^{-1/2}$ and $w = (1-aa^*)^{-1/2}pu(1-q)$. We have $v^*v = (1-a^*a)^{-1/2}qu^*(1-p)uq(1-a^*a)^{-1/2} = (1-a^*a)^{-1/2}(q-a^*a)(1-a^*a)^{-1/2} = q$ because $qa^*a = a^*a = a^*aq$. Similarly we obtain $ww^* = p$. In particular w and v are partial isometries. By definitions of v and w we have $(1-p)v = v$, $w(1-q) = w$,

$$(1-p)uq = v(1-a^*a)^{1/2} = vq(1-a^*a)^{1/2} = v(q-a^*a)^{1/2} ,$$

and $pu(1-q) = (p-aa^*)^{1/2}w$. Thus

$$vv^* \le 1-p,\ \ w^*w \le 1-q,\ \ v^*uq = (q-a^*a)^{1/2}$$

and $puw^* = (p-aa^*)^{1/2}$. Put $r = 1-p-vv^*$ and $s = 1-q-w^*w$. Then p, v, r, q, w, s satisfy the assumptions of Lemma A.17.5 and $T(u)$ defined there satisfies $T(u)^*T(u) = H(u^*u) = H(1) = \mathrm{diag}(q,p,s)$, $T(u)T(u)^* = G(1) = \mathrm{diag}(p,q,r)$ by Lemma A.17.5(ii,iii). Moreover, by Lemma A.17.5(i) and the above equations, the Lemma A.17.4 applies to $T(u)$:

$$T(u) = \begin{bmatrix} a, & (p-aa^*)^{1/2}, & 0 \\ (q-a^*a)^{1/2}, & -a^*, & 0 \\ 0, & 0, & e \end{bmatrix}$$

with $e^*e = s$, $ee^* = r$. We put $\tilde{u} = b + v(q-b^*b)^{1/2} + (p-bb^*)^{1/2}w - vb^*w + e$. By Lemma A.17.5(iv),

$$T(\tilde{u}) = \begin{bmatrix} b, & (p-bb^*)^{1/2}, & 0 \\ (q-b^*b)^{1/2}, & -b^*, & 0 \\ 0, & 0, & e \end{bmatrix} .$$

By Lemma A.17.3 and Lemma A.17.5(vi), the element $\tilde{u}$ is a unitary in A. We have $\|u-\tilde{u}\| = \|T(u-\tilde{u})\| = \|M(a)-M(b)\|$.
Now if $c \in pAq$ then $U(c) = M(c) + \mathrm{diag}(1-p, 1-q)Z$.
Thus $\|u-\tilde{u}\| = \|U(a)-U(b)\| = \|U(puq)-U(b)\|$. □

Lemma A.17.6. *Let be a, b contractions and h, k positive selfadjoint operators on a Hilbert space. Then*

(i) $\|h^{1/2}-k^{1/2}\| \le \|h-k\|^{1/2}$,
(ii) $\|a^*a-b^*b\| \le 2\|a-b\|$,
(iii) $\|U(a)-U(b)\| \le \|a-b\| + (2\|a-b\|)^{1/2}$.

PROOF. (i): Let $t = \|h-k\|$. Then $h+t \leq (h^{1/2}+t^{1/2})^2$ and $k \leq h+t$. The function $g(t) = t^{1/2}$ is operator monotone on $[0,\infty)$, cf. [**767**, Prop.I.6.3].

Thus $k^{1/2} \leq (h+t)^{1/2} \leq h^{1/2}+t^{1/2}$ and we can interchange k and h in this inequality.

(ii): $a^*a - b^*b = a^*(a-b) + (a-b)^*b$.

(iii): Let

$$c := \operatorname{diag}\big((1-aa^*)^{1/2} - (1-bb^*)^{1/2},\ (1-a^*a)^{1/2} - (1-b^*b)^{1/2}\big)\,.$$

By (i) and (ii) we get $\|c\| \leq (2\|a-b\|)^{1/2}$.
We have $U(a) - U(b) = \operatorname{diag}(a-b, (a-b)^*) + cZ$. □

PROOF OF COROLLARY A.17.2. :
Let be $a, b \in A$ and $x > 0$ such that $pbq = b$, $\|a\| < 1$, $\|b\| < 1$ and $\|paq - b\| < x$. Define $P := \operatorname{diag}(p, 0)$, $Q := \operatorname{diag}(q, 0)$, $B = \operatorname{diag}(b, 0)$ and $u := U(a)$ (almost Halmos unitary). Then u is a unitary in $M_2(A)$ such that $PuQ = \operatorname{diag}(paq, 0)$, $\|PuQ\| \leq \|a\| < 1$ and $\|PuQ - B\| = \|paq - b\| < x$.

Moreover $PBQ = B$ and $\|B\| = \|b\| < 1$. By Proposition A.17.1 there exists a unitary $\tilde{u} \in M_2(A)$ such that $\|u - \tilde{u}\| = \|U(PuQ) - U(B)\|$ and $\operatorname{diag}(pcq, 0) = P\tilde{u}Q = B = \operatorname{diag}(b, 0)$ where c means the (1,1)–element of the unitary 2×2–matrix $\tilde{u}$. Looking at the (1,1)–element of $u - \tilde{u}$ by Lemma A.17.6(iii) we obtain $\|a - c\| \leq \|u - \tilde{u}\| \leq \|U(PuQ) - U(B)\| < x + (2x)^{1/2}$. On the other hand, $\|c\| \leq \|\tilde{u}\| = 1$ and $pcq = b$. Now let $0 < t < 2$. Put $s = 1 - (t/2)$ and $e = (p + s(1-p))c(q + s(1-q))$. Then $peq = pcq = b$, $\|e - c\| \leq 2(1-s) = t$, $\|a - e\| < t + x + (2x)^{1/2}$,

$$\|(p + s(1-p))cq\| \leq (1-s)\|b\| + s\|cq\| \leq 1 - (1-s)(1 - \|b\|)$$

and $\|e\| \leq 1 - (1-s)^2(1 - \|b\|) < 1$.
Thus, $f(x, T) \leq x + (2x)^{1/2}$ by Lemma 2.3(i) (of some other paper!) ?. □

Partly TRANSPORT from old Chp. 2:

List of equivalent properties
of open projections is given below.

DEFINITION A.18.1. Let A a C^*-algebra.

The projection $p \in A^{**}$ is **open** (with respect to A) if $A^{**}p$ is the $\sigma(A^{**}, A)$-closure of the left ideal $L_p := \{a \in A\,;\ a(1-p) = 0\}$.

A projection $q \in A^{**}$ is **closed** if $p := 1 - q$ is an open projection.

The following proposition given equivalent characterizations of open projections $p \in A^{**}$, respectively of closed projections $q = 1 - p \in A^{**}$. (We use for a linear functional $\varphi \in A$ and its normal extension to A^{**} the same notation φ, i.e., we identify A^* and the predual $(A^{**})_*$ of the bi-dual W*-algebra A^{**} in a natural way.)

PROPOSITION A.18.2. *Let A a C^*-algebra, $p \in A^{**}$ a projection and $q := 1-p$. The following are equivalent:*

(i) *p is open (i.e., q is closed).*
(ii) *p is the (unique) smallest projection in A^{**} with $ap = a$ for all $a \in A_+$ with $a(1-p) = 0$.*
(iii) *The convex cone $C(q)$ of all normal positive functionals on A^{**} with $\varphi(q) = \|\varphi\|$ (i.e., with $\varphi(p) = 0$) is $\sigma(A_*, A)$-closed in A_*.*
(iv) *The convex subset*

$$Q(q) := \{\varphi \in (A_*)_+\,;\ \varphi(q) = 0\,,\ \|\varphi\| \leq 1\}$$

of the quasi-state space $Q(A) \subseteq A^*$ of A is $\sigma(A^*, A)$-closed (i.e., is a weakly closed face of $Q(A)$).
(v) *The left A^{**}-module A^*q is $\sigma(A^*, A)$-closed in A^*.*
(vi) *$A^{**}p$ is the $\sigma(A^{**}, A^*)$-closure of $A \cap (A^{**}p)$.*
(vii) *The projection p is the least upper bound in A^{**} for the set $\{a \in A_+\,;\ ap = a,\ \|a\| \leq 1\}$ of positive contractions.*
(viii) *The projection $p \in A^{**}$ is the support projection of the hereditary C^*-subalgebra $D \subseteq A$ of A defined by $D := \{a \in A\,;\ (aa^* + a^*a)q = 0\,\}$.*
(ix) This property is not? sufficient ?:

For every pure state φ of A with $\varphi(p) = 1$, (i.e., $\varphi(q) = 0$) there exists $a \in A_+$ with $\|a\| = 1$, $ap = p$ and $\varphi(a) = 1$.

(It delivers that $p \geq q$ for some open projection. Let $L_p = \{b \in A\ \ b(1-p) = 0\}$ it is a left ideal with open support projection

Hope? Perhaps next has to be added:

If ψ is a quasi-state on A with $\psi(p) = 1$ then there exists a pure state φ in the weakly closed face of $\mathrm{Q}(A)$ generated by ψ with $\varphi(p) \neq 0$.

Or: p is determined by its discrete part.

The equivalences of Parts (i)-(viii) are – at least implicitly – contained in the book of G.K. Pedersen, cf. [**616**, thm. 3.6.11,thm. 3.10.7] and its proofs, or are obvious reformulations of each other. We prove here only the equivalence of the Parts (viii) and (ix).

PROOF. (viii)⇒(ix): If $p \in A^{**}$ is an open projection and $\varphi \in A^*_+$ is a pure state on A with $\varphi(1-q) = 0$, then $\varphi|D$ is a state on D.

This restriction to D is pure on D: If ψ_1 and ψ_2 are states on D with $\psi_1+\psi_2 = 2\varphi$ then this happens also for the all (the unique) normal extensions $\overline{\psi_k}$ of ψ_k to states on A^{**} and implies that $\psi_1 = \psi_2 = \varphi$.

By ????? excision lemma??? reference ???? there exists for the pure state $\varphi|D$ an positive contraction $a \in D_+$ with $\varphi(a) = 1$. Clearly, $1 = \varphi(a) \leq \|a\| \leq 1$, and $ap = a$. because $a \in D_+$.

(ix)⇒(viii): Suppose that for every pure state φ of A with $\varphi(p) = 1$, (i.e., $\varphi(q) = 0$) there exists $a \in A_+$ with $\|a\| = 1$, $ap = p$ and $\varphi(a) = 1$.

Let $L := \{a \in A\,;\, a(1-p) = 0\} = \{a \in A\,;\, ap = a\}$. Then L is a closed left ideal of A and the positive contractions in L generate L. Clearly the open support projection $q \in A$ of the hereditary C^*-subalgebra $L^* \cap L$ satisfies again $(1-p)q(1-p) = 0$. Thus $qp = q$ and $r \leq q$ for all open projections $r \in A^{**}$ with $r(1-p) = 0$. □

Notice that Part (ix) of Proposition A.18.2 is a non-commutative version of the original definition of F. Hausdorff of open subsets $U \subseteq X$ of a metric space X: U is open, if and only if, for each point $x \in U$ there exists a (bounded) continuous function $f \in \mathrm{C_b}(X)_+$ with $f(x) = 1$, $\|f\| \leq 1$ such that the support of f is contained in U.

Notice that ???????

```
Before next:
Here we have first to show that
```
$a \in A \mapsto a + (R+L) \in A/(R+L)$ `maps`
```
the closed unit-ball onto the closed unit ball.!!!
```

One of the obvious consequences is the following Corollary is equivalent to the "advanced Kadison transitivity" in Lemma 2.1.15(i,ii).

COROLLARY A.18.3. *If $p \in A^{**}$ is a projection such that $pA^{**}p$ has finite dimension (as vector space) then p is a closed projection and there is a closed left-ideal $L \subseteq A$ such that $A^{**}(1-p)$ is the $\sigma(A^{**}, A^*)$-closure of L in A^{**}.*

In particular, the natural map $a \in A \to pap$ defines an isometric isomorphism from $A/(L^*+L)$ onto $pA^{**}p$, that maps the closed unit-ball of A onto *the closed unit-ball of $pA^{**}p$.*

It is well known for Banach spaces that π_X maps the open unit-ball of a Banach space A maps onto the open unit ball of A/X for each closed linear subspace of X.

Notice that $R + L$ is a closed subspace of a C^*-algebra A for any closed left-ideals L and right ideals R, cf. Proposition A.15.2.

The bipolar of $R+L$ ($=\sigma(A^{**},A^*)$-closure of $R+L$) is identical with $A^{**}P+QA^{**}$, where P and Q are the open support projections of the hereditary C^*-subalgebras $R^*\cap R$ and $L^*\cap L$. The second adjoint of $(A/(R+L))^{**}$ of $A/(R+L)$ is naturally isomorphic to $A^{**}/(A^{**}P+QA^{**})$. All this spaces are matrix-normed operator spaces and the canonical isomorphisms are complete isometries. It is easy to see that $A^{**}/(A^{**}P+QA^{**})$ is naturally completely isometric isomorphic to the ternary C^*-algebra $(1-Q)A^{**}(1-P)$.

REMARK A.18.4. The Proposition A.18.6 and Theorem **??**

main content:
$(A//D)\cap\mathcal{M}(A//D)\cong\mathcal{N}(D)/D$

yields an alternative, more general, conceptual and algebraic proof of the existence of a C^*-subalgebra $B\subseteq A$ with the property that $a\in B\mapsto pap\in pA^{**}p$ is a *-epimorphism onto $pA^{**}p$ if $pA^{**}p$ is finite-dimensional, as derived in Remark A.20.1 from the Kadison transitivity theorem.

In fact the proof is completely independent from the use of the non-commutative Lusin theorem [**616**, thm. 2.7.3] and is independent from all textbook versions of the Kadison transitivity theorem. It gives an alternative and “almost algebraic” proof of the Kadison transitivity theorem without any approximation arguments. (But uses the uniform Hölder continuity of that what we call “restricted perturbation”).

Let $p^*=p\in A^{**}$ a non-zero projection in the *socle* of A^{**}, i.e., $pA^{**}p$ is finite-dimensional. The set $S_p(A)$ of $f\in A^*$ with $\|f\|\le 1=f(p)$ is identical with the set of all normal states on $pA^{**}p$. The set of states on $pA^{**}p$ is compact in norm of $pA^*p\subseteq A^*$ if $pA^{**}p$ is finite dimensional.

Since the $\sigma(A^*,A)$-topology is Hausdorff and is continuous with respect to the norm on A^*, it follows that $S_p(A)$ is compact in the $\sigma(A^*,A)$-topology.

By ??? Proposition **??**, the $\sigma(A^*,A)$-compactness of $S_p(A)=C_p(A^{**})$

It seems better to consider the

quasi-states
in $Q(A)$?... No consequent terminology!!!

ρ on A with $\rho(1-p)=0$. And then require that this set is $\sigma(A^*,A)$ closed. Then apply then bi-polar theorem ...

Give -- or refer to -- Definition of the convex set
$C_p(M):=\{f\in M_*\,;\ \|f\|=1, f(p)=1\}$.

Open-ness of $1-p$ is not proven now!!!

implies that $p\in A^{**}$ is a closed projection, i.e., there is a closed left ideal $L\subseteq A$ such that $A^{**}(1-p)$ is the $\sigma(A^{**},A^*)$-closure of L.

Then p is a closed projection in A^{**} with respect to A, i.e., the hereditary C^*-subalgebra $D:=\{a\in A\,;\ ap=0=pa\}$ has $(1-p)$ as its *open* support projection

q_D of D in A^{**}, respectively $(1-p)A^{**}(1-p) \cong D^{**}$ is equal to the $\sigma(A^{**}, A^*)$-closure of $D \subseteq A^{**}$. We let $L := A \cdot D = \overline{\text{span}(A \cdot D)}$. It is a closed left-ideal of A with $\sigma(A^{**}, A^*)$-closure equal to $A^{**}(1-p)$.

If L is a closed left-ideal of A, and $q \in A^{**}$ is the *open* support projection of L, i.e.,

$$L^{**} \cong A^{**}q = \overline{L}^{\sigma(A^{**},A^*)},$$

then there is a natural isomorphism $pAp \cong (A/(R+L))^{**}$ for $R := \{a^* ;\ a \in L\}$ and $p := 1 - q_L$.

Let $D := R \cap L$. The C^*-space $A//D := A/(R+L) \cong pAp \subseteq A^{**}$ is c.p. and completely isometrically isomorphic to $pAp \subseteq pA^{**}p$ and $(A//D)^{**} \cong pA^{**}p$ as matrix-normed and matrix-ordered spaces. Since $pA^{**}p$ has finite dimension, it follows that $(A//D) \cong pAp = pA^{**}p$.

By Theorem ?? the quotient $\mathcal{N}(D)/D$ by D of the (two-sided) normalizer C^*-algebra $\mathcal{N}(D) := \{a \in A;\ aD \cup Da \subseteq A\}$ of D is naturally isomorphic to the intersection $pAp \cap \mathcal{M}(A//D)$ of $A//D \cong pAp$ with the C^*-subalgebra

$$\mathcal{M}(A//D) := \{T \in pA^{**}p;\ TpAp \cup pApT \subseteq pAp\}$$

of two-sided multipliers of the subset $A//D \subseteq (A//D)^{**} \cong pA^{**}p$.

Since $pAp \cong A//D$ is $\sigma(A^{**}, A^*)$ dense in $pA^{**}p \cong (A//D)^{**}$ and, in our special case, $pA^{**}p$ is of finite dimension, we get that $\mathcal{M}(A//D) = pAp = pA^{**}p$. Thus, the restriction $V|B$ to $B := \mathcal{N}(D)$ of the c.p. contraction $V: a \in A \mapsto pap \in pA^{**}p$ is a *-epimorphism from B onto $pA^{**}p \cong \mathcal{M}(A//D) \cong \mathcal{N}(D)/D$.

`New attempt Dec.2016:`

Define a projection $q = q^*q \in A^{**}$ as *open* projection if q is the support projection $q := q_D$ of a hereditary C^*-subalgebra D of A.

A projection $p \in A^{**}$ is - by definition - a *closed projection* if $1 - p \in A^{**}$ is open.

LEMMA A.18.5. *Let $p \in A^{**}$ a projection.*

The projection $q := 1 - p \in A^{**}$ is open, if an only if, the set $S_p(A)$ of $f \in A^*$ with $\|f\| = f(p) \leq 1$ is $\sigma(A^*, A)$-closed and for each pure state $g \in A^*$ with $g(p) = 0$ there exists an element $a \in A_+$ with $\|a\| = g(a) = 1$ and $f(a) = 0$ for all $f \in S_p(A)$.

PROOF. If the projection $1 - p$ is open then the set of $b \in A$ with $bp = 0$ is a closed left ideal L of A and $q := 1-p \in A^{**}$ is the support projection of $D := L^* \cap L$ (this by definition of open projections).

In particular $f(a) = 0$ for all $f \in S_p(A)$ and $a \in D$, and conversely $f(p) = 1$ for all normal states f on A^{**} with $f(D) = 0$. Clearly, the set of normal states with $f(D) = \{0\}$ is closed in the $\sigma(A^*, A)$-topology.

Thus, if $g \in A^*$ is a pure state with $g(p) = 0$ then $g|D$ is a pure state of D. It follows that there exists a contraction $a \in D_+$ with $g(a) = 1$, cf. [**616**, thm. 2.7.5]. Thus $f(a) = 0$ for all $f \in S_p(A)$.

Notice that generally $a \in A_+$ and $f(a) = 0$ for all $f \in S_p(A)$ is equivalent to $a(1-p) = a$.

The set $L := \{b \in A\,;\ f(b^*b) = 0\ \forall\ f \in S_p(A)\}$ is the maximal closed left-ideal of A with the property $L \cdot p = \{0\}$.

The support projection $Q \in A^{**}$ of the hereditary C^*-subalgebra $D := L^* \cap L$ of A is an open projection with $Qp = 0$.

Suppose that $Q \neq q := 1-p$. Then there exists a pure state $\rho \in A^*$ with $\rho(Q) = 0$ and $\rho(p) < 1$:

This is the case because $S_{1-Q}(A)$ is a $\sigma(A^*, A)$-compact convex set of states with the property that each extreme point f of $S_{1-Q}(A)$ is also an extreme point of of the quasi-state space of A, hence is a pure state of A with $f(Q) = 0$.

Each $f \in S_{1-Q}(A)$ is the $\sigma(A^*, A)$ limit of convex combinations of extreme points in $S_{1-Q}(A)$ (as it holds for every compact convex set). Thus, if there is no pure state $h \in A^*$ with $h(Q) = 0$ and $h(p) < 1$, then $Q = 1-p$, which contradicts our assumption $Q \neq q := 1-p$.

But if $h \in A^*$ is a pure state on A with $h(q) = 0$ and $h(p) < 1$, then we can consider the irreducible representation $R\colon A \to \mathcal{L}(\mathcal{H})$ corresponding to h. There is a cyclic vector $x \in \mathcal{H}$ with $\|x\| = 1$ such that $h(a) := \langle R(a)x, x\rangle$ for all $a \in A$.

Let $R\colon A^{**} \to \mathcal{L}(\mathcal{H})$ also denote the normalization of R. Then $R(Q)x = 0$ and $\|R(p)x\| < 1$. Thus $y := \gamma(x - R(p)x) \in \mathcal{H}$ with $\gamma := \|x - R(p)x\|^{-1}$ satisfies $R(Q)y = 0$, $R(p)y = 0$ and $\|y\| = 1$. The normal state $g(a) := \langle R(a)y, y\rangle$ on A^{**} is pure and satisfies $g(1 - (Q + p)) = 1$.

In particular, the assumption $1 - Q - p \neq 0$ gives a pure state on A with $g(Q) = 0$ and $g(p) = 0$.

But by assumption, there exists $a \in A_+$ with $\|a\| = 1 = g(a)$ and $ap = 0$. This implies $a \leq Q$ and $g(Q) \neq 0$.

Thus, $Q = 1-p$ (i.e., $1-p$ is open) if for each pure state $g \in A^*$ with $g(p) = 0$ there exists an element $a \in A_+$ with $\|a\| = g(a) = 1$ and $f(a) = 0$ for all $f \in S_p(A)$. □

Is it also equivalent to each of the following ???

The norm-closed left-ideal

$$L := (A^{**}(1-p)) \cap A = \{\, a \in A\,;\ ap = 0\,\}$$

of A is $\sigma(A^{**}, A^*)$-dense in $A^{**}(1-p)$.

This is equivalent to:

$A^*p := \{f \in A^*\,;\ f(ap) = f(a)\}$ is $\sigma(A^*, A)$-closed.

Clearly, L is a closed left-ideal of A and $L \subseteq A^{**}(1-p)$.

Let $q_L \in A^{**}$ denote the open support projection corresponding to L, i.e., $q_L := \sup\{d \in A_+\,;\ d \leq 1,\, d \in L\}$.

Then the $\sigma(A^{**}, A^*)$-closure of L is $A^{**}q_L$ and $q_L \leq 1 - p$.

Let L be $\sigma(A^{**}, A^*)$-dense in $A^{**}(1-p)$. Then $A^{**}q_L = A^{**}(1-p)$, hence $q_L = 1 - p$.

$A^*p = \{f \in A^*\,;\ f(ap) = f(a), \text{ for all}\, a \in A\,\} = \{f \in A^*\,;\ f(A(1-p)) = 0\}\,.$

It says that $A^*p = \{f \in A^*\,;\ f(L) = \{0\}\,\}$. The right side is $L^\perp$ in A^* and is there $\sigma(A^*, A)$-closed.

THE HARD stuff is the opposite direction:

Suppose $p \in A^{**}$ is a projection with the property that $A^* \cdot p$ is $\sigma(A^*, A)$-closed.

(Then $pA^*p = (p \cdot A^*) \cap (A^* \cdot p)$ is $\sigma(A^*, A)$-closed by $\sigma(A^*, A)$-continuity of $f \to \overline{f}$ on A^* given by the map $\overline{f}(a) := \overline{f(a^*)}$.)

Thus, there is closed subspace X of A such that ?????

$(A/X)^* \cong A^* \cdot p$???

?????

Let $L_p := \{a \in A\,;\ ap = 0\}$ i.e., $L_p = A \cap (A^{**}(1-p)) = \{a \in A\,;\ a = a(1-p)\}$.

And L_p is a closed left-ideal of A. Let Q denote the open support projection of A with $A^{**}Q = \overline{L_p}$ with respect to $\sigma(A^{**}, A^*)$-topology. We get $Q \leq (1-p)$.

Thus $p \leq 1 - Q$, and pA^*p is a subspace of $(A/(L_p^* + L_p))^* \cong (1-Q)A^{**}(1-Q)$

`HERE starts the difficulty of this rather special approach:`

Is $Q = 1 - p$????

Are p and Q determined by the there restrictions to the "discrete" type-I part of A^{**} ?

There are natural bijections between the following fairly different types of elements in A^{**}, quotient spaces of A, subspaces of A and certain subsets of A^*:

(a) closed projections in A^{**}

(b) open projections in A^{**}

(c) quotient C^*-spaces $A//D := A/(L^* + L)$ (with matrix order and matrix norms induced from A (respectively A^{**}).

(d) closed left-ideals $L \subseteq A$

(e) closed right-ideals $R \subseteq A$

(f) hereditary C^*-subalgebras D of A given by $D := L^* \cap L$ respectively $D := R^* \cap R$.

(g ??) hereditary $\sigma(A^*, A)$-closed convex sub-cones K of A^*_+. (The K should be of form $\mathbb{R}_+ \cdot C_p(A^{**})$ for some projection $p \in A^{**}$.)

(h ??) the set $S_p(A)$ of $f \in A^*$ with $\|f\| \leq 1 = f(p)$ is $\sigma(A^*, A)$-closed.

(if $1 - p$ is open ???).

Uses Lemma:

Each hereditary norm-closed sub-cone K of the positive part $(M_*)_+$ of the predual M_* of a W*-algebra M is of the form $K_q = (qM_*q)_+ \cong ((qMq)_*)_+$ for some projection $q \in M$.

$0 \neq p \in M := A^{**}$ is a closed projection, if and only if, the unit ball of K_p is $\sigma(A^*, A)$-closed, if and only if, $S_p(A) = C_p(M) := \{f \in M_* \, ; \; \|f\| \leq 1 = f(p)\}$ is $\sigma(A^*, A)$-compact.

In particular, every projection $p \in A^{**}$ with $pA^{**}p$ of finite dimension (as a vector-space over $\mathbb{R}$) is a closed projection.

This gives, e.g. by [**616**, thm. 1.5.2, thm. 3.10.7, cor. 3.10.8, prop. 3.11.9], the equivalences:

$D \subseteq A$ hereditary C^*-subalgebra,

$D \mapsto D_+$, D_+ is hereditary closed convex cone in A_+,

$M \subseteq A_+$ hereditary closed convex cone, build $M \mapsto L(M) := \{a \in A \, ; \; a^*a \in M\}$ then $L(M)$ is closed left-ideal of A.

$L \subseteq A$ closed left-ideal, $L \mapsto D_L := D(L) := L^* \cap L$, $D_L := L^* \cap L$ is a hereditary C^*-subalgebra of A.

Directly to L from D without passing through D_+:
Let $L(D) := D \cdot A$. To see that this a closed left-ideal simply apply Cohen factorization to the left Banach D-module $L := \overline{\mathrm{span}(D \cdot A)} \subseteq A$. It gives $L = D \cdot L \subseteq D \cdot A \subseteq L$.

The projection $p \in A^{**}$ is a *closed* projection for A, with $p := 1 - q$, if and only if,

$q \in A^{**}$ *open* projection for A.

A projection $q \in A^{**}$ is an *open* projection,

if and only if,

$q = \text{l.u.b.}\{a \in A_+ \, ; \; a \leq q\}$ in A^{**},

if and only if,

the closed left ideal $L_q := \{a \in A \, ; \; aq = a\}$ has $\sigma(A^{**}, A^*)$-closure $= A^{**}q$.

A non-zero projection $0 \neq p \in M := A^{**}$ is closed,

if and only if,

$S_p(A) = C_p(M) := \{f \in M_* \, ; \; \|f\| \leq 1 = f(p)\}$ with $M := A^{**}$ is $\sigma(A^*, A)$-closed,

if and only if,

$C_p(A^{**})$ is $\sigma(A^*, A)$-compact,

if and only if,

$q := 1 - p$ is open in A^{**},

if and only if,

$A^*p := \{f \in A^* ;\ f((\cdot)p) = f\}$ is closed in A^* with respect to $\sigma(A^*, A)$-topology.

Missing:

$D \mapsto A//D := A/(L^* + L)$,

$X := A//D \mapsto q := 1_{X^{**}} \in A^{**}$ *closed* projection, unit of the second conjugate $X^{**} \cong qA^{**}q$ of X. Given by $q := 1 - p_D$.

Passage to the *open* support projection $q_D \in A^{**}$ of D is given by $q_D := 1 - q$.

Proposition A.18.6. *Let A a C^*-algebra and $p \in A^{**}$ a (self-adjoint) projection.*

The following are equivalent:

(i) *p is a closed projection,*
(ii) *$1 - p$ is an open projection,*
(Definition of "open" ?
$1 - p$ is the l.u.b. in A^{**} of an upward directed family positive contractions in A?)
(iii) *$1 - p$ is the least upper bound of $\{a \in A_+ ;\ a \leq 1 - p\}$.*
(iv) *The convex subset $C_p(A^{**}) = S_p(A) := \{f \in A^* ;\ \|f\| \leq 1 = f(p)\}$ of A^* is $\sigma(A^*, A)$-closed.*
(v) *$C_p(A^{**})$ $(= S_p(A))$ is $\sigma(A^*, A)$-compact.*
(vi) *The closed left-ideal $L := \{a \in A ;\ ap = 0\}$ of A has $\sigma(A^{**}, A^*)$-closure equal to $A^{**}(1 - p)$.*

If $p \in A^{**}$ is a non-zero projection, then the $\sigma(A^*, A)$-compactness of $S_p := \{f \in A^* ;\ \|f\| \leq 1 = f(p)\}$ implies that $p \in A^{**}$ is a closed projection, i.e., there is a closed left ideal $L \subseteq A$ such that $A^{**}(1 - p)$ is the $\sigma(A^{**}, A^*)$-closure of L.

`Next is cited where !!!`
`Compare with following lemmata.`

The proof of the below stated Proposition A.21.4 concerning excision of pure states use a reduction method to the separable case that is established for arbitrary operator spaces and Banach spaces in full generality by the following Lemma B.14.1 and then applied for our basic observation on operator space quotients of C^*-algebras in Remark A.18.9.

Since we use them here the first time, we place here some "easy" facts – i.e., those that does not discuss the residually equivariant behavior of quotients by sums $L + R$ of left and right ideals L and R. We need reduction to separable subspaces with same perturbations conditions for quotients, because Ext-theory, KK-theory and our version of a stable but un-suspended E-theory (continuous versions of the approximate kind of E-theory used by Elliott and Rørdam) have to do with non-separable corona spaces.

We start with a very general observation:

LEMMA A.18.7. *Let* (R_1, ρ_1) *and* (R_2, ρ_2) *metric spaces of bounded diameters* ≤ 2, $T\colon R_1 \to R_2$ *a contractive map with* $T(R_1)$ *dense in* R_2.

Suppose that (R_1, ρ_1) *is complete (i.e., each Cauchy sequence in* R_1 *with respect to the metric* ρ_1 *has a limit in* R_1*).*

Need an increasing continuous function $\gamma \in \mathrm{C}([0,1], \mathbb{R})$ *with* $\gamma(0) = 0$, $t \leq \gamma(t)$ *and with the property:*

If $a, b \in R_1$ *then there exists for each* $\varepsilon > 0$ *an element* $c \in R_1$ *such that* $\rho_2(T(c), T(b)) < \varepsilon$ *and* $\rho_1(a, c) < \gamma(\rho_2(T(a), T(b))) + 2\varepsilon \leq 3\gamma(\rho_2(T(a), T(b)))$.

Suppose that there exists a function a continuous function λ *on* $[0, 2]$ *with* $\lambda(0) = 0$ *and the property that for* $p_1, p_2 \in R_1$ *and* $\varepsilon > 0$ *there exists* $p_3 \in R_1$ *with* $\rho_2(T(p_3), T(p_2)) < \varepsilon$ *and* $\rho_1(p_1, p_3) \leq \lambda(\rho_2(p_1, p_2)) + \varepsilon$ *????*

???? Then T *is surjective ????.*

PROOF. Find an decreasing sequence $r_1 > r_2 > \cdots$ in $(0, 1)$ such that $\sum_n \lambda(3^n r_n) < \infty$. In particular $\lim r_n = 0$.

Let $q \in R_2$. There exist $p_1, p_2, \ldots \in R_1$ with $\rho_2(p_n, q) < r_n/2$. Thus $\rho_2(p_m, p_n) \leq (r_m + r_n)/2$.

Find $P_{m,n} \in R_1$ with ???

??

Idea: ????

Take a point $q \in R_2$. Given any sequence $q_n \in T(R_1)$ with $\lim_n \rho_2(q_n, q) = 0$ "quickly enough", we can select a sub-sequence $r_k := q_{n_k}$ such that in the inverses $T^{-1}(B(r_k, \delta_k))$ of small balls around the r_k one finds inductively elements p_k that build a Cauchy sequence in R_1 ... □

Let E a Banach space and S the open unit ball of E. Recall that the **Hausdorff distance** between two bounded convex subsets K_1, K_2 of the Banach space E is given by

$$\mathrm{dist}_H(K_1, K_2) := \inf\{\, t \in [0, \infty)\,;\; K_1 \subseteq K_2 + tS \text{ and } K_2 \subseteq K_1 + tS \,\}\,.$$

DEFINITION A.18.8. Let E a real or complex Banach spaces $X \subseteq E$ a (not necessarily closed) linear subspace, S the open unit-ball of E and $t \in (0, \infty)$.

Define for $a, b \in S$ the Hausdorff distance between the intersection $K(a, X) := S \cap (a + X)$ and $K(b, X) = S \cap (b + X)$ of the affine spaces $a + X$ and $b + X$ with the open unit-ball S of E by

$$\rho(a, b) := \mathrm{dist}_H(K(a, X), K(b, X))\,.$$

We define the *function of restricted perturbation* $t \mapsto f(t;\, X)$ of the quotient map π_X by

$$f(t;\, X) := \sup\{\rho(a, b)\,;\; a, b \in S,\; \|\pi_X(a - b)\| \leq t\,\}$$

It turns out that $t \to f(t;\, L_1^* + L_2)$ is Hölder continuous near 0 if L_1 and L_2 are closed left ideals of a C^*-algebra E. The point is that

$$f(t;\, L_1^* + L_2) \le f(t;\, p_1 E^{**} + E^{**} p_2)$$

for the (open) support projections p_ℓ of the $\sigma(E^{**}, E^*)$ closures $E^{**}p_\ell$ of L_ℓ, an the latter is easily to estimate by an at zero Hölder continuous function of t.

The function $f(t;\, X)$ estimates in a symmetric way for given elements $a, b \in E$ with $\max(\|a\|\,, \|b\|) < 1$ the best value for the solution of the following "restricted perturbation" problem:

Let $a + X = \pi_X(a)$ and $b + X = \pi_X(b)$. What is the infimum $=: \lambda(a,b) \le \|a - b\|$ of $\|a - c\|$ over all $c \in b + X$ with $\|c\| < 1$?

Because then, for each $\varepsilon > 0$, we can find $c = c(\varepsilon) \in E$ with $\|c\| < 1$ and $\pi_X(c) = \pi_X(b)$ and

$$\|a - b\| + \varepsilon \ge \varepsilon + \lambda(a,b) \ge \|a - c\| \ge \|\pi_X(a) - \pi_X(b)\|\,.$$

We have that $\lambda(a,b) \le f(\|\pi_X(a) - \pi_X(b)\|; X)\,.$?????

`Need place for A CLEAR STATEMENT on the estimate of`

$$f(t;\, L_1^* + L_2) \le f(t;\, p_1 A^{**} + A^{**} p_2) \le t + (2t)^{1/2}$$

`!! ?? !!`

REMARK A.18.9. Let A denote a C^*-algebra, $L \subseteq A$ a closed left ideal, $R \subseteq A$ a closed right ideal, D a hereditary C^*-subalgebra of A. We use the notations $D_L := L^* \cap L$, $D_R := R^* \cap R$, $L_D := \overline{\mathrm{span}(A \cdot D)}$.

Let $\psi(\alpha) := \alpha + (2\alpha)^{1/2}$ for $\alpha \in [0, \infty)\,.$

??

Then there are the following elementary observations, cf. [**431**]:

(i) The vector space sum $R + L$ is a closed linear subspace of A.

The bi-duals and bi-polars in A^{**} are given by $L^{**} \cong (L^o)^o = A^{**}p_L$ where $p_L := p_D \in A^{**}$ is the open support projection of L respectively of $D := L^* \cap L$. Similarly $R^{**} = (R^o)^o$ for closed right ideals.

The bi-polar $\cong (R + L)^{**}$ in the W*-algebra A^{**} is identical with the (always $\sigma(A^{**}, A^*)$-closed) subspace

$$A^{**}q \,+\, pA^{**} = (1-p)A^{**}q + pA^{**}q + pA^{**}(1-q)$$

where $p, q \in A^{**}$ are the "open" support projections of the hereditary C^*-algebras $D_L := L^* \cap L$ and $D_R := R^* \cap R$ of A.

The bi-dual operator space $(A/(R+L))^{**}$ is naturally isomorphic to the *ternary algebra* (triple product algebra) $(1-q)A^{**}(1-p) \subseteq A^{**}$.

In particular, $(A/(L^* + L))^{**} \cong (1-q)A^{**}(1-q)$ is a W*-algebra.

The isomorphisms and natural embeddings are all completely isometric, and the quotient maps are completely contractive, because we can here alway replace A, R, L, D and p, q by $M_n(A), M_n(R), M_n(L), M_n(D)$ and $p \otimes 1_n$, $q \otimes 1_n$ for $n \in \mathbb{N}$.

The below considered constructions remain compatible via the obvious canonical completely isometric isomorphisms if we tensor by M_n, as e.g. $\mathcal{N}(D, A) \otimes M_n \cong \mathcal{N}(D \otimes M_n, A \otimes M_n)$ for $\mathcal{N}(D, A)$ in Part (iv).

(ii) Let $x, y \in A/(R+L)$ with $\|x\|, \|y\| \leq 1$ and $a \in A$ with $\|a\| \leq 1$ and $\pi_{R+L}(a) = x$, then there exist $b \in A$ with $\|b\| \leq 1$ that satisfies $\pi_{R+L}(b) = y$ and

$$\|a - b\| \leq \psi(\| y - x \|) \,.$$

In particular, we get the important fact that the quotient map π_{R+L} maps the closed unit-ball of A *onto* the closed unit-ball of $A/(R+L)$.

(iii) Let $D := L^* \cap L \subseteq A$ and $A//D := A/(L^* + L)$ the operator system defined by D.

Then $L := A \cdot D = \overline{\operatorname{span}(A \cdot D)}$ (because $D \subset L$ and L is a right D-module), and $(A//D)^{**}$ is an operator system that is naturally isomorphic to the W*-algebra $(1-q_D)A^{**}(1-q_D)$, where q_D denotes the open support projection of D in A^{**}.

(iv) Let $\mathcal{M}(A//D) \subset (1-p_D)A^{**}(1-p_D)$ denote the C^*-algebra of two-sided multipliers

$$T \cdot A//D \,,\; A//D \cdot T \quad \subseteq A//D$$

of the space $A//D \subseteq (1-p_D)A^{**}(1-p_D)$.

The natural epimorphism π_D from the two-sided normalizer algebra

$$\mathcal{N}(D, A) := \{a \in A \,;\; aD \cup Da \subseteq D\}$$

of D in A into

$$A//D := A/(L^* + L) \subseteq (1-p_D)A^{**}(1-p_D)$$

maps $\mathcal{N}(D, A)$ onto $(A//D) \cap \mathcal{M}(A//D)$, and has kernel

$$\operatorname{Ann}(D, A) := \{a \in A \,;\; aD = \{0\} = Da\} \,.$$

(v) An element $a \in A$ is in $\mathcal{N}(D, A)$ if and only if $\pi_{L^*+L}(a^*a) = \pi_{L^*+L}(a^*)\pi_{L^*+L}(a)$ and $\pi_{L^*+L}(aa^*) = \pi_{L^*+L}(a)\pi_{L^*+L}(a^*)$, i.e., if and only if a is in the multiplicative domain of π_{L^*+L}.

(vi) `The first part of this conclusion is also a corollary of a more elementary proposition: Corollary A.15.3!!`

For every separable C^*-subalgebra $G \subseteq A$ there exists a separable C^*-subalgebra $B \subseteq A$ such that $G \subseteq B$,

$$B \cap (L^* + L) = (B \cap L)^* + (B \cap L) \,,$$

and $B/(B \cap L) \to A/L$ is completely isometric, and (in addition) that $b \in B$ and $b(D \cap B) \subseteq D \cap B$ for $D := D_L$ implies $bD \subseteq D$ and the natural map $B//(B \cap D) \to A//D$ is completely isometric and defines a *-monomorphism

$$(B//(B \cap D)) \cap \mathcal{M}(B//(B \cap D)) \to (A//D) \cap \mathcal{M}(A//D) \,.$$

(vii) If A is unital, then naturally $\mathcal{M}(A//D) \cong \mathcal{N}(A,D)/\operatorname{Ann}(A,D)$ and B can be chosen such that in addition to the properties in (vi), B unital with $1_B = 1_A$, $\mathcal{N}(B, B\cap D) \subseteq \mathcal{N}(A,D)$ and $\operatorname{Ann}(B, B\cap D) = B\cap \operatorname{Ann}(A,D)$.

operator systems, $C*$-systems (definitions), nuclear operator system, c.p. and c.i. maps

needed statements:
indlim nuclear if maps are nuclear,
perhaps also:
indlim is $C*$-space, $B//D$ is $C*$-space,
nuclear OS is $C*$-space
definitions and listing of some result appear also further below.

?? ????

Matrix-normed operator spaces $(X, \|\cdot\|_n)$ can be defined as closed linear subspaces of $\mathcal{L}(\mathcal{H})$. An axiomatic characterization as Banach spaces X with a family of matrix norms $\|\cdot\|_n$ on $M_n(X) = X\otimes M_n$ has been given by E. Effros and Z.-J. Ruan, [**245**], that satisfy $\|a\oplus b\|_{m+n} = \max(\|a\|_m, \|b\|_n)$ and $\|\alpha c\beta\|_n \leq \|\alpha\|\|c\|_m\|\beta\|$ for $a, c\in M_m(X)$, $b\in M_n(X)$, $\alpha\in M_{n,m}$, $\beta\in M_{m,n}$, cf. [**245**]. If X is completely isometric embedded in $\mathcal{L}(\mathcal{H})$ then the Banach space second conjugate X^{**} of X is naturally embedded in the C^*-algebra $\mathcal{L}(\mathcal{H})^{**}$ as a $\sigma(\mathcal{L}(\mathcal{H})^{**}, \mathcal{L}(\mathcal{H})^*)$-closed linear subspace. One can see immediately that the norm-closed unit balls of the bi-dual Banach spaces

$$(M_n(X))^{**} \cong M_n(X^{**}) \subseteq M_n(\mathcal{L}(\mathcal{H})^{**}) = (M_n(\mathcal{L}(\mathcal{H}))^{**}$$

are just the $\sigma((M_n(X))^{**}, (M_n(X))^*)$ closures of the unit-balls of $M_n(X)$. Notice that this definition is completely independent from any chosen norm on $M_n(X^*) \cong M_n\otimes X^*$ that is equivalent on the subspaces $X^*\cong e_{ij}\otimes X^*$ to the usual dual Banach space norm on X^*, because the $\sigma((M_n(X))^{**}, (M_n(X))^*)$ topology depends only form the equivalence classes of norms on $M_n(X)^* = M_n(X^*) = M_n\otimes X^*$ and nothing else. For example, one can here use the usual Banach dual norms $\|\cdot\|_n^*$ on $M_n\otimes X^*$ that satisfy $\|f\oplus g\|^*_{m+n} = \|f\|^*_m + \|g\|^*_n$ instead of $\|f\oplus g\|^*_{m+n} = \max(\|f\|^*_m, \|g\|^*_n)$. This can be also abstractly described as the bi-dual matrix-normed space that is given by applying construction of matrix normed operator space X^* of X with matrix norms given the isomorphisms $M_n(X^*)\cong \operatorname{CB}(X, M_n)$ by E. Effros and Z.J. Ruan in [**245**, sec. 3.2]. The natural inclusion $M_n(X) \hookrightarrow M_n(X^{**})$ is isometric by [**245**, prop. 3.2.1]. But the above mentioned canonical isometry of $M_n(X^{**})\cong M_n(X)^{**}$ is a – formally – stronger statement.

Lemma A.19.1. *Let A a C^*-algebra, $\rho_1, \rho_2\in A^*$ Hermitian with $\|\rho_1\| = \|\rho_2\| = 1$. Suppose that there exists $b, c\in (A^{**})_+$ with*

$$\|b+c\| = \|b-c\| = \max(\|b\|, \|c\|) = 1 = \rho_1(b-c)$$

and $\rho_1(\beta b + \alpha c) = \rho_2(\beta b + \alpha c)$ *for all* $\alpha, \beta \in \mathbb{R}$. *Then for the polar decompositions* $\rho_j = \rho_{j+} - \rho_{j-}$ *holds* $\rho_1(b) = \rho_2(b) = \rho_{j+}(b) = \|\rho_{j+}\|$, *and* $\rho_1(c) = \rho_2(c) = -\rho_{j-}(c) = -\|\rho_{j-}\|$.

Proof. Recall that the polar decompositions $\rho_j = \rho_{j+} - \rho_{j-}$ of ρ_2 and ρ_2 satisfy $1 = \|\rho_{j+} + \rho_{j-}\| = \|\rho_{j+}\| + \|\rho_{j-}\|$.

Let $t_j := \rho_{j+}(b) + \rho_{j-}(c)$, $s_j := \rho_{j+}(c) + \rho_{j-}(b))$. Then $1 = \rho_j(b - c) = t_j - s_j$ and $1 \geq (\rho_{j+} + \rho_{j-})(b + c) = t_j + s_j$. They imply $s_j = 0$ and $\rho_j(b) = \rho_{j+}(b)$, $\rho_j(c) = -\rho_{j-}(c)$, for $j = 1, 2$.

On the other hand, $1 = \|\rho_{j+}\| + \|\rho_{j-}\| \geq t_j = 1$, $\|\rho_{j+}\| \geq \rho_{j+}(b)$ and $\|\rho_{j-}\| \geq \rho_{j-}(c)$, that gives $\rho_{j+}(b) = \|\rho_{j+}\|$ and $\rho_{j-}(c) = \|\rho_{j+}\|$. Now use that $\rho_1 = \rho_2$ on $\mathbb{R}b + \mathbb{R}c$. □

Remark A.19.2. A general (= not necessarily order-unital) **operator system** X is a closed linear subspace X of a C^*-algebra A such that X is invariant under passage to adjoints (i.e., $a \in X \Leftrightarrow a^* \in X$), and such that for each $n \in \mathbb{N}$, $a = a^* \in M_n(X) \subseteq M_n(A)$ and $\delta > 0$ there exist $b, c \in M_n(X)_+ := M_n(A)_+ \cap M_n(X)$ with

$$\|b + c\| = \max(\|b\|\,, \|c\|) \leq \|a\| \qquad \text{and} \qquad \|a - (b - c)\| < \delta\,.$$

If A is unital and $1 \in X$, then this property is trivially satisfied with $b := (\|a\|1 + a)/2$, $c := (\|a\|1 - a)/2$ and $\delta = 0$. The condition implies that functionals $f\colon M_n(X) \to \mathbb{C}$ with $f(T) \geq 0$ for $T \in M_n(X)_+$ satisfy $\|f\| = \sup\{f(T)\,;\, T \in M_n(X)_+ \ \|T\| = 1\}$, and (therefore) norm-preserving extensions of f to a hermitian functional $g\colon M_n(A) \to \mathbb{C}$ are positive functionals on $M_n(A)$. The condition also implies that hermitian linear functionals f on $M_n(X)$ have decompositions $f = f_+ - f_-$ into positive functionals f_+ and f_- on $M_n(X)$ that satisfy $\|f\| = \|f_+ + f_-\| = \|f_+\| + \|f_-\|$. The decompositions with this properties are not necessarily unique, but the norms $\|f_+\|$ and $\|f_-\|$ are independent from the chosen decomposition with this property, cf. Lemma A.19.1 and use the *weak compactness in $A^{**} \oplus A^{**}$ of the set of pairs (b, c) with $b, c \in X_+^{**} \subseteq A^{**}$ and $\|b + c\| \leq 1$.

It gives immediately, that the *weak closure ($\cong M_n(X^{**})$) of $M_n(X)$ in $M_n(A)^{**} \cong M_n(A^{**})$) contains a unique element E_n with the property $f(E_n) = \|f\|$ for each positive functional of f on $M_n(X)$. In this way, each $M_n(X^{**})_{sa}$ becomes an order-unit space, and X^{**} a unital operator system (with norms defined by the order-unit norms on $M_n(X^{**})$.

It allows to show that every completely positive contraction $V\colon X \to \mathcal{L}(H)$ extends to a completely positive contraction $V^e\colon A \to \mathcal{L}(H)$. In this way we get a "universal" c.p.c. map $V_u\colon X \to B$ for some suitable C^*-algebra B. We choose B such that $V_u(X)$ generates B and call $C^*_{\max}(X) := B$ (together with $V_u\colon X \to C^*_{\max}(X)$) the *universal C^*-algebra* generated by the (not necessarily unital) operator system X. There is a natural C^*-morphism $h\colon C^*_{max}(X) \to A$ such that $h \circ V_u(x) = x$ for all $x \in X$.

The induced norms on $M_n(X)$ and the closed cones of positive elements $M_n(X)_+$ provide X with a structure of matrix-norms and matrix orders ([9]).

Let, more generally, $X \subseteq A$ and $Y \subseteq B$ self-adjoint closed subspaces of C^*-algebras A and B, and let $T\colon X \to Y \subseteq B$ a linear map. We call T **completely positive** (respectively **completely contractive**, **completely isometric**) if the natural extensions $T \otimes \mathrm{id}_n$ of T to maps from $M_n(X) \cong X \otimes M_n$ to $M_n(Y)$ are positive (respectively contractive, isometric) for every $n = 1, 2, \ldots$. We write later **c.p.** , **c.c.** and **c.i.** maps (respectively).

We say that two self-adjoint closed subspaces $X \subseteq A \subseteq \mathcal{L}(H)$ and $Y \subseteq B \subseteq \mathcal{L}(K)$ are **c.i. and c.p. isomorphic** , if and only if, there are c.p. and c.c. maps $V\colon \mathcal{L}(H) \to \mathcal{L}(K)$ and $W\colon \mathcal{L}(K) \to \mathcal{L}(H)$ with $WV|X = \mathrm{id}_X$ and $VW|Y = \mathrm{id}_Y$.

The second conjugate space X^{**} of a selfadjoint closed subspace $X \subseteq A$ is naturally isomorphic to the $\sigma(A^{**}, A^*)$-closure of $X \subseteq A^{**}$. It is easy to check (because $M_n(X)^{**} \hookrightarrow M_n(A)^{**}$ is isometric) that the matrix-norms induced by $M_n(A^{**}) \cong M_n(A)^{**}$ on $M_n(X^{**})$ are the same as the second conjugate norms (i.e., bi-polar norms) on $M_n(X^{**})$ under the natural isomorphisms $M_n(X)^{**} \cong M_n(X^{**})$ (of vector spaces).

We say that inclusion $X \hookrightarrow A$ is **admissible** if the $\sigma(M_n(X)^{**}, M_n(X)^*)$-closure of $M_n(A)_+ \cap M_n(X)$ is the same as $M_n(A)_+^{**} \cap M_n(X)^{**}$ for each $n \in \mathbb{N}$. This is e.g. the case if every bounded positive functional on $M_n(A)_+ \cap M_n(X)$ extends to a positive functional on $M_n(A)_+$ with same norm. In general, the inclusion $X \hookrightarrow A$ is *not* admissible. But an arguments with bi-polars shows that $X \hookrightarrow A$ is admissible if X is an *operator system* (not necessarily unital) and is equipped with the matrix norms and orders induced on $M_n(X)$ by $M_n(A)$. On the other hand, there *always* exists a C^*-algebra B and c.p. and c.c. maps $V\colon X \to B$ and $W\colon B \to \mathcal{L}(H)$ such that $WV(x) = x$ for $x \in X$ and $V(X) \hookrightarrow B$ is admissible ([10])

If $X \subseteq A$ is *admissible* in A then an argument using the bi-polar shows:
$X^{**} \subseteq A^{**}$ is an operator system, if and only if, $X \subseteq A$ is an operator system.

Suppose that X is a self-adjoint closed subspace of A and that X^{**} (with bi-dual matrix norms and orders of the matrix norms coming from matrix orders of X) is c.i. and c.p. isomorphic to a C^*-algebra M . Then M is necessarily a W*-algebra.

Any (not necessarily unital) completely isometric and completely positive map V from a unital C^*-algebra C into an other C^*-algebra B (in our case with $B = A^{**}$) satisfies $V \otimes \mathrm{id}_n(c) \in M_n(B)_+$ if and only if $c \in M_n(C)_+$. (In fact, it is enough to require that C is a matrix ordered space with an order unit such that the matrix norms are given by the induced order norm: $\|c\| \leq 1$ for $c^* = c \in M_n(C)$ if and only if $-1 \otimes 1_n \leq c \leq 1 \otimes 1_n$.)

[9] One can give axiomatic descriptions of, not necessarily order-unital, operator systems independent from inclusions $X \hookrightarrow A$ into C^*-algebras – using ideas of Effros and Ruan [**245**].

[10] Here we consider A as C^*-subalgebra of $\mathcal{L}(H)$, and that V is a c.i. and c.p. isomorphism from X onto $V(X)$.

It follows: *If X^{**} is c.i. and c.p. isomorphic to a C^*-algebra, then X is a – not necessary order-unital – operator system*, ([11]).

Then any c.i. and c.p. embedding $V: X \hookrightarrow B$ into a C^*-algebra B satisfies that $M_n(B)_+ \cap V \otimes \mathrm{id}_n(M_n(X)) = V \otimes \mathrm{id}_n(M_n(A)_+ \cap M_n(X))$, and – therefore – that $V(X) \hookrightarrow B$ is admissible. In particular, the natural embedding $X \hookrightarrow X^{**}$ is admissible.

Since completely positive and completely isometric maps T from a C^*-algebra onto an other C^*-algebra is always a C^*-algebra isomorphism, we get that the C^*-algebra structure on X^{**} is uniquely determined if $X \subseteq A$ is admissible and X^{**} is c.i. and c.p. isomorphic to a C^*-algebra. We can define the **multiplier algebra** $\mathcal{M}(X)$ of a C^*-system X by

$$\mathcal{M}(X) := \{a \in X^{**}\,;\ aX \cup Xa \subseteq X\}\,.$$

It is a C^*-subalgebra of X^{**}. If $I: X \to Y$ is a c.i. and c.p. map from X onto a self-adjoint closed subspace $Y \subseteq B$ of a C^*-algebra B then Y is an operator system with Y^{**} c.i. and c.p. isomorphic to a C^*-algebra, $I^{**}: X^{**} \to Y^{**}$ is an isomorphism of C^*-algebras and $\mathcal{M}(I) := I^{**}|\mathcal{M}(X)$ is a C^*-isomorphism from $\mathcal{M}(X)$ onto $\mathcal{M}(Y)$.

Examples where X^{**} (together with its matrix norms and orders) is isomorphic to a C^*-algebra are:

(1) Let $X := B//D := B/(BD+DB) \subseteq A := (1-p_D)B^{**}(1-p_D)$ where D is a hereditary C^*-subalgebra of a C^*-algebra B and $p_D \in B^{**}$ is the "open" support projection of D with $D^{**} = p_D B^{**} p_D$ ([12]). The matrix norms and matrix orders on $M_n(X)$ that are induced by the inclusion $X \subseteq A$ are easily seen to be the same as those induced by the quotient maps $M_n(B) \to M_n(B//D) \cong M_n(B)//M_n(D)$. Therefore, X^{**} is naturally c.i. and c.p. isomorphic to the von Neumann algebra $(1-p_D)B^{**}(1-p_D)$.

(2) More generally, $Y \subseteq X$ and the quotients $X//Y := X/Z$ are in a natural manner operator systems (with second conjugates isomorphic to the C^*-algebras $pX^{**}p$ respectively $(1-p)X^{**}(1-p)$) if

(i) X^{**} is c.i. and c.p. isomorphic to a C^*-algebra,
(ii) the $\sigma(X^{**}, X^*)$-closure of Y in X^{**} is a hereditary C^*-subalgebra $pX^{**}p$ of X^{**} for a projection $p \in X^{**}$, and
(iii) Z is the set of $z \in X$ with $\rho(z) = 0$ for all positive functionals ρ on $A \supset X$ with $\rho(Y) = \{0\}$, i.e., $Z = X \cap (pX^{**} + X^{**}p)$.

(Then there is a natural c.i. and c.p. embedding $X//Y \subseteq A//D$ where D is the hereditary C^*-subalgebra of A generated by Y.)

[11] We consider X^{**} together with the second conjugate matrix norms on $M_n(X^{**}) \cong M_n(X)^{**}$ and the $\sigma(M_n(X)^{**}, M_n(X)^*)$-closure of $M_n(A)_+ \cap M_n(X)$ as matrix-order structure.

[12] The closed linear span $R \subseteq B$ of $DB := \{db\,;\ d \in D, b \in B\}$ is a non-degenerate left D-module. Thus $DR = R \subseteq DB \subseteq R$ by the Cohen factorization theorem, because D has a bounded approximate unit.

(3) A special case of (2) with $X//Y = X/Y$, $Y = Z$ is obtained if $Y \subseteq X$ is an M-ideal of X (i.e., the subspace $Y^\perp$ of X^* is ℓ_1-complemented in X^*: $X^* = Y^\perp + L$ with $\|f + l\| = \|f\| + \|l\|$ for $f, l \in X^*$ with $f(Y) = \{0\}$ and $l \in L$), because then there is a central projection p in the center of the W*-algebra X^{**} such that pX^{**} is the weak closure of Y in X^{**}.

(4) Inductive limits $\mathrm{indlim}(T_n : B_n \to B_{n+1})$ are C^*-systems, if $B_1, B_2, \ldots$ are C^*-algebras and $T_n : B_n \to B_{n+1}$ are c.p. contractions, cf. Lemma A.19.6(v).

(5) All nuclear operator systems (that are not necessarily unital), are C^*-systems (cf. Proposition A.19.4).

Definition A.19.3. Let A a C^*-algebra and $X \subseteq A$ a self-adjoint closed subspace of A. Then X is a (not necessarily with order-unit equipped) ***C*-system*** if X is a (not necessarily order-unital) operator system and there exists a c.i. and c.p. map I from a C^*-algebra M onto X^{**}, i.e., the second conjugate operator system X^{**} is c.i. and c.p. isomorphic to a C^*-algebra.

A similar definition for general *C^*-spaces* would be completely wrong, because there exist separable operator spaces that have injective C^*-algebras as second conjugate, but are not C^*-spaces and are not nuclear (are even not exact).

The unique C^*-algebra structure on X^{**} allows to define the **multiplier algebra** $\mathcal{M}(X) \subseteq X^{**}$ by

$$\mathcal{M}(X) := \{a \in X^{**}\, ;\, aX \cup Xa \subseteq X\}\,.$$

A closed subspace $X \subseteq A$ is **nuclear** if, for every $x_1, \ldots, x_n \in X$ and $\delta > 0$, there are $k \in \mathbb{N}$ and completely positive contractions $V : A \to M_k$, $W : M_k \to A$ with $W(M_k) \subseteq X$ and $\|WV(x_j) - x_j\| < \delta$ for $j = 1, \ldots, n$.

It is easy to see that nuclear X must be an operator system (that is not necessarily order-unital).

Below we see that X is moreover a C^*-system, cf. Lemma **??**. (??? lem:6.?nuc.cst.syst ???)

A C^*-system X is nuclear if X is a *nuclear subspace* of the C^*-algebra X^{**}.

Proposition A.19.4. *Let $X \neq 0$ a separable (not necessarily unital) matrix-ordered and matrix-normed space. TFAE:*

(i) *X is nuclear.*
(ii) *X is completely isometric and completely order isomorphic to the inductive limit of completely positive contractions $V_n : M_{k_n} \to M_{k_{n+1}}$.*
(iii) *X^{**} is completely isometric and completely order isomorphic to an injective W^*-algebra.*
(iv) *There exists hereditary C^*-subalgebras $D \subseteq E \subseteq M_{2^\infty}$ of the CAR-algebra $M_{2^\infty} = M_2 \otimes M_2 \otimes \cdots$ and a completely isometric matrix-order isomorphism from X onto $E//D := E/(E \cdot D + D \cdot E)$.*

REMARKS A.19.5. Before we start with the proof of Proposition A.19.4 we remind the reader that a (not necessarily unital) *operator system* X is a very special kind of much more general operator spaces defined and considered by E. Effros and Zh.-J. Ruan in [**245**].

The (as Banach space) separable operator systems are always completely isometric isomorphic to the quotient space $A/(R+L)$ of some separable C^*-algebra A by a sum $R+L$ of a closed right ideal R of A and and closed left ideal L of A. The algebraic sum is always closed, cf. Proposition A.15.2(iv)

An operator system has in addition to its matrix norms an involution map $x \in X \to x^* \in X$ and a matrix order structure with the property that the second order operator space X^{**} contains an order unit $1 \in X^{**}$ with the property that $-1_n \otimes 1_2 \leq x \otimes p_{12} + x^* \otimes p_{21} \leq 1_n \otimes 1_2$ is equivalent to $\|x\| \leq 1$ for $x \in M_n(X^{**})$. (Here the order unit $1 \in X^{**}$ is often not in X itself, and $p_{jk} \in M_2$ denote matrix units and $1_2 := p_{11} + p_{22}$.)

In this case holds: If X is an operator system and is in addition a *C^*-space* (as reminded below), then X^{**} is a W*-algebra.

A ***C^**-ternary space** (also called "***C^**-space**") X is by definition is an operator space that has the following two properties:

(c*-sp 1) The second conjugate operator-space X^{**} of X is completely isometric isomorphic to a ternary algebra (triple product algebra) pMq for some W*-algebra M and projections $p, q \in M$.

(c*-sp 2) The natural completely isometric embedding $\eta \colon X \hookrightarrow X^{**}$ of X into X^{**} is *weakly injective*, i.e., there is a completely contractive projection P from X^{4*} onto the $\sigma(X^{4*}, X^{***})$ closure of the image of $\eta^{**}(X)$ of the natural C^*-ternary morphism η from the W*-ternary algebra X^{**} into X^{4*}.

The general definition of **relative weakly injective** linear maps $T \colon X \hookrightarrow A$ into a C^*-ternary algebra A is that T is completely isometric and that there is a completely contractive $\sigma(A^{**}, A^*)$-continuous linear projection

$$P \colon A^{**} \to T^{**}(X^{**}) \subseteq A^{**}$$

with the property that $P \circ T^{**} = T^{**}$. The existence of this embedding shows that the operator space X is a C^*-space (C^*-ternary system).

An operator space X is **weakly injective** , if and only if, a suitable completely isometric linear embedding of X into $\mathcal{L}(\mathcal{H})$ for some Hilbert space $\mathcal{H}$ is *relative weakly injective*.

All separable C^*-ternary spaces are completely isometric isomorphic to quotient operator spaces $C^*(T)/(L+R)$ of the universal C^*-algebra $C^*(T)$ generated by a single contraction T, with sum $L+R$ of a suitable closed left-ideal L and a closed right-ideal R of $C^*(T)$ (this follows easily from the results of [**472**]).

An operator system X is a (not necessarily unital) ***C^**-system** if X^{**} is completely isometric and order isomorphic to a W*-algebra and the natural inclusion map $\eta\colon X \hookrightarrow X^{**}$ is relative weakly injective in X^{**}.

It is known that all (non-unital) separable C^*-systems X admit a canonical unitization $\widehat{X}$ that is completely order isomorphic to $C^*(F_\infty)/(L^* + L)$ for some closed left ideal L of $C^*(F_\infty)$, cf. [**472**].

It is not difficult to see that all inductive limits $A_1 \to A_2 \to \cdots$ defined by completely positive unital maps $V_n\colon A_n \to A_{n+1}$ are C^*-systems, cf. [**472**].

Proof of Proposition A.19.4. (i)⇒(ii): The definition of nuclearity for separable operator systems X is equivalent to the existence of

(α) linear subspaces $X_1 \subseteq X_2 \subseteq \cdots \subseteq X$ with $\dim(X_n) < \infty$ and $\bigcup_n X_n$ dense in X, and

(β) completely positive contractions $T_n\colon M_{k_n} \to X_{n+1}$ and $S_n\colon X_n \to M_{k_n}$ such that $\|(T_n \circ S_n)|X_n\| < 2^{-n}$.

It follows that $X = \text{indlim}_n(T_n \circ S_n)\colon X_n \to X_{n+1}$. One can check this in $X_\infty := \ell_\infty(X)/c_0(X)$ by comparing it in X_∞ on the subsets X_n with the inductive limit $X = \text{indlim}_n(\iota_n\colon X_n \to X_{n+1})$ for the natural inclusion maps ι_n from X_n into X_{n+1}. The asymptotic of the approximately commuting diagrams allow to see that

$$X \cong \text{indlim}_{n\to\infty} W_n := T_n \circ S_n\colon X_n \to X_{n+1}$$

by comparing the restrictions of the iterates

$$W_{k,\ell} := W_\ell \circ \ldots \circ W_k\colon X_k \to X_\ell$$

on $X_n \subseteq X_k$ for fixed $n \in \mathbb{N}$ and large $n < k < \ell$. It shows that the natural embedding in X modulo $c_0(X)$ in X_∞ coincides with this inductive limit, because it has a natural embedding into X_∞ given for $x \in X_n$ by

$$W_{n,\infty}(x) = (0, \ldots, 0, x, W_n(x), W_{n+1}W_n(x), \ldots) + c_0(X)\,.$$

The complete isometry from X onto the map

$$x \in X \mapsto (S_1(x), S_2(x), \ldots) + c_0(M_{k_1}, M_{k_2}, \ldots)$$

defines an a completely isometric and completely positive map from X onto the inductive limit defined by the sequence of c.p. contractions $V_n := S_{n+1} \circ T_n\colon M_{k_n} \to M_{k_{n+1}}$. The defining morphisms for the inductive limit of the V_n are given by

$$V_{n,n+\ell} := V_{n+\ell} \circ \ldots \circ V_{n+1} \circ V_n\colon M_{k_n} \to M_{k_{n+\ell}}$$

and for $a_n \in M_{k_n}$ by

$$V_{n,\infty}(a_n) = (0, \ldots, 0, a_n, V_n(a_n), V_{n+1}V_n(a_n), \ldots) + c_0(M_{k_1}, M_{k_2}, \ldots)\,.$$

Clearly this happens also for the map ???????

`To be filled in` ??

(ii)⇒(iv):

(iv)⇒(iii):

(iii)⇒(i): □

LEMMA A.19.6. *Suppose that $A, B_1, B_2, \ldots$ are C^*-algebra, that $T_n \colon B_n \to B_{n+1}$ $(n = 1, 2, \ldots)$ are completely positive contractions and that $X \subseteq A$ is a closed subspace of A, that is invariant under passage to adjoints, i.e., $X = X^* := \{x^* \ x \in X\}$.*

Then

(i) *Suppose that there is a c.p. contraction $V \colon A \to A^{**}$ such that $V(x) = x \in A \subseteq A^{**}$ for $x \in X$, $V(A)$ is contained in the $\sigma(A^{**}, A^*)$-closure of X in A^{**} and $(V \otimes \mathrm{id}_n)(M_n(A)_+)$ is contained in the $\sigma(M_n(A)^{**}, M_n(A)^*)$-closure of $M_n(A)_+ \cap M_n(X))$ in $M_n(A^{**}) \cong M_n(A)^{**}$.*

   Then X is a C^*-system.
(ii) *If X is a C^*-system and $\psi \colon X \to C$ is a c.i. and c.p. map into a C^*-algebra C such that $\psi(X)$ generates C, then there exists a unique *-algebra morphism φ from C into X^{**} with $\varphi(\psi(x)) = x$ for $x \in X$.*
(iii) *If, for every $x_1, \ldots, x_n \in X$ and $\delta > 0$, there is a completely positive contractions $V \colon A \to A$, such that $V(A) \subseteq X$ and $\|x_j - V(x_j)\| < \delta$ for $j = 1, \ldots, n$, then X is a (not necessarily unital) C^*-system.*
(iv) *$X \subseteq A$ is a C^*-system if X is a nuclear subspace of A.*
(v) $\mathrm{indlim}(T_n \colon B \to B) \subseteq \ell_\infty(B)/c_0(B)$ *is a C^*-system.*
(vi) *If the maps $T_n \colon B \to B$ are nuclear, then the C^*-system* $\mathrm{indlim}(T_n \colon B \to B)$ *is nuclear.*

PROOF. (vi): We show: If the B_n are separable (not necessarily unital) C^*-algebras and the maps $T_n \colon B_n \to B_{n+1}$ are nuclear c.p. contractions, then $\mathrm{indlim}_n(T_n \colon B_n \to B_{n+1})$ is a separable nuclear C^*-space.

This reduces to the case, where B_n is of finite dimension by Lemma A.14.2 and Lemma A.14.1.

In the non-separable case is $\mathrm{indlim}_n(T_n \colon B_n \to B_{n+1})$ the union of nuclear subspaces given by $\mathrm{indlim}_n(S_n \colon A_n \to A_{n+1})$ for separable C^*-subalgebras $A_n \subseteq B_n$ with $T_n(A_n) \subseteq A_{n+1}$, such that $S_n := T_n | A_n$ is still an nuclear map from A_n into A_{n+1}.

`to be filled in` ??

Let $X := \mathrm{indlim}_n(S_n \colon A_n \to A_{n+1})$, where the A_n are separable and the S_n are nuclear. Consider the natural embedding $X \subseteq \ell_\infty(A_1, A_2, \ldots)/c_0(A_1, A_2, \ldots)$. In the separable case we can find a increasing sequence $Z_1 \subseteq Z_2 \subseteq \cdots$ of finite-dimensional subspaces of X, and subspaces $Y_k \subseteq A_k$ of finite dimension, such that $\bigcup_k Z_k$ is dense in X, $S_k(Y_k) \subseteq Y_{k+1}$ and $Z_k = S_{k,\infty}(Y_k)$ for all $k \in \mathbb{N}$. Then we find ?????????? and

c.p. contractions $V_k \colon M_{\mu(k)} \to A_{k+1}$, $W_k \colon A_k \to M_{\mu(k)}$, such that $V_k \circ W_k \colon A_k \to A_{k+1}$ have the property that for $L_k := Y_k \cup V_{k-1}(M_{\mu(k-1)}) \subseteq A_k$ holds

$\|(V_k \circ W_k - S_k)|L_k\| < 8^{-k}$. It follows that $X = \mathrm{indlim}_{k\to\infty}(S_k \colon Y_k \to Y_{k+1})$ and $X = \mathrm{indlim}_{k\to\infty}(V_k \circ W_k \colon L_k \to L_{k+1})$ with matrix order and matrix norm inherited from $\ell_\infty(A_1, A_2, \ldots)/c_0(A_1, A_2, \ldots)$.

This implies, by Lemma A.14.1, that the matrix-normed and matrix-ordered space X is completely isometric and completely order isomorphic to $C := \mathrm{indlim}_{k\to\infty}(W_{k+1} \circ V_k \colon M_{\mu(k)} \to M_{\mu(k+1)}$. The $T_k := W_{k+1} \circ V_k$ are c.p. contractions.

By Proposition A.19.4 it follows that C and therefore X is a nuclear (not necessarily unital) C^*-system.

????? □

Remark A.19.7. "Non-unital" modifications of the proofs in [**438**] show that:

Compare next Definitions with those in work of J.Pisier or Effros–Lance ???

(1) There is a C^*-algebra C and a hereditary C^*-subalgebra $D \subseteq C$ such that $C//D \cong \mathrm{indlim}(T_n \colon B \to B)$ by a completely isometric and completely positive isomorphism.
(Use Stinespring dilation and [**438**, lem.2.5], compare the arguments in [**472**].)

(2) Every *separable* C^*-system X is isomorphic to $C//D$ for some separable C^*-algebra C and hereditary C^*-algebra $D \subseteq C$.
(Compare [**472**, prop.5] for the unital case.)

(3) Let X a C^*-system, i.e., X (considered e.g. as $X \subseteq \mathcal{L}(\mathcal{H})$ for some $\mathcal{H}$) is a matrix-ordered operator space with second conjugate X^{**} isometrically order isomorphic to a W*-algebra M *and* there is a normal conditional expectation P_X from M^{**} onto the $\sigma(M^{**}, M^*)$-closure of the image of the canonical map from X into M^{**} given by the natural map $X \to X^{****} \cong M^{**}$. This latter assumption is equivalent to the requirement that $X \subseteq X^{**}$ is relatively weakly injective in X^{**}, which can be expressed equivalently that the natural map from $X \otimes^{\max} C^*(F_2)$ to $X^{**} \otimes^{\max} C^*(F_2)$ is injective (in an isometric sense). Here $\otimes^{\max}$ is taken on the category of tannery algebras extended to operator spaces X with X^{**} isomorphic to a W*-ternary algebra pMq.

(To understand the latter extra requirement check by examples that P_X defines a normal c.p. contraction from M into M^{**} that is usually very different from both of the central normal embedding $M \cong p_M \cdot M^{**}$ and of the non-normal natural inclusion of M into M^{**}.)

Then: X is nuclear,

if and only if,

the second conjugate operator system X^{**} is an injective C^*-algebra,

if and only if,

the inclusion map from X into the W*-algebra X^{**} is weakly nuclear.

(Modify here [**438**, lem.2.8] for the implication

$$X^{**} \text{ injective } \Rightarrow X \text{ nuclear } .$$

The other directions follows from $(X^{**})^{op} \otimes^{\max} X = (X^{**})^{op} \otimes^{\min} X$ (where the tensor products are defined by the natural inclusion of X in the W*-algebra X^{**})

???????? Find reference ????????? by an argument of E. Effros and Ch. Lance [**241**, thm. ???] that uses here the standard representation of X^{**} and $(X^{**})^{op}$ in the sense of U. Haagerup).

If this is the case and X is separable then one can take $C := M_{2^\infty}$ in (2).

(4) Similar arguments show the analogs for C^*-operator spaces $X \cong C/(L+R)$ of the results (2) and (3) for separable C^*-spaces X, (by definition operator spaces X with with X^{**} completely isometric to pMq for some von-Neumann-algebra M and projections $p, q \in M$.)

Lemma A.19.8. *Suppose that D is a hereditary C^*-subalgebra of a C^*-algebra B with corresponding "open" support projection $p := p_D \in B^{**}$. Let*

$$\mathcal{M}(B//D) := \{a \in (B//D)^{**} \;:\; a(B//D) \cup (B//D)a \subseteq B//D\}.$$

(o) *The natural isomorphisms*

$$(B//D)^{**} \cong B^{**}/(pB^{**} + B^{**}p) \cong (1-p)B^{**}(1-p)$$

are unital and completely isometric. They equip $(B//D)^{**}$ with the unique von-Neumann algebra structure that is compatible with the bi-adjoint matrix order unit structure on $B//D$. It holds $B//D = (1-p)B(1-p)$ if we naturally identify $(1-p)B^{**}(1-p) \cong (B//D)^{**}$ and consider all operators as elements of $(1-p)B^{**}(1-p)$.

(i) *$\mathcal{M}(B//D)$ is a C^*-subalgebra of $(B//D)^{**}$, and $\mathcal{M}(B//D) \cap (B//D)$ is a closed ideal of $\mathcal{M}(B//D)$.*

The ideal $\mathcal{M}(B//D) \cap (B//D)$ is natural isomorphic to $\mathcal{N}(D)/D$ by the canonical epimorphism $B \ni b \mapsto b + R + L \in B//D = B/(R+L)$, where L and R denote the closures of BD respectively DB.

(ii) *An element $x \in (1-p)B^{**}(1-p)$ is in $\mathcal{M}(B//D) \cap (B//D)$, if and only if, $x, x^*x, xx^* \in B//D \subseteq (1-p)B^{**}(1-p)$.*

(iii) *If we identify $\mathcal{N}(D)/D$ and $\mathcal{M}(B//D) \cap (B//D)$ naturally via π_{R+L}, then, for every closed ideal J of B,*

$$\pi_D(\mathcal{N}(D) \cap J) = \pi_{R+L}(J) \cap \pi_D(\mathcal{N}(D)).$$

(iv) *Suppose that that $T \colon B//D \to C$ is a completely positive and completely isometric map from $B//D$ into a C^*-algebra C.*

*If a C^*-subalgebra A of C is contained in $T(B//D)$ then $\gamma := T^{-1}|A$ is a *-monomorphism from A into $B//D \cap \mathcal{M}(B//D) \cong \mathcal{N}(D)/D$.*

(v) *Let $\mathrm{Ann}(D, J) := \{b \in B\,;\; bD + Db \subseteq J\}$.*

If J is closed ideal of B, then $J \subseteq \mathrm{Ann}(D, J)$ and

$$\pi_J(\mathrm{Ann}(D, J)) = \mathrm{Ann}(\pi_J(D)) := \mathrm{Ann}(\pi_J(D), \{0\}).$$

In particular, $\pi_J(D)$ *is essential in* B/J*, if and only if,* $\mathrm{Ann}(D,J)=J$.

In particular, $\mathcal{N}(D)\cap\mathrm{Ann}(D,J)=\mathcal{N}(D)\cap J$ *for all* $J\lhd B$.

If $\pi_J(D)$ *is essential in* B/J *then*

$$\mathcal{N}(D)\cap\mathrm{Ann}(D,J)=\mathcal{N}(D)\cap J\,.$$

(vi) *Suppose that* $\mathrm{Ann}(D,J)=J$ *for all* $J\lhd B$*. Then there is a unique *-monomorphism*

$$\lambda\colon\,\mathcal{N}(D)\to\mathcal{M}(D)$$

such that $\lambda|D=\mathrm{id}_D$ *and*

$$\lambda(\mathcal{N}(D)\cap J)=\lambda(\mathcal{N}(D))\cap\mathcal{M}(D,D\cap J)$$

for all $J\lhd B$.

In particular,

$$\pi_D\circ\lambda(\mathcal{N}(D))\cap\pi_D(\mathcal{M}(D,D\cap J))=\pi_D\circ\lambda(\mathcal{N}(D)\cap J))\,.$$

(vii) *If* B *is separable, then there exist a completely positive contraction* $V\colon B//D:=B/(L+R)\to\mathcal{M}(D)/D$ *such that* $V|\mathcal{N}(D)=\pi_D\circ\lambda$ *and*

$$V\big(\pi_{L+R}(J)\big)\subseteq\pi_D\big(\mathcal{M}(D,D\cap J)\big)\qquad\textit{for all } J\lhd B\,.$$

Proof. Ad (o) and (i): If B is unital, then $\mathcal{M}(B//D)\subseteq B//D$ and the statements (o) and (i) are contained in [**437**, thm.1.4] (in the unital case).

If B is *non-unital*, we can pass to the unitization $\widetilde{B}=B+\mathbb{C}\cdot 1$ of B and have $\widetilde{B}^{**}\cong B^{**}\oplus\mathbb{C}$. Let e denote the unit of B^{**} in $\widetilde{B}^{**}$. Then $p\le e$, $B//D=(e-p)B(e-p)=(1-p)B(1-p)$ and

$$B//D\subseteq\widetilde{B}//D=(1-p)\widetilde{B}(1-p)\subseteq(e-p)B(e-p)\oplus\mathbb{C}\cdot(1-e)=B//D\oplus\mathbb{C}\cdot(1-e)\,.$$

It follows $\widetilde{B}//D=(1-p)B(1-p)+\mathbb{C}\cdot(1-p)=B//D+\mathbb{C}(1-p)$ and, therefore

$$B//D=(\widetilde{B}//D)\cap(e-p)B^{**}(e-p)\,,$$

and $\mathcal{M}(\widetilde{B}/D)\cap(e-p)B^{**}(e-p)=\mathcal{M}(\widetilde{B}//D)\cap B//D$.

If $x\in\mathcal{M}(B//D)\cap B//D$, then $x(B//D)+(B//D)x\subseteq B//D$ and $x(1-e)=(1-e)x=x\in\widetilde{B}//D$. Thus $x\in\mathcal{M}(\widetilde{B}//D)\cap B//D$. If $y\in\mathcal{M}(\widetilde{B}//D)$, then $y=x+z(1-p)$ with $x\in B//D$ and $z\in\mathbb{C}$. Since $(1-p)c=c=c(1-p)$ for $c\in\widetilde{B}//D$, we get $x(B//D)+(B//D)x\subseteq(\widetilde{B}//D)\cap(e-p)B^{**}(e-p)$. The right side is equal to $B//D$, which shows that $\mathcal{M}(\widetilde{B}//D)=(\mathcal{M}(B//D)\cap B//D)+\mathbb{C}\cdot(1-p)$.

The normalizer algebra $\mathcal{N}(D)\subseteq B$ of D in B, is the intersection of B with the normalizer algebra $\mathcal{N}(D)+\mathbb{C}\cdot 1$ of D in $\widetilde{B}$.

By [**437**, thm.1.4(iii), lem.4.9], the natural epimorphism from $\widetilde{B}$ onto the unital C^*-system $\widetilde{B}//D$ defines a unital *-epimorphism from $\mathcal{N}(D)+\mathbb{C}\cdot 1\subseteq\widetilde{B}=B+\mathbb{C}\cdot$ onto $\mathcal{M}(\widetilde{B}/D)=\mathcal{M}(B//D)+\mathbb{C}\cdot(1-p)\subseteq\widetilde{B}//D=B//D+\mathbb{C}\cdot(1-p)$ with kernel D. It follows that the natural epimorphism from B onto $B//D$ defines a *-epimorphism from $\mathcal{N}(D)$ onto $\mathcal{M}(B//D)\cap B//D$ with kernel $=D$.

Ad(ii): Let e with $e\widetilde{B}^{**}=B^{**}$ as in the proof of parts (o,i).

If $x, x^*x, xx^* \in B//D \subseteq \widetilde{B}//D$, then $x \in \mathcal{M}(\widetilde{B}//D) \cap B//D = \mathcal{M}(B//D) \cap B//D$ by [**437**, lem.4.8(ii)] and proof of part(i).

Conversely, $x, x^*x, xx^* \in B//D$ if x is in $\mathcal{M}(B//D) \cap B//D \subseteq (1-p)B^{**}(1-p)$, because $\mathcal{M}(B//D) \cap B//D$ is a closed ideal of the C^*-subalgebra $\mathcal{M}(B//D)$ of $(1-p)B^{**}(1-p)$ by part(i).

Ad(iii): Because π_D and $\pi_{L+R}|\mathcal{N}(D)$ are the same, $\pi_D(\mathcal{N}(D) \cap J)$ is contained in $\pi_D(\mathcal{N}(D)) \cap \pi_{L+R}(J)$.

If $a \in J$ and $\pi_{L+R}(a) \in \pi_D(\mathcal{N}(D))$, then there exists $b \in \mathcal{N}(D)$ with $b - a \in R + L$. If we apply the quotient map π_J from B onto B/J to b, then $\pi_J(b) \in \pi_J(R) + \pi_J(L)$, and $\pi_J(b)$ is in the normalizer algebra $\mathcal{N}(\pi_J(D))$.

Since $\pi_J(R)$ and $\pi_J(L)$ are the closed right and left ideals generated by $\pi_J(D)$, we have that $\mathcal{N}\big(\pi_J(D) \cap (\pi_J(R) + \pi_J(L))\big) = \pi_J(D)$. It follows $\pi_J(b) \in \pi_J(D)$, i.e., $b \in D + J$. If $b = d + c$ with $d \in D$ and $c \in J$, then $c = b - d \in \mathcal{N}(D) \cap J$ and $\pi_D(c) = \pi_D(a)$.

Ad(iv): Since T is completely positive and completely isometric, it follows that $\gamma\colon A \to B//D$ is completely positive and completely isometric. Thus, in $(B//D)^{**} \cong (1-p)B^{**}(1-p)$ holds $\gamma(a)^*\gamma(a) \le \gamma(a^*a)$ and $a^*a \le T^{**}(\gamma(a)^*\gamma(a)) \le a^*a$. It gives $\gamma(a^*a) = \gamma(a)^*\gamma(a)$ for $a \in A$, i.e., $\gamma\colon A \to \gamma(A) \subseteq (B//D)^{**}$ is a C^*-morphism. Hence $\gamma(A) \subseteq \mathcal{M}(B//D)$ by part (ii).

Ad(v): Let $J \lhd B$. We get $J \subseteq \mathrm{Ann}(D, J)$ from the definition $\mathrm{Ann}(D, J) := \{b \in B\,;\; bD + Db \subseteq J\}$.

An element $b \in B$ satisfies $\pi_J(bD) = \pi_J(b)\pi_J(D) = \{0\}$ if and only if $bD \subseteq J$. Thus,

$$\pi_J(\mathrm{Ann}(D, J)) = \mathrm{Ann}(\pi_J(D)) := \mathrm{Ann}(\pi_J(D), 0)\,.$$

It follows that $\mathcal{N}(D) \cap \mathrm{Ann}(D, J) = \mathcal{N}(D) \cap J$ if $\pi_J(D)$ is essential in B/J.

If $\pi_D(\mathcal{N}(D) \cap \mathrm{Ann}(D, J)) = \pi_D(\mathcal{N}(D) \cap J)$, and $\pi_J(bD) = \pi_J(b)\pi_J(D) = \{0\}$, then $b^*b \in \mathrm{Ann}(D, J)$

20. Open projections and Kadison transitivity

Remark A.20.1. We use the following lemmata and the Lemma 2.2.3 in the proof of Proposition 2.2.5 and in proofs in Chapter 3.

The proofs do not allow something "up to ε" instead they require "precise" algebraic variants of the Kadison transitivity theorem (cf. [**616**, thm. 2.7.5]) for projections $p^* = p \in A^{**}$ with $pA^{**}p$ of finite linear dimension (i.e., p is in the C^*-algebra-"socle" of A^{**} considered as C^*-algebra).

The variant [**616**, thm. 2.7.5] of the Kadison transitivity theorem *implies* that, for each projection $q \in pA^{**}p$, there exists a self-adjoint contraction $a^* = a \in A$, $\|a\| \leq 1$ with $p - 2q = (1-2q)p = ap$.

It shows that the natural C^*-morphism $A_0 := p' \cap A \ni a \mapsto ap \in pMp$ is surjective.

The theorem [**616**, thm. 2.7.5] covers also that case of any projections p in the "socle" socle(A^{**}) of A^{**}, because there exists a normal non-degenerate *-representation $D\colon A^{**} \to \mathcal{L}(\mathcal{H})$ such that $D|pA^{**}p$ is faithful and $D(p)$ has finite rank, i.e., $\mathrm{Dim}(D(p)\mathcal{H}) < \infty$, cf. Lemma 2.1.15(i).

Here the (french) notation "socle" ("pedestal", "base"?) of a Banach *-algebra B is defined (since ca. 1950) by

$$\mathrm{socle}(B) := \{ b \in B\,;\ \mathrm{Dim}(b^*Bb) < \infty \}\,.$$

See ?????

It gives that for each selfadjoint contraction $b^* = b \in pA^{**}p = pAp$ there is a self-adjoint *contraction* $a^* = a$ in A with $pa = ap = b$.

Notice that all this happens also in the cases of real C^*-algebras, C^*-ternary algebras etc., e.g. in the case of real C^*-algebras, the same result with skew-adjoint elements $b^* = -b \in A$:

Then $c := e_{12} \otimes b - e_{21} \otimes b$ is self-adjoint in $(p \oplus p)M_2(A)(p \oplus p) = M_2(pAp)$.

A self-adjoint contraction $a^* = a \in M_2(A)$, $a(p \otimes p) = (p \otimes p)a$ and $a(p \otimes p) = c$ satisfies for its entries

$$[a_{jk}] = e_{11} \otimes a_{11} + e_{12} \otimes a_{12} + e_{21} \otimes a_{21} + e_{22} \otimes a_{22}$$

that $a_{12}^* = a_{21}$, $a_{11}^* = a_{11}$, $a_{22}^* = a_{22}$, $pa_{jk} = a_{jk}p$, $pa_{11} = 0$, $pa_{22} = 0$, $pa_{12} = b$, $pa_{12}^* = -b$. Thus, $a := (1/2)(a_{12} - a_{12}^*)$ is skew-adjoint and $pa = ap = b$.

It follows that p commutes with a and $pap^2 = pap$. Hence, a is in the **multiplicative domain** $\mathrm{Mult}(V) \subseteq A$ of the completely positive map

$$V\colon a \in \widetilde{A} \to pap \in pA^{**}p\,.$$

Since the finite-dimensional real C^*-algebra $pA^{**}p$ is the linear span of its projections, the restriction of V to the C^*-subalgebra $\mathrm{Mult}(V)$ of A is a *-epimorphism from $\mathrm{Mult}(V)$ onto $pA^{**}p$.

In particular, for each irreducible representation $d\colon A \to \mathcal{L}(\mathcal{H})$, we get that for $x, y \in \mathcal{H}$ with $\|x\| = \|y\| = 1$ there exists $e \in A$ with $d(e)x = y$ *and* $\|e\| = 1$. Then $\psi(e^*e) = 1$ if ψ denotes the pure state $\psi(a) := \langle d(a)x, x\rangle$.

Compare Remark A.18.4 for an alternative proof of the existence of a C^*-subalgebra $B \subseteq A$ such that $B \ni b \mapsto pbp \in pA^{**}p$ is a *-epimorphism.

21. On excision of pure states

We need non-separable and "precise" versions of well-known excision results e.g. in [**6**]. Here we consider only excision for pure states on C^*-algebras A. The idea is, to show that every separable C^*-subalgebra is contained in an eventually bigger separable C^*-subalgebra with the property that the restriction of the pure state to this bigger one is again a pure state. For use in proofs, recall here that all hereditary C^*-subalgebras D of separable C^*-algebras are σ-unital.

HERE some comments (important ??, check it, erase unnecessary discussions):

Before the proofs of some Lemmata and the Proposition A.21.4 let us mention some of the conclusions from them. One of it is the following important property:

For every C^*-algebra A and any pure state φ on A, the separable C^*-subalgebras B of A with the property that $\varphi|B$ is again an irreducible state on B build an upward directed net of separable C^*-subalgebras of A such that each separable C^*-subalgebra of A is contained in one member of this net.

In particular, A is the (algebraic, set-theoretic) union of this special separable C^*-subalgebras, and one can combine it with a countable number of other properties of separable C^*-subalgebras of A, as considered in other sections in the Appendices A and B, e.g. B can be chosen that it is relative weakly injectivity in A, that all ideals of B are intersections of ideals of A with B .... And we can see that A is the set-theoretic union of the upward directed family of all separable C^*-algebras that have all this countably many properties together...

The sequence $(e^n)_{n\geq 1}$ of elements in $B \subseteq A$ with $G \subseteq B$ in Proposition **??** "excises" in a very sharp sense the restriction $\varphi|B$ of the pure state φ. If one allows to do the same with some more general nets of positive contractions for some state φ on A then this φ can be "excised", if and only if, φ is in the $\sigma(A^*, A)$-closure of the pure states on A – compare [**6**, def. 2.1, prop. 2.2] for this more general excision property, which is not equivalent to our demand of accuracy for our definition of "strict excision".

Here we equip the reader with necessary information on this topic to understand our methods for a detailed study of sufficient conditions on simple C^*-algebras A that cause pure infiniteness of A. (In fact we provide a big list of equivalent properties for simple C^*-algebras in Sections 2 to 4 of Chapter 2 that each imply or are equivalent to pure infiniteness.)

The here constructed special fixed element e is a contraction that "supports" φ sharply if A is separable and $G = A$, i.e., then the extreme point φ of the quasi-state space A, i.e., the set of *all* linear functional on A of norm one, is the unique *peak point* for suitable $e \in A_+$ and $e \leq 1$ with $A = \overline{eAe}$.

For given pure states φ on separable or non-separable A there are many positive contractions e of norm $\|e\| = 1$ with the property that φ is a peak point of $e \in A_+$ if A has no sub-quotient of type I, e.g. e^t for $t \in (0, \infty)$.

We use another terminology that describes all with help of quotient C^*-spaces $A/(L^* + L)$ build from C^*-algebras by using left-ideals L because those anyway play a role in some of our proofs e.g. for the embedding theorem.

For non-separable A one gets usually only a convex subset of positive contraction $k \in A_+$ with $\varphi(k) = 1$. Then $\varphi(k^2) = 1$. If $\varphi \neq \psi$ for some other pure state ψ then there exists a positive contraction $k \in A_+$ with

$$\min(\varphi(k), \psi(k)) < \max(\varphi(k), \psi(k)) = 1$$

by application of Kadison transitivity to projections in $p \in A^{**}$ with $pA^{**}p$ isomorphic to M_2 or $\mathbb{C} \oplus \mathbb{C}$.

This follows e.g. from Remark A.18.9 by considering the C^*-algebra

$$A/\big((L_\varphi \cap L_\psi)^* + (L_\varphi \cap L_\psi)\big)\,.$$

It is an, – at most 4-dimensional and at least 2-dimensional –, quotient C^*-space of A (which is automatically a C^*-algebra because of its finite dimension as a vector space).

Lemma A.21.1. *Let E a C^*-algebra and $J \triangleleft E$ a non-zero σ-unital closed ideal of E such that E/J is one-dimensional.*

Then E contains a strictly positive contraction $e \in E_+$ such that $\pi_J(e) = 1_{E/J}$ and that $e - e^2$ is a strictly positive element of J.

Proof. Let $\psi(t) := \min(t, 1)$ for $t \in [0, \infty)$. Since E/J is one-dimensional, there is unique element $d \in (E/J)_+$ with $\|d\| = 1$, i.e., $d = 1_{E/J}$. Let $g \in E$ a lift of d, i.e., $\pi_J(g) = d^{1/2} = d$. Then $c := \psi(g^*g)$ is a positive contraction $c \in E_+$ with $\pi_J(c) = d = 1_{E/J}$. By assumption, J_+ contains a strictly positive element h. We may suppose that $\|h\| = 1/2$, – otherwise replace h by $\|2h\|^{-1}h$.

We have now $c \in E_+$ with $0 \leq c \leq 1$ in $E + \mathbb{C} \cdot 1 \subseteq \mathcal{M}(E) \subseteq E^{**}$ and $\pi_J(c) = 1_{E/J}$ and a strictly positive element $h \in J_+$ for J with norm $\|h\| = 1/2$. Then $1/2 \leq 1 - h \leq 1$ and $2 \cdot 1 \leq (1 - h)^{-1}$ in $\mathcal{M}(E)$. (Here 1 denotes the unit of $\mathcal{M}(E)$.)

This implies that $c + h$ is strictly positive in E and $c + h \leq (1 - h)^{-1} \in \mathcal{M}(E)$. We define a positive contraction by

$$e := (1 - h)^{1/2}(c + h)(1 - h)^{1/2} \quad \in E_+\,.$$

The element e is strictly positive in E because $(1 - h)^{1/2}$ is invertible in $\mathcal{M}(E)$ and $c + h$ is strictly positive in E.

Obviously $(1 - h)^{1/2}h(1 - h)^{1/2} = h - h^2 \in J_+$ and $c^{1/2}hc^{1/2} \in J_+$. Thus $\pi_J(e) = \pi_J(c) = 1_{E/J}$ by the MvN-equivalence

$$(1 - h)^{1/2}c(1 - h)^{1/2} \sim_{MvN} (c - c^{1/2}hc^{1/2})\,.$$

It implies $e - e^2 \in J_+$ because $0 \leq e \leq 1$.

If we use that $0 \leq c \leq 1$ to get $e \leq (1 - h)^{1/2}(1 + h)(1 - h)^{1/2} = 1 - h^2$, i.e., that $h^2 \leq 1 - e$. It implies that $e^{1/2}h^2e^{1/2} \leq e - e^2 \in J_+$.

The contraction h^2 is strictly positive in J because h is strictly positive in J. Now observe that if J is a closed ideal, h^2 is strictly positive in J and e is strictly positive in E, then $e^{1/2}h^2e^{1/2}$ is strictly positive in J. □

DEFINITION A.21.2. Let A C^*-algebra and ρ a state on A. We say that ρ has the **excision property** if there exists a net of positive contractions $\{e_\tau\}_{\tau\in\Sigma} \subseteq A_+$ that satisfy that $\rho(e_\tau) = 1$ for all $\tau \in \Sigma$ and

$$\lim_{\tau\in\Sigma} \| \, e_\tau a e_\tau \, - \, \rho(a)e_\tau^2 \, \| \, = 0 \, .$$

We say that a state ρ on A has the **strict excision property** if A contains a positive contraction $e \in A_+$ with $\rho(e) = 1$ such that

$$\lim_{n\to\infty} \|e^n a e^n - \rho(a)e^{2n}\| = 0 \quad \text{for all } \; a \in A \, .$$

It is not difficult to see that a state ρ on A with the property that there exists $e \in A_+$ with $\|e\| \leq 1$, $\rho(e) = 1$ and $\lim_n \|e^n a e^n - \rho(a)e^{2n}\| = 0$ must be necessarily a pure state on A:
The assumptions show that $\|e\| = 1$, i.e., there is a pure state λ on A with $\lambda(e) = 1$. Then $\lambda(xe^k) = \lambda(e^k x) = \lambda(x)$ for all $x \in A$, and this implies $\lim_n \, (\lambda(a) - \rho(a)) \, = 0$, for all $a \in A$, i.e., $\rho = \lambda$ is pure.

LEMMA A.21.3. *Let B separable C^*-algebra, ρ a state on B.*

The state ρ is a pure state on B, if and only if, there exists $e \in B_+$ with $\|e\| = 1$, $\rho(e) = 1$ and

$$\{b \in B; \, \rho(b) = 0\} \, \subseteq \, \overline{(e - e^2)B} + \overline{B(e - e^2)} \, . \tag{21.1}$$

In particular, then ρ has the strict excision property *in Definition A.21.2, i.e., there there exists $e \in B_+$ with $\rho(e^n) = 1 = \|e\|$ for all $n \in \mathbb{N}$, and*

$$\lim_{n\to\infty} \|e^n b e^n - \rho(b)e^{2n}\| = 0 \quad \textit{for all } \; b \in B \, .$$

PROOF. Suppose that ρ is a state on B and $e \in B_+$ with $\rho(e) = 1 = \|e\|$. Then $1 \leq \rho(e)^2 \leq \rho(e^2) \leq \rho(e) = 1$, It follows that $0 \leq e - e^2 \leq e$ and $0 \leq \rho((e - e^2)^2) \leq \rho(e - e^2) = 0$ imply that $\rho((e - e^2)b^*b(e - e^2)) = 0$ for all $b \in B$. Thus, $\rho(b^*b) = 0$ for all $b \in L := \overline{B(e - e^2)}$. It says that the closed left ideal L is contained in $L_\rho := \{b\, ; \; b \in B, \rho(b^*b) = 0\}$, i.e., $L \subseteq L_\rho$. It is easy to see that always $L_\rho^* + L_\rho \subseteq \rho^{-1}(0)$. If we combine this containment with the containment $\rho^{-1}(0) \, \subseteq \, L^* + L$ in (21.1), then we get that

$$\rho^{-1}(0) = L_\rho^* + L_\rho \, .$$

But this shows that the state ρ is a pure state, because [**616**, prop. 3.13.6.(i,ii)] says that ρ is pure state on B, if and only if, $L_\rho^* + L_\rho = \rho^{-1}(0)$, i.e., ρ is a pure state, if and only if, $L_\rho^* + L_\rho$ is equal to the null-space of ρ.

Now let ρ be a pure state on the separable C^*-algebra B. We are going to show that there exists a strictly positive contraction $e \in B_+$ with $\rho(e) = 1$, that satisfies with $L := \overline{B(e-e^2)}$ the equation

$$\rho^{-1}(0) \,=\, L^* + L\,.$$

In particular, then e is a strictly positive contraction in B, $L^* + L + \mathbb{C}\cdot e = B$, and $e - e^2$ is a strictly positive element of $L^* \cap L$.

A special case of the Kadison transitivity theorem shows then the existence of $c \in B_+$ with $\|c\| = \rho(c) = 1$, cf. [**616**, thm. 2.7.5, thm. 3.13.2(vi)]. – or use our more engaged Lemma 2.1.15(ii,iii) for that.

The positive contraction $c \in B_+$ satisfies then $1 = \rho(c)^2 \le \rho(c^2) \le \rho(c) = 1$. Thus, $\rho(c^2) = 1$ and $\rho(c - c^2) = 0$.

Let $h\colon B \to \mathcal{L}(\mathcal{H})$ the corresponding irreducible representation with cyclic vector $v \in \mathcal{H}$ corresponding to ρ, i.e., $\|v\| = 1$ and $\langle h(b)v, v\rangle = \rho(b)$ for $b \in B$. Then $\|c\| = 1 = \rho(c) = \rho(c^2)$ and $c \ge 0$ imply that $h(c)v = v$, because $\|(1 - h(c))v\|^2 = \langle h(c)v, h(c)v\rangle + \langle v, v\rangle - \langle v, h(c)v\rangle - \langle h(c)v, v\rangle = \rho(c^2) + 1 - 2\rho(c) = 0$, – here with $\mathrm{id}_{\mathcal{H}}$ is denoted by 1.

It follows that $\rho(b) = \rho(bc) = \rho(cbc) = \rho(cb)$ for all $b \in B$. In particular, $\rho(cb^*bc) = \rho((bc)^*bc) = \rho(b^*b)$ for all $b \in B$.

Thus, the closed left ideal $L := \{b \in B\,;\ \rho(b^*b) = 0\}$ of B has the property $L \cdot c \subseteq L$. Notice that $B = L^* + L + \mathbb{C}\cdot c$, because $L^* + L$ is the kernel of the pure state ρ and $\rho(c) = 1$.

Since B is separable, the hereditary C^*-subalgebra $D := L^* \cap L$ of B contains a strictly positive element $g \in D_+$ for D. The positive part D_+ of D consists of all $b \in B_+$ with $\rho(b) = 0$. In particular, $c - c^2 \in D_+$. It follows that $g + c$ is a strictly positive element of B.

The relation $L \cdot c \subseteq L$ impies that $D \cdot c \subseteq D$ and $c \cdot D \subseteq D$. It says that the $E := D + \mathbb{C}\cdot c$ is a C^*-subalgebra of B, D is a closed ideal of E, $\rho|E$ is a character on E with kernel equal to D and $\rho(\xi \cdot c) = \xi$ for all $\xi \in \mathbb{C}$, i.e., E/D is one-dimensional. If we identify $\mathbb{C}$ naturally with $\pi_D(E) = E/D$, then the quotient map π_D is just the character $\rho|E$.

By Lemma A.21.1, E contains a strictly positive contraction $e \in E_+$ such that $\pi_D(e) = 1_{E/D}$ and that $e - e^2$ is a strictly positive element of $D = L^* \cap L$ that is the kernel of $\rho|E$ – if we adjust the identification of $\mathbb{C}$ with E/D such that $1 \in \mathbb{C}$ corresponds to $1_{E/D}$, i.e., $\rho|E$ maps e and c in $D + \mathbb{C}\cdot c$ onto the unit-element of $E/D \cong \mathbb{C}\cdot\rho(c) = \mathbb{C}$ by the character $\rho|E$ with $\rho(e) = \rho(c) = 1$.

Now we return to $B = L^* + L + \mathbb{C}\cdot c$. We got also $B = L^* + L + \mathbb{C}\cdot e$, because $\rho(e) = \rho(c)$ and $L^* + L$ is the kernel of ρ. Since $e - e^2$ is a strictly positive element of $D = L^* \cap L$ (by above construction of e), it follows that $L = B \cdot D = \overline{B \cdot (e - e^2)}$ and $L^* = \overline{(e - e^2)\cdot B}$.

Finally we estimate the norms $\|e^n b e^n - \rho(b) e^{2n}\|$ for large $n \in \mathbb{N}$:
Each element $b \in B = L^* + L + \mathbb{C}\cdot e$ can be written as $b = b_1 + b_2 + \alpha\cdot e$ with $b_1^* \in L$, $b_2 \in L$, $\alpha \in \mathbb{C}$. Then $\rho(b) = \alpha$ and the equation $L = \overline{Be(1-e)}$ implies

that, for given $\delta \in (0,1)$, there exist $c_1, c_2 \in B$ with $\|b_1 - e(1-e)c_1\| < \delta$ and $\|b_2 - c_2 e(1-e)\| < \delta$. Notice that $\|e^n c_1 (1-e)e^n\| \leq \|c_1\| \|(1-e)e^n\|$ and use that $\lim_{n\to\infty} \|e^n(1-e)\| = 0$ to get that $\lim_n \|e^n b e^n - \rho(b)e^{2n}\| \leq 3\delta$ for arbitrary $\delta \in (0,1)$. □

The following Proposition is essentially [**93**, lem. 2.14]. But we give here together with Lemma A.21.3 a more detailed proof, because it plays a basic role for proofs of some other results.

Proposition A.21.4. *Let φ be a pure state on a C^*-algebra A and $G \subseteq A$ a separable C^*-subalgebra.*

Then there exist a separable C^*-subalgebra $B \subseteq A$ and an element $e \in B_+$ with the properties $G \subseteq B$, $\|e\| = 1$, $\varphi(e) = 1$ and

$$\{b \in B;\, \varphi(b) = 0\} \subseteq \overline{(e-e^2)B} + \overline{B(e-e^2)}\,.$$

In particular, $\varphi|B$ is a pure state on B and has the strict excision property in Definition A.21.2 by Lemma A.21.3.

It shows that every pure state on a C^*-algebra A has the excision property *of Definition A.21.2.*

Proof of Proposition A.21.4. Let $\varphi \in A^*_+$ a pure state, i.e., an extreme point of the convex set of positive linear functionals on A of norm $= 1$. There are many equivalent properties of a state φ that imply that φ is a pure state, e.g. by [**616**, prop. 3.13.6(i,ii)]: The closed left ideal $L := L_\varphi$ of A defined by $L := L_\varphi := \{a \in A;\, \varphi(a^*a) = 0\}$ satisfies $\varphi^{-1}(0) = L^* + L$, if and only if, φ is a pure state on A.

`compare with text:`

Then a special case of the Kadison transitivity theorem shows the existence of $c \in A_+$ with $\|c\| = \varphi(c) = 1$, e.g. use [**616**, thm. 2.7.5, thm. 3.13.2(vi)] or use our farer going Lemma 2.1.15(ii,iii) to get such $c \in A_+$.

The purity of φ implies that

$$\{a - \varphi(a)c;\; a \in A\} = L^* + L = \ker(\varphi)\,,$$

cf. [**616**, thm. 3.13.2(iv), prop. 3.13.6] for the second equation. It yields that $P\colon A \to A$ defined by $P(a) := a - \varphi(a)c$ maps A into $\ker(\varphi)$ and satisfies $P(a) = a$ for all $a \in \ker(\varphi)$, $\|P\| \leq 2$ and $P^2 = P$, i.e., is a linear projection of norm $\|P\| \leq 2$ from A onto $\ker(\varphi)$.

The maps $a \in A \mapsto \varphi(a) \cdot c \in A$ and id_A are completely positive contractions. Thus, the map $P(a) := a - \varphi(a)c$ on A has a cb-norm $\|P\|_{cb} \leq 2$, in particular $\|P\| \leq 2$. Obviously, $\varphi(P(a)) = 0$ for all $a \in A$, – i.e., $P(A) \subseteq \varphi^{-1}\{0\}$ –, and $\varphi(a) = 0$ implies $P(a) = a$. Thus, $\varphi^{-1}\{0\} \subseteq P(A)$. It shows that

$$P(A) = \varphi^{-1}\{0\} = L^* + L \quad \text{and} \quad P^2 = P\,.$$

In particular, $P(a) = a$ if and only if $a \in L^* + L$. The same arguments (– but with $b \in B$ in places of a –) show that $P(B) = B \cap (L^* + L)$ for every linear subspace B of A with $c \in B$ ([13]).

The projection map P has following property: If $B_1 \subseteq B_2 \subseteq \cdots$ and $B := \overline{\bigcup_n B_n}$ then $P(B) = \overline{\bigcup_n P(B_n)}$.

Now let $G \subseteq A$ a separable C^*-subalgebra of A, and let B_1 the separable C^*-subalgebra of A generated by $G \cup \{c\}$. Then $(L^* + L) \cap B_1 = P(B_1)$, in particular $P(B_1) \subseteq B_1$.

By the – here very crucial – Corollary A.15.3, there exists a separable C^*-subalgebra $B_2 \subseteq A$ with the properties that $B_1 \subseteq B_2$ and

$$B_1 \cap (L^* + L) \subseteq (L^* \cap B_2) + (L \cap B_2)\,.$$

We can repeat this construction and argument by induction, and get an increasing sequence of separable C^*-subalgebras $B_1 \subseteq B_2 \subseteq B_3 \subseteq \cdots$ of A with the property

$$B_n \cap (L^* + L) \subseteq (L^* \cap B_{n+1}) + (L \cap B_{n+1}) \subseteq B_{n+1} \cap (L^* + L)\,.$$

Let B denote the closure of $\bigcup_{n \in \mathbb{N}} B_n$. Then, for all $n \in \mathbb{N}$,

$$B_n \cap (L^* + L) \subseteq (L^* \cap B) + (L \cap B) \subseteq B \cap (L^* + L)\,.$$

(Use here that $(L \cap B) \subseteq B \cap (L^* + L)$ and $L \cap B_{n+1} \leq L \cap B$.)

The space $\bigcup_n B_n \cap (L^* + L)$ is dense in $B \cap (L^* + L)$:
$P(B_n) = B_n \cap (L^* + L)$ and $P(B) = B \cap (L^* + L)$, because $c \in B_n \subseteq B$. Since P is a bounded projection and $\bigcup_n B_n$ is dense in B we get that $\bigcup_n P(B_n)$ is dense in $P(B)$.

The sum $(L^* \cap B) + (L \cap B)$ is the sum of a closed left and closed right ideal of B. Sums $K^* + K := \{x^* + y\,;\ x, y \in K \subseteq B\}$ build by closed left ideals $K \subseteq B$ of B are always closed subspaces of B by Proposition A.15.2.

We get that $P(B) \subseteq (L^* \cap B) + (L \cap B)$, because $B_n \cap (L^* + L) = P(B_n) \subseteq B_{n+1} \cap L^* + B_{n+1} \cap L$ and $\|P\| \leq 2$.

It follows that $P(B) = B \cap (L^* + L) = B \cap \varphi^{-1}\{0\}$ is equal to $(L^* \cap B) + (L \cap B)$ and is the kernel of the restriction $\psi := \varphi|B$ of φ to B. Notice that $b \in L \cap B$, if and only if, $\psi(b^*b) = 0$, i.e., $L \cap B = L_\psi$, where $L_\psi := \{b \in B\,;\ \psi(b^*b) = 0\}$. The characterization of pure states on B, given by the above cited [**616**, prop. 3.13.6(i,ii)], shows that $\psi := \varphi|B$ is a pure state on B, because ψ satisfies the purity criterium $\psi^{-1}(0) = L_\psi^* + L_\psi$.

Notice that $G \subseteq B_1 \subseteq B$ and that B is separable.

---

[13] Notice here that it could be that $\varphi|B$ is not a pure state on a C^*-subalgebra B of A with $c \in B$ ... except in some special cases where $\varphi|B$ is the only state ρ on B with $\rho(c) = 1$. For example, take $A := M_2$, $c := 1_2$ and let $B \subseteq A$ the diagonal elements in A. Then $\varphi([\alpha_{jk}]) = 2^{-1} \sum_{jk} \alpha_{jk}$ is a pure state on A but not on B.

By Lemma A.21.3 there exists an element $e \in B_+$ with the properties $\|e\| = 1$, $\varphi(e) = 1$ and

$$\{b \in B;\, \varphi(b) = 0\} \subseteq \overline{(e - e^2)B} + \overline{B(e - e^2)}\,,$$

and B has the strict excision property of Definition A.21.2.

Since we can do this selection procedure for every given separable subset G of A with with respect to a given fixed pure state of A, we can see that each pure state of A has the (in general not “strict”) excision property of Definition A.21.2. □

22. Some technical functions on $[0, 1]$

We use often for some very elementary approximation technics the increasing piecewise linear functions $h_n \in \mathrm{C}_0(0, 1]_+$ with break points at 2^{-n}, $n = 0, 1, 2, \ldots$, given by

$$h_n(t) := \min(1, \max(2^n t - 1, 0)) \quad \text{for } t \in [0, 1],\ n = 0, 1, \ldots\ .$$

In the C^*-algebra $\mathrm{C}_0(0, 1]$ and $n \in \mathbb{N}$ they are given by

$$h_0 := 0\,,\ h_1 := (2f_0 - 1)_+\,,\ \ldots\,,\ h_n := (2^n f_0 - 1)_+ - (2^{n-1} f_0 - 1)_+\,,$$

where $f_0 \in \mathrm{C}_0(0, 1]$ denotes the identity map $f_0(t) := t$ on $(0, 1]$.

The below listed properties of the h_n can be easily seen on the intervals $[2^{-n}, 2^{-(n-1)}]$, because the functions h_n are linear on two of this intervals and take outside them only the values 0 and 1:

(i) $h_n|[0, 2^{-n}] = 0$, $h_n|[2^{-n}, 2^{-(n-1)}]$ is the linear map

$$h_n(t) := (2^{-(n-1)} - 2^{-n})^{-1}(t - 2^{-n}) \quad \text{for } t \in [2^{-n}, 2^{-(n-1)}]$$

and $h_n|[2^{-(n-1)}, 1] = 1$. In particular, $h_n \in \mathrm{C_c}(0, 1]_+ \subset \mathrm{C}_0(0, 1]_+$ for all $n \in \mathbb{N}$, and $h_0 := 0$ on $[0, 1]$.

(ii) The set $(2^{-n}, 1]$ is the open support of h_n in $[0, 1]$, and is contained in $h_{n+1}^{-1}(1) = [2^{-n}, 1]$. In particular,

$$0 \le h_{n+1} h_n = h_n \le h_{n+1} \le 1 \quad \text{for all } n \in \mathbb{N}\,.$$

(iii) The non-negative function $h_{n+1} - h_n$ has support in the open interval $(2^{-(n+1)}, 2^{-(n-1)})$, i.e., is zero on $[0, 2^{-(n+1)}]$ and $[2^{-(n-1)}, 1]$, is linear increasing on $[2^{-(n+1)}, 2^{-n}]$ with value $(h_{n+1} - h_n)(2^{-n}) = 1$ and is linear decreasing on $[2^{-n}, 2^{-(n-1)}]$.

In particular, $h_{n+2}(t) - h_{n+1}(t) = 1 - h_{n+1}(t)$ for $t \in [2^{-(n+1)}, 2^{-n}]$.

(iv) The restriction to $[2^{-(n+1)}, 2^n]$ of the, – in $\mathrm{C}_0(0, 1]$ absolute convergent and on all intervals $[1/n, 1]$ uniformly convergent –, series

$$\sum_{n=0}^{\infty} 2^{-n}(h_{n+1}(t) - h_n(t))$$

is on $[2^{-(n+1)}, 2^n]$ just equal to the increasing linear function

$$2^{-(n+1)}(1 + h_{n+1})|[2^{-(n+1)}, 2^n]$$

with values $2^{-(n+1)}$ and 2^{-n} at the end-points.

Thus, the series $\sum_{n=0}^{\infty} 2^{-n}(h_{n+1} - h_n)$ converges uniformly on $[0,1]$, and converges *absolute* in the Banach space $C_0(0,1]$ to $f_0(t) := t$, because

$$\sum_{n=0}^{\infty} 2^{-n}\|h_{n+1} - h_n\| \leq 2\,.$$

(v) The h_n have the othogonality property $h_n(h_{n+2} - h_{n+1}) = 0$.

(vi) For each $\gamma \in (0,1]$ only finitely many functions $h_n - h_{n-1}$ have support in $[\gamma, 1]$. In particular, $\sum_{n\geq 1}(h_n - h_{n-1})$ converges on each interval $[\gamma, 1]$ uniformly to 1.

(vii) The functions $\psi_n := (h_n - h_{n-1})^{1/2} \in C_0(0,1]$ (applied to $t = f_0(t)$) are well-defined, have support in in $[2^{-n}, 2^{-n}4]$.

In particular, $\psi_n\psi_m = 0$ for $|n-m| > 1$.

(viii) The sum $\sum_{n=1} \psi_n^2$ converges in the multiplier algebra $\mathcal{M}\big(C_0(0,1]\big) \cong C_b\big((0,1]\big)$ strictly to 1, because $\sum_{n=1}(h_n - h_{n-1})$ converges on each interval $[2^{-n}, 1]$ uniformly to $1 = \lim_n h_n$. (See Remark 5.1.1(2) concerning strict convergence.)

An Application of the functions $h_1, h_2, \ldots$ is the below given simple Example A.22.1. It shows that the $\approx$-classes in $W(A)$ and the corresponding $\approx$-classes in $\mathrm{Cu}(A)$ are not the same for $A := C_0(0,1]$. Notice that the Pedersen ideal of this C^*-algebra A is $C_c(0,1]$ and our "small Cuntz semigroup $\mathrm{CS}(A)$" defined and used in

where ????????

is also different from $W(A)$ and $\mathrm{Cu}(A)$. (But here $\mathrm{Cu}(A)$ has "good comparison" because of $\mathrm{Dim}((0,1]) = 1$!)

Check calculations and notations in example:
Seems to be no real progress with comparison.
But it is likely to be true ... Perhaps pass to $M_{2n}(C_0(0,1])$ ... and combine with the h_n

EXAMPLE A.22.1. The $\approx$-classes in $W(A)$ and the corresponding $\approx$-classes in $\mathrm{Cu}(A)$ are not the same for $A := C_0(0,1]$.

Consider $A := C_0(0,1]$ and define $g_n(t) := \big(2^{-n}(h_{n+1}(t) - h_n(t))\big)^{1/2}$. Let $T := \sum_{n=1}^{\infty} g_n \otimes p_{1,n}$.

Then $T \in C_0(0,1] \otimes \mathbb{K}$ and $TT^* = (\sum g_n^2) \otimes p_{11} = f_0 \otimes p_{11}$ for $f_0(t) := t$, but the "almost diagonal" matrix

`check formula for` T^*T `!!!`

$$T^*T = \sum_n g_n g_{n+1} \otimes p_{n,n+1} + g_n g_{n-1} \otimes p_{n+1,n} + \sum_n 2^{-n}(h_{n+1} - h_n) \otimes p_{nn}$$

is not contained in $\bigcup_n M_n(A)$.

23. K_1-injectivity and generalized Kuiper theorem

Compare with related topics in Section 2 of Chapter 4
in particular with the squeezing property in Definition 4.2.14.
It is the basic observation used in the proof of Part(c) of
Proposition 4.2.15.

We reformulate some technical lemmata of J. Cuntz and N. Higson in [**172**] and [**180**], that we use for example to derive generalizations of Kuiper's Theorem [**505**] in the spirit of J. Cuntz, N. Higson [**180**] and J. Mingo [**557**] by generalizing their ideas to C^*-algebras that have our "squeezing" Property (sq) of Definition 4.2.14.

We modify ideas in [**180**] to get a proof of the following easier applicable Lemma.

Lemma A.23.1. *If B is a σ-unital and stable, then, for every separable C^*-sub-algebra C of $\mathcal{M}(B)$, $e \in C$ and $\varepsilon > 0$, there exist isometries $S, T \in \mathcal{M}(B)$ with $T^*CS \subseteq B$, $T^*S = 0$ and $\|T^*eS\| < \varepsilon$.*

Proof. The stability of B causes that for each given $b \in B$ and $\varepsilon > 0$ there exists an isometry $r \in \mathcal{M}(\mathbb{K}) \subseteq \mathcal{M}(B)$ such that $\|r^*br\| < \varepsilon$ (with r depending on b and ε).

Thus, if we later are only interested in showing that $\mathcal{M}(B)$ has the "squeezing" Property (sq) in Definition 4.2.14 for $A := \mathcal{M}(B)$, then it is enough to find, for a given $a \in \mathcal{M}(B)$, isometries $S, T \in \mathcal{M}(B)$ with $T^*aS \in B$ and $S^*T = 0$.

The claimed property $S^*T = 0$ is not important for this proof, because we could replace a considered sequence $b_1, b_2, \ldots$ of contractions in $\mathcal{M}(B)$ anyway by $Q^*b_1R, Q^*b_2R, \ldots$ with isometries $Q, R \in \mathcal{M}(B)$ with $Q^*R = 0$ for this proof, because the isometries QS and RT have the additional orthogonality property $(RT)^*(QS) = 0$.

We describe now a selection method that shows for a given separable C^*-subalgebra C of $\mathcal{M}(B)$ the existence of isometries $S, T \in \mathcal{M}(B)$ with orthogonal ranges and the property that $S^*CT \subseteq B$.

Let $c_1, c_2, \ldots \in \mathcal{M}(B)$ a sequence of contractions in $\mathcal{M}(B)$. Likewise this could be a sequence that is dense in the unit ball of a given separable C^*-subalgebra C of $\mathcal{M}(B)$ and with $c_1 := c$ the particular element that should be squeezed below $\varepsilon > 0$ with help of "squeezing isometries" S and T in $\mathcal{M}(B)$, i.e., with the additional property $\|S^*cT\| < \varepsilon$.)

We describe an inductive selection method for the construction of isometries $S, T \in \mathcal{M}(B)$ with $S^*T = 0$ and $S^*c_nT \in B$ for all $n \in \mathbb{N}$, such that we can apply Remark 5.1.1(2) concerning strict convergence on $\mathcal{M}(B)$ for σ-unital stable B:
The stability of B is equivalent to the existence of a sequence $s_1, s_2, \ldots \in \mathcal{M}(B)$ of isometries with the property that $\sum_k s_k s_k^*$ converges strictly to $1 \in \mathcal{M}(B)$, i.e.,

with respect to the strict topology on $\mathcal{M}(B)$, cf. Remark 5.1.1(8) and Lemma 5.1.2. In particular, the sequence $k \in \mathbb{N} \to \|s_k^* b\| + \|b s_k\|$ converges to 0 for each $b \in B$.

Describe first the selection process.
Because now comes an other observation
about producing new isometries:

The sums $\sum_n s_{\lambda(n)} s_{\lambda(n)}^*$ converge in $\mathcal{M}(B)$ strictly to a projection if $\lambda \colon n \in \mathbb{N} \to \lambda(n) \in \mathbb{N}$ is an injective map. Moreover, the sum $\sum_n s_{\lambda_n} f_n$ converges strictly to an isometry $S_\lambda \in \mathcal{M}(B)$ if $f_1, f_2, \ldots \in \mathcal{M}(B)$ is any sequence with the property that $\sum_n f_n^* f_n$ converges strictly to 1 in $\mathcal{M}(B)$ by Remark 5.1.1(2).

??

We use the following method to construct isometries in $\mathcal{M}(B)$:
Let $e \in B_+$ a strictly positive contraction with $\|e\| = 1$. Apply the functions $h_n, \psi_n \in \mathrm{C}_0(0,1]_+$ as defined in Section 22 with $\psi_n = (h_n - h_{n-1})^{1/2}$ to $e \in A$, i.e., $f_n := \psi_n(e) = (h_n(e) - h_{n-1}(e))^{1/2} \in A_+$. The $\sum_n f_n^2$ converges strictly in $\mathcal{M}(A)$ to $1_{\mathcal{M}(A)}$ and $\sum_n 2^{-n} h_n(e)$ is absolute convergent to e in A.

< Check above?

Thus $S := \sum_{n=1}^{\infty} s_{\lambda(n)} f_n$ converges strictly to an isometry in $\mathcal{M}(A)$ if $\sum_{n=1} s_n s_n^*$ converges strictly to $1_{\mathcal{M}(A)}$ by (two-fold application of) Remark 5.1.1(2).

If $\kappa(n) \in \mathbb{N}$ is another strictly increasing sequence, then for each $b \in \mathcal{M}(A)$ the sequence

$$\sum_{m,n} f_n s_{\kappa(m)}^* b s_{\lambda(n)} f_n$$

unconditional ??? Has to be checked !!!

is strictly convergent in $\mathcal{M}(A)$ with limit $= T^* b S \in \mathcal{M}(A)$ for the isometries $T := \sum_{n=1}^{\infty} s_{\kappa(n)} f_n$ and above defined S.

Let $b_1, b_2, \ldots \in \mathcal{M}(A)_+$ a sequence of positive contractions.

We find inductively a sequences of even numbers $k_n \in 2 \cdot \mathbb{N}$ with $k_1 := 2$, $k_n < k_{n+1}$ and odd numbers $\ell_n \in 1 + 2 \cdot \mathbb{N}$ with $\ell_n < \ell_{n+1}$ that satisfy

$\|(s_{\ell_n})^* b_j s_{k_m} f_m\| < 4^{-n}$ for all $j \le n$ and $m < n$ and $\|f_m (s_{\ell_m})^* b_j s_{k_n}\| < 4^{-n}$ for all $j \le n$ and $m < n$.

Beginning step:

Since $b_j s_2 f_1 \in A$ for $j \in \{1, 2\}$ there exists an odd number $\ell_1 > 1$ with $\|s_{\ell_1}^* b_j s_2 f_1\| < 1/4$ for $j \in \{1, 2\}$.

Then use that $f_1 s_{\ell_1}^* b_j$ are in A for $j \le 3$. It follows that there exists even $k_2 \in \mathbb{N}$ with $k_2 > 2$ and $\|f_1 (s_{\ell_1})^* b_j s_{k_2}\| < 4^{-n}$ for all $j \le 3$.

Still to define/arrange the selection procedure!

Let $m \in \mathbb{N}$ an odd natural number, and given isometries s_{k_j} , $j = 1, \ldots, m$ then find an even index $\ell_m \in \mathbb{N}$ such that $\ell_m > \ell_{m-1}$ and $\|s^*_{\ell_m} b_n s_{k_j} f_j\| < 4^{-n}$ for all $n \leq m + 2$ and $j < m$.

Then go one step higher and select the next odd index k_{m+1} in a similar way.

We select below suitable sequences $f_n \in B_+$ and injective maps $\kappa \colon \mathbb{N} \to \mathbb{N}$ with odd values and $\lambda \colon \mathbb{N} \to \mathbb{N}$ with even values such that $S^*_\lambda b_n S_\kappa \in B$ for all $n \in \mathbb{N}$.

Let $e \in B_+$ a strictly positive element with $\|e\| = 1$. The stability of B implies that 0 is not isolated in the spectrum $\mathrm{Spec}(e) \subseteq [0, 1]$. We take the piecewise linear functions $h_n(\xi) := \min(1, \max(2^n \xi - 1, 0))$ (with break points at 0, 2^{-n}, 2^{1-n} and 1), that is defined in Section 22 (and studied there in every detail), and consider the non-negative functions $\varphi_n(\xi) := \big(h_n(\xi) - h_{n-1}(\xi)\big)^{1/2}$ for $n = 1, 2, \ldots$, where we let $h_0 := 0$. Notice that $\varphi_m \cdot h_n = \varphi_m$ for $m \leq n - 1$.

Then the series $\sum_n \varphi_n(\xi)^2 \xi$ converges uniformly on $[0, 1]$ to f_0, where $f_0(\xi) := \xi$, cf. Property (iv) in Section 22.

It follows that the contractions $f_n := \varphi_n(e) \in A_+$ and $e_n := h_{n+1}(e) \in A_+$ have the property that $f_m e_n = f_m$ for all $m \leq n$ and $\sum_n f_n^2 e$ converges in norm inside B to $e \in B$.

Refere to Property (iv???) in Section 22???

Hence, $\sum_n f_n^2$ converges strictly to $1_{\mathcal{M}(B)}$ in $\mathcal{M}(B)$.

The above observations imply that $S_\kappa := \sum_n s_{\kappa(n)} f_n$ is an isometry in $\mathcal{M}(A)$ for each strictly increasing map $\kappa \colon \mathbb{N} \ni n \mapsto \kappa(n) \in \mathbb{N}$ for the above defined $f_n \in A_+$.

If the ranges of two injective maps $\kappa \colon \mathbb{N} \to \mathbb{N}$ and $\lambda \colon \mathbb{N} \to \mathbb{N}$ are disjoint then the isometrics S_λ and S_κ have orthogonal ranges. (And if the intersection $\kappa(\mathbb{N}) \cap \lambda(\mathbb{N})$ is a finite subset of $\mathbb{N}$ then $S^*_\kappa S_\lambda \in B$.)

Start with $k_1 := 1$, and define inductively strictly increasing maps $\kappa \colon n \mapsto k_n \in \mathbb{N}$ with odd k_n and $\lambda \colon n \mapsto \ell_n \in \mathbb{N}$ with even ℓ_n such that

$$\|e_{n+2} s^*_{\ell_m} b_j s_{k_{n+1}}\| < \varepsilon \cdot 2^{-(n+3)}/(n+1)$$

for all $m \leq n$ and $j \leq n + 2$, and $k_{n+1} > \max(k_n, \ell_n)$ and that in the next step

$$\|s^*_{\ell_{n+1}} b_j s_{k_m} e_{n+2}\| < \varepsilon \cdot 2^{-(n+4)}/(n+2)$$

for all $m \leq n + 1$ and $j \leq n + 2$, and $\ell_{n+1} > \max(\ell_n, k_n)$.

It is possible to find the desired odd number k_{n+1} and then the desired even number ℓ_{n+1}, because the sum $\sum_n s_n s^*_n$ of the range projections converges strictly to 1 and this implies, e.g. for the finitely many elements $e_{n+2} s^*_{\ell_m} b_j \in B$ with $m \leq n+1$ and $j \leq n+2$ that $\lim_{\nu \to \infty} \|e_{n+2} s^*_{\ell_m} b_j s_\nu\| = 0$.

Estimates to be checked again.
In particular the case $j = 1$. ??

For each $j \in M$ the element $S^*_\lambda b_j S_\kappa \in \mathcal{M}(B)$ is contained in B:

For fixed b_j in the sequence $(b_1, b_2, \ldots)$ the summands $X_{1,j} := f_1 s_{\ell_1}^* b_j s_{k_1} f_1$ and partial sums

$$X_{\ell,j} := \sum_{m,n=1}^{\ell} f_n s_{\ell_n}^* b_j s_{k_m} f_m$$

are in B. For each b_j $\sum_\ell \|X_{\ell+1,j} - X_{\ell,j}\| < \infty$, because $\|X_{\ell+1,j} - X_{\ell,j}\| < \varepsilon \cdot 2^{-(n+1)}$ for $n \geq j$. It implies convergence in B itself.

In the particular case $b_1 := c$, we get $\|S_\lambda^* c S_\kappa\| < \varepsilon$, because we have managed that the norm of $X_{1,1}$ and of all $(X_{\ell+1,1} - X_{\ell,1})$ is small enough to get the desired estimate.

To see that $X := \lim_n S_n \in B$ and $S^* b_j T \in \mathcal{M}(B)$ are equal for it suffices to see that $cS^* b_j T d = cXd$ for all $c, d \in B$. But this is evident even with $c = d := e$ and easy to see

It follows $S^* C T \subseteq B$ and S, T are isometries with $S^* T = 0$ if the sequence $b_1, b_2, \ldots$ is dense in the positive part of the unit ball of $C \subseteq \mathcal{M}(B)$.

□

Remark A.23.2. Lemma A.23.1 implies that $A := \mathcal{M}(B)$ has the "squeezing" Property (sq) of Definition 4.2.14. Therefore, all non-zero quotients of $A \otimes^{\max} D$ for unital C^*-algebras D are K_1-bijective, by Proposition 4.2.15.

This covers the results of [**180**], e.g. that $\mathcal{U}(\mathcal{M}(B)) = \mathcal{U}_0(\mathcal{M}(B))$ and that all pointed homotopy groups $\pi_n(\mathcal{U}(\mathcal{M}(B)), 1)$ are trivial ([14]).

M. Mingo [**557**] obtained the following generalization of Kuiper's theorem in the special case where $B = C \otimes \mathbb{K}$ for unital C^*-algebras C.

Theorem A.23.3 (J.Cuntz, N. Higson,[**180**]). *Let B σ-unital stable C^*-algebra, and A a unital C^*-algebra.*

The K_*-groups of $\mathcal{M}(B) \otimes A$ and $\mathcal{M}(B) \otimes^{\max} A$ are trivial, and any quotient algebra of $\mathcal{M}(B) \otimes^{\max} A$ is K_1-injective.

The unitary groups $\mathcal{U}$ of the algebras $\mathcal{M}(B) \otimes^{\max} A$ are connected (with respect to the operator-norm topology), and have only trivial homotopy groups $\pi_n(\mathcal{U}, 1) = 0$.

Every continuous map from a locally finite CW-complex X into $\mathcal{U}$ is homotopic in $\mathcal{U}$ to the constant map $X \ni x \mapsto 1$.

Proof. The C^*-algebra $\mathcal{M}(B)$ has the "squeezing" property (sq) of Definition 4.2.14 by Lemma A.23.1. It causes the property (sq) for all C^*-algebras $(\mathcal{M}(B) \otimes^{\max} A) \otimes \mathrm{C}(X)$, all unital C^*-algebras A and compact Polish spaces X (e.g. let $X := S^n$). The property (sq) of $\mathcal{M}(B)$ implies K_1-injectivity of this algebras.

[14] The there deduced contractibility of the non-separable (!) Banach-space manifold $\mathcal{U}(\mathcal{M}(B))$ requires some set-theoretic discussion that is not given in detail. We doubt that it is possible without using a version of the Axiom of Choice (which is not provable), that should be mentioned.

The infinite repeat $D := \delta_\infty \otimes^{\max} \mathrm{id}_A$ satisfies $D \oplus \mathrm{id} \cong D$. It implies that $\mathrm{K}_*(\mathcal{M}(B) \otimes^{\max} A) = 0$ for all C^*-algebras.

The K_1-triviality and K_1-injectivity for all $X = S^n$ imply together that every continuous map from a locally finite CW-complex into $\mathcal{U}$ is homotopic in $\mathcal{U}$ to the constant map 1. □

The following Corollary A.23.4 (see J.Cuntz, N. Higson,[**180**]) of Theorem A.23.3 uses that a complete metrizable space that is locally uniformly homeomorphic to a (not necessarily separable !) Banach space is homotopic to a (locally finite) CW-complex, cf. [**556**] for open subsets of *separable* Banach spaces and [**542**, chp. IV, lem.5.2, cor.5.5] for the *non-separable* case ([15]). Then the vanishing of the – by 1 – pointed homotopy groups yields that $\mathcal{U}(C)$ is contractible if $\mathcal{U}(\mathrm{C}(S^n) \otimes C) = \mathcal{U}_0(\mathrm{C}(S^n) \otimes C)$ for each $n \in \mathbb{N}$. It implies:

Corollary A.23.4. *If B is stable and σ-unital and A is unital, then the unitary groups $\mathcal{U}(\mathcal{M}(B) \otimes A)$ and $\mathcal{U}(\mathcal{M}(B) \otimes^{\max} A)$ are contractible.*

Remark A.23.5. The following independent conclusion does not use arguments from [**542**] (dependent from additional axioms on set theory?):

If A is unital and B is stable and σ-unital, then each C^*-quotient $C \neq \{0\}$ of $\mathcal{M}(B) \otimes^{\max} A$ satisfies $\mathcal{U}(C)/\mathcal{U}_0(C) \cong \mathrm{K}_1(C)$.

Indeed: The quotients C have Property (sq) of Definition 4.2.14 and are K_1-bijective by Proposition 4.2.15.

24. Tensor Intersection lemma

Next lemma to App.B? To Reduction to separable case?

In the following lemma $X \otimes^\nu Z$ means the closure of $X \odot Z$ in the completion $A \otimes^\nu B$ of the algebraic tensor product $A \odot B$ with respect to a C^*-norm $\|\cdot\|_\nu$ on $A \odot B$. Notice that, e.g. in the case of the maximal C^*-tensor product $A \otimes^{\max} B$ of C^*-algebras A and B, one has for C^*-subalgebras $C \subset A$ not necessarily that the natural C^*-morphism $C \otimes^{\max} B \to A \otimes^{\max} B$ is injective. This C^*-morphism is injective for all C^*-algebras B if and only if C is relatively weakly injective in A (i.e., if there is a c.p. map $V : A \to C^{**}$ with $V(c) = c$ for $c \in C \subseteq A$), because – otherwise – the natural *-epimorphism $C \otimes^{\max} B \to \overline{C \odot B} \subset A \otimes^{\max} B$ is not injective for $B = C^*(F_2)$.

The following Lemma is the *Intersection Lemma* [**438**, lem. 3.9].

Lemma A.24.1. *Let A, B Banach spaces and $N : A \odot B \to \mathbb{R}_+$ a norm on $A \otimes B$ with $N(a \otimes b) \leq \gamma_1 \|a\| \cdot \|b\|$ for some $\gamma_1 < \infty$. Let $A \otimes_N B$ denote the completion of $A \odot B$ w.r.t. N. Furthermore let $X \subset A$ and $Y \subset B$ closed linear*

[15] [**542**] does not say what kind of set theory axioms are precisely needed in case of open subsets of non-separable Banach spaces.

subspaces such that there is net of linear maps $T_\mu\colon B \to Y$ *and* $\gamma_2 < \infty$ *with* $N((\mathrm{id} \otimes T_\mu)(z)) \le \gamma_2 N(z)$ *for* $z \in A \odot B$*, and* $\|T_\mu(y) - y\| \to 0$ *for all* $y \in Y$ *. Then*

$$\overline{X \odot B} \cap \overline{A \odot Y} = \overline{X \odot Y}$$

in the completion of $A \odot B$ *w.r.t.* N*.*

In particular,

$$(C \otimes^\nu B) \cap (A \otimes^\nu Y) = C \otimes^\nu Y$$

for C^**-algebras* A*,* B*,* C^**-norms* $\|\cdot\|_\nu$ *on the algebraic tensor product* $A \odot B$*, any* C^**-subalgebra* $C \subset A$ *and sums* $Y = L + R \subseteq B$ *(respectively intersection* $Y = L \cap R$*) of closed right ideals* R *and closed left ideals* R *of* B*.*

Proof. Let $z \in \overline{X \odot B} \cap \overline{A \odot Y}$ and $\varepsilon > 0$. Define $\delta := \varepsilon/(3 + 2\gamma_2)$. We find $z_1 \in X \odot B$ and $z_2 \in A \odot Y$ with $N(z_j - z) < \delta$ for $j = 1, 2$. Let $a_k \in A$ and $y_k \in Y$ with $z_2 = \sum_k a_k \otimes y_k$. By assumption, there is T_μ with $N(z_2 - (\mathrm{id} \otimes T_\mu)(z_2)) \le \gamma_1 \sum_k \|a_k\| \|T_\mu(y_k) - y_k\| < \delta$. Since $(\mathrm{id} \otimes T_\mu)(z_1) \in X \otimes Y$ and

$$z - (\mathrm{id} \otimes T_\mu)(z_1) = (z - z_2) + (z_2 - (\mathrm{id} \otimes T_\mu)(z_2)) + (\mathrm{id} \otimes T_\mu)(z_2 - z_1)\,,$$

we get $\mathrm{dist}(z, X \odot Y) \le \delta + \delta + \gamma_2(2\delta) < \varepsilon$, – with respect to the semi-norm N on $A \odot B$. □

25. Characterization of closed ideals by inner automorphisms

Lemma A.25.1. *Let* A *a (complex)* C^**-algebra and let* $X \subseteq A_+$ *a hereditary, closed convex cone in* A_+*,* $\exp(-ih) X \exp(ih) \subseteq X$ *for all* $h = h^* \in A$ *with* $\|h\| < \pi$*, then* X *is the positive part* J_+ *of a closed ideal* J *of* A*.*

Proof. `There should be also some reference to text books`
e.g. `Pedersen, Kadison, Dixmier, ???  ...`

It is "easy to see" that the hereditary C^*-subalgebra J of A generated by the linear span of X has the property that X is dense in $J_+ := A_+ \cap J$. Thus, $X = J_+$.

The hereditary C^*-subalgebra J is an ideal of A, because it is invariant under conjugation with unitaries $\exp(ih)$ (and $\exp(-ih)$) from any set $S \subseteq A$ of elements $h = h^*$ that has dense linear span in A, because then the open support projection of the hereditary C^*-subalgebra J is necessarily in the center of A^{**}. (In case of a "real" C^*-algebra A one has here to take as S a suitable set of $k \in A$ with $k^* = -k$ and to apply that $\exp(-k) X \exp(k) \subseteq X$ and to rediscover X.)

Therefore it suffices for a proof to show that the linear subspace $J := (X - X) + i(X - X)$ is a hereditary C^*-subalgebra and that $J_+ = X$ if X is a hereditary sub-cone of A_+ that satisfies $\exp(-ih) X \exp(ih) \subseteq X$ for all $h^* = h \in A$.

We show that a hereditary, closed convex cone $X \subseteq A_+$, has the property $A_+ \cap (X - X) = X$ and that this implies that $X - X$ is closed in A and, therefore, $J := (X - X) + i(X - X)$ is a closed linear subspace of A with the property $J_+ := A_+ \cap J = X$.

Moreover we show that $X = A_+ \cap L_X$ for the subset $L_X \subseteq A$ defined by $L_X := \{a \in A\,;\ a^*a \in X\,\}$ and that L_X is a closed left-ideal of A. It implies that $J = L_X^* \cap L_X$, i.e., that J is a hereditary C^*-subalgebra of A.

If $x_1 - x_2 \geq 0$, $x_2 \in A_+$ and $x_1 \in X$ then $x_1 \geq x_1 - x_2 \geq 0$. It follows $x_1 - x_2 \in X$ because X is hereditary.

Let $L_X := \{a \in A\,;\ a^*a \in X\}$. Then L_X is a closed left ideal of A and $X = A_+ \cap L_X$.

Indeed: Use that $x^2 \leq \|x\|x$ and $(a-b)^*(a-b)+(a+b)^*(a+b) = 2(a^*a+b^*b)$ and that $X + X \subset X$, $2X = X$, X is hereditary and closed. In particular $x \in A_+ \cap L_X$ for all $x \in X$, because $x^2 \in X$ for all $x \in X$ by $x^2 \leq \|x\|x$.

Conversely, if $y \in A_+ \cap L_X$ then $y^2 \in X$. But $\delta(y-\delta)_+ \leq y^2$ for all $\delta \in (0,1)$. It yields that $(y-\delta)_+ \in X$ for each $\delta \in (0,1)$. Since X is closed, it results that $X = A_+ \cap L_X$. In particular $(X - X) + i(X - X) = L_X^* \cap L_X$ is a hereditary C^*-subalgebra of A. □

26. On the Corona Factorization Property (CFP)

Proposition A.26.1. *Let A denote a non-zero simple σ-unital C^*-algebra of real rank zero.*

If $A \otimes \mathbb{K}$ contains an infinite projection and A has the corona factorization property (CFP), then A is purely infinite.

By *definition*, a C^*-algebra A has the **Corona Factorization Property** (CFP), if and only if, every *full* projection P in the multiplier algebra $\mathcal{M}(A \otimes \mathbb{K})$ of $A \otimes \mathbb{K}$ is properly infinite, i.e., $P \oplus_{S,T} P \precsim P$ in $\mathcal{M}(A \otimes \mathbb{K})$ for isometries $S, T \in \mathcal{M}(A \otimes \mathbb{K})$ with $S^*T = 0$.

Here a projection $P \in \mathcal{M}(A \otimes \mathbb{K})$ is *full* in $\mathcal{M}(A \otimes \mathbb{K})$ if the ideal J of $\mathcal{M}(A \otimes \mathbb{K})$ generated by P is equal to $\mathcal{M}(A \otimes \mathbb{K})$.

This is obviously equivalent to the property that a finite Cuntz sum $Q := P \oplus P \oplus \cdots \oplus P \in \mathcal{M}(A \otimes \mathbb{K})$ and an isometry $R \in \mathcal{M}(A \otimes \mathbb{K})$ exists with the property $RR^* \leq Q$.

`How to produce full projections?` By sequences of properly infinite projections in $A \otimes \mathbb{K}$?

Others from old Part in Part B:

We discuss the corona factorization property (CFP) for some classes of σ-unital C^*-algebras of real rank zero.

Does the Elliott conjecture hold for simple, separable, unital, nuclear C^*-algebras A of real rank zero that have no non-trivial lower semi-continuous 2-quasi-trace?

The latter property (no non-trivial l.s.c. 2-quasi-traces) is equivalent to the existence of a properly infinite projection in $A \otimes \mathbb{K}$, and we can pass to some algebra $p(A \otimes M_n)p$ that contains a unital copy of $\mathcal{O}_2$.

A more general open question is:

Has every separable nuclear simple C^*-algebra A of real rank zero the following "corona factorization property"?

(CFP): Every full projection in $P \in \mathcal{M}(A \otimes \mathbb{K})$ is properly infinite.

(Then the projection P is the range $P = TT^*$ of an isometry $T \in \mathcal{M}(A \otimes \mathbb{K})$, because $\mathcal{M}(A \otimes \mathbb{K})$ has trivial K_*-groups.)

(It is equivalent to:
If $p \in \mathcal{M}(A \otimes \mathbb{K})$ is a projection with $1 \precsim (p \oplus p)$ then $1 \precsim p$.)

Every simple purely infinite σ-unital C^*-algebra A has property (CFP) because, – for σ-unital (!) A –, the stable corona $\mathrm{Q}^{\mathrm{s}}(A) := \mathcal{M}(A \otimes \mathbb{K})/(A \otimes \mathbb{K})$ is simple (and then automatically purely infinite), if and only if, A is simple and purely infinite, cf. Corollary 2.2.11(i). It implies that $\mathcal{M}(A \otimes \mathbb{K})$ is (strongly) purely infinite. Since $\mathrm{K}_*(\mathcal{M}(A \otimes \mathbb{K})) = \{0\}$ it follows that each full projection in $\mathcal{M}(A \otimes \mathbb{K})$ is the range of an isometry.

For simple σ-unital $A \otimes \mathbb{K}$ and every non-zero projection $p \in A \otimes \mathbb{K}$, $p(A \otimes \mathbb{K})p \otimes \mathbb{K} \cong A \otimes \mathbb{K}$. Thus we may suppose that A is unital if A is simple and p.i.

An ideal system preserving isomorphism $p(A \otimes \mathbb{K})p \otimes \mathbb{K} \cong A \otimes \mathbb{K}$ exists if A is σ-unital and $A \otimes \mathbb{K}$ contains a projection $p \in A \otimes \mathbb{K}$ that generates $A \otimes \mathbb{K}$ as a closed ideal.

It comes from $P := \delta_\infty(p) \in \mathcal{M}(A \otimes \mathbb{K})$ as $P(A \otimes \mathbb{K})P \cong p(A \otimes \mathbb{K})p \otimes \mathbb{K}$ and the fact that there is an isometry $s \in \mathcal{M}(A \otimes \mathbb{K})$ with $ss^* = P$.

Let $T \in \mathcal{M}(A \otimes \mathbb{K})_+$ a positive contraction with $\|\pi_{A\otimes\mathbb{K}}(T)\| = 1$. Define with matrix units $e_{jk} \in \mathbb{K}$ and identify $c_0(\mathbb{C})$ with $c_0 := C^*(e_{11}, e_{22}, \cdots) \subset \mathbb{K}$ and let $g_n := \sum_{k=1}^{n} 1 \otimes e_{kk} \in 1 \otimes c_0$.

We find an increasing quasi-central approximate unit for $C^*(T) \subseteq \mathcal{M}(A \otimes \mathbb{K})$ in the *convex hull of the approximate unit* consisting of the projections $g_n \in A \otimes \mathbb{K}$. This can be seen from our cf. Lemma B.23.1 or arguments in the proof for [**616**, thm. 3.12.14] and combine them with the arguments for [**616**, cor. 3.12.15,cor. 3.12.16].

To be shown:
We find projections $p_n \in c_0 \subset \mathbb{K}$ with $p_n := \sum_{k=r_n}^{t_n} e_{kk}$ where $t_{n-1} + 1 < r_n \leq t_n$ are in $\mathbb{N}$, $\|(1 \otimes p_n)T(1 \otimes p_n)\| \geq (n-1)/n$, $p_n p_m = 0$ for $m \neq n$, $(1 \otimes p_n)g_n = 0$, and $\|(1 \otimes p_k)T(1 \otimes p_n)\| < 1/n^2$ for $k < n$.

Notice here that for $T \in \mathcal{M}(A \otimes \mathbb{K})_+$ and $q := \sum_{k=1}^{n-1} p_k \in \mathbb{K}$ holds $(1 \otimes q)T = \lim_\ell (1 \otimes q)T1 \in \mathcal{M}(A \otimes \mathbb{K})$ It has to be checked if there exists the p_n!

Notice that $\sum_n 1 \otimes p_n$ converges strictly to a projection $Q \in (1_{\mathcal{M}(A)} \otimes \mathcal{M}(\mathbb{K})) \subseteq \mathcal{M}(A \otimes \mathbb{K})$.

If such $p_1, p_2, \ldots$ exist, then there are contractions $d_n \in A \otimes \mathbb{K}$

(likely such that $d_n^* d_n \leq 1 \otimes e_{nn}$ and $d_n \in (1 \otimes p_n)(A \otimes \mathbb{K})(1 \otimes e_{nn})$)

with $1 \geq d_n^*(1 \otimes p_n)T(1 \otimes p_n)d_n \geq (1 - 2/n)(1 \otimes e_{nn})$. Check Conjecture: $\sum_n (1 \otimes p_n)d_n(1 \otimes e_{nn})$ is strictly convergent to a contraction $S \in \mathcal{M}(A \otimes \mathbb{K})$ with $1 - S^*TS \in A \otimes \mathbb{K}$.

One can find/use a partial isometries $U \in \mathcal{M}(\mathbb{K})$ with $e_{nn}U^* = e_{n,r_n}$, i.e., with $e_{nn}U^* = e_{n,n}e_{n,r_n}$ where $e_{r_n,r_n} \leq p_n$ for all $n \in \mathbb{N}$. The sum $\Gamma := \sum_n (1 \otimes p_n)d_n(1 \otimes e_{n,\ell_n})$ converges strictly in $\mathcal{M}(A \otimes \mathbb{K})$ and defines a contraction. Let $S := \Gamma \circ U$.

Then S is a contraction in $\mathcal{M}(A \otimes \mathbb{K})$ such that $1 - S^*TS \in A \otimes \mathbb{K}$ and this shows that $\mathrm{Q^s}(A)$ is simple if A is σ-unital, simple and purely infinite. See above attempt.

The strong pure infiniteness of $\mathcal{M}(A)$ is known if A is s.p.i. and σ-unital!

More general: (With $\mathbb{K} := \mathbb{K}(\ell_2(\mathbb{N}))$.) If σ-unital A is s.p.i. then $\mathcal{M}(A \otimes \mathbb{K})$ is s.p.i. (It requires to show that $\mathcal{M}(A)$ is s.p.i. if A is σ-unital and A is s.p.i.)

It implies in particular that A has (CFP), because each (non-zero) projection in $\mathcal{M}(A \otimes \mathbb{K}) \setminus (A \otimes \mathbb{K})$ is properly infinite if the stable corona $\mathrm{Q^s}(A)$ is purely infinite, because $\mathrm{K}_0(\mathrm{Q^s}(A)) = 0$.

The stable corona $\mathrm{Q^s}(A)$ is simple if and only if A σ-unital, simple and p.i. if and only if $\mathrm{Q^s}(A)$ is simple and purely infinite, cf. Corollary 2.2.11.

Check:

Are some relations between [**670**, prop. 9.3] (on CFP) and our non-existence of "infinitesimal" sequences??!!

(Is not very likely.)

Corona Factorization Property (CFP):

"Every *full* projection in the multiplier algebra $\mathcal{M}(A \otimes \mathbb{K})$ of $A \otimes \mathbb{K}$ is properly infinite."

(Who has really introduced this definition?)

If $T_1, \ldots, T_n \in \mathcal{M}(A \otimes \mathbb{K})$ exists with $\sum_{k=1}^n T_k^* P T_k = 1$, then P is properly infinite, i.e., there exists $S \in \mathcal{M}(A \otimes \mathbb{K})$ with $1 - S^*PS \in A \otimes \mathbb{K}$.

???? Is Def. of what???

Is it equivalent to the following if A is σ-unital?:

(CFPI) := "Corona-full are properly infinite" defined by:

"Every full projection of $\mathrm{Q^s}(A)$ is properly infinite."

Implies (CFP), because if P is a full projection in $\mathcal{M}(A \otimes \mathbb{K})$ then $\pi_{A \otimes \mathbb{K}}(P)$ is a full projection in $\mathrm{Q^s}(A)$. By (CFPI) there exists a contraction $R \in \mathcal{M}(A \otimes \mathbb{K})$ with $1 - R^*PR \in A \otimes \mathbb{K}$. We can find an isometry $X \in \mathcal{M}(\mathbb{K})$ such that $\|1 - (1 \otimes X)^* R^* PR(1 \otimes X)\| < 1/4$. Thus, there exists an element $Y \in \mathcal{M}(A \otimes \mathbb{K})$ with

$Y^*PY = 1$. Then $T := PY$ is an isometry with $TT^* \leq P$. It follows that P is properly infinite. Now use that $\mathrm{K}_0(\mathcal{M}(A \otimes \mathbb{K})) = \{0\}$ and get that $[P] = [1]$, i.e., there is an isometry $Z \in \mathcal{M}(A \otimes \mathbb{K})$ with $ZZ^* = P$.

(Similar arguments show that each full element of $\mathcal{M}(A \otimes \mathbb{K})_+$ dominates the range of an isometry if this is the case for every full *element* of $\mathrm{Q}^{\mathrm{s}}(A)$.)

Thus, we can show that (CFPI) implies (CFP).

Consider now the property (of ?????):

If $1 \precsim P \oplus P$ *then* $1 \precsim P$ *for projections* $P \in \mathcal{M}(A \otimes \mathbb{K})$.

This property implies (CFP), because a projection P is full in $\mathcal{M}(A \otimes \mathbb{K})$ if there exist $n \in \mathbb{N}$ such that $[1] \leq 2^n[P]$ in $\mathrm{Cu}(\mathcal{M}(A \otimes \mathbb{K}))$.

There is a projection $Q \in \mathrm{Cu}(\mathcal{M}(A\otimes\mathbb{K}))$ with $[Q] = 2^{n-1}[P]$. Thus $1 \precsim Q\oplus Q$. reduces to $[1] \leq [Q] = 2^{n-1}[P]$.

It follows also from (CFP), because $1 \precsim P\oplus P$ implies that P is a full projection in $\mathcal{M}(A \otimes \mathbb{K})$.

More on the question if (CFP) implies (CFPI) (in case that A has real rank zero):

Let $T \in \mathcal{M}(A \otimes \mathbb{K})_+$ a positive contraction, with $\pi(T) = T + (A \otimes \mathbb{K})$ a projection in $\mathrm{Q}^{\mathrm{s}}(A)$ for $\pi := \pi_{A\otimes\mathbb{K}}$.

When does there exist $Y_k := 1\otimes X_k$ that such that $\pi(Y_k)$ is unitary and $Y_1^*TY_2$ is a partial isometry?

If $\pi(T)$ is a full projection in $\mathrm{Q}^{\mathrm{s}}(A)$ the there are elements $S_1, \ldots S_n \in \mathcal{M}(A\otimes\mathbb{K})$ with $1 - \sum_k S_k^*TS_k \in A \otimes \mathbb{K}$

There exists an isometry $I \in 1 \otimes \mathcal{M}(\mathbb{K})$ with $\sum_k I^*S_k^*TS_kI = 1_{\mathcal{M}(A)} \otimes 1_{\mathcal{M}(K)}$.

Seems that we need a stronger property, e.g. that every full positive contraction T in $\mathcal{M}(A \otimes \mathbb{K})$ with $\pi(T)$ a projection is properly infinite ...

Then $(1 - T)T \in A \otimes \mathbb{K}$.

Let $G := f(T)$ for $f(t) := 1$ for $t \geq 1/4$ and $f(t) := 0$ for $t \leq 1/8$ and $f(t) := 8t - 1$ on $[1/8, 1/4]$. Then $\pi(G) = \pi(T)$, $G(T - 1/4)_+ = (T - 1/4)_+$ and $G \leq 4T$.

If $\pi(T)$ is full in $\mathrm{Q}^{\mathrm{s}}(A)$, then $\pi(sTs^*)$ is full in $\mathrm{Q}^{\mathrm{s}}(A)$.

But it is not clear if sTs^* can be "extended" to a projection in $\mathcal{M}(A\otimes\mathbb{K})$ such that ????

Let $S := (T - 1/2)_+^{1/2} \in \mathcal{M}(A \otimes \mathbb{K})$, and $a_0 \in A_+$, $b_0 \in \mathbb{K}$ strictly positive contractions. Notice $GS = S = SG$. And let $D := \overline{S(A \otimes \mathbb{K})S}$ the hereditary C^*-subalgebra of $A \otimes \mathbb{K}$ generated by the strictly positive element $S(a_0 \otimes b_0)S$ of D.

We find $d_1, \ldots, d_n \in \mathcal{M}(A \otimes \mathbb{K})$ with $\sum_j d_j^*Sd_j = 1$. Thus, $L := (A \otimes \mathbb{K})S$ is not contained in a non-trivial closed ideal of A.

Thus, D a "full" hereditary C^*-subalgebra of $A \otimes \mathbb{K}$. $Gd = d = dG$ for all $d \in D$.

`Next ''green'' to be shown:`

We find a projection $P \in \mathcal{M}(A \otimes \mathbb{K})$ and an element $z \in A \otimes \mathbb{K}$ such that $zz^* = S(a_0 \otimes b_0)S$ and z^*z is a strictly positive element of $P(A \otimes \mathbb{K})P$.

Does there exists an element $Y \in \mathcal{M}(A \otimes \mathbb{K})$ with $YY^* \geq P$ and $Y^*YG = Y^*Y$? Is P full in $\mathcal{M}(A \otimes \mathbb{K})$?

The true question is:
Can we find for each full projection Q in $\mathrm{Q}^{\mathrm{s}}(A)$ a full projection $P \in \mathcal{M}(A \otimes \mathbb{K})$ such that $\pi(P) \precsim Q$.

`OK. Above seems not to work.  !!!`

Other approach:

Let $d_1, \ldots, d_n \in \mathcal{M}(A \otimes \mathbb{K})$ (w.l.o.g.) with $\sum_k \pi(d_k)^* \pi(T) \pi(d_k) = 1$ and $\| \sum_k d_k^* d_k \| \leq 1$.

Here "w.l.o.g.", because we can replace the d_k by $e_k := T^{1/2} d_k S$, with some suitable isometry $S \in \mathcal{M}(A \otimes \mathbb{K})$.

Then $\sum_k \pi(e_k)^* \pi_(e_k) = 1$, and we can lift the column $[\pi(e_1), \ldots, \pi(e_n)]^\top$, which defines a partial isometry in $M_n(\mathrm{Q}^{\mathrm{s}}(A))$, of norm $= 1$ to a contraction in $\mathcal{M}(A \otimes \mathbb{K})$.

Then there exists isometry $S \in 1_{\mathcal{M}(A)} \otimes \mathcal{M}(\mathbb{K})$ with $\|1 - \sum_k S^* d_k^* T d_k S\| < 1/4$ and $1 - \sum_k S^* d_k^* T d_k S \in A \otimes \mathbb{K}$.

Let $D := (\sum_k S^* d_k^* T d_k S)^{-1/2}$. Then $1 = \sum_k R_k^* T R_k$ in $\mathcal{M}(A \otimes \mathbb{K})$ for $R_k := d_k S D$. ...

Suppose (!) now that $T \in \mathcal{M}(A \otimes \mathbb{K})$ itself is a full projection and that each full projection in $\mathrm{Q}^{\mathrm{s}}(A)$ is properly infinite.

Then we can take $n = 1$ and get isometry $R \in \mathcal{M}(A \otimes \mathbb{K})$ with $R^*TR = 1$, i.e., $T \geq RR^*$, $R^*R = 1$.

Thus, T is full and infinite, $R\mathcal{O}_2 R^* \in T\mathcal{M}(A \otimes \mathbb{K})T$, $RsTs^*R^* \leq T$ and $RtTt^*R^* \leq T$. Thus $[T] + [T] \leq [T] \leq [1]$, $[1] \leq [T]$.

Can we lift each projection in $\mathrm{Q}^{\mathrm{s}}(A)$ to a projection in $\mathcal{M}(A \otimes \mathbb{K})$?

Is not possible in general, because the elements of the K_0-groups are represented by projections and $\mathrm{K}_0(\mathcal{M}(A \otimes \mathbb{K})) = 0$.

Then we can consider the case ?????

If every closed (two-sided) ideal of A has the Corona Factorization Property, then we say that A has the *strong Corona Factorization Property*.

Or is this the "strong" (CFP)? : See the green text further below!

It is known that A has property (CFP) if $A' \cap A_\omega$ does not have a character, cf. [**467**, thm. 4.2]. But the converse implication is wrong:

The example [**467**, ???] is a simple purely infinite exact unital separable C^*-algebra A that has property (CFP) but where $A' \cap A_\infty$ has a character.

Where it is shown that $A' \cap A_\infty$ has a character for A in example ????

Thus the opposite direction is wrong.

Give citation for ''no character'' on $A' \cap A_\infty$ of example. Likely in [467]

It follows from [**467**, thm. 4.2] that for every σ-unital C^*-algebra A the algebra $A \otimes \mathcal{Z}$ has property (CFP), because of $\mathcal{Z} \otimes \mathcal{Z} \otimes \cdots \cong \mathcal{Z}$.

This is because one can show that each separable C^*-subalgebra of $\mathcal{M}(\mathbb{K} \otimes A \otimes \mathcal{Z})$ commutes modulo $\mathbb{K} \otimes A \otimes \mathcal{Z}$ with a unital copy of $\mathcal{Z}$.

Check now outlined proof
of property (CFP) for $A \otimes \mathcal{Z}$!

The preparations for [**467**, thm. 4.2] and the many needed technical facts from other papers make it useful to give a more elementary proof of property (CFP) for the algebras $A \otimes \mathcal{Z}$.

A less engaged proof can be based on the property $\mathcal{Z} \cong \mathcal{Z} \otimes \mathcal{Z} \otimes \cdots$ and that there is a unital C^*-morphism $\eta \colon \mathcal{Z} \to \mathcal{E}(\mathcal{Z}, \mathcal{Z}) \subseteq \mathrm{C}([0,1], \mathcal{Z} \otimes \mathcal{Z})$ with $\pi_0 \circ \eta(a) = 1 \otimes a$ and $\pi_1 \circ \eta(a) = a \otimes 1$.

Thus, in the stable corona each "full" projection P is also properly infinite, because – by the above mentioned property – the elements $t_1, \ldots, t_n \in \mathcal{M}(\mathbb{K} \otimes A \otimes \mathcal{Z})$ with $t_1^* P t_1 + \ldots + t_n^* P t_n = 1$ (calculated modulo $\mathbb{K} \otimes A \otimes \mathcal{Z}$) and a unital copy of $\mathcal{O}_2$ generate a separable C^*-subalgebra of $\mathcal{M}(\mathbb{K} \otimes A \otimes \mathcal{Z})$ that commutes modulo $\mathbb{K} \otimes A \otimes \mathcal{Z}$ with a unital copy of $\mathcal{Z}$.

Let $B := C^*(P, t_1, \ldots, t_n, s_1, s_2; R)$ the *free* C^*-algebra – with relations R given by $s_1^* s_1 = s_2^* s_2 = s_1 s_1^* + s_2 s_2^* = 1$, $P^* = P = P^2$ and $\sum_k t_k^* P t_k = 1$, $\|t_k\| \leq 1$ –. Then one can see that $1 \otimes P$ is in the C^*-algebra tensor product $\mathcal{Z} \otimes C^*(P, t_1, \ldots, t_n, s_1, s_2; R)$ a properly infinite full projection:

$(n+1)[1] = [1] \leq n[P] \leq n[1] = [1]$

After $\mathcal{Z}$-tensoring this becomes $[1] = [P]$ in the Cuntz semigroup $W(\mathcal{Z} \otimes C^*(P, t_1, \ldots, t_n, s_1, s_2; R))$ and carries then over to the stable corona.

Look to the explicit formula in the green below given calculation.

What about replacing $\mathcal{Z}$ by infinite tensor products of $A(n,2)$ with fixed $n \geq 3$, where $A(n,2) := C^*(a_1, \ldots a_n, b_1, \ldots b_n, R)$ with relations (R) given by:

$$(R) := \{ \sum_{k=1}^{n} a_k^* a_k = 1,\ b_j^* a_j = 0,\ b_j^* b_j = a_j^* a_j,\ j = 1, \ldots, n \} .$$

The $A(n,p)$ are similar defined and are contained ???? in suitable tensor products of $A(n,2)$:

Instead $a_1, \ldots a_n, b_1, \ldots b_n$ we consider $a_{k\ell}$ ($k = 1, \ldots, n$, $\ell = 1, \ldots, p$) with $\sum_{k=1}^n a_{k,1}^* a_{k,1} = 1$, $a_{k,\ell}^* a_{k,m} = \delta_{\ell,m} a_{k,1}^* a_{k,1}$.

Which elements of $\mathcal{O}_\infty \otimes A(n,p)$ are full in $\mathcal{O}_\infty \otimes A(n,p)$???

In particular, those of form $1 \otimes X$ with X looking how ???

$\sum_{\ell=1} t_\ell^* P t_\ell = 1$ Gets only elements Y_k with

$Y_k^*(P \otimes 1)Y_k = 1 \otimes a_{k,1}^* a_{k,1}$. (Does not work so simple as it was hoped.)

Question:

Can we prove $\mathcal{Z}$-absorption for separable simple unital *nuclear* A if A satisfies (CFP)?

There exist a separable simple *exact* unital C^*-algebra A that is p.i. (thus $\mathrm{Q}^s(A) := \mathcal{M}(A \otimes \mathbb{K})/(A \otimes \mathbb{K})$ is simple and s.p.i., ... give citation for simplicity and p.i. of $\mathrm{Q}^s(A)$!!!), but $A' \cap A_\omega$ has a character:

The algebra $A := C^*(F_2) \otimes \mathcal{R}$ is an example with is property.

Give citation for the character on $A' \cap A_\omega$ in case $A := C^*(F_2) \otimes \mathcal{R}$!!!

Where is the algebra $\mathcal{R}$ defined ?

It follows (from which conditions ?) that each full projection in $\mathcal{M}(A \otimes \mathbb{K})$ is the range of an isometry in $\mathcal{M}(A \otimes \mathbb{K})$. Thus, this algebra A has the (CFP) but $A' \cap A_\infty$ has a character.

Has (at least) $A' \cap A_\infty$ a character if A is a simple unital separable and *nuclear* C^*-algebra that does not satisfy (CFP)?

It is known that separable unital A has (CFP) if $A' \cap A_\infty$ has no character, see: [**467**, thm. 4.3].

But it is not known if stably infinite simple A with (CFP) is infinite ?????

Does (CFP) of simple separable A imply that $A' \cap A_\infty$ has no character?

Answer: No! Counterexample with exact A is in [**467**]. (But this counterexample is not nuclear!)

What happens for exact simple separable unital p.i. A? Has A (CFP) ?? (Answer: Yes). Notice that simple p.i. A are s.p.i. !!!

Proposition **??** says that $\mathcal{M}(A \otimes \mathbb{K})$ s.p.i. if A is a σ-unital s.p.i. C^*-algebra. Thus, s.p.i. σ-unital A have property (CFP).

Part (2) of Theorem [**499**, thm.3.1] says that property (CFP) for separable B passes to non-zero quotients.

This shows that P is properly infinite modulo $\mathbb{K} \otimes A \otimes \mathcal{Z}$.

By Remark 5.10.3, this implies that $P = TT^*$ for some isometry $T \in \mathcal{M}(\mathbb{K} \otimes A \otimes \mathcal{Z})$.

(Reference? What about converse in simple nuclear case?)

(Here "full" means equivalently that a finite Cuntz sum $P \oplus P \oplus \ldots \oplus P$ of P in $\mathcal{M}(A \otimes \mathbb{K})$ majorize 1, which implies that this sum is properly infinite.)

`Open question:`

Are all simple (separable, nuclear) stably infinite C^*-algebras of real rank zero automatically purely infinite?

Long standing question? Compare Chp. 2.!

By [**581**, cor. 5.16], a separable simple C^*-algebra of real rank zero with the Corona Factorization Property (CFP) is either stably finite or purely infinite.

This was also proved in an unpublished paper by S. Zhang, who didn't explicitly introduce/mention the (CFP). (He simply considered something like it – or something equivalent to it – for granted).

S. Zhang: (Reference ??? unpublished)

If A is a simple C^*-algebra of real rank zero with Property (CFP), then A is either stably finite or purely infinite.

(One can pass to the case of σ-unital simple C^*-algebras, by passage to suitable separable subalgebras to drop the separability assumption by passing to a suitable separable C^*-subalgebra.)

The example $A_0 := C^*_{red}(F_2) \otimes \mathcal{R}$ is simple, exact and p.i. (thus is s.p.i.). Simple σ-unital purely infinite C^*-algebras have the (CFP) (cite for proof?). But $F(A_0)$ has a character. Thus (CFP) does not imply that $F(A)$ has no character if A is exact, simple and p.i.

A result for non-simple σ-unital C^*-algebra A of real rank zero says:

[**581**, cor. 5.15]: Let A be a σ-unital C^*-algebra of real rank zero, and let p be a projection in A such that the m-fold direct sum $p \oplus p \oplus \ldots \oplus p$ is properly infinite (in $M_m(A)$) for some natural number m. Then p itself is properly infinite if one of the following two conditions (i) or (ii) below hold:

(i) Every ideal in A has the (CFP)
(ii) A has the (CFP) and p is a full projection in A.

(The Part (i) should immediately follow from Part (ii).)

It comes from:

[**581**, thm. 5.13]: Let A be a σ-unital C^*-algebra of real rank zero. Then $V(A)$ has the strong Corona Factorization Property (for monoids), if and only if, every ideal I in A has the Corona Factorization Property (for C^*-algebras).

Is here A suppose to be stable? [**581**, lem. 5.6]: Let A be a σ-unital C^*-algebra, let P be a properly infinite, full projection in $\mathcal{M}(A)$ and let $p \leq P$ be a projection in A. Then $P - p$ is properly infinite and full in $\mathcal{M}(A)$.

[**581**, lem. 5.7]: Let A be a C^*-algebra, let $\{p_n\}$ and $\{q_n\}$ be sequences of pairwise orthogonal projections in A such that the sums $P = \sum_{n=1}^{\infty} p_n$ and $Q = \sum_{n=1}^{\infty} q_n$ are strictly convergent in the multiplier algebra $\mathcal{M}(A)$, and hence define projections P and Q in $\mathcal{M}(A)$.

(i) Suppose that there are sequences $\{k_n\}$ and $\{\ell_n\}$ of natural numbers such that $1 \le k_1 < \ell_1 < k_2 < \ell_2 < k_3 < \cdots$, and such that

$$[p_n] \le [q_{k_n}] + [q_{k_n+1}] + \ldots + [q_{l_n}]$$

for all $n \in \mathbb{N}$. Then $P \precsim Q$ in $\mathcal{M}(A)$.

(ii) If $P \precsim Q$ in $\mathcal{M}(A)$, then for every natural number k there exists a natural number ℓ such that

$$[p_1] + [p_2] + \ldots + [p_k] \le [q_1] + [q_2] + \ldots + [q_\ell]$$

in $V(A)$.

Proof of (i): For each n, let $s_n \in A$ be a partial isometry with

$$s_n^* s_n = p_n\,, \quad s_n s_n^* \le q_{k_n} + q_{k_n+1} + \ldots + q_{l_n}\,.$$

As the sums $\sum p_n$ and $\sum q_n$ are strictly convergent, it follows that the sum $S := \sum_{n=1}^{\infty} s_n$ is strictly convergent in $\mathcal{M}(A)$. Hence $P = S^*S \sim SS^* \le Q$.

From [**467**, thm. 4.3] (When central sequence algebras have a character.) we get:

Theorem 4.3:

Let A be a unital separable C^*-algebra such that the central sequence algebra $F(A)$ has no characters. Then A has the strong Corona Factorization Property.

D. Kucerovsky and P.W. Ng show in [**499**, thm. 3.1] that the quotient of any separable C^*-algebra with the Corona Factorization Property again has the Corona Factorization Property.

"It follows from this result that the quotient of any separable C^*-algebra with the strong Corona Factorization Property again has the strong Corona Factorization Property."

It was shown in [**670**, prop. 6.3] that $A \otimes_{\max} (\bigotimes_{\max} D)$ has the strong Corona Factorization Property.

(For D with what kind of properties??? Likely D has to be unital and without characters???)

The corollary [**581**, cor. 5.16]: says that a separable simple C^*-algebra of real rank zero with the Corona Factorization Property is either stably finite or purely infinite.

(It shows that we could add the (CFP) to the assumptions of **(Q1)** then the answer becomes positive. Moreover (Q1.implies.CFP for A), (Q1.implies.pi of A), (Q1.implies.$F(A)$ has no character) and (Q1.implies. ... are equivalent positive answers.)

(It was also proved in an unpublished paper by S. Zhang, but without explicit realizing / recognition that something like the (CFP) is needed.)

(One can drop the separability assumption by passing to suitable separable C^*-subalgebras.)

There exist exact simple separable unital C^*-algebras, e.g. $C^*_\rho(F_2)\otimes\mathcal{R}$, that are purely infinite but have not the (CFP). (Because $F(C^*_\rho(F_2)\otimes\mathcal{R})$ has a character.)

If A is separable simple and σ-unital and $F(A)$ has not a character then A has (CFP).

(Recall: (CFP) = "Corona factorization property")

`END of (CFP) Discussion !`

27. On dense algebraic Ideals

The following definition is perhaps not identical with the definition given by Pedersen in his book [**616**] on C*-algebras A ... He requires (!) that his dense ideal is "hereditary".

We consider later the set $A_{0,+}$ of all ε-cut downs of positive elements in A_+ and show that this set is contained in any dense algebraic ideal J of A. We do not know if the Pedersen ideal is identical with the algebraic ideal A_0 of A generated by all cut-down elements $(a-\varepsilon)_+$ for $a\in A_+$.

The ideal A_0 is dense in A and is contained in any dense algebraic ideal of A.

Since the Pedersen ideal of A contains all the cut-down elements $(a-\varepsilon)_+$ (for $a\in A_+$ and $\varepsilon>0$), it is likely that they are the same: Find a proof ...

Consider first the case $A:=C_0(0,\infty)$ ... ???

But ?????

Are semi-finite (2-)quasi-traces on the Pedersen ideal l.s.c.?

Thm. 1.3.3.: (in Pedersen Book) The set A_+ is a closed real cone in A_{sa}, and $x\in A_+$, if and only if, $x=y^*y$ for some $y\in A$.

Thm. 1.3.5.: (in Pedersen Book) If $0\le x\le y$ then $a^*xa\le a^*ya$ for all $a\in A$ and $\|x\|\le\|y\|$.

Prop. 1.4.5.: (in Pedersen Book) Let $x\in A$ and $x^*x\le a\in A_+$. If $0<\alpha<1/2$, then there exists $u\in A$ with $\|u\|\le\|a^{(1/2)-\alpha}\|$ such that $x=ua^\alpha$.

(The element $u\in A$ is not necessarily unitary.)

Sec. 5.6.: The minimal dense ideal. (But Pedersen considered only "hereditary" algebraic ideals. The true minimal dense ideal is the ideal ideal

Thm. 5.6.1.: (in Pedersen Book, p.175) !!!!!!! For each C*-algebra A there is a dense hereditary ideal $K(A)$, which is minimal among all dense ideals. (of A).

My question: Is it identical with the algebraic ideal of A that is generated by the set of all ε-cut-downs $(a-\varepsilon)_+$? (Here $a\in A_+$ and $\varepsilon\in(0,\|a\|)$.)

Proof of Pedersen Thm. 5.6.1: Let $K((0,\infty)):=$ set of all continuous function on $(0,\infty)$ with compact support (inside $(0,\infty)$). Define

$$K(A)_0:=\{f(x):x\in A_+,f\in K((0,\infty))_+\}.$$

Let

$$K(A)_+ := \{x \in A_+ : x \leq \sum_{k=1}^{n} x_k,\ x_k \in K(A)_0\}$$

so that $K(A)_+$ is the smallest hereditary cone in A_+ containing $K_0(A)$.

If $K(A)$ denotes the linear span of $K(A)_+$ we conclude as in (Pedersen Book) Proposition(5.1.3) that $K(A)$ is a hereditary (!!!) *-algebra with $(K(A))_+ = K(A)_+$.

Since $u^*f(x)u = f(u^*xu)$ for any unitary $u \in \widetilde{A}$ we have $u^*K(A)_0u = K(A)_0$, and (as in subsection 5.2.1 of Pedersen book) this implies that $K(A)$ is an ideal:

If u is a unitary in $\widetilde{A} = A + \mathbb{C}1$ then

$$4u^*x = 4(x^{1/2}u)^*x^{1/2} = \sum_{k=0}^{3} i^k(1 + i^k u)^* x(1 + i^k u)$$

(the polarization identity), ... ?

Let (f_n) be a sequence in $K(A)$ ...

Now use that each element of $\widetilde{A}$ is a combination of unitaries ...

28. Dimension-Functions in Sense of J.Cuntz

The following definition of Dimension functions (is quoted to J.Cuntz).

Definition A.28.1. Let $D\colon X_A \to ???$ be a (non-negative) semi-finite *Dimension function* on $X_A := \bigcup_n M_n(\mathrm{Ped}(A))$ "in sense of J.Cuntz".

Claim: $D(a) = D(a^*a)$, $D(a) \leq D(b)$ if $a \precsim b$.

$$D^*(a) := \sup_{\varepsilon>0} D((a-\varepsilon)_+)$$

Then

- α $0 \leq D(a) \leq D^*(a)$ for all $a \in X$,
- β D^* is again a Dimension function,
- γ $D - D^*$ is a Dimension function,
- δ If D is a Dimension function, then then the kernel $\mathrm{Ker}(D)$ satisfies

$$\mathrm{Ker}(D) = (\bigcup_n M_n(\mathrm{Ped}(A))) \cap (\bigcup_n M_n(J))$$

  for some (closed ?) ideal J of A.
- ε ? $(D - D^*)^* = D^* - D^* = 0$?

Has it following property?: $D(a) \neq 0$ implies $D(b) \neq 0$ for some b.

Are semi-finite (2-) quasi traces on the "Pedersen ideal" l.s.c.?

Are semi-finite Dimension functions (in the sense of J.Cuntz) "lower semi-continuous"?

APPENDIX B

Exact C*-algebras and examples

We discuss in this Appendix B some facts related e.g. to the following questions:

(0) Passage to suitable separable subalgebras that preserve important properties of the algebra.

(1) Monotone maps between partially ordered sets.

(2) Some properties of exact C^*-algebras.

(3) Example of a nuclear and approximately inner c.p. map that is not residually nuclear, and its relation to the possible existence of group vN-algebras that are not weakly exact. (Is there an example of Ozawa of vN-alg. that is not "weakly exact"?)

(4) Example of a (simple?) unital nuclear separable C^*-algebra A and a unital *-monomorphisms $\iota\colon A \hookrightarrow \mathcal{O}_2$ of A into the Cuntz algebra $\mathcal{O}_2$ such that there is no conditional expectation from $\mathcal{O}_2$ onto $\iota(A)$.

It shows that there exist unital *-monomorphisms ι_1 and ι_2 of a (simple?) unital nuclear separable C^*-algebra A with the property that if we tensor the ι_k with $\mathrm{id}_{\mathcal{O}_2}$, then the unital *-monomorphisms $\mathrm{id}_{\mathcal{O}_2} \otimes \iota_k \colon \mathcal{O}_2 \otimes A \to \mathcal{O}_2 \otimes \mathcal{O}_2 \cong \mathcal{O}_2$ of the nuclear C^*-algebras $\mathcal{O}_2 \otimes A$ are not unitarily equivalent, – even not equivalent if we change it by an automorphism of $\mathcal{O}_2 \cong \mathcal{O}_2 \otimes \mathcal{O}_2$ and an automorphism of $\mathcal{O}_2 \otimes A$, because the existence/non-existence of conditional expectations onto the image remains unchanged if we tensor with $\mathcal{O}_2$ and apply any of this operations.)

(5) Some open questions concerning p.i. algebras.

(6) Examples of D where $\mathbb{O}(\mathrm{Prim}(D))$ is not the projective limit of lattices $\mathbb{O}(X_n)$ of Hausdorff l.c. spaces X_n with *lower s.c. and monotone upper s.c.* maps from $\mathbb{O}(X_{n+1})$ into $\mathbb{O}(X_n)$.

(7) A family of pi-sun C^*-algebras that exhausts the UCT-classes up to KK-equivalence.

(8) This is more a *conjecture* than a given proof:

If the "exponential length" of all unitaries in $\mathcal{U}_0(A)$ in a unital A is bounded by some constant $\gamma \in (0, \infty)$ then $\mathcal{U}_0(A)$ is uniformly contractible, i.e., there exists an (uniformly) continuous map

$$\psi \colon \mathcal{U}_0(A) \times [0,1] \to \mathcal{U}_0(A)$$

such that $\psi((u,0)) = 1$ and $\psi((u,1)) = u$

(The proof uses [**553**, thm. 3.2"], because

$$\phi(u) := \{(h_1,\ldots,h_n)\in A^n\,;\; h_k^* = -h_k\,,\; u=\exp(h_1)\cdot\ldots\cdot\exp(h_n)\,\}$$

is an l.s.c. carrier $\phi\colon \mathcal{U}_0(A)\mapsto \mathcal{F}(A^n)$. if $\phi(u)$ is non-empty on each $u\in\mathcal{U}_0(A)$.

`The l.s.c.-property of` ϕ `has to be checked again !!!`

Open and at the same time closed subsets of complete metric spaces are complete metric spaces, hence are para-compact.

We use this to get an alternative proof of the uniform contractibility of $\mathcal{U}(\mathcal{M}(A))$ for all σ-unital stable C^*-algebras A. (NOW STILL OPEN QUESTION !!!).

1. Operations on Multiplier algebras (1)

List of properties of Multiplier algebras:

A σ-unital (and $e\in A_+$ strictly positive contraction):

If $e\in B\subseteq A$ then the natural C^*-morphism $h\colon B\to A$ given by the inclusion map defines defines a *-monomorphism from $\mathcal{M}(B)$ into $\mathcal{M}(A)$. The image consists of all $T\in\mathcal{M}(A)$ with $Te, eT\in B$.

For each separable C^*-subalgebra C of $\mathcal{M}(A)$ exists separable $B\subseteq A$ with $e\in B$, and $eC\cup Ce\in B$.
In particular $C\subseteq\mathcal{M}(B)\subseteq A$.

If $J\subseteq A$ is closed ideal then A/J has the strictly positive element $f:=\pi_J(e)$.

If $D\subseteq\mathcal{M}(A/J)$ is a separable C^*-subalgebra, then there exists a separable C^*-subalgebra B of A such that $e\in B$ and $Df\cup fD\subseteq\pi_J(B)$. Thus, $D\subseteq\mathcal{M}(\pi_J(B))\subseteq\mathcal{M}(A/J)$. Then the natural epimorphism $\pi_J|B$ from B onto $\pi_J(B)$ defines an epimorphism from $\mathcal{M}(B)\subseteq\mathcal{M}(A)$ onto $\mathcal{M}(\pi_J(B))$, and $D\subseteq\mathcal{M}(\pi_J(B))\subseteq\mathcal{M}(A/J)$. In particular, $D\subseteq\mathcal{M}(\pi_J)(\mathcal{M}(A))$. Thus, $\mathcal{M}(\pi_J)\colon\mathcal{M}(A)\to\mathcal{M}(A/J)$ is surjective.

`Compare with Remark B.1.1 !!!`

REMARK B.1.1 (Non-commutative Tietze extension). Let A a σ-unital C^*-algebra, i.e., there exists a an element $e\in A_+$ with $\|e\|=1$ that is a strictly positive element of A.

Then for every closed ideal J of A the natural (on bounded parts strictly continuous) C^*-morphism $\mathcal{M}(\pi_J)\colon\mathcal{M}(A)\to\mathcal{M}(A/J)$ is surjective.

The kernel of $\mathcal{M}(\pi_J)$ is $\mathcal{N}(A,J) := \{T\in\mathcal{M}(A)\,;\; Te, eT\in J\}$.

In case where A is separable, this is [**616**, prop. 3.12.10].

If A is not separable and $e\in A_+$ as strictly positive element with $\|e\|=1$ then, for every unital separable C^*-subalgebra $B\subseteq\mathcal{M}(A/J)$ there exists a separable C^*-subalgebra $E\subseteq A$ with $e\in E$ and $BD\cup DB\subseteq D$ for $D:=\pi_J(E)\cong E/(J\cap E)$.

The strictly continuous extension $\mathcal{M}(\pi_{J\cap E})\colon\mathcal{M}(E)\to\mathcal{M}(E/(J\cap E))$ of the epimorphism $\pi_{J\cap E}\colon E\to E/(J\cap E)\cong D$ is surjective by [**616**, prop. 3.12.10].

The algebra B is contained in $\mathcal{M}(D) \subseteq \mathcal{M}(A/J)$ – if we naturally identify $\mathcal{M}(D)$ with the two-sided multipliers of D in $\mathcal{M}(A/J)$. In the same way $\mathcal{M}(E)$ is naturally isomorphic to algebra the two-sided multipliers of E in $\mathcal{M}(A)$. The strictly continuous extension $\mathcal{M}(\pi_J)\colon \mathcal{M}(A) \to \mathcal{M}(A/J)$ of π_J maps $\mathcal{M}(E)$ into $\mathcal{M}(D)$. It becomes there under natural identification of $E/(J \cap E)$ with D the same as the natural strictly continuous unital C^*-morphism $\mathcal{M}(\pi_{E\cap J})$ from $\mathcal{M}(E)$ into $\mathcal{M}(E/(J \cap E))$.

Thus, $B \subseteq \mathcal{M}(A/J)$ is contained in the image of $\mathcal{M}(\pi_J)\colon \mathcal{M}(A) \to \mathcal{M}(A/J)$.

Above has to be discussed / reformulated

2. Actions and monotone maps

The Chapter 0 of [**321**] could be a reference for this section, but all results mentioned here are elementary exercises for the reader. Recall that a set Y with transitive, reflexive and antisymmetric relation $x \leq y$ is a *partially ordered set* (poset). We need only very special posets, namely those that are order isomorphic or order anti-isomorphic to the lattice of the ideals (or: ideal lattice) of a ring.

Obviously, the family $\mathbb{O}(X)$ of open subsets of a T_0 space X and the family $\mathbb{F}(X)$ of closed subsets of X, and the set X itself are all partially ordered sets with the inclusions $U \subseteq V$, $F \subseteq G$, and $x \leq y$ if and only if $x \in \overline{\{y\}}$.

The order reversing isomorphisms $F \mapsto X \setminus F$ and $U \mapsto X \setminus U$ show that $\mathbb{F}(X)$ is just the opposite ordered space of $\mathbb{O}(X)$.

Subsets Z of $\mathbb{O}(X)$ or $\mathbb{F}(X)$ have unique $\inf Z$ a and $\sup Z$, i.e., they are complete lattices. Moreover $\mathbb{O}(X)$ is a *Heyting algebra* (also called *frame*), because

$$W \cap \bigcup_\gamma U_\gamma = \bigcup_\gamma W \cap U_\gamma \,.$$

The infimum $\bigwedge\{U_\gamma\}$ is the interior $(\bigcap_\gamma U_\gamma)^\circ$ of the intersection of a family $\{U_\gamma\} \subseteq \mathbb{O}(X)$. The supremum in $\mathbb{F}(X)$ of a family of closed subsets is the closure of its union.

A closed subset F of a T_0 space X is *prime* if it is not the union of two closed subsets $F_1, F_2 \subseteq F$, that are both different from F. Equivalently this means: If $F \subseteq Z_1 \cup Z_2$, then $F \subseteq \overline{Z_1}$ or $F \subseteq \overline{Z_2}$. A T_0 spaces X is **sober** (also called point-wise complete, or *point-complete*) if each prime closed subset $F \subseteq X$ is the closure of a point of X.

For any T_0 space X there is a unique (up to natural isomorphisms) *sober* space X^c and an embedding $\eta\colon X \to X^c$ such that $U \in \mathbb{O}(X^c) \mapsto \eta^{-1}(U) \in \mathbb{O}(X)$ is a lattice isomorphism. X^c is called the **sobrification** of X.

In particular, each *sober* T_0 space X is completely determined likewise by each of the lattices $\mathbb{O}(X)$ or $\mathbb{F}(X)$.

The sobrification $\mathrm{Prim}(A)^c$ of the space of primitive ideals $\mathrm{Prim}(A)$ is naturally isomorphic to $\mathrm{prime}(A)$ (the space of prime ideals of A) if A is a C^*-algebra.

If A is a C^*-algebra, then there are natural order isomorphisms $\mathcal{I}(A) \cong \mathbb{O}(\mathrm{Prim}(X))$ and order reversing isomorphism from the lattice of closed ideals $\mathcal{I}(A)$ onto onto $\mathbb{F}(A)$.

$\mathcal{I}(A)$, $\mathbb{O}(X)$, $\mathbb{F}(X)$ `as posets`

lower s.c. and upper s.c. maps

case $\mathcal{I}(A)$ (lattice of closed sets of

notation $\uparrow X$, $\uparrow t$, $\downarrow X$, $\downarrow t$

`Galois connections`

Definition B.2.1. Let X and Y posets and $\phi\colon Y \to X$ and $\psi\colon X \to Y$ maps that satisfy:

(i) ϕ and ψ are monotone (order preserving), and
(ii) the relations $\phi(y) \geq x$ and $y \geq \psi(x)$ are equivalent for all $(x, y) \in X \times Y$.

Then (ϕ, ψ) is called **Galois connection** or *adjunction* between X and Y.

The map ϕ is the *upper adjoint* and ψ is the *lower adjoint*.

Let $\mathcal{C} \subseteq \mathrm{CP}(A, B)$ a matricially operator-convex cone. Consider the lower semi-continuous action $\Psi_{\mathcal{C}}\colon \mathcal{I}(B) \to \mathcal{I}(A)$ and the upper semi-continuous action $\Phi_{\mathcal{C}}\colon \mathcal{I}(A) \to \mathcal{I}(B)$ as defined in Definition **??**. Then $(\Psi_{\mathcal{C}}, \Phi_{\mathcal{C}})$ is a Galois connection, and $\Psi_{\mathcal{C}}$ is the upper adjoint and $\Phi_{\mathcal{C}}$ is the lower adjoint of the connection.

The following proposition equips us with the in Chapters 3 and 6 needed observation on Galois connections.

Proposition B.2.2. *Let X and Y partially ordered sets and $\phi\colon Y \to X$ and $\psi\colon X \to Y$ monotone (increasing) maps.*

(i) *The formula $\psi(x) := \inf \phi^{-1}(\uparrow x)$ for $x \in X$ defines a lower adjoint of ϕ (such that (ϕ, ψ) is a Galois connection), if $\phi(\inf Z) = \inf \phi(Z)$ so far as $\inf Z$ exists in X, and Y is a complete lattice, or Y is a complete semi-lattice and $\phi\colon Y \to X$ is* co-final *(i.e., for all $x \in X$ there is $y \in Y$ with $x \leq \phi(y)$ — or equivalently: $\phi^{-1}(\uparrow x) \neq \emptyset$).*
(ii) *If (ϕ, ψ) is a Galois connection, then $\psi(x) := \min \phi^{-1}(\uparrow x)$ for all $x \in X$ and $\phi(y) := \max \psi^{-1}(\downarrow y)$ for all $y \in Y$.*
   In particular, they determine each other.
(iii) *If (ϕ, ψ) is a Galois connection, then the upper adjoint ϕ is* inf*-preserving and the lower adjoint ψ is* sup*-preserving.*
(iv) *`compare products with`* id
(v) *`when` $\psi \circ \phi$ `or` $\psi \circ \phi$ `is identity?`*

`definitions and uniqueness of adjoints`

uniqueness of the upper and lower Galois adjoints

in particular, the upper and the lower map of a Galois connection determine each other uniquely.

A reference could be [**321**, chp. 0].

3. Topological actions

Let $\mathcal{L}$ denote a set (or a lattice), X and Y topological spaces, $\Psi_1\colon \mathcal{L} \to \mathbb{O}(X)$ and $\Psi_2\colon \mathcal{L} \to \mathbb{O}(Y)$ map (increasing if $\mathcal{L}$ is a lattice). We say that an increasing map $\Psi\colon \mathbb{O}(Y) \to \mathbb{O}(X)$ is **fitting** (or **Ψ_1-Φ_2 compatible**) if $\Psi(\Psi_2(\ell)) \supset \Psi_1(\ell)$ for $\ell \in \mathcal{L}$.

Recall that a map $\Psi\colon \mathbb{O}(Y) \to \mathbb{O}(X)$ is is *lower semi-continuous* if the image $\Psi(V)$ of the interior $V := (\bigcap_\alpha V_\alpha)^\circ$ of the set $\bigcap_\alpha V_\alpha$ is the interior of $\bigcap_\alpha \Psi(V_\alpha)$, for each family $\{V_\alpha\}$ of open subsets $V_\alpha \subseteq Y$. Lower s.c. actions Ψ are increasing.

Lemma B.3.1. *Let $\mathcal{L}$ denote a set (or a lattice), X and Y topological spaces, $\Psi_1\colon \mathcal{L} \to \mathbb{O}(X)$ and $\Psi_2\colon \mathcal{L} \to \mathbb{O}(Y)$ maps (increasing if $\mathcal{L}$ is a lattice).*

(i) *Let S and A sets and $(\psi,\alpha) \in S \times A \mapsto W_{\psi,\alpha} \in \mathbb{O}(X)$ a map. Then*

$$\left(\bigcap_\alpha \left(\bigcap_\psi W_{\psi,\alpha}\right)^\circ\right)^\circ = \left(\bigcap_\psi \left(\bigcap_\alpha W_{\psi,\alpha}\right)^\circ\right)^\circ .$$

(ii) *If $S \neq \emptyset$ is a set of lower semi-continuous maps $\Psi\colon \mathbb{O}(Y) \to \mathbb{O}(X)$, then the map*

$$\Psi'\colon \mathbb{O}(Y) \ni V \mapsto (\bigcap_{\Psi\in S} \Psi(V))^\circ \in \mathbb{O}(X)$$

is lower semi-continuous.

(iii) *There is a minimal element $\Psi'\colon \mathbb{O}(Y) \to \mathbb{O}(X)$ in the set S of the fitting lower s.c. maps, i.e., $\Psi'(V) \subseteq \Psi(V)$ for every open subset V of Y and every fitting l.s.c. map $\Psi\colon \mathbb{O}(Y) \to \mathbb{O}(X)$.*
Moreover, $\Psi'(V) \supset \bigcup_{\ell\in\mathcal{L}(V)} \Psi_1(\ell)$ for every open subset V of Y, where $\mathcal{L}(V) := \{\ell \in \mathcal{L}\,;\ \Psi_2(\ell) \subseteq V\}$.

(iv) *If $\Psi_2(\ell_1) \subseteq \Psi_2(\ell_2)$ implies $\Psi_1(\ell_1) \subseteq \Psi_1(\ell_2)$ for $\ell_1, \ell_2 \in \mathcal{L}$, and if $x \in \bigcap_\alpha \Psi_1(\ell_\alpha) \neq \emptyset$ implies the existence of $\ell \in \mathcal{L}$ with $\Psi_2(\ell) \subseteq \Psi_2(\ell_\alpha)$ for all $\alpha \in A$ and $x \in \Psi_1(\ell)$, then the minimal fitting map Ψ' in part (iii) satisfies $\Psi'(V) = \bigcup_{\ell\in\mathcal{L}(V)} \Psi_1(\ell)$ for each $V \in \mathbb{O}(Y)$, and $\Psi'(\Psi_2(\ell)) = \Psi_1(\ell)$ for all $\ell \in \mathcal{L}$.*

(v) *An increasing map $\Psi\colon \mathbb{O}(Y) \to \mathbb{O}(X)$ is lower semi-continuous,*
if and only if,
the map

$$\lambda\colon Y \ni y \to \lambda(y) := X \setminus \Psi(Y \setminus \overline{\{y\}}) \in \mathbb{F}(X)$$

from Y to $\mathbb{F}(X)$ satisfies $\lambda(y) \subseteq \overline{\bigcup_{z\in Z} \lambda(z)}$ for each subset $Z \subseteq Y$ and $y \in \overline{Z}$,
if and only if,
the function $g(y) := \sup f(\lambda(y))$ is lower semi-continuous for every bounded lower semi-continuous function $f\colon X \to [0,\infty)$.

PROOF. (i): Since $(\bigcap_\psi W_{\psi,\alpha})^\circ$ is contained in $W_{\psi,\alpha}$ for each (ψ,α), we get that $\bigcap_\alpha(\bigcap_\psi W_{\psi,\alpha})^\circ$ is contained in $\bigcap_\alpha W_{\psi,\alpha}$ for each $\psi\in S$. Thus, the interior of $\bigcap_\alpha(\bigcap_\psi W_{\psi,\alpha})^\circ$ is contained in $(\bigcap_\alpha W_{\psi,\alpha})^\circ$ for each $\psi\in S$. This implies that

$$(\bigcap_\alpha \left(\bigcap_\psi W_{\Psi,\alpha}\right)^\circ)^\circ \;\subseteq\; (\bigcap_\psi \left(\bigcap_\alpha W_{\psi,\alpha}\right)^\circ)^\circ .$$

The interior of $\bigcap_\psi(\bigcap_\alpha W_{\psi,\alpha})^\circ$ is contained in $\bigcap_\alpha(\bigcap_\psi W_{\psi,\alpha})^\circ$ by a similar argument.

(ii): Let $\{V_\alpha\}_{\alpha\in A}$ a family of open subsets of Y, and let $W_{\Psi,\alpha}:=\Psi(V_\alpha)$ for $\Psi\in S$ and $\alpha\in A$. Then $\Psi'((\bigcap_\alpha V_\alpha)^\circ)$ is the interior of $\bigcap_\Psi\Psi\big((\bigcap_\alpha V_\alpha)^\circ\big)=\bigcap_\Psi(\bigcap_\alpha W_{\Psi,\alpha})^\circ$ (by lower semi-continuity of $\Psi\in S$). On the other hand, $\bigcap_\alpha\Psi'(V_\alpha)=\bigcap_\alpha(\bigcap_\Psi W_{\Psi,\alpha})^\circ$ by definition of Ψ' and of $W_{\Psi,\alpha}$. Now apply part (i) and the definition of lower semi-continuity.

(iii): Let $\Psi_0(V):=X$ for all open subsets $V\subseteq Y$ (including the case $V=\emptyset$). It is lower s.c. and is fitting. Thus, the set S of fitting l.s.c. maps $\Psi\colon\mathbb{O}(Y)\to\mathbb{O}(X)$ is not empty.

Let $\Psi'(V)\in\mathbb{O}(X)$ denote the interior of the set $\bigcap_{\Psi\in S}\Psi(V)$ for each $V\in\mathbb{O}(Y)$. Then, $\Psi_1(\ell)\subseteq\Psi'(\Psi_2(\ell))$ for all $\ell\in\mathcal{L}$ and $\Psi'\colon\mathbb{O}(Y)\to\mathbb{O}(X)$ is lower semi-continuous by part (ii). Since $\Psi'\in S$, it is the minimal l.s.c. map $\Psi\in S$. Since Ψ' is fitting, $\Psi_1(\ell)\subseteq\Psi'(V)$ for each $\ell\in\mathcal{L}$ with $\Psi_2(\ell)\subseteq V$.

(iv): We define $\mathcal{L}(V):=\{\ell\in\mathcal{L}\,;\,\Psi_2(\ell)\subseteq V\}$. Then, $\bigcap_\alpha\mathcal{L}(V_\alpha)=\mathcal{L}((\bigcap_\alpha V_\alpha)^\circ)$, $\ell\in\mathcal{L}(\Psi_2(\ell))$ for $\ell\in\mathcal{L}$, and $\mathcal{L}(V_1)\subseteq\mathcal{L}(V_2)$ for $V_1\subseteq V_2$.

Now let $\Phi(V):=\bigcup_{\ell\in\mathcal{L}(V)}\Psi_1(\ell)$ for $V\in\mathbb{O}(Y)$. Then $\Psi_1(\ell)\subseteq\Phi(\Psi_2(\ell))$ for $\ell\in\mathcal{L}$, $\Phi(V)\subseteq\Psi'(V)$ for all $V\in\mathbb{O}(Y)$ (by Part (iii)), and $\Phi(V_1)\subseteq\Phi(V_2)$ for $V_1\subseteq V_2$. In particular, $\Phi((\bigcap_\alpha V_\alpha)^\circ)$ is contained in the interior of $\bigcap_\alpha\Phi(V_\alpha)$.

The reversed inclusion can be derived from the rather strong assumption, that $x\in\bigcap_\alpha\Psi_1(\ell_\alpha)\neq\emptyset$ implies the existence of $\ell\in\mathcal{L}$ with $\Psi_2(\ell)\subseteq\Psi_2(\ell_\alpha)$ for all $\alpha\in A$ and $x\in\Psi_1(\ell)$.

In particular Φ is lower s.c. and fitting. Thus, $\Phi(V)\supset\Psi'(V)$.

Since $\ell_2\in\mathcal{L}(\Psi_2(\ell_2))=\{\ell_1\in\mathcal{L}\,;\,\Psi_2(\ell_1)\subseteq\Psi_2(\ell_2)\}$, we have $\Psi_1(\ell_1)\subseteq\Psi_1(\ell_2)$ for $\ell_1\in\mathcal{L}(\Psi_2(\ell_2))$, if $\Psi_2(\ell_1)\subseteq\Psi_2(\ell_2)$ implies $\Psi_1(\ell_1)\subseteq\Psi_1(\ell_2)$. Thus $\Psi'(\Psi_2(\ell))=\Psi_1(\ell)$ in this case.

(v): We write $\lambda(Z)$ for the union $\bigcup_{z\in Z}\lambda(z)\subseteq X$.

Suppose that $\Psi\colon\mathbb{O}(Y)\to\mathbb{O}(X)$ is an increasing lower semi-continuous map, i.e.,

$$(\bigcap_\tau\Psi(U_\tau))^\circ=\Psi((\bigcap_\tau U_\tau)^\circ)\,.$$

Let $Z\subseteq Y$, then $y\in\overline{Z}$, if and only if,

$$Y\setminus\overline{\{y\}}\supset Y\setminus\overline{Z}=(\bigcap_{z\in Z}Y\setminus\overline{\{z\}})^\circ\,.$$

It follows that

$$\Psi(Y \setminus \overline{\{y\}}) \supset (\Psi(\bigcap_{z\in Z} Y \setminus \overline{\{z\}}))^\circ .$$

The right side is the same as $X \setminus \overline{\lambda(Z)}$, by the rule $X \setminus (\bigcap_\tau V_\tau)^\circ = \overline{\bigcup_\tau (X \setminus U_\tau)}$. Thus, $\lambda(y) \subseteq \overline{\lambda(Z)}$ for each subset $Z \subseteq Y$ and $y \in \overline{Z}$.

Suppose that the map

$$\lambda \colon Y \ni y \to \lambda(y) := X \setminus \Psi(Y \setminus \overline{\{y\}}) \in \mathbb{F}(X)$$

from Y to $\mathbb{F}(X)$ satisfies:
$\lambda(y) \subseteq \overline{\lambda(Z)}$ for each subset $Z \subseteq Y$ and $y \in \overline{Z}$.
Let $f \colon X \to [0,\infty)$ l.s.c., and let $g(y) := \sup f(\lambda(y))$. Then $W := f^{-1}[0,t]$ is closed, and $y \in Z := g^{-1}[0,t]$, if and only if, $\lambda(y) \subseteq W$. Since W is closed and $\lambda(Z) \subseteq W$ we have $\lambda(y) \subseteq W$ for all $y \in \overline{Z}$. Thus, $g^{-1}[0,t]$ is closed for all $t \in [0,\infty)$, i.e., g is l.s.c.

Suppose that the function $g(y) := \sup f(\lambda(y))$ is lower semi-continuous for every bounded lower semi-continuous function $f \colon X \to [0,\infty)$.
Consider the map $F \colon \mathbb{F}(Y) \to \mathbb{F}(X)$ given by $F(Z) := X \setminus \Psi(Y \setminus Z)$. F is increasing. $F(\overline{\{y\}}) = \lambda(y)$.

We must show that $\bigcup F(Z_\tau)$ has closure $F(\overline{\bigcup Z_\tau})$ for each family $\{Z_\tau\}$ of closed subsets of Y. Since F is increasing,

$$\overline{\bigcup F(Z_\tau)} \subseteq F(\overline{\bigcup Z_\tau}) .$$

Let $Z := \bigcup Z_\tau$. Then $Z = \bigcup_{z\in Z} \overline{\{z\}}$, and

$$\bigcup F(Z_\tau) \supset \bigcup_{z\in Z} F(\overline{\{z\}}) = \lambda(Z)$$

holds because F is increasing. Let $U := X \setminus \overline{\lambda(Z)}$ and let $f \colon X \to [0,1]$ the characteristic function of U. Then $g(y) := \sup f(\lambda(y))$ is lower s.c. and the *closed* subset $G := g^{-1}(0)$ is given by $y \in Y$ with $\lambda(y) \in \overline{\lambda(Z)}$. In particular, G contains the closure of Z. We get $F(\overline{Z}) \subseteq X \setminus U$. Thus,

$$F(\overline{\bigcup Z_\tau}) = F(\overline{Z}) \subseteq \overline{\lambda(Z)} \subseteq \overline{\bigcup F(Z_\tau)} .$$

□

4. Some properties of exact C^*-algebras

DEFINITION B.4.1. We say that a C^*-subalgebra $E \subseteq A$ is a **regular subalgebra** of A, if, for all closed ideals J_1, J_2 of A,

(i) $E \cap (J_1 + J_2) = (E \cap J_1) + (E \cap J_2)$, and
(ii) $J_1 = J_2$ if $E \cap J_1 = E \cap J_2$.

In other words this says, that $\Psi^{\mathrm{up}}_{A,E}(J) := E \cap J$ defines a continuous action of $X := \mathrm{Prim}(A)$ on E in the sense of Definition 1.2.6, because of (i), and this action is injective if considered as a map from $\mathbb{O}_X \cong \mathcal{I}(A)$ into $\mathcal{I}(E)$, by (ii).

It is shown in [**464**] that $A \otimes \mathcal{O}_2$ contains a regular Abelian C^*–subalgebra E for every separable nuclear C^*-algebra A. We obtain in Chapter 12, that this implies the same for separable exact C^*-algebras A.

The Lemma 2.2.3 yields another useful result:

Proposition B.4.2. *Suppose that A and B are separable C^*-algebras, and that A is exact.*

(i) *Every primitive ideal J of $A \otimes B$ is a sum $J = (J_1 \otimes B) + (A \otimes J_2)$, where J_1 and J_2 are primitive ideals of A and B, respectively.*
(ii) *Every closed ideal J of $A \otimes B$ is the closure of the sum of the family of all elementary ideals $J_1 \otimes J_2 \subseteq J$ containing in J, where $J_1 \subseteq A$ and $J_2 \subseteq B$ are closed ideals.*

Here ''elementary'' ideals are defined as the tensor products $J_1 \otimes J_2$??

(iii) *The 1-1-map from $\mathrm{Prim}(A) \times \mathrm{Prim}(B)$ onto $\mathrm{Prim}(A \otimes B)$ which is given by (i) is a homeomorphism from the Tychonoff product of $\mathrm{Prim}(A)$ and $\mathrm{Prim}(B)$ onto $\mathrm{Prim}(A \otimes B)$.*
(iv) *If $E \subseteq A$ and $F \subseteq B$ are C^*-subalgebras which separate the closed ideals of A and B, in the sense that e.g. $E \cap J_1 = E \cap J_2$ implies $J_1 = J_2$, then again $E \otimes F$ separates the closed ideals of $A \otimes B$.*

If, moreover, E and F are regular subalgebras of A and B in the sense of Definition B.4.1, then $E \otimes F$ is a regular subalgebra of $A \otimes B$.

Proof. (i): The tensor product $d = d_1 \otimes d_2$ of irreducible representations d_1 of A and d_2 of B is irreducible. d defines a faithful representation of $(A/J_1) \otimes (B/J_2)$, where J_1 and J_2 are the kernels of d_1 and d_2. Since A and, therefore, A/J_1 and J_1 are exact, the kernels of $A \otimes B \to A \otimes (B/J_2)$, of $(A/J_1) \otimes B \to (A/J_1) \otimes (B/J_2)$ and of $J_1 \otimes B \to J_1 \otimes (B/J_2)$ are $A \otimes J_2$, $(A/J_1) \otimes J_2$ and $J_1 \otimes J_2$, respectively. Since exact C^*-algebras are locally reflexive, the kernels of $A \otimes B \to (A/J_1) \otimes B$ and of $A \otimes (B/J_2) \to (A/J_1) \otimes (B/J_2)$ are $J_1 \otimes B$ and $J_1 \otimes (B/J_2)$. Thus the kernel of d is $(J_1 \otimes B) + (A \otimes J_2)$, as the 3×3-lemma shows.

Thus $\lambda\colon (J_1, J_2) \mapsto J_1 \otimes B + A \otimes J_2$ maps $\mathrm{Prim}(A) \times \mathrm{Prim}(B)$ into $\mathrm{Prim}(A \otimes B)$.

A general irreducible representation d of $A \otimes B$ defines commuting factorial representations d_1 of A and d_2 of B, such that $d(a \otimes b) = d_1(a)d_2(b)$. By a result of J. Dixmier, the kernels J_1 of d_1 and J_2 of d_2 are primitive. $(J_1 \otimes B) + (A \otimes J_2)$ is contained in the kernel of d, and d defines a C^*-norm on the algebraic tensor product $A/J_1 \odot B/J_2$ which majorize the spatial norm, cf. [**704**, prop.1.20.5,prop.1.22.7]. Thus the kernel of d is $(J_1 \otimes B) + (A \otimes J_2)$.

(ii):

Check again

Let J_0 be the closure of the sum of all elementary ideals which are contained in J. Suppose that there exists $d \in J_+$ such that d is not in J_0. Then, by (i), there exists primitive ideals $J_1 \subseteq A$ and $J_2 \subseteq B$ such that $J_0 \subseteq J_1 \otimes B + A \otimes J_2$ and $A \otimes B \to (A/J_1) \otimes (B/J_2)$ maps d into a non-zero positive element of $(A/J_1) \otimes (B/J_2)$. Thus there exist pure states φ on A and ψ on B such that $\varphi \otimes \psi(J_0) = 0$ and $\varphi \otimes \psi(d) > 0$. By Lemma 2.2.3, there exists $z \in A \otimes B$, $e \in A_+$ and $f \in B_+$ with $z^* z \in dAd$, $e \otimes f = zz^*$, $\varphi(e) > 0$ and $\psi(f) > 0$. Hence $e \otimes f \in J$, $\varphi \otimes \psi(e \otimes f) > 0$ and the elementary ideal generated by $e \otimes f$ is contained in J_0. A contradiction to the choice of φ and ψ.

(iii): Every open subset of the Tychonoff product $\mathrm{Prim}(A) \times \mathrm{Prim}(B)$ is the union of cartesian products $Y \times Z$ of open subsets Y of $\mathrm{Prim}(A)$ and Z of $\mathrm{Prim}(B)$. They correspond to closed ideals $K_1 \subseteq A$ and $K_2 \subseteq B$, and λ maps $Y \times Z$ onto the open subset of $\mathrm{Prim}(A \otimes B)$ which corresponds to $K_1 \otimes K_2$. Thus, by (ii), λ maps the open subsets of the Tychonoff product $\mathrm{Prim}(A) \times \mathrm{Prim}(B)$ onto the open subsets of $\mathrm{Prim}(A \otimes B)$.

(iv): The natural map $J \mapsto E \cap J$ defines a monotone map $\Psi_1 := \Psi^{\mathrm{up}}_{A,E}$ from the open subsets of $\mathrm{Prim}(A)$ into the open subsets of $\mathrm{Prim}(E)$ ($\cong$ closed ideals of E), which satisfies the conditions (ii),(iii) and (iv) of Definition 1.2.6. E and F separate the closed ideals of A and B, if and only if, Ψ_1 and $\Psi_2 := \Psi^{\mathrm{up}}_{B,F}$ are injective.

We consider $\Psi_3 := \Psi^{\mathrm{up}}{}_{A \otimes B, E \otimes F}$ as a map from the open subsets of $\mathrm{Prim}(A) \times \mathrm{Prim}(B)$ into the open subsets of $\mathrm{Prim}(E) \times \mathrm{Prim}(F)$. By the monotony and by condition (ii) of Definition 1.2.6 for Ψ_3, it is enough to check the injectivity of the map Ψ_3 on the base of the topology of $\mathrm{Prim}(A) \times \mathrm{Prim}(B)$. This base is given by the cartesian products of open subsets of $\mathrm{Prim}(A)$ and of $\mathrm{Prim}(B)$. $\Psi_3(Y \times Z) = \Psi_1(Y) \times \Psi_2(Z)$, for open subsets Y of $\mathrm{Prim}(A)$ and Z of $\mathrm{Prim}(B)$, because, for closed ideals $J \subseteq A$ and $K \subseteq B$, $(E \otimes F) \cap (J \otimes K) = (E \cap J) \otimes (F \cap K)$. The latter identity follows from the exactness of $E \subseteq A$. The cartesian product map $\Psi_1 \times \Psi_2$ is injective, because Ψ_1 and Ψ_2 are injective.

Now suppose that, moreover, that E is regular in A and that F is regular in B. E and F are regular, if and only if, moreover, Ψ_1 and Ψ_2 satisfy condition (i) of Definition 1.2.6, e.g., $\Psi_1(Z_1 \cup Z_2) = \Psi_1(Z_1) \cup \Psi_1(Z_2)$ for open subsets Z_1 and Z_2 of $\mathrm{Prim}(A)$. We want to deduce that $\Psi_3(X_1 \cup X_2) = \Psi_3(X_1) \cup \Psi_3(X_2)$ for open subsets X_1 and X_2 of $\mathrm{Prim}(A \otimes B)$.

By the monotony and by condition (ii) of Definition 1.2.6 for Ψ_3, it suffices to show that, for open subsets Y_k of $\mathrm{Prim}(A)$ and Z_k of $\mathrm{Prim}(B)$,

$$\Psi_3\Big(\bigcup_{1 \le k \le n} Y_k \times Z_k\Big) \subseteq \bigcup_{1 \le k \le n} \Psi_3(Y_k \times Z_k)\,.$$

Note that $\Psi_1(\mathrm{Prim}(A)) = \mathrm{Prim}(E)$ and $\Psi_2(\mathrm{Prim}(B)) = \mathrm{Prim}(F)$.

If $J \subseteq A$ and $K \subseteq B$ are closed ideals, then the natural epimorphism from $A \otimes B$ onto $(A/J) \otimes (B/K)$ has kernel $A \otimes K + J \otimes B$, because A is exact and, therefore, locally reflexive. The same applies to $J \cap E$, $K \cap F$, E and F, and $E/(E \cap J) \otimes F/(F \cap K)$ is a subalgebra of $A/J \otimes B/K$. Thus

$$((A \otimes K) + (J \otimes B)) \cap (E \otimes F) = (E \otimes F) \cap (A \otimes K) + (E \otimes F) \cap (J \otimes B),$$

which means that

$$\Psi_3(Y \times \mathrm{Prim}(B)) \cup \Psi_3(\mathrm{Prim}(A) \times Z) = \Psi_3((Y \times \mathrm{Prim}(B)) \cup (\mathrm{Prim}(A) \times Z))\,.$$

Let (I_1, I_2) be a point of $\mathrm{Prim}(E) \times \mathrm{Prim}(F)$ which is not in in the union of the sets $\Psi_1(Y_k) \times \Psi_2(Z_k)$ for $k = 1, \ldots, n$. Then there are subsets S and T of $\{1, \ldots, n\}$, with $S \cup T = \{1, \ldots, n\}$, such that I_1 is not in $\bigcup_{k \in S} \Psi_1(Y_k)$ and I_2 is not in $\bigcup_{k \in T} \Psi_2(Z_k)$.

Since E and F are regular subalgebras, we have $\Psi_1(Y) = \bigcup_{k \in S} \Psi_1(Y_k)$ and $\Psi_2(Z) = \bigcup_{k \in T} \Psi_2(Z_k)$, where $Y := \bigcup_{k \in S} Y_k$ and $Z := \bigcup_{k \in T} Z_k$.

Thus (I_1, I_2) is not in $(\Psi_1(Y) \times \mathrm{Prim}(F)) \cap (\mathrm{Prim}(E) \times \Psi_2(Z))$. The latter is the same as $\Psi_3((Y \times \mathrm{Prim}(B)) \cap (\mathrm{Prim}(A) \times Z))$.

But Ψ_3 is monotonous, and $\bigcup Y_k \times Z_k \subseteq (Y \times \mathrm{Prim}(B)) \cap (\mathrm{Prim}(A) \times Z)$. □

COROLLARY B.4.3. *Suppose that $A_1, A_2, \ldots$ is a sequence of separable exact C*-algebras (with A_n unital for $n \geq n_0$).*

(i) *There is a natural homeomorphism from the Tychonoff product* $\mathrm{Prim}(A_1) \times \mathrm{Prim}(A_2) \times \ldots$ *onto* $\mathrm{Prim}(A_1 \otimes A_2 \otimes \ldots)$.
(ii) *If B_n are regular C*-subalgebras of A_n, $n = 1, 2, \ldots$, then $B_1 \otimes B_2 \otimes \ldots$ is a regular C*-subalgebra of $A_2 \otimes A_2 \otimes \ldots$.*

PROOF. Let $A := A_1 \otimes A_2 \otimes \ldots$, $C_n := A_1 \otimes A_2 \otimes \ldots \otimes A_n$, $D_n := A_{n+1} \otimes A_{n+2} \otimes \ldots$, and let 1_n denote the unit element of D_n. Then, for every closed ideal J of A, A/J is the inductive limit of $\pi_J(C_n \otimes 1_n)$. Thus J is the inductive limit both of $J_n \otimes 1_n$ and, therefore, of $J_n \otimes D_n$, where $J_n \subseteq C_n$ is defined by $J_n \otimes 1_n = (C_n \otimes 1_n) \cap J$.

(i): By Proposition B.4.2, we get that every primitive ideal of A is the closure of the sum of ideals $C_{n-1} \otimes J_n \otimes D_n$, where J_n is a primitive ideal of A_n for $n = 1, 2, \ldots$.

Conversely, let $J_n \subseteq A_n$ a sequence of primitive ideals. We find pure states ψ_n on A_n which define irreducible representations with kernel J_n. By [**704**, prop. 4.3.4], the infinite tensor product of pure states is pure. Thus, the kernel of the natural epimorphism from A onto the infinite tensor product of the quotients A_n/J_n is primitive. This shows the set-theoretic isomorphism of $\mathrm{Prim}(A)$ with the Tychonoff product of the sequence $\mathrm{Prim}(A_n)$. The topological isomorphism means that one can find for both a bases of the topology which is mapped by the set-theoretic isomorphism onto each other. By definition of the Tychonoff product this means that every ideal of A is the closure of a sum of ideals $J_1 \otimes \ldots \otimes J_n \otimes D_n$. This follows from Proposition B.4.2 and the remark at the beginning of the proof.

(ii): By, Proposition B.4.2(iv), for $n = 1, 2, \ldots$, $G_n := B_1 \otimes \ldots \otimes B_n \otimes 1_n$ is a regular subalgebra of $C_n \otimes 1_n$. This and $G_n \subseteq G_{n+1}$ imply that the closure $B_1 \otimes B_2 \otimes \ldots$ of $\bigcup_n G_n$ is regular in the closure A of $\bigcup_n C_n$. □

If we combine Proposition B.4.2 with the criteria in [**432**], we get:

Corollary B.4.4. *A separable C^*-algebra A is exact, if and only if, for every separable C^*-algebra B, the natural map from $\mathrm{Prim}(A) \times \mathrm{Prim}(B)$ to $\mathrm{Prim}(A \otimes B)$, which is induced by the tensor product of irreducible representations, is a topological isomorphism. The isomorphism is the same as in Proposition B.4.2(i).*

Remark B.4.5.
(1) A lower s.c. quasi-trace $\tau \colon A_+ \to [0, \infty]$ is 2-additive if and only if it is an integral $\tau(a) = \int_{0_+}^{\infty} D((a-t)_+)\, \mathrm{d}t$ of a lower s.c. *sub-additive* dimension function $D \colon A \to [0, \infty]$. One gets D back from τ by $D(a) = \sup_{\delta > 0} \tau(f_\delta(a^* a))$, where $f_\delta(t) := \min(\delta^{-1}(t-\delta)_+, 1)$ for $\delta > 0$.

(2) Every lower semi-continuous 2-quasi-trace $\tau \colon A \to [0, \infty]$ on an exact C^*-algebra is additive. (In case of a unital A this is a result of Haagerup and Thorbjørnsen, [**342**] and [**348**, cor. 9.14]. It extends to the non-unital case by the below given Lemma B.4.6.)

(3) Every lower semi-continuous dimension function $D \colon A \to [0, \infty]$ on A integrates to a l.s.c. 2-quasi-trace τ_D on A_+ by $\tau_D(a) = \int_{0_+}^{\infty} D((a-t)_+) \mathrm{d}t$.

(4) A stable simple C^*-algebra A contains a (non-zero) properly infinite projection, if and only if, there is no non-zero dimension function D on the Pedersen ideal of A (cf. Blackadar and Cuntz [**78**]).

(??? This should be also my remark in the 1994 book from Canada workshop ???)

(5) Summing up (1)–(4), we get:
If A is simple and exact, then $T^+(A) = \{0\}$ if and only if A is stably infinite.
In particular, *simple stably projection-less exact C^*-algebras have always non-zero* additive *traces, cf.* [**441**]. *The $T^+(A) = \{0\}$ implies for simple nuclear A that $A \otimes \mathbb{K}$ contains a (non-zero) properly infinite projection.*

Lemma B.4.6. *Let $\tau \colon A_+ \to [0, \infty]$ a lower semi-continuous 2-quasi-trace.*

(i) *The map τ and its dimension function $D \colon A \to [0, \infty]$ are order monotone on A_+, and D with respect to Cuntz majorization $a \precsim b$ on A_+.*
(ii) *If, for every contraction $c \in A_+$ with $\tau(c) < \infty$, the restriction $\tau | B_+$ is additive for $B := \{a \in A\, ;\ ac = a = ca\}$, then τ is additive on A_+.*
(iii) *If $\tau(A_+) \subseteq [0, \infty)$ then $\gamma := \sup\{\tau(a)\, ;\ \|a\| \leq 1,\ a \in A_+\} < \infty$ and $\widetilde{\tau}(b + z1) := z\gamma + \tau(b_+) - \tau(b_-)$ (for $b + z1 \in \widetilde{A}_+$) defines a bounded 2-quasi-trace on the unitization $\widetilde{A}$ of A.*

PROOF. (i): Let $D\colon A \to [0,\infty]$ the l.s.c. dimension function corresponding to τ, i.e.,

$$D(a) := \limsup_{\delta>0,\gamma>0} \tau((((a^*a)-\delta)_+)^\gamma)$$

and let $0 \leq a \leq b$ or $a \precsim b$.

Then $(a-t)_+^3 \leq (a-t)_+(b-t)_+(a-t)_+ \leq \|b\|(a-t)_+^2$, because $(b-t)_+ \leq b \leq \|b\|$ by $(b-t)_+ = (b-t)+(b-t)_- \leq b$ and $(a-t)_+ - (a-t)_- = a-t \leq b-t \leq (b-t)_+$ and the order preserving map $X \mapsto (a-t)_+X(a-t)_+$ on $X^* = X$ implies $(a-t)_+^3 \leq (a-t)_+(b-t)_+(a-t)_+$.

It induces: For $\varepsilon > \delta > 0$ there is $x \in A$ with $x^*x = f_\varepsilon(a)$ and $xx^*f_\delta(b) = xx^*$. It follows $\tau(f_\delta(a)) \leq \tau(f_\epsilon(b)) \leq D(b)$. Thus $D(a) \leq D(b)$. From $D(a^\alpha) = D(a)$ and the monotony and centrality of D it follows $D((a-t)_+) \leq D((b-t)_+)$ for all $t > 0$ if $0 \leq a \leq b$. Since $\tau(a) = \int_{0+}^\infty D((a-t)_+)\,dt$, we get from it that $\tau(a) \leq \tau(b)$,

(ii): Let $a, b \in A_+$ with $\tau(a) + \tau(b) < \infty$.

Then ?????

show that $\tau((a-\varepsilon)_+ + (b-\varepsilon)_+) < \infty$???? `Fill Proof in !!! ??`

(iii): Suppose that $\gamma = \infty$ then there exists positive contractions $a_1, a_2, \ldots \in A_+$ with $\tau(a_n) > 4^n$. Then $a := \sum 2^{-n}a_n$ is a positive contraction in A with $a_n \leq 2^n a$, and $4^n < 2^n\tau(a)$ for all $n \in \mathbb{N}$ by part (i). Thus $\tau(a) = \infty$, contradicting ????? that ???

If $b \in A$ and $z \in \mathbb{C}$ then $b + z1 \geq 0$ implies $z \geq 0$, $b^* = b$ and $\|b_-\| \leq z$. Thus $\widetilde{\tau}(b + z1) \geq 0$ for $b + z1 \geq 0$. If $0 \leq b_j + z_j1$ $(j = 1, 2)$ commute, then b_1 and b_2 commute. The additivity of τ on $C^*(b_1, b_2)$ induces the additivity of $\widetilde{\tau}$ on $C^*(b_1, b_2, 1)_+$.

It follows that $\widetilde{\tau}$ is a bounded local quasi-trace on $\widetilde{A}$ with bounded lower semi-continuous rank-function $\widetilde{D}(x + z1) = \gamma$ if $z \neq 0$ and $\widetilde{D}(x) = D(x)$ for $x \in A$ and $z \in \mathbb{C}$.

??????????????????? check

`the point is the existence of` $\widetilde{D_2}$ `!!` □

5. Approximate divisible algebras

REMARK B.5.1. Recall that a separable C^*-algebra B is called **approximately divisible** if there exist a sequence of unital *-morphisms $h_n\colon M_2 \oplus M_3 \to \mathcal{M}(B)$ with $\lim_{n\to\infty} \|h_n(a)b - bh_n(a)\| = 0$ for all $a \in M_2 \oplus M_3$ and $b \in B$.

$B := A \otimes \mathcal{O}_\infty$ is approximately divisible for every separable C^*-algebra A.

(Proof: $C^*(s_1, s_2, \cdots) \cong \mathcal{O}_\infty \cong \mathcal{O}_\infty \cong \mathcal{O}_\infty \otimes \mathcal{O}_\infty \otimes \cdots$ by Corollary F(ii), – or the argument following Corollary H –, and $M_2 \oplus M_3$ is unitally contained in $\mathcal{O}_\infty = C^*(s_1, s_2, \ldots)$.

This is because we can take $M_3 := C^*(s_i s_j^*\,;\, 1 \leq i, j \leq 3)$ and $M_2 := C^*(t_k t_\ell^*\,;\, 1 \leq k, \ell \leq 2)$, where t_1, t_2 are suitable partial isometries with $t_1 t_1^* + t_2 t_2^* = p := 1 - (s_1 s_1^* + s_2 s_2^* + s_3 s_3^*)$ and $t_1^* t_1 = t_2^* t_2 = q := 1 - (s_1 s_1^* + s_2 s_2^*)$.

The existence of t_1 and t_2 follows from $\mathrm{K}_0(\mathcal{O}_\infty) \cong \mathbb{Z}$, with $[p] = -2$ and $[q] = -1$ and the pure infiniteness of $p\mathcal{O}_\infty p$, e.g. by cf. Lemma 4.2.6.

In fact, the projections $r := s_4 q s_4^* + s_5 q s_5^*$ and p satisfy $r \leq p$ and $-2 = [p] = [r] \in \mathrm{K}_1(\mathcal{O}_\infty)$. Thus p and r are MvN-equivalent in $\mathcal{O}_\infty$. Let $z \in \mathcal{O}_\infty$ a partial isometry with $zz^* = p$ and $z^* z = r$. The partial isometries $t_1 := zs_4 q$, $t_2 := zs_5 q$ have the desired property.

It is known that the infinite tensor product $(M_2 \oplus M_3)^{\otimes\infty} := (M_2 \oplus M_3) \otimes (M_2 \oplus M_3) \otimes \cdots$ contains the *GICAR*-algebra unitally, which is a simple unital AF-algebra defined by the "Pascal triangle" with multiplicities given by the integer coefficients of the polynomials $P_n(t) := (t+1)^n$, cf. [**270**].

Every infinite-dimensional simple unital AF-algebra contains the Jiang-Su algebra $\mathcal{Z}$, [**391**, cor. 6.3]. It implies that $A \otimes \mathcal{Z} \cong A$ for all "approximately divisible" A, i.e., those A that have a unital C^*-morphism of $M_2 \otimes M_3$ into $F(A) := (A' \cap A_\omega)/\operatorname{Ann}(A, A_\omega)$. (The $F(A)$ is a"stable" invariant of separable C^*-algebras A in the sense that $F(A) \cong F(A \otimes \mathbb{K})$.)

It seems that one can replace the assumption of approximate divisibility in most applications by the weaker requirement that A tensorial absorbs $\mathcal{Z}$, i.e., that $A \otimes \mathcal{Z} \cong A$. The main reason could be something like the pull-back proposition [**690**, prop. 6.5] of M. Rørdam.

E.g., *separable exact A is* strongly *p.i., if $A \cong A \otimes \mathcal{Z}$ and every l.s.c. trace $\tau\colon A_+ \to [0, \infty]$ takes only values in $\{0, \infty\}$*. (For *separable nuclear A holds also the converse, because then $A \cong A \otimes \mathcal{O}_\infty$ and one can use that $\mathcal{O}_\infty \otimes \mathcal{Z} = \mathcal{O}_\infty$*.)

Is above partly shown in Chapter 2?
That $A \otimes \mathcal{Z}$ s.p.i. for nuclear separable
trace-less A is [690, thm. 5.2].
The proof in [690, thm. 5.2] shows
that this holds also for exact trace-less A,
and more generally for all C^*-algebras
that have only trivial l.s.c. traces. ???????

Further topics. To be filled in. ??

6. Positions of C^*-subalgebras in $\mathcal{O}_2$

There exist a separable unital nuclear C^*-algebra A and a unital monomorphisms $i\colon A \to \mathcal{O}_2$ of A into the Cuntz algebra $\mathcal{O}_2$, such that, there does not exist a conditional expectation from $\mathcal{O}_2$ onto $i(A)$.
But all separable unital nuclear C^*-algebras A have a unital $*$-monomorphism

$\iota\colon A \to \mathcal{O}_2$ such that there exists a conditional expectation from $\mathcal{O}_2$ onto $\iota(A)$, i.e., a completely positive contraction $E\colon \mathcal{O}_2 \to \iota(A)$ with $E \circ \iota = \iota$.

There is an interesting connection to some conjecture on equivalence of embeddings that are in "sufficiently general position" (see below).

Weaker results on embeddings $\iota\colon A \hookrightarrow \mathcal{O}_2$, as there are (for example):
One finds always for separable unital nuclear C^*-algebras A at least one unital embedding $\iota\colon A \hookrightarrow \mathcal{O}_2$ such that there is a conditional expectation E from $\mathcal{O}_2$ onto $\iota(A)$.

On the other hand, for any other embedding $\kappa\colon A \hookrightarrow \mathcal{O}_2$, there is a norm-continuous path $t \in [0,\infty) \mapsto U(t)$ into the unitary group of $\mathcal{O}_2$ such that $U(0) = 1$ and $\lim_{t\to\infty} \|U(t)^*\iota(a)U(t) - \kappa(a)\|$ for all $a \in A$. One can use this to show that for the (more general type of) embedding $\kappa\colon A \hookrightarrow \mathcal{O}_2$ there is a norm-continuous path $t \in [0,\infty) \mapsto V(t)$ into the *isometries* in $\mathcal{O}_2$ such that $\lim_{t\to\infty} \|V(t)^*\kappa(a)V(t) - \kappa(a)\|$ for all $a \in A$ and $\lim_{t\to\infty} \operatorname{dist}(V(t)^*bV(t), \kappa(A)) = 0$ for all $b \in \mathcal{O}_2$. (This could replace the non-existing conditional expectations onto $\kappa(A)$ by expectations in an approximate sense.)

The examples below produce also counter-examples

`to the above question ???`,

but are also counter-examples to the following more interesting question (which was suggested by the `above recalled results` and by the example of finite-dimensional A):

We call a separable unital nuclear C^*-algebra A **transportable in $\mathcal{O}_2$**, if, for any two unital *-monomorphisms $i\colon A \hookrightarrow \mathcal{O}_2$, and $j\colon A \hookrightarrow \mathcal{O}_2$ in *general position* there is an automorphism ψ of $\mathcal{O}_2$ with $\psi \circ i = j$.

We say that a unital *-monomorphisms $i\colon A \hookrightarrow \mathcal{O}_2$, is **in general position** if the commutant $i(A)' \cap \mathcal{O}_2$ of the image $i(A)$ in $\mathcal{O}_2$ contains a copy of $\mathcal{O}_2$ unitally.

Let $i\colon \mathcal{O}_2 \to \mathcal{O}_2$ and $j\colon \mathcal{O}_2 \to \mathcal{O}_2$ in general position. Is there an automorphism of $\mathcal{O}_2 \otimes \mathcal{O}_2$ that conjugates $i \otimes \mathrm{id}$ and $i \otimes \mathrm{id}$?

Case: $\mathcal{O}_2 \otimes \mathrm{C}[0,1] \to \mathcal{O}_2$ unital and injective and $\mathcal{O}_2 \otimes \mathcal{O}_2 \to \mathcal{O}_2$ an isomorphism?

Is there an automorphism of $\mathcal{O}_2 \otimes \mathcal{O}_2$ that maps $1 \otimes i(A)$ onto $1 \otimes j(A)$?

Obviously all unital *-monomorphisms of finite-dimensional C^*-algebras A are unitary equivalent in $\mathcal{O}_2$. It implies that each *-monomorphism of A is in general position, and that A is "transportable" inside $\mathcal{O}_2$.

We do not know if separable unital AF-algebras A are transportable in $\mathcal{O}_2$. Perhaps one could find a unital endomorphism $\iota\colon M_{2^\infty} \hookrightarrow M_{2^\infty}$ such that there does not exist a conditional expectation from M_{2^∞} onto $\iota(M_{2^\infty})$. (Compare the below given reasoning.)

Then the ??????

The below given examples show that C[0,1] is not transportable in $\mathcal{O}_2$:

There exists nuclear A and unital embeddings $i\colon A \hookrightarrow \mathcal{O}_2$ and $j\colon A \hookrightarrow \mathcal{O}_2$ such that there is a conditional expectation from $\mathcal{O}_2$ onto $i(A)$, but that there does not exist a conditional expectation from $\mathcal{O}_2$ onto $j(A)$ (see the examples discussed below). It yields that for $i'(a) = i(a) \otimes 1$ and $j'(a) = j(a) \otimes 1$ there does not exist a *-isomorphism ψ of $\mathcal{O}_2 \otimes \mathcal{O}_2$ ($\cong \mathcal{O}_2$) with $\psi \circ i' = j'$ (see the explanation below).

Let A a separable unital nuclear C^*-algebra.

First:
If one uses the proof of the existence of embeddings $j\colon A \hookrightarrow \mathcal{O}_2$ with help of the generalized Voiculescu-Weyl-vonNeumann theorem 5.4.1 (with $\mathcal{O}_2 \otimes \mathbb{K}$ in place of the compact operators $\mathbb{K}$) and with help of $\mathrm{Ext}(A, \mathcal{O}_2) = 0$, then one gets (as an additional result) that the unital embedding $j\colon A \hookrightarrow \mathcal{O}_2$ can be found such that there is a conditional expectation P from $\mathcal{O}_2$ onto $j(A)$. (In fact the conditional expectation can be chosen "extreme", i.e., that P is an extreme point in the convex set of contractive linear maps from $\mathcal{O}_2$ into $\mathcal{O}_2$.)

Second:
If $i\colon A \hookrightarrow \mathcal{O}_2$ is an other unital embedding such that there does not exist a conditional expectation from $\mathcal{O}_2$ onto $i(A)$, then there does not exist an isomorphism ψ of $\mathcal{O}_2 \otimes \mathcal{O}_2$ with $\psi(j(a) \otimes 1) = i(a) \otimes 1$ for $a \in A$, because otherwise $E(b) := id \otimes f(\psi(P(b) \otimes 1))$ for $b \in \mathcal{O}_2$ and a (fixed pure) state f on $\mathcal{O}_2$ defines a conditional E expectation from $\mathcal{O}_2$ onto $i(A)$.

Third:
If A is a nuclear C^*-subalgebra of a separable unital nuclear C^*-algebra B such that $1_B \in A$ and such that there does not exist a conditional expectation from B onto A (We list below some examples), then:
If $k\colon B \hookrightarrow \mathcal{O}_2$ is a unital embedding and if we define $i := k|A$ as the restriction of k to A, then there can not exist any conditional expectation E from $\mathcal{O}_2$ onto $i(A) = k(A)$, because otherwise $k^{-1} \circ E \circ k$ would be a conditional expectation from B onto A.

Some Examples:
(o) Suppose that D is a hereditary C^*-subalgebra of a unital C^*-algebra B such that the normalizer algebra $\mathcal{N}(D) := \{b \in B\,;\, bD + Db \subseteq D\}$ is different from $A := D + \mathbb{C}1$ and that $bD \neq \{0\}$ for all $b \in B_+ \setminus \{0\}$. Then there does not exist a conditional expectation E from B onto A.
(Here $\mathbb{C}$ denotes the complex numbers.)
Indeed, $(E(b) - b)^*(E(b) - b)d = 0$ for all $b \in \mathcal{N}(D)$, $d \in D$, i.e., $E|\mathcal{N}(D) = \mathrm{id}$.
It yields e.g. the following two examples (i) and (ii):

(i) Consider $\mathcal{O}_2$ as a C^*-subalgebra of $\mathcal{L}(\ell_2)$ (by some unital *-representation). Let $\mathbb{K}$ denote the compact operators, and let $A := \mathbb{K} + \mathbb{C}1$, $B := \mathbb{K} + \mathcal{O}_2$.

(ii) Let $B := \mathcal{T}$, $A := \mathbb{K} + \mathbb{C}1$, where $\mathcal{T}$ denotes the Toeplitz algebra, generated as C^*-algebra by the Toeplitz operator T (i.e. the unilateral shift of ℓ_2).

(iii) Consider the natural continuous epimorphism σ from the Cantor space $\Omega := \{0,1\}^\infty$ onto $[0,1]$ given by

$$\sigma\colon (a_1, a_2, ...) \mapsto \sum_{n=1}^{\infty} a_n 2^{-n} \,.$$

Then $\gamma\colon f \in \mathrm{C}[0,1] \mapsto \gamma(f) := f \circ \sigma \in \mathrm{C}(\Omega)$ gives a unital embedding of $\mathrm{C}[0,1]$ into $\mathrm{C}(\Omega) = \bigotimes_{n=1}^{\infty}(\mathbb{C} \oplus \mathbb{C}) \subseteq M_{2^\infty}$.

The pairs $A \subseteq B$ with $A := \gamma(\mathrm{C}[0,1])$ and $B := \mathrm{C}(\Omega)$ or with $B := M_{2^\infty}$ have the property that there does not exist a conditional expectation from B onto A, because the continuous map σ is not open.

(It is an exercise to check that σ is *not* open, and that this implies the non-existence of the conditional expectation onto A .)

Some Remarks:

A related open question is:
Suppose that $i, j\colon A \hookrightarrow \mathcal{O}_2$ are unital embeddings such that there are *extremal* conditional expectations from $\mathcal{O}_2$ onto $i(A)$, respectively onto $j(A)$. Is there an automorphism ψ of $\mathcal{O}_2 \otimes \mathcal{O}_2$ with $\psi(i(a) \otimes 1) = j(a) \otimes 1$ for all $a \in A$?

It is likely that there exists *simple* separable nuclear unital C^*-algebras $A \subseteq B$ such that $1_B \in A$ and such that there does not exist conditional expectation from B onto A. (Perhaps, even with $A \cong B \cong M_{2^\infty}$?)
Then it would follow that there are unital endomorphisms $i\colon \mathcal{O}_2 \hookrightarrow \mathcal{O}_2$ such that there does not exist a conditional expectation from $\mathcal{O}_2$ onto $i(\mathcal{O}_2)$, because $\mathcal{O}_2 \cong A \otimes \mathcal{O}_2 \subseteq B \otimes \mathcal{O}_2 \cong \mathcal{O}_2$. (This would show that the position of $i(\mathcal{O}_2)$ in $\mathcal{O}_2$ could be very random.)

(It seems likely that $\mathcal{O}_2$ is not transportable in $\mathcal{O}_2$).

7. Quotients of nuclear maps

Example of a nuclear and approximately inner c.p. map that is not residually nuclear.

Its relation to the existence of group vN-algebras that are not weakly exact.

Here we explain the reason for principal difficulties with nuclear maps (coming from the existence of non-exact discrete groups), and we point out, that nuclear and approximately inner (respectively nuclear and Ψ-equivariant) c.p. maps are in general not residually nuclear if they are ideal-system preserving.

We introduce also some tools that allow to overcome this problems at least in special cases.

LEMMA B.7.1. *Suppose that M is a W^*-algebra with faithful normal state ρ and let $b_1, b_2, \ldots \in M_+$.*

(i) *If* $\sum_n \rho(b_n) \leq 1$, *then for each* $\varepsilon > 0$ *there exists a projection* $p \in M$ *such that*

$$\rho(1-p) \leq \varepsilon \quad \text{and} \quad \| \sum_{n=1}^{k} p b_n p \| \leq \varepsilon^{-1} \quad \text{for all } k \in \mathbb{N}. \tag{7.1}$$

(ii) *Let* $d, c_1, c_2, \ldots \in M$ *contractions such that* $\sum_n \rho(b_n) \leq 1$ *for the elements* $b_n := (d - c_n)^*(d - c_n) \in M_+$.

If $p \in M$ *is a projection that satisfies the inequalities* (7.1) *of part* (i) *for this* $b_1, b_2, \ldots \in M_+$ *then*

$$\lim_n f(p c_n p) = f(pdp) \quad \text{for all } f \in M^* .$$

Proof. (i): The functions $g_t(x) := x/(1 + t^{-1}x) = t(1 - 1/(1 + t^{-1}x))$ on $[0, \infty)$ are operator monotone continuous functions, cf. [**616**, sec. 1.3.7]. They satisfy $g_s(x) \leq g_t(x) \leq x$ for $s \leq t$, $g_t(x) \leq t$ for all $x \geq 0$, and $|x - g_t(x)| \leq t^{-1}\alpha^2$ for $x \in [0, \alpha]$. Let $a_k := \sum_{n=1}^{k} b_n$, then $0 \leq g_t(a_k) \leq g_t(a_{k+1})$, $\|g_t(a_k)\| \leq t$,

more ?? check again?

It follows that the increasing sequence $(g_t(a_k))_k$ of positive elements of M has an ultra-weak limit (at first only an ultra-weak cluster point) $A(t) \in M_+$ with $\|A(t)\| \leq t$ and $g_t(a_k) \leq A(t)$. Then $d_k := (A(t) - g_t(a_k))^{1/2} \in M_+$ is a bounded sequence with $\lim_k \psi(d_k^* d_k) = 0$ for all positive normal functionals ψ on M. It follows that (d_k) converges ultra-strongly to zero, and implies that d_k^2 also converges ultra-strongly to zero, i.e., $A(t)$ is uniquely determined and is the ultra-strong limit of $(g_t(a_k))_k$ in M.

Since $g_t(a_k) g_s(a_k) = g_s(a_k) g_t(a_k)$, $g_s(a_k) \leq g_t(a_k)$ for $s \leq t$ and $\rho(g_t(a_k)) \leq \rho(a_k) \leq 1$, we get for the strong limits $\lim_k g_t(a_k) = A(t) \in M_+$ that $A(t)A(s) = A(s)A(t)$, $A(s) \leq A(t)$ for $s \leq t$ and $\rho(A(t)) \leq 1$ for all $t \in [0, \infty)$. Let C denote the commutative W*-subalgebra of M generated by 1 and $A(m)$ ($m \in \mathbb{N}$). Let $q_m \in C$ the support projection of $(A(m) - \varepsilon^{-1})_+$, i.e., $q_m = 1 - p_m$, where p_m is the support of the annihilator of $(A(m) - \varepsilon^{-1})_+$ in C. Then $q_m \leq q_{m+1}$ and $\varepsilon^{-1} q_m \leq A(m)$. Thus, $\rho(q_m) \leq \varepsilon$ for all $m \in \mathbb{N}$. It follows that $p := 1 - \bigvee_m q_m \in C$ satisfies $pA(m)p = A(m)p \leq \varepsilon^{-1} p$ for all $m \in \mathbb{N}$ and $\rho(1 - p) = \sup_m \rho(q_m) \leq \varepsilon$. We get $p g_m(a_k) p \leq pA(m)p \leq \varepsilon^{-1} p$ for all $k, m \in \mathbb{N}$. If we fix (arbitrary) $k \in \mathbb{N}$ and let m tend to ∞, then this shows that $p a_k p \leq \varepsilon^{-1} p$ for all $k \in \mathbb{N}$.

(ii): If f is a (not-necessarily normal) state on M, then $|f(p(d - c_n)p)|^2 \leq f(p b_n p)$. Thus, $\sum_n |f(pdp) - f(p c_n p)|^2 \leq \varepsilon^{-1} f(p)$. In particular $\lim_n f(p c_n p) = f(pdp)$. Finally use that M^* is the linear span of the states on M. □

Lemma B.7.2. *Suppose that* M *is a W*-algebra,* A *is a separable C*-algebra and* $\mathcal{C} \subseteq \mathrm{CP}(A, M)$ *a matrix operator-convex cone.*

If $V : A \to M$ *is in the point-ultraweak closure of* $\mathcal{C}$, *then there is a net of projections* p_μ *such that* $p_\mu V(\cdot) p_\mu$ *is in the point-norm closure of* $\mathcal{C}$ *and the net* $\{p_\mu\}$ *converges strongly to* 1_M.

*In particular, if $e \in A_+$ satisfies $V(e) = 0$, then there is a net of contractions $T_\mu \in \mathcal{C}$ in the point-*norm *closure of $\mathcal{C}$ with $T_\mu(e) = 0$ such that T_μ converges in point-ultra-strong topology to V.*

Proof. We can replace in the statement $\mathcal{C} \subseteq \mathrm{CP}(A, M)$ by its point-norm closure $\overline{\mathcal{C}}$, which is again an m.o.c. cone. Then $\mathcal{C}$ is a hereditary sub-cone of $\mathrm{CP}(A, M)$ in the sense that $W_1+W_2 \in \mathcal{C}$ implies $W_1, W_2 \in \mathcal{C}$, cf. Corollary 3.6.28. Let R denote the set of $b \in M$ such that $b^*V(\cdot)b \in \mathcal{C}$. Since $(b+c)^*V(\cdot)(b+c)+(b-c)^*V(\cdot)(b-c) = 2b^*V(\cdot)b+2c^*V(\cdot)c$ and $\mathcal{C}$ is hereditary, point-norm closed and invariant under composition with inner c.p. maps, it follows that R is a (norm-) closed right-ideal of M. The hereditary C^*-subalgebra $D := R^* \cap R$ of M contains an approximate unit p_σ of D consisting of projections. Let R_1 denote the weak closure and let $E \in M$ the projection with $EM = R_1$. Then p_σ converges ultra-strongly to E, $p_\sigma V(\cdot)p_\sigma \in \mathcal{C}$, and $\{p_\sigma V(\cdot)p_\sigma\}_\sigma$ converges to $EV(\cdot)E$ in point-ultra-strong topology. In particular, $E = \bigvee\{p\,;\ p \in R, p^2 = p = p^*\}$. It remains to show that $E = 1_M$.

Since for every non-zero projection $P \in M$ there is a non-zero countably decomposable projection $Q \in M$ with $Q \leq P$, it suffices to show that for every countably decomposable projection Q there is a projection $p \leq Q$ with $p \in R$. If we replace M, V and $\mathcal{C}$ by QMQ, $QV(\cdot)Q$ and $Q\mathcal{C}Q := \{QW(\cdot)Q\,;\ W \in \mathcal{C}\}$, then the proof reduces to the case, where M has a faithful normal state ρ.

We introduce the norm $\|b\|_\rho := \rho(b^*b)^{1/2}$ on M. The topology defined by the norm $\|\cdot\|_\rho$ coincides on *bounded parts* of M with the (ultra-)strong topology on M.

A separation argument shows that that $V\colon A \to M$ is moreover in the point-**ultra-strong* closure of of $\mathcal{C}$ if V is in the point-ultra-weak closure of $\mathcal{C}$. We may suppose that $\|V\| \leq 1$, then Lemma 3.1.8 implies that V can be approximated in point-strong topology by contractions $W \in \mathcal{C}$.

Let $\mathcal{C}_1$ the convex set of $W \in \mathcal{C}$ with $\|W\| \leq 1$, and let (a_n) denote a sequence that is dense in the unit ball of A. We find $W_n \in \mathcal{C}_1$ with $\|V(a_k)-W_n(a_k)\|_\rho < 8^{-n}$ for $k \leq n$. Let $b_n := \sum_{k\leq n}(V(a_k)-W_n(a_k))^*(V(a_k)-W_n(a_k))$. Then $\sum \rho(b_n) \leq 1$. Thus, for each $\varepsilon > 0$, there is a projection $p := p(\varepsilon) \in M$ with $\rho(1-p) \leq \varepsilon$ and $\sum_{n=1}^\infty pb_np \leq \varepsilon^{-1}p$, cf. Lemma B.7.1(i). It follows from Lemma B.7.1(ii) that $\lim_n f(pW_n(a_k)p) = f(pV(a_k)p)$ for every bounded linear functional $f \in M^*$ on M and every k. Since $\mathcal{C}_1 \subseteq \mathcal{L}(A, M)$ consists of contractions and since $\{a_1, a_2, \ldots\}$ is dense in the unit ball of A, the map $pV(\cdot)p$ is in the point-$\sigma(M, M^*)$ closure of the convex subset $p(\mathcal{C}_1)p := \{pW(\cdot)p\,;\ W \in \mathcal{C}_1\}$. Thus $pV(\cdot)p$ is the point-norm closure of $p(\mathcal{C}_1)p \subseteq \mathcal{C}$, i.e., $pV(\cdot)p \in \mathcal{C}$, $p \in R$. □

Remark B.7.3. A special case of Lemma B.7.2 is:
Suppose that M is a W^*-algebra, A is separable, $V\colon A \to M$ is weakly nuclear and that $e \in A_+$ satisfies $V(e) = 0$. Then there is a net of (norm-)nuclear contractions $T_\mu\colon A \to M$ with $T_\mu(e) = 0$ and $T_\mu \to V$ in point-ultrastrong topology.
It is in general not possible to find factorable maps T_μ with this property. See the following Remark B.7.4.

REMARK B.7.4. Let $C \subseteq \mathcal{M}(D)$ and $V: C \to B$ with $V(C \cap D) = \{0\}$ a nuclear map. Then $V_D(c+d) := V(c)$ for $c \in C$ and $d \in D$ is a well-defined completely positive map from the C^*-algebra $C + D$ into B, because $(C+D)/D \cong C/(C \cap D)$ naturally.

When $V_D: C + D \to B$ is again a nuclear map ? (It is an equivalent formulation of the general quotient problem for nuclear maps in Remark 3.1.2(iv), as our considerations below indicate.)

From [**238**] and [**438**] it follows that V_D is nuclear if C is exact (see Remark B.7.8). Clearly, V_D is nuclear if $[V]_{C \cap D}: C/(C \cap D) \to B$ is nuclear.

For a long time it was expected that V_D is always nuclear. But N. Ozawa [**597**] has shown that the von Neumann algebra generated by the regular representation of a non-exact discrete group is not weakly exact. M. Gromov [**335**] has shown the existence of discrete non-exact groups. (And Guentner and Kaminker [**338**] and Ozawa [**592**] discovered this connections between Gromov's work to non-exactness.)

By Definition 3.1.1, a map $T: C \to N$ from a C^*-algebra C to a von Neumann algebra N is **weakly nuclear** if T is the point-wise weak limit of factorable maps ([1]), compare Definition 3.1.1.

By [**597**] there exists a von-Neumann algebra that is not weakly exact. That means (equivalently) that there exists a von Neumann factor N of type II_1 with separable predual N_* and a weakly nuclear maps T from a separable C^*-algebra C into N and a closed ideal J of C such that $T(J) = \{0\}$ and that $[T]_J: C/J \to N$ is not weakly nuclear.

It implies that the same happens with a (norm-)nuclear map $V: C \to N$ with $V(J) = \{0\}$ (in place of T): An Egoroff type argument (see B.7.2) shows that every weakly nuclear c.p. contraction $T: C \to N$ from a separable C^*-algebra C into a von Neumann algebra with separable predual N_* is the point-strong limit of a sequence of (norm-)nuclear c.p. contractions $V_n: C \to N$ with $V_n(J) = \{0\}$. It follows that $[V_n]_J: C/J \to N$ is not weakly nuclear for almost all $n \in \mathbb{N}$. In particular, $[V]_J: C/J \to N$ is not nuclear for suitable $n \in \mathbb{N}$ and $V := V_n$.

Let $I := \mathrm{Ann}(J)$ denote the annihilator of J in C, let $p \in C^{**}$ be the support projection of J in the second conjugate C^{**} of C and consider $E := C^*(C, p) \subseteq C^{**}$, $D := I + pE$. Then $E = C + pE = C + D$ is naturally a C^*–subalgebra of $\mathcal{M}(D)$, $a \in C \to (1_p)a \in E$ defines a C^*-morphism $W: C/J \to C + D = E$ such that $[V]_J = V_D \circ W$. Thus $V_D: C + D \to N$ can not be (weakly) nuclear.

In a similar way one finds a C^*-subalgebra $C_1 \subseteq B := C \oplus N \overline{\otimes} \mathcal{L}(\ell_2)$ and an inner c.p. contraction $W: B \to B$ such that $(W|C_1): C_1 \to B$ is nuclear but not residually nuclear (with respect to the action of $\mathrm{Prim}(B)$ on C_1): Stinespring dilation and application of an infinite repeat lead to a *-representation ρ of C into the von Neumann algebra tensor product $N \overline{\otimes} \mathcal{L}(\ell_2)$ and a projection $e \in \mathcal{L}(\ell_2)$ of

---

[1] It is also a point-$\tau(N, N_*)$-limit of factorable maps, because the set of factorable maps is an operator convex cone.

rank one, such that $V(a) \otimes e = (1 \otimes e)\rho(a)(1 \otimes e)$ for all $a \in C$. Let $\rho_1(a) := (a, \rho(a)) \in B$, $C_1 := \rho_1(C)$ and $W(b) := (0, 1 \otimes e)b(0, 1 \otimes e)$ for $b \in B$. Then $W|C_1$ is nuclear and is inner in B, but is not residually nuclear on $C_1 \subseteq B$.

We use the following Lemmata B.7.5 and B.7.7 and the Definitions B.7.6 to bypass the above mentioned problems at least under certain good conditions.

LEMMA B.7.5. *Let $V : A \to \mathcal{M}(B) \subseteq B^{**}$ a completely positive map from A into the multiplier algebra $\mathcal{M}(B)$ of B. Then the following are equivalent:*

(i) *For every $d \in B$ the completely positive map $a \in A \mapsto d^*V(a)d \in B$ is nuclear.*
(ii) *V is a weakly nuclear map from A to the W^*-algebra B^{**} in sense of Definition 3.1.1 if V is considered as a completely positive map from A to the second conjugate B^{**} of B*

PROOF. One can see from the definition (of weakly nuclear maps), that the weakly nuclear maps build a point-weakly closed m.o.c. cone $\subseteq \mathcal{L}(A, B^{**})$. Since the unit-ball B is *-strongly dense in the unit-ball of B^{**} (by Kaplansky density theorem), a map $V : A \to B^{**}$ is weakly nuclear, if and only if, the maps $a \mapsto d^*V(a)d$ are weakly nuclear for every $d \in B$.

`Old Prop. 3.1.9(i) has been changed. Compare again!!`
`No! Next is not Part of Proposition 3.1.9(i-iv) !!!`

By Proposition 3.1.9(i), the map $a \in A \mapsto d^*V(a)d \in B$ is nuclear, if and only if, it is weakly nuclear as a map from A to B^{**}, cf. Proposition 3.1.9(i). □

DEFINITION B.7.6. We call a completely positive map $V : A \to \mathcal{M}(B)$ **weakly nuclear** if V satisfies the equivalent conditions (i) and (ii) of Lemma B.7.5.

An example of a weakly nuclear completely positive map is given by $B := \mathbb{K}(\mathcal{H})$, $V : A \to \mathcal{L}(\mathcal{H})$ a faithful *-representation of A. It is nuclear if and only if A is exact, cf. Remark 3.1.2(ii) and Corollary 5.6.3.

Let $D \subseteq B$ be a hereditary C^*-subalgebra of a C^*-algebra B. D is a **corner** of B, if there is a projection $p \in \mathcal{M}(B)$ such that $D = pBp$. Certainly the (two-sided) annihilator $\{b \in B : bD = 0 = Db\}$ of D is just the orthogonal corner $(1-p)B(1-p)$ of pBp. A corner is σ-unital if B is σ-unital, because the compression pbp of a strictly positive element b of B is a strictly positive element of pBp. The unital, in particular σ-unital, Calkin algebra $\mathrm{Q}(\mathbb{K})$ contains hereditary C^*-subalgebras which are not σ-unital.

We say that a *-subalgebra $E \subseteq B$ **generates a corner** of B if the closure D of EBE is a corner of B. The annihilator of E in B is then a corner of B, and is therefore σ-unital if B is σ-unital.

A hereditary C^*-subalgebra $D \subseteq B$ is **full** , if it generates B as a closed ideal. A theorem of L.G. Brown [**107**] says that $B \otimes \mathbb{K}$ and $D \otimes \mathbb{K}$ are isomorphic if B is σ-unital and D is a σ-unital full hereditary C^*-subalgebra of B. The isomorphism is induced in the sense of Remark 2.3.1 by an element $z \in B \otimes \mathbb{K}$ such that z^*z is an strictly positive element of $B \otimes \mathbb{K}$ and zz^* is a strictly positive element of $D \otimes \mathbb{K}$, cf. Corollary 5.5.6.

A subalgebra D of a C^*-algebra A will be called an **essential** subalgebra if zero is the only left annihilators of D in A, i.e., if $aD = \{0\}$ implies $a = 0$.

It is easy to see, that an ideal I of a C^*-algebra A is essential if and only if it has non-zero intersection with every non-zero ideal of A.

An extension E, i.e. an exact sequence $0 \to J \to E \to A \to 0$ (defined by the epimorphism $\eta \colon E \to A$), is **semisplit** if there is a completely positive contraction $V \colon A \to E$ with $\eta \circ V = \mathrm{id}_A$.

LEMMA B.7.7. *Suppose C is C^*–subalgebras of $\mathcal{M}(D)$, and that $V \colon C \to \mathcal{M}(B)$ is a weakly nuclear completely positive contraction. Then:*

(i) $\widetilde{V}(c + z1) := V(c) + z1$ *is a unital weakly nuclear map from the (outer) unitization $\widetilde{C}$ of C into $\mathcal{M}(B)$.*
(ii) *If $C \cap D$ generates a corner of D, then every weakly nuclear contraction $V \colon C \to \mathcal{M}(B)$ with $V(C \cap D) = \{0\}$ and with $V(C \cap (1 + D)) \subseteq \{1\}$ extends naturally to a unital weakly nuclear map $W \colon D + C + \mathbb{C}1 \to \mathcal{M}(B)$ with $W(D) = 0$ by $W(d + c + \xi 1) := V(c) + \xi 1$ for $d \in D$, $c \in C$ $1 \in \mathcal{M}(D)$ and $\xi \in \mathbb{C}$.*

PROOF. (i): For a contraction $d \in C$ holds $V(d^*d) \le 1$, $b^*V(d^*cd)b + zb^*b = b^*V(d^*(c + z)d)b + zb^*(1 - V(d^*d))b$, and $c + z1 \mapsto z \mapsto zb^*(1 - V(d^*d))b$ is a nuclear c.p. map, because 1 is not in C if the unit element 1 is outer adjoined. Therefore, for contractions $d \in C$, $c + z1 \mapsto b^*V(d^*cd)b + zb^*b$ is nuclear as a sum of two nuclear maps. The map $c + z1 \mapsto b^*\widetilde{V}(c + z1)b$ is the point-norm limit of those maps.

(ii): Let $C_1 := D + C + \mathbb{C}1 \subseteq \mathcal{M}(D)$.

If $1 \in C + D$ then $C_1 = D + C$ and $C_1/D \cong C/(D \cap C)$. If $1 \notin D + C$ then $C_1 = \widetilde{D + C}$ (respectively $C_1/D \cong \widetilde{C/(D \cap C)}$) is the outer unitization of $D + C$ (respectively of $C/(D \cap C)$). The condition $V(C \cap (1 + D)) \subseteq \{1\}$ says that $[V]_{D \cap C} \colon C/(D \cap C) \cong (D + C)/D \to \mathcal{M}(B)$ is unital if $1 \in C + D$. We can define in both cases a unital c.p. map $W \colon C_1 \to \mathcal{M}(B)$ by $W := [V] \circ \pi_D$, respectively by its extension to the outer unitization of $C + D$. Here $[V] := [V]_{D \cap C} \colon (C + D)/D \cong C/(D \cap C) \to \mathcal{M}(B)$ is well-defined because $V(D \cap C) = \{0\}$. Thus, W is a well-defined, unital c.p. map with $W(D) = \{0\}$. In both cases holds

$$W(d + c + \xi 1_{\mathcal{M}(D)}) = W(c + \xi 1) = V(c) + \xi 1_{\mathcal{M}(B)} \ .$$

It suffices to prove that for every $b \in B$ the c.p. map $W_b \colon c + d \mapsto b^*V(c)b$ is nuclear, because the outer unitization of W is then also weakly nuclear.

Let $p \in \mathcal{M}(D)$ the orthogonal projection such that pDp is the closure of $(C \cap D)D(C \cap D)$. Then $E := (1 - p)D(1 - p)$ is the (two-sided) annihilator $\{d \in D\, ;\ d(C \cap D) = 0 = (C \cap D)d\}$ of $C \cap D$. Therefore $CE \subseteq E$, $EC \subseteq E$ and

$pc(1-p) = 0$, i.e., $pc = cp$ for $c \in C$. Thus $F := E + C$ is a C^*-algebra, E is an ideal of $F \subseteq \mathcal{M}(D)$, F commutes with p and $pF = pC$. $C \cap E = C \cap (D \cap E) = (C \cap D) \cap E = 0$. Therefore $T|F$ is the composition of $F \to F/E \cong C$ with $c \in C \to b^*V(c)b$. Thus $T|F$ is nuclear and $T(F \cap D) = 0$.

Let X be any C^*-algebra. By the criteria in Remark 3.1.2(i), the algebraic tensor product $\mathrm{id}_X \odot (T|F)\colon X \odot F \to X \odot B$ extends to completely positive map S_1 from the minimal (=spatial) tensor product $X \otimes F$ into the maximal C^*-algebra tensor product $X \otimes^{\max} B$. Since $S_1(X \odot (F \cap D)) = 0$, we have that $S_1(X \otimes (F \cap D)) = 0$. Since F commutes with p, $F \cap D = p(F \cap D)p + (1-p)(F \cap D)(1-p)$. But $E = (1-p)(F \cap D)(1-p)$ and $C \cap D \subseteq p(F \cap D)p \subseteq p(C \cap D)p = C \cap D$. Thus $F \cap D = (C \cap D) + E$. It follows that D is the closure of $D(F \cap D)$.

It is now the essential point of the proof that, therefore, the distance lemma [**438**, lem. 3.9] applies and gives the identity $(X \otimes F) \cap (X \otimes D) = X \otimes (F \cap D)$ in the C^*-algebra $X \otimes (C + D)$ for every C^*-algebra X.

It follows $(X \otimes (C + D))/(X \otimes D) \cong (X \otimes F)/(X \otimes (F \cap D))$, because $X \otimes D$ is a closed ideal of $F \otimes (C + D)$.

Let $S_2\colon (X \otimes F)/(X \otimes (F \cap D)) \to X \otimes^{\max} B$ be the completely positive map that is induced by S_1. The composition of $X \otimes (C + D) \to (X \otimes F)/(X \otimes (F \cap D))$ with the completely positive map S_2 defines a completely positive map S_3 from $X \otimes (C + D)$ into $X \otimes^{\max} B$. The restriction of S_3 to the algebraic tensor product is just $\mathrm{id}_X \odot T$.

Since S_3 can be found for every C^*-algebra X, T is nuclear by the criteria in Remark 3.1.2(i). □

Remark B.7.8. To understand the essential point of the proof of Lemma B.7.7(ii), the reader should note, that the intersection formula $(F \otimes C) \cap (F \otimes D) = F \otimes (C \cap D)$ holds for every C^*-algebra D and $C \subseteq \mathcal{M}(D)$, *if and only if, F is exact*. This happens even if we consider here only separable C and require, in addition, that D is a simple, purely infinite and separable C^*-algebra.

The intersection formula it true for every pair of C^*-algebras $C, D \subseteq \mathcal{L}(\mathcal{H})$, if and only if, F satisfies the slice map property (S) of S. Wassermann. The Property (S) implies exactness, but it is unknown if (S) is equivalent to exactness.

On the other hand, for every C^*-algebra F, every locally reflexive C^*-algebra $C \subseteq \mathcal{M}(D)$, one can show that $(F \otimes C) \cap (F \otimes D) = F \otimes (C \cap D)$. (The ideal $C \cap D$ of C is a locally reflexive C^*-subalgebra of D.)

Thus our proof of Lemma B.7.7(ii) also shows that the natural extension V_D of V to $C + D$ with $V_D(D) = 0$ is weakly nuclear if C is locally reflexive in the sense of [**238**] (without any assumptions about the behavior of $C \cap D$ in D). All exact C^*-algebras are locally reflexive, cf. [**432**, rem. on p. 71] (compare [**802**] for the case of separable C^*-algebras).

8. Questions about pure infiniteness

compare and sort following questions !! Below, we list some open questions concerning the verification of pure infiniteness, and K_1-injectivity.

QUESTION B.8.1. Denote by $A * B$ the unital universal free C^*-algebra of unital A and B, and define the *free joint* $\mathcal{E}_{\text{free}}$ of A and B by

$$\mathcal{E}_{\text{free}}(A,B) := \{f \in \mathrm{C}([0,1], A * B)\, ;\; f(0) \in A * 1\,,\; f(1) \in 1 * B\,\}\,.$$

(1) Suppose that A is non-unital, separable and *locally purely infinite.*
Does there exist $n \in \mathbb{N}$ such that the unit of $M_n(\mathcal{M}(A))$ is properly infinite?
(It is the case for weakly purely infinite A, or if $\mathcal{M}(A)$ itself is locally purely infinite. in the sense of Definition 2.0.3)

(2) Suppose that A is unital and weakly p.i. (respectively locally p.i.) and that $1_{A/J}$ is properly infinite for every non-zero closed ideal $\{0\} \neq J \lhd A$.
Is 1_A properly infinite if A is not prime *?*
It leads to the –equivalent– question, whether or not n-purely infinite quotients of the unital C^*-subalgebra $\mathcal{E}_{\text{free}}(\mathcal{O}_\infty, \mathcal{O}_\infty)$ of $\mathrm{C}([0,1], \mathcal{O}_\infty * \mathcal{O}_\infty)$ have properly infinite unit elements. See the farer going question (8) below.

(3) Let $D := \{z \in \mathbb{C}\, ;\; |z| \leq 1\}$ and $S^1 = \partial D$. Then $\mathrm{C}(D)$ is naturally isomorphic to the (unital) algebra $\mathrm{cone}(\mathrm{C}(S^1))$ and the corresponding epimorphism from $\mathrm{C}(D)$ onto $\mathrm{C}(S^1)$ is given by $\varphi(f) := f|S^1$. Let $f_0(z) := z$ and $u := \varphi(f_0)$. The unitary u defines an inner automorphism $\sigma(x) := u^*xu$ of $\mathcal{O}_\infty * \mathrm{C}(S^1)$. One can show ([2]) that a positive answer to the following question implies a positive answer to question (2):
Does the pull-back

$$(\mathcal{O}_\infty * \mathrm{C}\,(D)) \oplus_{\pi,\sigma\circ\pi} (\mathcal{O}_\infty * \mathrm{C}\,(D))$$

of the unital epimorphisms

$$\pi := \mathrm{id} * \varphi\colon\; (\mathcal{O}_\infty * \mathrm{C}\,(D)) \to \left(\mathcal{O}_\infty * \mathrm{C}\left(S^1\right)\right)$$

and of $\sigma \circ \pi$ have a properly infinite unit?
(Unfortunately, it is likely that (3) has a negative answer. And it seems that the same happens for $\mathcal{O}_2$ – in place of $\mathcal{O}_\infty$.)

(4) Suppose that A is a purely infinite (non-simple) algebra, and $a \in A_+$.
Are the (unital!) fibers of the upper (!) semi-continuous C^*–bundle

$$F(C^*(a), A) := (\{a\}' \cap A_\omega)/\, \mathrm{Ann}(a, A_\omega)$$

over $\mathrm{Spec}(a)$ *purely infinite?*
(The fibers are 2-p.i. by [**443**].)

More precise and actual citation?

[2] by [**448**, prop.1.6,rem.1.15(2), prop.A.4], because two unital *-endomorphisms of $\mathcal{O}_\infty$ are approximately unitarily equivalent by Theorem B

(5) *Are the fibers* B_t *(of* $F(C^*(a), A)$ *,* $t \in \mathrm{Spec}(a)$ *)* K_1*-injective ?*
(I.e., is $\mathcal{U}_0(B_t)$ the kernel of the natural map $\mathcal{U}(B_t) \to \mathrm{K}_1(B_t)$.)

(6) *Is* $\mathcal{O}_\infty * \mathrm{C}(S^1)$ K_1*-injective ?*
With other words:

Does there exist $v \in \mathcal{U}_0(\mathcal{O}_\infty * \mathrm{C}(S^1))$ *with* $ut_1 = vt_1$*, where* $t_1, t_2, \ldots$ *(respectively u) are the canonical generators of* $\mathcal{O}_\infty$ *(respectively of* $\mathrm{C}(S^1)$*)?*
If the answer is positive, then $\mathcal{U}(B)/\mathcal{U}_0(B) \cong \mathrm{K}_1(B)$. for every unital algebra B that contains a a copy of $\mathcal{O}_\infty$ unitally. (The answer could be negative. The question is possibly related to question (3). See also Proposition 4.3.6(iv).)

(7) *Is* $\mathcal{O}_\infty * \mathcal{O}_\infty$ K_1*-injective?*
Note that (6) and (7) are related, because unital copies of $\mathcal{O}_\infty$ in a unital C^*–algebra A are unitarily homotopic by a continuous path $u(t) \in \mathcal{U}(A)$, and one can manage that $[u(t)]_1 = 0$ in $\mathrm{K}_1(A)$.
(Since $h_i \colon \mathcal{O}_\infty \to A$, $i = 1, 2$, are unital, it follows from Theorem B – and from the UCT for $\mathcal{O}_\infty$ – that there is a continuous path $u(t)$ in the unitaries of A such that $\lim_{t\to\infty} \|u(t)^* h_1(b)u(t) - h_2(b)\| = 0$.)

Perhaps, $\mathcal{O}_\infty * \mathcal{O}_\infty$ and $\mathcal{O}_\infty * \mathrm{C}(S^1)$ are KK-equivalent.

At least, there are unital *-morphisms $\alpha \colon \mathcal{O}_\infty * \mathcal{O}_\infty \to \mathcal{O}_\infty * \mathrm{C}(S^1)$ $(\alpha(a * 1) := a * 1$ and $\alpha(1 * a) := (1 * U)^*(a * 1)(1 * U))$ and $\beta \colon \mathcal{O}_\infty * \mathrm{C}(S^1) \to \mathrm{C_b}(\mathbb{R}_+, \mathcal{O}_\infty * \mathcal{O}_\infty)$ $(\beta(a * 1) = a^*1$, $\beta(U) := u)$ such that $\pi \circ \beta \circ$ is the natural – constant – embedding from $\mathcal{O}_\infty * \mathcal{O}_\infty$ into $\mathrm{Q}(\mathbb{R}_+, \mathcal{O}_\infty * \mathcal{O}_\infty)$.)

(8) *Does* $\mathcal{E}_{\mathrm{free}}(\mathcal{O}_\infty, \mathcal{O}_\infty)$ *contain a non-trivial projection?*
Is the unit of $\mathcal{E}_{\mathrm{free}}(\mathcal{O}_\infty, \mathcal{O}_\infty)$ *properly infinite?*

(9) Let J a separable weakly purely infinite C^*–algebra such that there is a sequence of positive contractions $e_1, e_2, \ldots \in J_+$ and contractions $v_{n,k}$, such that $e_n v_{m,k} = v_{m,k}$, $v_{n,k} e_m = v_{m,k}$, $e_n e_m = e_m$, for $m < n$, $k, l \in \mathbb{N}$, $v_{m,k}^* v_{n,l} = \delta_{k,l}\delta_{m,n} e_n^2$ for $k, l, m, n \in \mathbb{N}$, moreover, we suppose that (e_n) is an approximate unit of J.
Is the unit $1_{\mathcal{M}(J)}$ *of* $\mathcal{M}(J)$ *infinite?*

(10) Suppose, in addition to the assumptions of (9), that J of (9) is an ideal of a unital C^*-algebra A and that there is a *-monomorphism $\varphi \colon \mathrm{C}_0(0, 1] \otimes \mathcal{O}_\infty \hookrightarrow A$ with $\varphi(f_0 \otimes 1) = \sum_n 2^{-n} e_n$.
Is the unit of A *properly infinite?*

A positive answer would imply that weakly purely infinite algebras are purely infinite, and that purely infinite algebras A satisfy the assumption of the question (12).

(11) Suppose that $a_1, a_2 \in A_+$ are *stable* elements of A (i.e., $D_k := \overline{a_k A a_k}$ is stable for $k = 1, 2$).

Is $a_1 + a_2$ a properly infinite element of A?

A positive answer would imply that locally purely infinite algebras are purely infinite, and that every purely infinite algebra A satisfies the assumption of the question (12).

(But it is even unknown whether or not sums of σ-unital stable ideals have a properly infinite strictly positive element.

What happens in the case where D_1 and D_2 are ideals of A and where A is moreover locally purely infinite?)

(12) Suppose that $F(C, A) := (C' \cap A_\omega)/\operatorname{Ann}(C, A_\omega)$ has a properly infinite unit for every separable commutative C^*-subalgebra C of A.
Is A strongly purely infinite?

(13) Suppose that A is p.i. *Is* $\mathrm{C}([0,1], A)$ *p.i.?*. (It is 2-p.i.)

Special case:

Let A a purely infinite separable nuclear C^*-algebra. *Is* $\mathrm{C}([0,1], A)$ *purely infinite?*.
For simple A the answer is positive, because simple p.i. algebras are strongly p.i.

(14) *Are local p.i. C^*-algebras A with the global Glimm halving property purely infinite?*
(A is p.i. if and only if A is l.p.i. and the sum $D = \overline{(D_1 + D_2)A(D_1 + D_2)}$ of any two stable hereditary C^*-subalgebras D_1 and D_2 of A contains a family $(D_\tau)_\tau$ of stable hereditary C^*-subalgebras of A such that each element of the Pedersen ideal of D can be approximated by elements from $\bigcup_\tau A(D_\tau)A$ – only elements of the union, not sums of them! –.)

The next question asks what happens with pure infiniteness if we have a conditional expectation of finite index onto a subalgebra.

Question B.8.2. Suppose that $A \subseteq B$ (both not necessarily simple) and that $P\colon B \to A$ is a *conditional expectation from B onto A of finite index*, i.e., $P|A = \mathrm{id}_A$, $\|P\| = 1$, and there exists $0 < \lambda < \infty$ with $\lambda^{-1} b \leq P \otimes \mathrm{id}_n(b)$ for all $b \in (B \otimes M_n)_+$ and $n \in \mathbb{N}$. (Note that the existence of P implies that A is unital if and only if B is unital, and that then P must be necessarily unital. More generally, A is a non-degenerate C^*-subalgebra of B in the non-unital case. This can be seen by passage to the second conjugate P^{**}.)

What about of the following statements (1)–(6) concerning versions of pure infiniteness?

(1) Every l.s.c. 2-quasi-trace of A is trivial, if and only if, every l.s.c. 2-quasi-trace of B is trivial.

(2) A is locally p.i., if and only if, B is locally p.i.

(3) A is p.i. (respectively is weakly p.i., strongly p.i.), if and only if, B is p.i. (respectively is weakly p.i., strongly p.i.).

(4) If B is unital, then 1_A is stably properly infinite (respectively is properly infinite), if and only if, 1_B is stably properly infinite (respectively is properly infinite).

(5) There are a *-monomorphism $h\colon B \to A \otimes \mathbb{K}$ and a conditional expectation $P'\colon D \to h(B)$ of finite index from the hereditary C^*-algebra D of $A \otimes \mathbb{K}$ generated by $h(B)$ onto $h(B)$.

(6) If $\varphi\colon A \to F$ is a *-epimorphism onto a finite AW*-factor F, then there exists a finite AW*-algebra G with finite-dimensional centre and a *-epimorphism $\psi\colon B \to G$, a unital *-morphism $\epsilon\colon F \to G$ and a conditional expectation $E\colon G \to \epsilon(F)$ of finite index, such that $\epsilon \circ \varphi = \psi|A$ and $\psi \circ P = E \circ \psi$.

(Alternatively, and almost equivalent: If the multiplier algebra $\mathcal{M}(X) \cap X$ of a not-necessarily unital C^*-system X contains a finite AW*-factor $F \subseteq \mathcal{M}(X) \cap X$ and if there is a conditional expectation from X onto F of finite index, then $X = \mathcal{M}(X)$ and X is a finite AW*-algebra with finite centre.)

(7) For every $b \in B_+$ there are $n \in \mathbb{N}$, a projection $q \in M_n$ and $a \in (A \otimes M_n)_+$ such that $b \otimes q$ is Cuntz-equivalent to a in $B \otimes M_n$. (At least, if $J = (A \cap J)B(A \cap J)$ for each closed ideal J of B, and $I = A \cap \overline{\mathrm{span}(BIB)}$ for each closed ideal of I of A.)

QUESTIONS B.8.3. *Are inductive limits A of pi(n) algebras $A_1, A_2, \ldots$ again pi(n)?*
Can the ultra-product $\prod_\omega A_k$ of pi(n) algebras A_k $(k = 1, 2, \ldots)$ have a non-zero finite-dimensional quotient? (Equivalently: *Is the c_0-sum of pi(n) C^*-algebras $\bigoplus_k A_k$ a pi(n) algebra?*)
Is there a general function $f\colon \mathbb{N} \to \mathbb{N}$ such that $A \otimes \mathbb{K}$ is pi$(f(n))$ if A is pi(n)?

The implication
$\{\ A$ is pi$(n)\ \} \Rightarrow \{\ A$ has property pi-m for *some* $m \geq n\ \}$
(m depending on A) was shown by an indirect argument (showing that A_ω is l.p.i. and, therefore, A_ω is traceless). Our there given argument does not indicate a way to find a uniform bound for m (if $n \in \mathbb{N}$ is given).

Fix $n \in \mathbb{N}$. Suppose that A is σ-unital, has no non-zero finite-dimensional quotient A/J of dimension $\leq n$, and that for each $a \in A_+$, positive $b \in \mathrm{span}(AaA)$ and $\varepsilon > 0$ there are $d_1, \ldots, d_n \in A$ such that $\|b - \sum_j d_j^* a d_j\| < \varepsilon$.

Further let $e \in A$ a strictly positive element of A. Then *each hereditary C^*-subalgebra $A_k := \overline{(e - 1/k)_+ A (e - 1/k)_+}$ is pi(n)*, by Lemma 2.12.4(iii).

Hence, positive answers to the above (equivalent) questions, would imply, that one can replace the condition (ii) in Definition 2.0.4 by the (possibly weaker) condition that A has no quotient A/J of dimension $\leq n^2$.

QUESTION B.8.4. *Is the unit 1_F of a unital weakly purely infinite C^*-algebra F properly infinite?*

By definition, F is pi(n) for some $n \in \mathbb{N}$. We know at least that $1_F \otimes 1_m$ is properly infinite for some $m \in \mathbb{N}$, because pi(n) implies that F is l.p.i.

Proof of Corollary 2.7.18

Proposition **??**, that there exists $m \geq n$ such that $a \otimes 1_m$ is properly infinite for every element $0 \neq a \in A$. In particular $1_A \otimes 1_m$ is properly infinite.

A positive answer would imply that every weakly p.i. algebra is purely infinite. Moreover, this would imply that each weakly p.i. algebra is commutant-p.i. in the sense of Definition 2.16.6.

QUESTION B.8.5. Is every commutant-p.i. algebra A (cf. Def. 2.16.6), strongly purely infinite?

QUESTION B.8.6. Suppose that Prim(A) is isomorphic to the Hilbert cube $[0, 1]^\infty$ and that each fiber (= each simple quotient) is isomorphic to $\mathcal{O}_2$.
Is A purely infinite?
(The question considers a special case of [**462**, ques. 4.8].)
Is A purely infinite if A is weakly purely infinite?

QUESTION B.8.7. l.p.i. implies w.p.i.?

w.p.i. implies p.i.?

p.i implies l.c.p.i.?

l.c.p.i. implies c.p.i.?

c.p.i. implies s.p.i.?

(Is special case of [**462**, ques. 4.8].)

`Merge below blue questions into above questions`

??????

QUESTION B.8.8. Is the unit of $\mathcal{M}(\overline{aAa})$ p.i. if $a \in A_+$ is properly infinite in A? ([**462**, ques.3.10])

A special open question is: *Is the unit of $\mathcal{M}(A)$ properly infinite if A is a separable purely infinite algebra?*

QUESTION B.8.9. $a, b \in A_+$ *commuting* and $(a - t)_+$ and $(b - t)_+$ properly infinite or zero for all $t > 0$. Is $a + b$ properly infinite?

(It is a special case of [**462**, ques.3.10].)

QUESTION B.8.10. Let A a separable unital C^*-algebra and that J and K are closed ideals of A with $J \cap K = \{0\}$. Suppose that the units $1_{A/J}$ and $1_{A/K}$ are properly infinite in A/J and A/K. It is easy to see that $1_A \otimes 1_2$ is properly infinite in $M_2(A)$.

Is 1_A properly infinite in A ?

If the unitary group of $A/(J + K)$ is connected, then the answer is positive. (Notice that $A = A/(J \cap K)$ is just the pull-back $A/J \oplus_{\mu,\nu} A/K$ of the epimorphisms $\mu \colon A/J \to A/(J + K)$ and $\nu \colon A/K \to A/(J + K)$.)

The question considers a test case of the question whether the proper infiniteness of a projection $p \in A$ can be verified by looking only to $p + J$ in all *prime* quotients A/J.

QUESTION B.8.11. Suppose that A is separable and is w.p.i. and $a, b \in A_+$ are *stable* contractions such that $a + b$ is strictly positive in A.

Does there exist a stable element $c = c(\gamma) \in A_+$ such that $(a + b - \gamma)_+$ is in the closed ideal of A generated by c?

The question is equivalent to the question, if every w.p.i. algebra is p.i. (And then, automatically, every p.i. algebra is c.p.i.)

QUESTION B.8.12. Is $\mathcal{M}(A)$ weakly purely infinite if A is weakly purely infinite and σ-unital?

QUESTION B.8.13. Is the unit of $\mathcal{M}(A)$ properly infinite if A is purely infinite and σ-unital?

9. On the properties "IR" and "stable rank one"

It's all related to the almost ridiculous Part (xvii) of Proposition 2.2.1.

`ALL HAS TO BE SORTED!!`

`DESIRE OF Remark 2.2.2:`

See Section 9 in Appendix B for the definitions of "Property *IR*" and "stable rank one", and for an explanation, why Part (xvii) of Proposition 2.2.1 is one of the needed observations for the proof of the Brown-Friis-Rørdam alternative for simple C^*-algebras with Property *IR* between pure infiniteness and "stable rank one".

`BEGIN OF LIST OF MATERIAL`

DEFINITION B.9.1. A C^*-algebra B has **stable rank one** if each element of $B + \mathbb{C} \cdot 1_{\mathcal{M}(B)}$ is in the operator-norm closure of the invertible elements in $C^*(B, 1_{\mathcal{M}(B)}) = B + \mathbb{C} \cdot 1_{\mathcal{M}(B)} \subseteq \mathcal{M}(B)$.

Obviously, C^*-algebras B that contain an infinite projection do not have this is never the case for any simple purely infinite C^*-algebras.)

A is simple, and has the property that each element T of $A + \mathbb{C} \cdot 1 \subseteq \mathcal{M}(A)$ that is not in the norm-closure of invertible elements of $A + \mathbb{C} \cdot 1$ must be right-invertible or left-invertible in $A + \mathbb{C} \cdot 1$, – which would be the correct interpretation of Property *IR* in the special case of simple C^*-algebras A – then this property holds also for $(A \oplus +\mathbb{C} \cdot 1_{\mathcal{M}(A)}) \oplus \mathbb{C}$ and for any non-zero hereditary C^*-subalgebra $D \subseteq A$, i.e., also for $D + \mathbb{C} \cdot 1 \subseteq A + \mathbb{C} \cdot 1$ holds that any element that can not be approximated by invertible elements in $D + \mathbb{C} \cdot 1$ is left- or right-invertible (but is not invertible).

This passage to hereditary C^*-subalgebras is a key point and is equivalent to the Morita equivalence of property *IR* on the class of simple C^*-algebras.

It seems that it suffices to consider: passage to $M_2(A)$, to inductive limits, and to (non-zero) corners of (simple) C^*-algebras, to get Morita equivalence of property *IR*.

The same happens with property “real rank zero”.

as the property that there exists a hereditary C^*-subalgebra

there exist elements in $\widetilde{A} := A + \mathbb{C} \cdot 1 \subseteq \mathcal{M}(A)$ that are not in the closure of of the invertible elements ... ,if and only if, A contains an infinite projection. Thus ????

Each element in $A + \mathbb{C} \cdot 1 \subseteq \mathcal{M}(A)$ that is not in the closure of the set of invertible elements in $A + \mathbb{C} \cdot 1$ has a left or a right inverse (but not both of them) and $A + \mathbb{C}$ has not stable rank one, i.e., the invertible elements are not dense in $A + \mathbb{C}$. (Or is $M_n(A + \mathbb{C})$ to consider also? And its stabilizations ...? Is it a stable problem?)

This gives immediately that $A + \mathbb{C}$ contains a non-unitary isometry ... Delivers a projection in A. Then to every non-zero hereditary C^*-subalgebra of A...?

It carries over to $D + \mathbb{C}$ for all non-zero hereditary C^*-subalgebras D of A (by stabilization ?)

`ABOVE TEXT VERY RANDOM!`
`COMPARE WITH BELOW`
`GIVE ONLY SHORT SUMMARIES ...`

The C^*-algebras with stable rank one are – in a sense – opposites to (weak) purely infinite C^*-algebras, ... at least in case of simple C^*-algebras.

Definition B.9.2. A C^*-algebra B has “stable rank one” (denoted by “*SR1*”) if each element of $B + \mathbb{C} \cdot 1_{\mathcal{M}(B)} \subseteq \mathcal{M}(B)$ can be approximated in norm by invertible elements in $B + \mathbb{C} \cdot 1$.

It is easy to see from the definition that the class of C^*-algebras with stable rank one are invariant under following operations:

(i) forming direct sums $B_1 \oplus B_2$,
(ii) passage to quotients B/J,
(iii) forming of inductive limits, e.g. B has SR1 if there are C^*-subalgebras $B_1 \subset B_2 \subset \cdots \subset B$ of C^*-subalgebras B_n with SR1 such that $\bigcup_n B_n$ is dense in B,
(iv) pBp has SR1 if B has SR1 and $p^* = p \in \mathcal{M}(B)$ is a projection.
(v) $M_2(B)$ has SR1 if B has SR1. (use a modification of the classical Gauss algorithm here in an approximate manner). It follows that $M_n(B)$ has SR1 (in conjunction with Part (iv)).
(vi) $B \otimes \mathbb{K}$ has SR1 if B has SR1.
(vii) B has SR1 and separable and A is a separable C^*-algebra that is Morita equivalent to B then A has SR1.

WHAT about hereditary subalgebras/ideals?

The following Lemma B.9.3 is due to L.G. Brown [**109**].

LEMMA B.9.3. *Let D a hereditary C^*-subalgebra of B and $d \in D+\mathbb{C}\cdot 1 \subseteq \mathcal{M}(B)$.*

Suppose that there exists a sequence (b_n) of elements in $b_n \in B+\mathbb{C}\cdot 1$ that are invertible in $B+\mathbb{C}\cdot 1$ and satisfy $\lim_n \|b_n - d\| = 0$. Then there exists a sequence of $c_n \in D+\mathbb{C}\cdot 1$ that are invertible in $D+\mathbb{C}\cdot 1$ and satisfy $\lim_n \|c_n - d\| = 0$.

It allows to show that (non-zero) simple C^*-algebras A are purely infinite if A has not SR1 but satisfies property *IR*.

`Next is my Definition!!  Better name needed?`

DEFINITION B.9.4. We say (for a moment and only here) that an element $x \in B+\mathbb{C}\cdot 1_{\mathcal{M}(B)} \subseteq \mathcal{M}(B)$ is "*well-behaved*" if, for every closed ideal $J \subseteq B$ of B, the element $\pi_J(x)$ is invertible in $(B+\mathbb{C})/J$ if $\pi_J(x)$ is left or right invertible in $(B+\mathbb{C})/J$.

If B is simple, then this says that $x \in B+\mathbb{C}\cdot 1_{\mathcal{M}(B)}$ is "well-behaved" if x is invertible if it is left or right invertible.

If, for example, $\pi_J(x)$ is neither left- nor right-invertible for all closed ideals J of B, then x is well-behaved

Notice that P. Friis and M. Rørdam have 1996 in [**305**] the following property *IR* that sounds a bit like a weakening of the property *SR1* ???, but is rather different.

DEFINITION B.9.5. A C^*-algebra B has the property *IR* if each element $b \in B+\mathbb{C}\cdot 1 \subseteq \mathcal{M}(B)$, that is "well-behaved" in sense of Definition B.9.4, is in the norm-closure of the invertible elements in $B+\mathbb{C}\cdot 1$.

Thus property IR causes:
If $b \in B+\mathbb{C}\cdot 1$ is not in the norm-closure of the invertible elements in $B+\mathbb{C}\cdot 1$ and B has property IR, then there exists an closed ideal J of B such that $\pi_J(b)$ is left- or right-invertible but is not invertible in $(B+\mathbb{C}\cdot 1)/J$.

The point is now the following: `Is it the Proposition 2.2 ???`

If $b = c + \lambda 1_{\mathcal{M}(B)}$ (with $c \in B$) can be approximated by invertible elements in $B+\mathbb{C}\cdot 1_{\mathcal{M}(B)}$ and D is a hereditary C^*-subalgebra of B with $c \in D$, then $c+\lambda 1_{\mathcal{M}(D)}$ can be approximated by invertible elements of $c+\lambda 1_{\mathcal{M}(D)}$

(Lemma of Brown, which one?).

THEOREM B.9.6. *Simple C^*-algebras with property* IR *have stable rank one or are purely infinite.*

For the proof see [**305**] and [**109**].

Can proceed as follows:

If A is simple and has property IR and A has not stable rank one.

Then every non-zero hereditary C^*-subalgebra D of A has not stable rank one, because “stable rank one” is invariant under Morita equivalence.

So, if A has not stable rank one, then D can not have stable rank one.

If D has not stable rank one then there exists $d \in D$ such that d or $d + 1_{\mathcal{M}(A)}$ can not be approximated by invertible elements in $D + \mathbb{C} \cdot 1$.

The point is now, that one must show that d (or $d+1$) can not be approximated by invertible elements in $A+\mathbb{C}\cdot 1$ if d (or $d+1$) can not be approximated by invertible elements in $D + \mathbb{C} \cdot 1 \subseteq \mathcal{M}(A)$.

– This is because *IR* is not proven to be Morita equivalent so far –

Possible way:

1.) Passage to $M_2(A)$, 2.) Passage to corner, 3.) to inductive limits, ...

If there is no passage to σ-unital hereditary C^*-subalgebras, this does not help ...

How to check if *IR* passes to hereditary C^*-subalgebras D: All closed ideals of D are intersections $J \cap D$ with closed ideals J of A.

Let $d \in D \subseteq A$ well-behaved in $D + \mathbb{C} \cdot 1_{\mathcal{M}(D)}$, is it then also well-behaved in $A + \mathbb{C} \cdot 1_{\mathcal{M}(D)}$?

And conversely?

Suppose that $\pi_J(d) + z1$ is approx-invertible in $A + \mathbb{C} \cdot 1$, the also approx-invertible in $D + \mathbb{C} \cdot 1$? And conversely?

(Is it not so, that there exists $\rho > 0$ such that $d - z1_{\mathcal{M}(A)}$ is not invertible for every $z \in \mathbb{C}$ with $|z| < \rho$?

Otherwise, we find a zero-sequence $z_n \in \mathbb{C}$ with $d - z_n$ invertible in for every $n \in \mathbb{N}$ and $|z_n| \to 0$. Then d is in the closure if the invertible elements in $D + \mathbb{C} \cdot 1$.

Multiplying d or $d + 1$ with a constant we may suppose that $d - z1$ is not invertible for all $z \in \mathbb{C}$ with $|z| \leq 1$.

That implies that, e.g. , d can not be approximated by invertible elements in $A + \mathbb{C}1$ because ...

If T is invertible, then $(T - z)$ is invertible for all $z \in \mathbb{C}$ with $|z| < \|T^{-1}\|$??

and $\|T - d\| < \gamma$, implies $\mathrm{Spec}(T) \subseteq (\gamma \circ D_2) + \mathrm{Spec}(d)$,

$\|1 - T^{-1}d\| \leq \|T^{-1}\| \cdot \|T - d\|$

?????

Now in the class of C^*-algebras ?????

(Other idea:
Try to show directly that $D+\mathbb{C}1$ has also property *IR*, because then we get directly that d (or $d+1$) are right or left invertible. It is a sort of invariance of property *IR* under Morita equivalence.)

(But a Lemma/Preposition of L.G. Brown gives this!).

L.G. Brown:

`Is it the proposed Proposition 2.2 ???`

The intersection of $D + \mathbb{C} \cdot 1_{\mathcal{M}(A)}$ with the operator-norm closure in $\mathcal{M}(A)$ of the invertible elements in $A + \mathbb{C} \cdot 1_{\mathcal{M}(A)}$ is equal to the operator-norm closure of the invertible elements in $D + \mathbb{C} \cdot 1$ in $\mathcal{M}(A)$.

All ???? inside ????? in $\mathcal{M}(A)$?

If ????

If A has property IR*, this implies* that d (or $d+1$) is right-invertible or left-invertible in A or $A + \mathbb{C} \cdot 1_{\mathcal{M}(A)}$.

If $d+1$ is not invertible but is right-invertible in $A + \mathbb{C}1$, it implies that there exists right-inverse $R = e + z1 \in A + \mathbb{C} \cdot 1_{cM}$ for $d + 1_{\mathcal{M}}$ shows that $(e+z1)(d+1) = 1$ (respectively $(e+z1)d = 1$).

Thus, $\|e + z1\|^2 (1+d)^*(d+1) \geq 1$ and $d+1$ (respective d) is right invertible in $D + \mathbb{C}1$ by $[(1+d)^*(d+1)]^{-1}(1+d)^*$. Thus, $D + \mathbb{C} \cdot 1$ contains a non-unitary isometry ...

Perhaps there exists a proof that works without Lemma of Brown?

The "opposite" direction is "Corollary 1.11":
Any purely infinite simple C^*-algebra satisfies property IR.

`Here is a collection of excerpts:`

Material for Part (xvii) of Proposition 2.2.1!!!

ON BROWN CRITERIUM:
M. Rieffel: "Stable rank one":
$\mathrm{GL}(\widetilde{A})$ is dense in $\widetilde{A}$.

For a unital C^*-algebra A, P. Friis and M. Rørdam [**305**] defined $R(A)$ as follows:
The element a is in $R(A)$ if and only if there does not exist a (closed two-sided) ideal I such that $\pi_I(a)$ is one-sided invertible but not invertible, where $\pi_I \colon A \to A/I$ is the quotient map.

They then said that A satisfies IR if $R(A)$ is in the (norm) closure of $\mathrm{GL}(A)$.

Of course it is obvious that $GL(A) \subseteq R(A)$, since no element that is one-sided invertible but not invertible (in some quotient algebra of A) can be approximated by invertible elements of A.
For non-unital A, they said A satisfies IR if $\widetilde{A}$ does. Here $\widetilde{A} = A$ if A is unital and $\widetilde{A} = C^*(A, 1) \subseteq \mathcal{M}(A)$ if A is not unital.

For expository purposes we introduce a formally weaker property, but in Proposition 2.2 we will show it is equivalent.
An arbitrary C^*-algebra A satisfies IR_0 if every element of $R(A^+) \cap (1 + A)$ is in

the closure of $\mathrm{GL}(A^+)$.

Obviously IR_0 is equivalent to IR in the unital case, but for non-unital A we are leaving open (for now) the possibility that $R(\widetilde{A}) \cap A$ is not contained in the closure of $\mathrm{GL}(A^+)$.

Lemma 1.2. (cf. [4, Theorem 3.5]).

Let B be a proper hereditary C^*-subalgebra of a unital C^*-algebra A, and identify B^+ with $B + \mathbb{C}1$. For t in $1 + B$, if $t \in GL(A)$, then $t \in GL(B^+)$.

Proposition 1.9.

If A is the direct limit of an upward directed family $\{B_i\}$ of hereditary C^*-subalgebras, and if each B_i satisfies IR, then A satisfies IR.

Corollary 1.10.

If A has an approximate identity of projections, in particular if A is of real rank zero, then A satisfies IR if and only if pAp satisfies IR for each projection p in A.

Corollary 1.11.

Any purely infinite simple C^*-algebra satisfies property IR.

Theorem 2.5.

Let I be a closed two-sided ideal of a C^*-algebra A. Then A has IR if and only if both I and A/I have IR and invertibles lift from $\widetilde{A}/I$ to $\widetilde{A}$.

Theorem 3.2.

Let A be a C^*-algebra of real rank zero. Then A has IR, if and only if, whenever p and q are projections in A generating the same ideal, then $(1 - p) \sim (1 - q)$ in A^+ implies $p \sim q$.

Proposition 4.1.

If A is a simple C^*-algebra, then A has IR if and only if either A has stable rank one or A is purely infinite.

My comment: “stable rank one” is in case of simple C^*-algebras what ? ...

It was pointed out in [**305**] that stable rank one implies IR

(“Stable rank in this sense was introduced by Rieffel [9] and stable rank one means that $GL(\widetilde{A})$ is dense in $\widetilde{A}$.”)

(Thus, in case of simple A, excluding “stable rank one” means that there exist elements in $\widetilde{A}$ that can not be approximate by invertible elements.)

Rieffel showed in [9] that C^*-algebras of stable rank one satisfy a stronger cancellation property: If p and q have the same image in $\mathrm{K}_0(A)$, then $p \sim q$. Of course $p \sim q$ implies that p and q generate the same ideal I and have the same image in $K0(I)$. We show next that stable IR implies a

?????

Proof.

For the direction not already proved, assume that A has IR and is not of stable rank one. We need to show that every non-zero hereditary C^*-subalgebra B of A contains a non-zero projection and that every non-zero projection is infinite.

For the first, note that B cannot have stable rank one, since B is strongly Morita equivalent to A and the stable rank one property is preserved by strong Morita equivalence. We may assume B is not unital, and thus $\widetilde{B}$ can be identified with $B + \mathbb{C} \cdot 1 \subseteq \widetilde{A}$. Then there must be $t \in 1 + B$ such that $t \notin R(\widetilde{B})$ (since B has IR by Proposition 1.4). Since the only relevant quotient of $\widetilde{B}$ is $\widetilde{B}$ itself, t is one-sided invertible but not invertible, and B contains a proper isometry u. Then $1 - uu^*$ is the desired non-zero projection in B. For the second, let p be a non-zero projection in A, and let $B = pAp$. The same sort of reasoning as above shows that there is a proper isometry in B, whence p is infinite. □

`Decide what is really needed from below!!`

Some More Text from L.G. Brown, to support the relation of this this Dichotomy Property with the rather simple property in Part (xvii) of Proposition 2.2.1:

Text comes mainly from [**109**]:

For a non-unital C^*-algebra A, $\widetilde{A}$ denotes the result of adjoining an identity, and $\widetilde{A}$ if A is unital. Let A^+ denote $\widetilde{A}$ if A is non-unital and $A^+ := A \oplus \mathbb{C}$ if A is unital.

DEFINITION OF $R(A)$ and IR:
For a unital C^*-algebra A, Friis and Rørdam [**305**] defined $R(A)$ as follows:

The element a is in $R(A)$, if and only if, there does not exist a (closed two-sided) ideal J such that $\pi_J(a)$ is one-sided invertible but not invertible, where $\pi_J \colon A \to A/J$ is the quotient map. They then said that A satisfies IR if $R(A)$ is in the (norm) closure of $GL(A)$.

Of course it is obvious that $\overline{GL(A)} \subseteq R(A)$, since no element that is one-sided invertible but is not invertible (in some quotient algebra of A) can be approximated by invertible elements of A.

For non-unital A, they said A satisfies IR if $\widetilde{A}$ does.

We introduce a formally weaker property, but in Proposition 2.2 we will show it is equivalent.

An arbitrary C^*-algebra A satisfies IR_0 if every element of $R(A^+) \cap (1 + A)$ is in the closure of $GL(A^+)$.

Obviously IR_0 is equivalent to IR in the unital case, but for non-unital A we are leaving open (for now) the possibility that $R(\widetilde{A}) \cap A$ is not contained in the closure of $GL(\widetilde{A})$.

Lemma [**305**, lem. 4.3] shows that direct products (also known as ℓ_∞-direct sums) of C^*-algebras with IR have IR, and the proof contains the assertion that IR

passes to ideals (see Remark 1.5 below for more on this). We proceed to generalize the latter result. Our proof relies on Proposition 2.2, but the result is included in this section for expository purposes.

Lemma 1.2.
([**114**, thm. 3.5]).
Let B be a proper hereditary C^*-subalgebra of a unital C^*-algebra A, and identify B^+ with $B + \mathbb{C} \cdot 1$, where 1 means 1_A. For all t in $1 + B$ holds: If $t \in \overline{GL(A)}$, then $t \in \overline{GL(B^+)}$.

Proposition 1.4.
Any hereditary C^*-subalgebra of a C^*-algebra with IR also has IR.

(HERE A CRITICAL REMARK TO [**305**, lem. 4.3])

Remark 1.5.
The argument given in the proof of [**305**, lem. 4.3] for the fact that any ideal I in a C^*-algebra with IR also has IR actually shows only that I has IR_0. Of course this is remedied by our Proposition 2.2, but it is not hard to see, without using any results from the present paper, that [**305**, lem. 4.3] is correct as stated.

Proposition 1.6.
Let B be a hereditary C^*-subalgebra of a unital C^*-algebra A. Then $(1 + B) \cap R(A) \subseteq R(B + \mathbb{C} \cdot 1)$.

DEFINITION OF $R(A)$ is where ???

Example 1.7.
The last result is not true for elements of B; i.e., $B \cap R(A)$ need not be contained in $R(B + \mathbb{C} \cdot 1)$.

To see this let A_0 be a non-unital purely infinite simple C^*-algebra, let $A := \widetilde{A_0}$, and let $B := pAp$ for a non-zero projection p in A_0. If u is a proper isometry in B, then $u \notin R(B + \mathbb{C} \cdot 1)$, since $B + \mathbb{C} \cdot 1 \cong B \oplus C$, but $u \in R(A)$, since the only relevant quotient of A is A itself.

Lemma 1.8.
If A is the direct limit of a directed family $\{B_i\}$ of hereditary C^*-subalgebras, and if each B_i satisfies IR_0, then A satisfies IR_0.

Proposition 1.9.
If A is the direct limit of
an upward directed

family $\{B_i\}$ of hereditary C^*-subalgebras, and if each B_i satisfies IR, then A satisfies IR.

`What is correct??`

If A is the direct limit of
a directed family $\{B_i\}$ of hereditary C^*-subalgebras, and if each B_i satisfies IR_0, then A satisfies IR_0.

10. Uniform global Glimm halving

REMARK B.10.1. Let $A_\omega := \ell_\infty(A)/J_\omega$, and $B \subseteq A_\omega$ a C^*-subalgebra. We define

$$F(B, A) := (B' \cap A_\omega)/\operatorname{Ann}(B, A_\omega)$$

and the special case $F(A) := F(A, A)$.

One can formulate "uniform variations" of the global Glimm halving property for A, respectively of the non-existence of characters on A:

(i) There is (universal) $n \in \mathbb{N}$ such that, for every $a \in A_+$, $c \in A_+$ with $\|c\| \leq 1$, $ca = a$, and $\varepsilon > 0$, there exists $b, d_1, \ldots, d_n \in A$, $b \in aAa$, $b^2 = 0$, $\|b\| = 1$, $\|[b, a]\| < \varepsilon$, $\|[d_j, a]\| < \varepsilon$, $\sum d_j^* bb^* d_j = c$.
(ii) For all $a^* = a \in A_\omega$, $F(C^*(a), A)$ has the global Glimm halving property (Notice here that $F(C^*(a_+), A) \oplus F(C^*(a_-), A) \cong F(C^*(a), A)$.)
(iii) A_ω has the global Glimm halving property, i.e., for all $a \in (A_\omega)_+$, $\varepsilon > 0$, there exist $b_{\varepsilon,a} \in a(A_\omega)_+ a$ with $b_{\varepsilon,a}^2 = 0$, $(a - \varepsilon)_+ \in I(b_{\varepsilon,a})$ (i.e., for every $\delta \in (0, \varepsilon)$, there exist $n = n(\delta)$ and $d_1, \ldots, d_n \in A_\omega$ such that $\sum_j d_j^*(b_{\varepsilon,a}^* b_{\varepsilon,a}) d_j = (a - (\varepsilon + \delta))_+$).
(iv) There is (universal) $n \in \mathbb{N}$ such that for $a, c \in A_+$ with $\|c\| = 1$ and $ca = a$ there exists $b \in A$ with $b^2 = 0$, $cb = bc = b$ and $d_1, \ldots, d_n \in A$ with $\sum d_j^*(bb^* + b^*b) d_j = a$.
(v) No hereditary C^*-subalgebra of A_ω has a character $\neq 0$. (It suffices to consider σ-unital hereditary subalgebras.)
(vi) There exists (universal) $n \in \mathbb{N}$, such that for all $a, c \in A_+$, $\|c\| = 1$, $ca = a$ there are $b_1, \ldots, b_n, d_1, \ldots, d_n \in A$ with $b_j^2 = 0$, $\|b_j\| = 1$, $cb_j = b_j c = b_j$, $cd_j = d_j c = d_j$, and $\sum d_j^*(b_j^* b_j + b_j b_j^*) d_j = a$.

Then (i)⇔(ii), (iii)⇔(iv), and (v)⇔(vi). Moreover (iv)⇒(vi).

11. Examples that exhaust the UCT-class

The following Lemma B.11.1 shows that every $\mathbb{Z}_2$-graded countable Abelian group $G = G_0 \oplus G_1$ is isomorphic to $\mathrm{K}_*(C_0(X))$ for some Polish l.c. space X that is locally homeomorphic to an at most 3-dimensional CW-complex – optical not visibly because some of them can be considered as topological subspaces of $\mathbb{R}^7$ but not of $\mathbb{R}^6$ or the they can be in the "visible" class of subsets of $\mathbb{R}^3$. In particular, *each separable C^*-algebra in the UCT class is* KK*-equivalent to* $\mathrm{C}_0(X)$ *for at least one of such* X.

LEMMA B.11.1. *Let W denote the compact Alexandroff (one-point)-completion of $\mathbb{N} \times \mathbb{R}$. If G is a countable Abelian group, then there exists a continuous map*

$\varphi\colon W \to W$ such that $\varphi(\infty) = \infty$ and that $\mathrm{K}^1(X) = 0$ and $\mathrm{K}^0(X) \cong G$ for $X := Y \setminus ((0,1] \times \{\infty\})$ where Y denotes the mapping cone of

$$Y := ((0,1] \times W) \cup_\varphi W$$

of φ.

Proof. Let $\mathbb{Z}^\infty$ denote the free Abelian group with free generators $y_1, y_2, \ldots$. If $x_1, x_2, \ldots \in G$ is a sequence that generates G, then there is an epimorphism $\lambda\colon \mathbb{Z}^\infty \to G$ with $\lambda(y_p) := x_p$. We can suppose that 0 appears in the sequence (x_n) infinitely often. Then the kernel $F \subseteq \mathbb{Z}^\infty$ of λ is not finitely generated. By [**308**, thm. 14.2], there is an isomorphism $\mu\colon \mathbb{Z}^\infty \to F$ from $\mathbb{Z}^\infty$ onto F.

It is not difficult to see that there is an automorphism σ of $\mathbb{Z}^\infty$ (given by an inductively selected new basis $y'_1, y'_2, \ldots$ of $\mathbb{Z}^\infty$), such that $\nu := \mu \circ \sigma\colon \mathbb{Z}^\infty \to \mathbb{Z}^\infty$ has the property that

$$\nu(y_p) = \sum_{j=k_p}^{l_p} g_{p,j} y_j$$

with $k_p \leq l_p$, $g_{p,j} \in \mathbb{Z}$ and $\lim_{p\to\infty} k_p = \infty$.

It follows that it suffices to define suitable continuous maps φ_p from $C_p := \{p\} \times S^1 \cong (\mathbb{R} \cup \{\infty\})$ (where we identify $\mathbb{R}$ with $\{e^{is}\,;\ s \in (0, 2\pi)\}$) onto the rosette

$$W_p := (\{k_p, k_p+1, \ldots, l_p - 1, l_p\} \times \mathbb{R}) \cup \{\infty\}\,.$$

The latter is the identification of the points $(j,1)$ (representing our infinite point of W_p) in the $m_p := 1 + l_p - k_p$ disjoint copies $C_j = \{j\} \times S^1$ of S^1. There exists maps $\varphi_p\colon C_p \to W_p$ that satisfy $\varphi_p(\infty) := \infty$ and that the maps

$$\mathrm{K}^1(\varphi_p)\colon\ \mathrm{K}^1(W_p) \to \mathrm{K}^1(C_p)$$

satisfy $\mathrm{K}^1(\varphi_p)[U_j] = g_j[V_p]$ in $\mathrm{K}^1(W_p)$. Here $U_j\colon W_p \to S^1$ and $V_p\colon C_p \to S^1$ are defined by $U_j(k,z) := 1$ if $k \neq j$ and $U_j(j,z) := z$, and by $V_j(j,z) := z$. The map $\varphi_p\colon C_p \to W_p$ can be defined as follows:
Select $t_0 = 0 \leq t_1 \leq \cdots \leq t_{m_p} = 2\pi$ with $t_{j-1} = t_j$ if $g_j = 0$ and $t_{j-1} < t_j$ if $g_j \neq 0$. If $g_j = 0$, let $\varphi_p((p, e^{t_j 2\pi i})) := (j,1) = \infty$. If $g_j \neq 0$, then define homeomorphisms $\gamma_j\colon [t_{j-1}, t_j] \to [0, 2|g_j|\pi]$ by the affine maps $\gamma_j(s) := (s - t_{j-1})(t_j - t_{j-1})^{-1} 2 g_j \pi$ if $g_j > 0$ and $\gamma_j(s) := (t_j - s)(t_j - t_{j-1})^{-1} 2|g_j|\pi$ if $g_j < 0$. Now define $\varphi_p((p, e^{2\pi s})) := (j, e^{i\gamma_j(s)})$??? for $s \in [t_{j-1}, t_j]$ (where we identify all $(j,1)$ with ∞).

Then we define $\varphi\colon W \to W$ by $\varphi((p,z)) := \varphi_p((p,z))$ -

Let $Y := ((0,1] \times W) \cup_\varphi W$ denote the mapping cone of $\varphi\colon W \to W$. It follows, that $X := Y \setminus ((0,1] \times \{\infty\})$ is locally a 2-dimensional CW-complex, that $\mathrm{K}^1(W) = \mathrm{K}^1(\mathbb{N} \times \mathbb{R}) \cong \mathbb{Z}^\infty$ and that $\mathrm{K}^1(\varphi)\colon \mathrm{K}^1(\mathbb{N} \times \mathbb{R}) \to \mathrm{K}^1(\mathbb{N} \times \mathbb{R})$ defines the monomorphism $\nu\colon \mathbb{Z}^\infty \to \mathbb{Z}^\infty$. In particular,

$$\mathrm{K}_1(\mathrm{C}_0(\varphi))\colon\ \mathrm{K}_1(\mathrm{C}_0(\mathbb{N} \times \mathbb{R})) \to \mathrm{K}_1(\mathrm{C}_0(\mathbb{N} \times \mathbb{R}))$$

is an injective map with co-kernel isomorphic to G.

The Mayer-Vietoris sequence shows that the 6-term K_*-sequence of the short-exact sequence

$$\mathrm{C}_0((0,1)\times(\mathbb{N}\times\mathbb{R})\to \mathrm{C}_0(X)\to \mathrm{C}_0(\mathbb{N}\times\mathbb{R})$$

(defined by a pull-back) has injective boundary map

$$\partial\colon\ \mathrm{K}_1(\mathrm{C}_0(\mathbb{N}\times\mathbb{R}))\to \mathrm{K}_0(\mathrm{C}_0((0,1)\times(\mathbb{N}\times\mathbb{R}))\cong \mathrm{K}_1(\mathrm{C}_0(\mathbb{N}\times\mathbb{R}))$$

given by $\mathrm{K}_1(\mathrm{C}_0(\varphi))$. Since $\mathrm{K}_1(\mathrm{C}_0((0,1)\times(\mathbb{N}\times\mathbb{R}))=\mathrm{K}_0(\mathrm{C}_0(\mathbb{N}\times\mathbb{R}))=0$, we get $\mathrm{K}^1(X)=\mathrm{K}_1(\mathrm{C}_0(X))=0$ and $\mathrm{K}^1(X)=\mathrm{K}_0(\mathrm{C}_0(X))\cong G$. □

REMARK B.11.2. If the group G is finitely generated then one can take for X with $\mathrm{K}^0(X)\cong G$ and $\mathrm{K}^1(X)=0$ likewise:

(i) $X :=$ a finite disjoint union of points and of pointed Moore spaces

$$(\mathbb{D}/\sim_n)\setminus\{0\}$$

(For construction of Moore spaces see [**692**, ex.12.2]), or – alternatively –

(ii) $X :=$ the mapping cone of a continuous map from a not necessarily finite cloverleaf $(A\times\mathbb{R})\cup\{\infty\}$ into a not necessarily finite cloverleaf (or a point) $(B\times\mathbb{R})\cup\{\infty\}$, where A is a finite set of cardinality $|A|=$ minimal number of generators of G and $|B|\le|A|$ (and B can be empty).

12. S.p.i. subalgebras B with Hausdorff $\mathrm{Prim}(B)$

We say that a C^*-algebra D *can be locally approximated by C^*-subalgebras B with Hausdorff primitive ideal space* $\mathrm{Prim}(B)$, if, for every finite subset $X\subseteq D$ and for each $\varepsilon>0$, there is a C^*-subalgebra $B:=B(X,\varepsilon)\subseteq D$ of D such that $\mathrm{Prim}(B)$ is Hausdorff and $\mathrm{dist}(x,B):=\inf_{b\in B}\|x-b\|<\varepsilon$ for every $x\in X$.

It is likely that Theorem ??K?? can be used to show, that this property can be reformulated as a property of the primitive ideal space $\mathrm{Prim}(D)$ alone, provided that D is separable and nuclear and $D\cong D\otimes\mathcal{O}_2\otimes\mathbb{K}$:

If $B\subseteq D$ has Hausdorff $Y:=\mathrm{Prim}(B)$, then the action $\mathcal{I}(D)\cong\mathbb{O}(\mathrm{Prim}(D))\to\mathbb{O}(Y)$ of $\mathrm{Prim}(D)$ on Y is l.s.c. and monotone upper s.c. Conversely those actions define C^*-morphisms from $\mathrm{C}_0(Y,\mathcal{O}_2\otimes\mathbb{K})$ into D.

Consider all local approximations of this type.

Is the above local "Hausdorff" approximation property equivalent to the following property:

Property (???): *The family of adjoint maps from* $\mathrm{C}_0(Y)_+$ *to the Dini functions on* $\mathrm{Prim}(D)$ *contain in its images every finite set of Dini functions on* $\mathrm{Prim}(D)$ *up to* $\varepsilon>0$.

We give an almost minimal example D, that can *not* be locally approximated by C^*-subalgebras B with Hausdorff primitive ideal space $\mathrm{Prim}(B)$, and contains regular abelian C^*-subalgebras with rather different properties.

Proofs are not complete ??

Remark B.12.1. Let $A := \{f \in \mathrm{C}([0,1], M_2)\,;\ f(1) \in \Delta\}$ where Δ denotes the diagonal matrices of M_2.

We fix a unital monomorphism $h_1 \colon M_2(\mathcal{O}_\infty) \to \mathcal{O}_2$ and a non-degenerate monomorphism $h_2 \colon (\mathcal{O}_2 \oplus \mathcal{O}_2) \otimes \mathbb{K} \to \mathcal{O}_\infty \otimes \mathbb{K}$.

Further let $D := A \otimes \mathcal{O}_2 \otimes \mathbb{K}$, $D_1 := \{f \in \mathrm{C}([0,1], \mathcal{O}_2)\,;\ f(1) \in h_1(\Delta \otimes \mathcal{O}_\infty)\}$, and let

$$D_2 := \{f \in \mathrm{C}([0,1], \mathcal{O}_\infty \otimes \mathbb{K})\,;\ f(1) \in h_2((\mathcal{O}_2 \oplus \mathcal{O}_2) \otimes \mathbb{K})\}\,.$$

Then:

(1) The abelian C^*-subalgebra $B := \mathrm{C}([0,1], \Delta)$ of A is *regular* in A and in D, but $B \hookrightarrow A$ does not define a $\mathrm{KK}(\mathrm{Prim}(A), \cdot, \cdot)$ equivalence.
(2) D can not be locally approximated by C^*-subalgebras of D that have Hausdorff primitive ideal spaces.
(3) The algebras $D_0 := D$, D_1 and D_2 have same primitive ideal spaces, and contain regular abelian C^*-algebras C_0, C_1 respectively C_2, such that the inclusion maps define $\mathrm{KK}(\mathrm{Prim}(D_k); \cdot, \cdot)$-equivalences $(k = 0, 1, 2)$.

Proof. We embed A into D by $A \ni a \mapsto a \otimes r \in D := A \otimes \mathcal{O}_2 \otimes \mathbb{K}$, where r is a non-zero projection in $\mathcal{O}_2 \otimes \mathbb{K}$. Notice that $\mathrm{Prim}(A) \cong \mathrm{Prim}(D)$ by restriction of primitive ideals $I \lhd D \mapsto I \cap A \lhd A$.

The two characters χ_1 and χ_2 on Δ define characters on A and, therefore, define closed points x_1 and x_2 of $\mathrm{Prim}(A)$ (and of $\mathrm{Prim}(D)$). Since $[0,1)$ is naturally homeomorphic to the primitive ideal space of the closed ideal $\mathrm{C}_0([0,1), M_2)$ of A, there is an open subset U of $\mathrm{Prim}(A)$ that is homeomorphic to $[0,1)$. The closed complement is $\mathrm{Prim}(A) \setminus U = \{x_1, x_2\}$, where x_1 and x_2 denote the kernels of χ_1 respectively χ_2.

Since $A \subseteq \mathrm{C}([0,1],\, M_2)$, the set-valued map $\mu(t) := \{t\}$ for $t \in [0,1)$ and $\mu(1) := \{x_1, x_2\}$ from $[0,1] = \mathrm{Prim}(\mathrm{C}([0,1],\, M_2))$ into $\mathrm{Prim}(A)$ is lower semi-continuous and is montone upper semi-continuous. The corresponding map

$$\Phi_0 \colon \mathbb{O}([0,1]) \;\to\; \mathbb{O}(\mathrm{Prim}(A)) \cong \mathbb{O}([0,1) \cup \{x_1, x_2\})$$

is given by $\Phi_0(V) := V$ if $1 \notin V$ and $\Phi_0(V) := (V \cap (0,1]) \cup \{x_1, x_2\}$.

Clearly, $B \cong \mathrm{C}([0,1]) \oplus \mathrm{C}([0,1])$ is a commutative C^*-subalgebra of A (and, hence of D) that separates the ideals of A (and, hence, that of D).

The set-valued map Φ from $\mathrm{Prim}(A)$ into the closed subsets of $\mathrm{Prim}(B) \cong [0,1] \times \{1,2\}$ satisfies $\Phi(x_j) = \{(1,j)\}$ for $j = 1,2$ and $\Phi(t) = \{(t,1), (t,2)\}$ for $t \in [0,1)$.

The montone upper semi-continuity and the lower semi-continuity of the corresponding map Ψ from the lattice of open subsets of $\mathrm{Prim}(A)$ to the lattice of open subsets of $\mathrm{Prim}(B)$ imply that in good cases (e.g. if B separable and exact)

????????????????

we may suppose that $B \subseteq A \otimes \mathcal{O}_2$

We have for the injective map $\Psi \colon \mathbb{O}(\mathrm{Prim}(A)) \to \mathbb{O}(\mathrm{Prim}(B))$, that an open subset of W of $\mathrm{Prim}(B) \cong [0,1] \times \{1,2\}$ is in the image of Ψ, if and only if, $(t,1), (s,2) \in W$ and $s,t \in [0,1)$ imply that $(t,2),(s,1) \in W$.

It follows ????

that the image of Ψ consists of the family of open subsets of $V \times \{1,2\} \setminus G$ with V an open subset of $[0,1]$ and G a subset of $\{(1,1),(1,2)\}$.

If I is a closed ideal of A, then $(I \cap B)$ contains a strictly positive element of I: This is clear, if $I \subseteq \mathrm{C}_0([0,1), M_2)$, because then $I = \mathrm{C}_0(Y, M_2)$ for some open subset of Y of $[0,1)$.

In the other cases, there is an open subset Y of $[0,1]$ with

????????????????????????

Suppose now that for every finite subset $Z \subseteq D$. and every epsilon there is C^*-subalgebra F of D such that $\mathrm{dist}(z,F) < \varepsilon$ for all $z \in Z$.

The two projections $p = 1 \otimes e_{11} \otimes r$ and $q = 1 \otimes e_{22} \otimes r$ of B and its sum $1 \otimes 1_2 \otimes r$ are (up to MvN-equivalence) the only non-zero projections in D.

Indeed: If $Q \in D$ is a projection, it defines a continuous map $Q(t)$ from $[0,1]$ to $M_2 \otimes \mathcal{O}_2 \otimes \mathbb{K}$ with $Q(1) \in \Delta \otimes \mathcal{O}_2 \otimes \mathbb{K}$. If we let $P(t) := Q(1)$ for $t \in [0,1]$, then Q and P are in D and

$Q_s := Q(s + t^s)$

?????????

is a homotopy that connects Q and P in the projections of D.

Now use that all non-zero projections in $\Delta \otimes \mathcal{O}_2 \otimes \mathbb{K}$ are MvN-equivalent to the above mentioned three,

????

We have: *If. P, Q, R_1, R_2 are projections in D such that R_1 is MvN-equivalent to R_2 in B, $R_1 + P = p$ and $R_2 + Q = q$, then $R_1 = R_2 = 0$.*

Indeed: The R_i must be in the intersection of the primitive ideals defined by the characters χ_k on A, Thus, the R_i are in the ideal $\mathrm{C}_0([0,1), M_2) \otimes \mathcal{O}_2 \otimes \mathbb{K}$ of D, which contains only the zero projection.

???????????

`check last until here`

Since ?????

The reason should be the contradictory observation, that such an inductive limit decomposition eventually would lead to a continuous map f from $[0,1]$ into the Hausdorff space of subsets of $\{1,2,3\}$ which is not constant:

Let $C := \mathrm{C}([0,1], M_2) \otimes \mathcal{O}_2$. To see such a map, the reader should remark that then also $A \otimes \mathcal{O}_2$ has such an inductive limit decomposition by unital subalgebras with Hausdorff primitive ideal spaces. Thus, eventually, one finds, at least after application of an inner automorphism of $A \otimes \mathcal{O}_2$, a C^*-subalgebra B of $A \otimes \mathcal{O}_2$ which has Hausdorff primitive ideal space $Y := \mathrm{Prim}(B)$ and contains the constant diagonal projections $p = \mathrm{diag}(1,0)$ and $q = \mathrm{diag}(0,1)$ of $M_2 \cap A \subseteq C$, and contains also a contraction b of A with $\|bb^*(0) - p\| < 1/8$ and $\|b^*b(0) - q\| < 1/8$. In particular, B is unital. The two primitive ideals I_1 and I_2 of $A \otimes \mathcal{O}_2$ corresponding to the point 1 of $\mathrm{Prim}(C) \cong [0,1]$ separate p and q. Thus there are primitive ideals $J_1 \supset I_1 \cap B$ and $J_2 \supset I_2 \cap B$ of B with $p \in J_1$, $q \notin J_1$, $p \notin J_2$ and $q \in J_2$. Every primitive ideal J_3 of B which contains the intersection of B with the kernel of the evaluation map $g \mapsto g(0)$ contains neither p nor q. Let Z_1 and Z_2 be the open and closed subsets of Y which correspond to the norm functions $\widehat{p}$ and $\widehat{q}$ respectively. Since $p + q = 1$, $Z_1 \cup Z_2 = Y$. Therefore, the open and closed subsets $W_1 := Z_1 \setminus Z_1 \cap Z_2$, $W_2 := Z_2 \setminus Z_1 \cap Z_2$ and $W_3 := Z_1 \cap Z_2$ define a partition of Y with $J_n \in W_n$, $n \in \{1,2,3\}$.

Since $\mathrm{Prim}(B)$ is Hausdorff and B is unital, we get that there are four orthogonal projections P, Q, R_1, R_2 in B such that R_1 is MvN-equivalent to R_2 in B, $R_1 + P = p$ and $R_2 + Q = q$.

Above, we have seen, that this can not happen in $A \otimes \mathcal{O}_2$.

??????

`To be explained` ??

We define a continuous and open map λ from Y onto $\{1,2,3\}$ by $\lambda(x) := n$ for $x \in W_n$ and $n \in \{1,2,3\}$.

Then

$$f \colon t \in [0,1] \mapsto \lambda(Y \setminus \Psi^{\mathrm{up}}_{B,C}([0,1] \setminus \{t\}))$$

is a map from $[0,1]$ into the Hausdorff space of subsets of $\{1,2,3\}$, and $f(0) = \{3\}$, $f(1) = \{1,2\}$, which leads to a contradiction. Recall here that $\Psi^{\mathrm{up}}_{B,C}$ is a set-valued upper semi-continuous and monotone lower semi-continuous map. Thus f satisfies $\overline{f(S)} = f(\overline{S})$ for every subset S of $[0,1]$. □

`Next proofs not complete` ??

Remark B.12.2. Let A a unital C^*-algebra with Hausdorff $\mathrm{Prim}(A)$ and $p, q \in A$ projections with $\|p + q - 1\| < 1$ such that $\{(p-q)^2\}' \cap A$ has again Hausdorff primitive ideal space.

Then A decomposes into a direct sum $A \cong B \oplus C$ such that $C^*(\pi_2(p), \pi_2(q), 1_C)$ is a commutative C^*-subalgebra of C, $\pi_2(q) = 1_C - \pi_2(p)$, and that $1 \otimes C^*(\pi_1(p), \pi_1(q), 1_B)$ is contained in a 2-homogenous C^*-subalgebra $\cong \mathrm{C}(Y, M_2)$ of $\mathcal{O}_2 \otimes B$ with Y an open and closed subset of $X \times [0, \pi/2]$.

`Next has to be checked !`

Moreover, it can be managed that the induced unital C^*-morphism

$$h\colon C^*(P,Q,1) \to 1 \otimes C^*(\pi_1(p), \pi_1(q), 1_B)$$

extends to a unital C^*-morphism $\mathrm{C}([0,\pi/2], M_2) \to \mathcal{O}_2 \otimes B$.

`Above seems not to be obvious !!`
`Check if extension exists for irreducible rep's of` B `!!`

Let $D := \{f \in \mathrm{C}([0,1], M_2)\,;\ f(1)\,\text{diagonal}\}$. The quotient

$$\mathcal{O}_2 \otimes (C^*(P,Q,1)|[\pi/4,\pi/2]) \cong \mathcal{O}_2 \otimes D$$

of $\mathcal{O}_2 \otimes C^*(P,Q,1)$ does not contain a unital C^*-subalgebra A that satisfies $1 \otimes (P|[\pi/4,\pi_2]) \in A$ and $\operatorname{dist}(1 \otimes (Q|[\pi/4,\pi_2]); A) < 1/32$ and has *Hausdorff* primitive ideal space.

This non-existence implies that the C^*-algebras

$$\mathbb{K} \otimes \mathcal{O}_2 \otimes [\mathrm{C}_0([0,\pi/2), M_2) + \mathbb{C}P + \mathbb{C}(1-P)] \cong \mathbb{K} \otimes \mathcal{O}_2 \otimes D$$

and

$$\mathbb{K} \otimes \mathcal{O}_2 \otimes C^*(P,Q,1)$$

can not be an inductive limit of C^*-algebras A_n with Hausdorff primitive ideal spaces $\operatorname{Prim}(A_n)$.

It follows that the lattice $\mathcal{I}(C^*(P,Q,1)) \cong \mathbb{O}(\operatorname{Prim}(C^*(P,Q,1)))$ of open subsets of the (non-coherent) primitive ideal space $\operatorname{Prim}(C^*(P,Q,1))$ of $C^*(P,Q,1)$ can not be an algebraic limit of lattices $\mathbb{O}(X_n)$ for locally compact Hausdorff spaces X_n with respect to lower s.c. and monotone upper s.c. actions of X_{n+1} on X_n.

Proof. The C^*-algebra $A_0 := \mathrm{C}([0,\pi/2], M_2)$ and its C^*-subalgebra $C^*(P,Q,1)$ can be described by a universal C^*-algebra $C^*(R,S)$ with following universal relations:

R is a partial isometry, i.e., $RR^*R = R$, with relations $R^2 = 0$ and $(R-R^*)^4 = -(R-R^*)^2$. And S satisfies $0 \le S^* = S \le -(R-R^*)^2$ and $SR = RS$.

In particular, $-(R-R^*)^2$ is the unit element of $C^*(R,S)$, $C^*(R) \cong M_2$, S is in the centre of $C^*(R,S)$ and S has spectrum $\operatorname{Spec}(S) \subseteq [0,1]$. It follows that $\arcsin(S)$ is a well-defined positive element in the centre of $C^*(R,S)$, has spectrum in $[0,\pi/2]$ and $C^*(\arcsin(S)) = C^*(S)$. It follows that the natural C^*-morphism from $M_2 \otimes \mathrm{C}(\operatorname{Spec}(\arcsin(S)))$ onto $C^*(R, \arcsin(S)) = C^*(R,S)$ is an isomorphism.

To define a unital C^*-morphism λ from $C^*(R,S)$ onto $\mathrm{C}([0,\pi/2], M_2) \cong M_2 \otimes \mathrm{C}[0,\pi/2]$ we can choose the matrix-unit $R(\varphi) := e_{21}$ and $S(\varphi) := \sin(\varphi)1_2$. This epimorphism shows in particular that $\operatorname{Spec}(S) = [0,1]$ and $\operatorname{Spec}(\arcsin(S)) = [0,\pi/2]$. Notice that $\lambda(S^2) = (P-Q)^2$ is a positive contraction in the centre of A_0 and $\lambda(S) = |P-Q|$.

An inverse $\mu\colon \mathrm{C}([0,\pi/2], M_2) \to C^*(R,S)$ of λ can be defined by the natural epimorphism from $\mathrm{C}([0,\pi/2], M_2) = M_2 \otimes \mathrm{C}(\operatorname{Spec}(\arcsin(S)))$ onto $C^*(R,S)$, i.e., is determined by a $\mu(e_{2,1}) := R$ and $\mu(f_0 \cdot 1_2) := \arcsin(S)$ for $f_0(t) := t$ on $[0,\pi/2]$.

Then $\mu(M_2) = C^*(R) \subseteq C^*(R,S)$, $\mu(P) = R^*R \in C^*(R)$, $\mu(Z) = R - R^*$, $\mu((P-Q)^2) = S^2$, $\mu(H) = \arcsin(S)\cdot Z$, and $\mu(Q) = \exp(-H)R^*R\exp(\mu(H)$.

Let A a unital C^*-algebra and $p,q \in A$ projections such that p and $1-p$ are full projections in $\{(p-q)^2\}' \cap A$. Let $B := \mathcal{O}_2 \otimes (\{(p-q)^2\}' \cap A)$. Then there exists a partial isometry $V \in B$ with $V^*V = 1\otimes p$ and $VV^* = 1 \otimes (1-p)$, because 1_B is properly infinite and $1\otimes p$ and $1\otimes(1-p)$ are full and properly infinite projections in $\mathcal{O}_2 \otimes B$, cf. Lemma 4.2.6(ii).

If we let $T := 1 \otimes |p-q|$, then $U(1\otimes q) = (1\otimes p)U$ for $U := \exp(\arcsin(T)\cdot (V - V^*))$ and there is a unique unital C^*-morphism $\rho\colon C^*(R,S) \to B \subseteq \mathcal{O}_2 \otimes A$ with $\rho(R) = V$ and $\rho(S) := T$. Then $\rho(Z) = \rho(R+R^*) = V + V^*$, $\rho((P-Q)^2) = \rho(S^2) = T^2 = 1\otimes (p-q)^2$,

$$\rho(H) = \rho(\arcsin(S)\cdot Z) = (1\otimes \arcsin(|p-q|))(V - V^*)\,.$$

`Why` $\rho(Q) = 1\otimes q$ `???`

It follows that $\rho(P) = \rho(R^*R) = 1\otimes p$, $\rho(H) = \rho(\arcsin(S)\cdot(R-R^*)) = (1\otimes \arcsin(|p-q|))\cdot(V-V^*)$, and

$$\rho(Q) = \exp(-\rho(H))(1\otimes p)\exp(\rho(H)) = 1\otimes q\,.$$

Let A a unital C^*-algebra with Hausdorff primitive ideal space $X := \mathrm{Prim}(A)$ and $p \in A$ a projection. Then X is compact and the generalized Gelfand transforms $\widehat{p} : x \in X \mapsto \|\pi_x(p)\| = \|p + J_x\| \in [0,1]$ and

$$\widehat{1-p} : x \in X \mapsto \|\pi_x(1-p)\| = \|(1-p) + J_x\| \in [0,1]$$

are continuous functions on X with values in $\{0,1\}$ such that $\max(\widehat{p}\,, \widehat{1-p}\,) = 1$, because Dini functions on compact Hausdorff spaces X are continuous on X.

The support U_1 of $\widehat{p}$ (respectively U_2 of $\widehat{1-p}$) is the open subset of X corresponding to the closed ideal J_1 of A generated p (respectively J_2 generated by $1-p$). Since $1-\widehat{p}$ (respectively $1-\widehat{1-p}$) is continuous and non-negative, its support is open. Thus, U_1 and U_2 are open and compact subsets of X. In particular U_1 and U_2 are also closed subsets of the Hausdorff space X. Then $V := U_1 \cap U_2$, $W_1 := U_1 \setminus V$ and $W_2 := U_2 \setminus V$ are disjoint open and closed subsets of the compact Hausdorff space X with $X = V \cup W_1 \cup W_2$.

Since the J_k correspond to $U_k = W_k \cup V$, the ideal $K := J_1 \cap J_2$ has open and closed support V in $X = \mathrm{Prim}(A)$. Recall that $1 \in J_1 + J_2 = A$, $\pi_{J_1}(p) = 0$ and $\pi_{J_2}(p) = 1$.

Let I denote the closed ideal of A corresponding to the open and compact subset V of X. Then $I + K = A$, $J_1 + J_2 = A$ and $K \cap I = \{0\}$. If we define $B_1 := A/I$, $D_1 := A/J_1$ and $D_2 := A/J_2$. Then $\pi_I|K$ is an isomorphism from K onto B_1, and $\pi_K|I$ defines an isomorphism from I onto $C_1 := A/K \cong D_1 \oplus D_2$, where the isomorphism from C_1 onto $D_1 \oplus D_2$ is induced by $a \in A \mapsto \pi_{J_1}(a) \oplus \pi_{J_2}(a)$. In particular, $\pi_I(p)$ and $\pi_I(1-p)$ are full projections of B_1. Since $\pi_{J_1}(p) \oplus \pi_{J_2}(p) = 0 \oplus 1$, it follows that $\pi_K(p)$ is in the centre of the unital C^*-algebra C_1.

`Is next the critical case?`

Let $q \in A$ another projection and and let $Y := \arcsin(\mathrm{Spec}(|p-q|))$. Recall that there is a natural unital C^*-morphism from $\mathrm{C}(X \times Y)$ into $\{(p-q)^2\}' \cap A$ which makes $\{(p-q)^2\}' \cap A$ into a $\mathrm{C}(F)$-algebra for some closed subset F of $X \times Y$. Our assumptions imply that the $\mathrm{C}(F)$-algebra $\{(p-q)^2\}' \cap A$ is in a natural way a C^*-bundle over $X \times \arcsin \mathrm{Spec}(|p-q|)$.

Then $\pi_K(q)$ and $\pi_K(p)$ commute in C_1, and we can repeat the arguments with $(\pi_I(\{(p-q)^2\}' \cap A), \pi_I(q))$ in place of (A, p).

We get finally a direct sum decomposition $A \cong B \oplus C$ such that $\pi_1 \colon A \to B$ and $\pi_2 \colon A \to C$ have the property that $\pi_1(p)$, $1-\pi_1(p)$, $\pi_1(q)$ and $1-\pi_1(q)$ are projections in B which are full in $\{\pi_1(p-q)^2\}' \cap B$, and that $\pi_2(qp) = \pi_2(pq)$. Notice that $B = \pi_1(A)$ and $\{\pi_1(p-q)^2\}' \cap B$ have Hausdorff primitive ideal space Y that is homeomorphic to an open and closed subset of $X \cong \mathrm{Prim}(A)$, respectively of $X \times \arcsin(\mathrm{Spec}(|p-q|))$.

To simplify notation we suppose from now on that A itself has the property that $p, 1-p, q, 1-q$ are full projections (and that $X := \mathrm{Prim}(A)$ is Hausdorff) and that $(p-q)^2$ is an essential element of the centre of A, i.e., that $\mathrm{Ann}((p-q)^2, A) = \{0\}$.

In the considered case, we still have that our additional assumption $\|(p+q)-1\| = \|(1-p)-q\| < 1$ remains in charge in the new A, – our renamed B and $\pi_1(p), \pi_1(q)$.

If we apply part (v) of Lemma 4.1.3 to $1-p, q$ in place of p, q then we get $-h^* = h \in C^*(p,q,1) \subseteq A$ with $\|h\| = \arcsin\|p+q-1\| < \pi/2$ and $php = 0 = (1-p)h(1-p)$ such that $\exp(-h)(1-p)\exp(h) = q$. Thus $h = a - a^*$ for some $a \in A$ with $a = pa(1-p)$ and $\|a\| = \arcsin\|p+q-1\|$.

Need ???

the existence of $c \in \mathcal{O}_2 \otimes pA(1-p)$ with $cc^* = 1 \otimes p$, $c^*c = 1 \otimes (1-p)$ and $b \in A_+$ with $bp = pb$, $bq = qb$ and $a = bc$

???????

We can use that $1 \otimes (p-q)^2$ is in the centre of $\mathcal{O}_2 \otimes A$ and that $1 \otimes p$ and $1 \otimes (1-p)$ are both full and properly infinite projections of $\mathcal{O}_2 \otimes A$.

`Explicit formula for` $H|[0,\psi]$ `for study of the inclusion` $C^*(P,Q,1)|[0,\pi/4] \subseteq \mathrm{C}([0,\pi/4], M_2)$.

An explicit formula for $H|[0,\psi] \in C^*(P,Q)|[0,\psi]$ for $\psi \in [0,\pi/2)$ is given by $H(\varphi) := \varphi(e_{2,1} - e_{1,2})$.

Notice that

$$PQ(\varphi)(1-P) = P\exp(-H)(\varphi)P \cdot P\exp(H)(\varphi)(1-P) = -\cos(\varphi)\sin(\varphi)e_{1,2}\,.$$

and

$$PQ(\varphi)(1-P) - (1-P)Q(\varphi)P = \cos(\varphi)\sin(\varphi)Z$$

and $(P - Q(\varphi))^2 = \sin(\varphi)^2 1_2$, because

$$Q(\varphi) - P = [\cos(\varphi), -\sin(\varphi)]^\top [\cos(\varphi), -\sin(\varphi)] - P = \sin(\varphi) I$$

with $I = [\alpha_{jk}]$ with $\alpha_{11} = -\sin(\varphi) = -\alpha_{22}$, $\alpha_{12} = \alpha_{21} = -\cos(\varphi)$, i.e., orthogonal with determinant -1, $I^2 = 1_2$. Similarly: $(P + Q(\varphi) - 1)^2 = (Q(\varphi) - (1-P))^2 = \cos(\varphi)^2 1_2$.

I.e., always $(p-q)^2 + (p+q-1)^2 = 1$, $|p-q|$ and $|p+q-1|$ are in the centre of $C^*(p,q,1)$.

Alternatively one can use symmetry of sin and cos at $\pi/4$ $(= 45°)$.

$H := a - a^*$, $a = -\varphi e_{1,2}$ for $a = CPQ(1-P)$ with $C := D^{-1} \arcsin |P-Q|$ where $D := (1 - (P-Q)^2)^{1/2} \cdot |P-Q|$

?????????.

Let $A \subseteq \mathcal{O}_2 \otimes (C^*(P,Q,1)|[\pi/4, \pi/2])$ a unital C^*-subalgebra such that $p_0 := 1_{\mathcal{O}_2} \otimes P|[\pi/4,\pi/2] \in A$. Suppose that $X := \mathrm{Prim}(A)$ is Hausdorff. Since A is separable and unital, X is second countable and compact, i.e., is a compact Polish space.

Each quotient C^*-algebra of $\mathrm{C}[\pi/4,\pi/2] \otimes A$ has again Hausdorff primitive ideal space. Thus, the C^*-subalgebra $C^*(\mathrm{C}[\pi/4,\pi/2] \cdot 1, A)$ generated by A and $\mathrm{C}[\pi/4, \pi_2] \cdot 1$ is a again a unital C^*-subalgebra of $\mathcal{O}_2 \otimes (C^*(P,Q,1)|[\pi/4,\pi/2])$ that contains p_0 and has again a Hausdorff primitive ideal space. Thus, we can suppose in addition that $1 \otimes \mathrm{C}[\pi/4,\pi/2]$ is contained in A.

If we use that $\mathcal{O}_2 \cong \mathcal{O}_2 \otimes \mathcal{O}_2 \otimes \cdots$, then we can tensor here all algebras in question again by $\mathcal{O}_2$ and suppose moreover that $\mathcal{O}_2 \otimes A \cong A$. Then A is purely infinite and the MvN-equivalence classes of projections in A are in 1-1-correspondence with the open and compact subsets of X.

Since $A \subseteq \mathcal{O}_2 \otimes C^*(P,Q,1)|[\pi/4, 1\pi/2]$ is contained in $\mathrm{C}([\pi/4,\pi/2], \mathcal{O}_2 \otimes M_2) \cong \mathcal{O}_2 \otimes \mathrm{C}[\pi/4,\pi/2]$ and $1 \otimes \mathrm{C}[\pi/4,\pi/2] \subseteq A$ is contained in the centre of $\mathcal{O}_2 \otimes (C^*(P,Q,1)|[\pi/4,\pi/2])$, the C^*-algebra A is C^*-bundle over $[\pi/4,\pi/2]$, i.e., is the C^*-algebra of continuous sections of a continuous field

$$\varphi \in [\pi/4, \pi/2] \mapsto A_\varphi \subseteq \mathcal{O}_2 \otimes M_2 \subseteq \mathcal{O}_2\,.$$

The same happens with the C^*-subalgebras p_0Ap_0 and $(1-p_0)A(1-p_0)$ of A, because, they are invariant under multiplications with $1 \otimes f$ where $f \in \mathrm{C}[\pi/4,\pi/2]$.

The generalized Gelfand transforms $\widehat{a}(J) := \|a + J\|$ for $J \in \mathrm{Prim}(A) \cong X$ are Dini functions on X. The class of Dini functions on Hausdorff spaces X coincides with the bounded non-negative continuous functions $f \in \mathrm{C}_0(X)$ with σ-compact locally compact open support $f^{-1}(0,\infty)$ in X. The Gelfand transforms $\widehat{q} \in \mathrm{C}_0(X)$ of projections $q \in A$ are the characteristic functions of open and compact subsets of X corresponding to the closed ideal $\overline{\mathrm{span}(AqA)}$ generated by q.

Let $J_1 \subseteq A$ the closed ideal of A generated by $p := 1 \otimes (P|[\pi/4, \pi/2])$, $J_2 \subseteq A$ the closed ideal generated by $1 - p = 1 \otimes (1 - P)|[\pi/4, \pi/2]$ and $U_1, U_2 \subseteq X$ are the corresponding open subsets.

Their characteristic functions are given by $\widehat{p}$ and by $\widehat{1-p} = 1 - \widehat{p}$. It implies that U_1 and U_2 are compact (and open) and satisfy $U_1 \cup U_2 = X$.

The set $F := X \setminus (U_1 \cap U_2)$ is an open and compact subset of X and is a metric space with $F_1 := F \cap U_1$ and $F_2 := F \cap U_2$, that are disjoint open and closed subsets of F with $F = F_1 \cup F_2$.

`To be filled in ??`

Suppose that the lattice $\mathcal{I}(C^*(P, Q, 1))$ is an algebraic limit of the lattices $\mathbb{O}(X_n)$, where the corresponding actions are l.s.c. and monotone upper s.c.

Then the corresponding actions

$$\Psi_n : \mathbb{O}(X_{n+1}) \to \mathbb{O}(X_n)$$

are induced from suitable C^*-morphisms

$$\mathrm{C}_0(X_n, \mathbb{K} \otimes \mathcal{O}_2) \to \mathrm{C}_0(X_{n+1}, \mathbb{K} \otimes \mathcal{O}_2)$$

and $\mathbb{K} \otimes \mathcal{O}_2 \otimes C^*(P, Q, 1)$ is isomorphic to an inductive limit of $\mathrm{C}_0(X_n, \mathbb{K} \otimes \mathcal{O}_2)$ coming from suitable compatible C^*-morphisms

$$\phi_n : \mathrm{C}_0(X_n, \mathbb{K} \otimes \mathcal{O}_2) \to \mathbb{K} \otimes \mathcal{O}_2 \otimes C^*(P, Q, 1) .$$

For some n_0 there exists a unitary $u \in \mathcal{M}(\mathbb{K} \otimes \mathcal{O}_2 \otimes C^*(P, Q, 1))$ and projections $r, s \in \mathrm{C}_0(X_n, \mathcal{O}_2)$ such that $s \leq r$ $e_{11} \otimes 1 \otimes 1 = u^* \phi_{n_0}(e_{11} \otimes r)u$, $e_{11} \otimes 1 \otimes p = u^* \phi_{n_0}((e_{11} \otimes s)u$ and $\mathrm{dist}(\, q;\ \phi_{n_0}(e_{11} \otimes (r\, \mathrm{C}_0(X_{n_0}, \mathcal{O}_2)r)) < 1/32$.

`The proof depends from above un-verified local uniqueness !!!`

□

13. Approximate locally liftable maps

Let $J \triangleleft A$ a closed ideal. We say that a completely contractive linear map $T : C \to A/J$ (e.g. $T = \mathrm{id}_{A/J}$) is *ε-approximately locally liftable* if for every finite-dimensional subspace $X \subseteq C$ there is a completely contractive linear map $S = S_{(T,X,\varepsilon)} : X \to A$ with $\|\pi_J \circ S - \eta_X\| \leq \varepsilon$. The map T is *approximately locally liftable* if T is ε-approximately locally liftable for all $\varepsilon > 0$. The map T is *locally liftable* if T is ε-approximately locally liftable for $\varepsilon = 0$.

Let $A \subseteq \mathcal{L}(\mathcal{H})$ and denote by F the hereditary C^*-subalgebra of $\mathcal{L}(\mathcal{H})$ that is generated by J. Then $A \cap F = J$, F is approximately injective (in the sense of [**238**]), and $A + F$ is C^*-algebra with the intersection properties $(F \otimes D) \cap (A \otimes D) = J \otimes D$ and $((A + F) \otimes D)/(F \otimes D) = (A \otimes D)/(A \otimes J)$ (because J contains an approximate unit of F). The approximation arguments in [**238**] show that on each separable C^*-subalgebra $C_1 \subseteq C$ there is a complete contraction $S : C_1 \to A + F$ with $\pi_F \circ S = T|C_1$ if $T : C \to A/J$ (and then $T : C \to (A + F)/F$) is approximately locally liftable.

In fact, it follows (by using arguments in [**238**]) that $T: C \to A/J$ is approximately locally liftable (into A), if and only if, $T: C \to (A+F)/F$ is locally liftable, if and only if, on every separable C^*-subalgebra $C_1 \subseteq C$ there is a completely contractive map $S_1: C_1 \to A+F$ with $\pi_F \circ S_1 = T|C_1$.

If we apply this to $T = \mathrm{id}_{A/J}$, then we get: $\mathrm{id}_{A/J}$ *is approximately locally liftable, if and only if,* $J \otimes D \to A \otimes D \to (A/J) \otimes D$ *is exact for every* C^**-algebra* D.

For exact A (and more generally for "locally reflexive" A in the sense of [**238**]) it is true that $W: A/J \to B$ is nuclear if $V = W \circ \pi_J$ is nuclear.
Indeed, more generally, one can check with help of the criteria (i) in Remark 3.1.2.

????? that the identity map $\mathrm{id}_{A/J}$ of A/J is *locally* liftable, in the sense that for every subspace $X \subset A/J$ of finite dimension and every $\varepsilon > 0$ there exists a completely $(1+\varepsilon)$-contractive map $T: X \to A$ with $\pi_J \circ T = \mathrm{id}_X$, then this is sufficient to prove the nuclearity of W if $W \circ \pi_J$ is nuclear on A:
This can be seen by an (elementary but unpleasant) approximation and extension argument, or by the following more conceptual argument.
If $\mathrm{id}_{A/J}$ is locally liftable, then (the reader can check that) `Give argument for proof!`

$$J \otimes D \to A \otimes D \to (A/J) \otimes D$$

is an exact sequence for each C^*-algebra D.

If A is locally reflexive, then this sequence is exact, – almost directly by the definition of (matricial) local reflexivity.

One can show that the local reflexivity of A is equivalent to the (metric) exactness of all sequences

$$L \otimes D \to A \otimes D \to (A/L) \otimes D$$

for all closed left-ideals $L \subseteq A$ and *all* C^*-algebras D.

`Give refs or arguments for proof of this!`

14. Reductions to separable subspaces (sep 1)

The following lemma on "reductions to the separable case" is used in some cases, where we need to apply a kind of "excision" methods. Such type of reductions can be managed by iterated application of the variant [**553**, prop. 7.2] by E. Michael of the Bartle-Graves theorem [**52**, thm. 4]. Our elementary "separable" selection of sequences does not involve the axiom of choice for sets of uncountable cardinalities (as all selections principles do implicitly!), but we use the Open Mapping Theorem that is an application of the (almost – but not really – "constructive") Baire category theorem.

Lemma B.14.1. *Let* B *denote a Banach space, and let* $X, Y \subset B$ *closed linear subspaces of* B*, such that the (algebraic) sum* $X + Y$ *is closed in* B*.*

Then for every separable linear subspace $G \subseteq B$ there exist a separable closed linear subspace D of B such that D has following properties:

(i) $G \subseteq D$,
(ii) $(D \cap X) + (D \cap Y) = D \cap (X + Y)$,
(iii) $\operatorname{dist}(d, V) = \operatorname{dist}(d, V \cap D)$ *for all* $d \in D$, *where* V *means each of the closed subspaces* $X + Y$, X, Y *and* $X \cap Y$ *of* B.

If B is a C-algebra, then a separable C*-subalgebra D of B with properties* (i)–(iii) *can be found.*

If B is an operator space, and $M_n(X)$ and $M_n(Y)$ are equipped with the induced matrix norms then a separable closed subspace D of B can be found such that D satisfies in addition the matrix versions (iii*) *of Part* (iii)*:*

(iii*) $\operatorname{dist}(d, M_n(V)) = \operatorname{dist}(d, M_n(V \cap D))$ *for all* $d \in M_n(D)$, $n \in \mathbb{N}$, *where* V *stands for each of the spaces* $X \cap Y$, X, Y *and* $X + Y$.

That the linear space $X+Y$ of B is closed in B is a necessary extra assumption because there exist closed linear subspaces X and Y e.g. of $\mathrm{C}[0,1]$ and of $\mathcal{L}_1[0,1]$ such that the algebraic sum $X + Y$ is not closed.

Give Refs. to counter examples !

The proof of Part (ii) uses the open mapping theorem.

We prove first a sub-lemma that describes an inductive selection procedure.

Sublemma B.14.2. *Let B a closed linear subspace of $\mathcal{L}(\mathcal{H})$ for some Hilbert space $\mathcal{H}$, and X, Y closed linear subspaces of B such that $X + Y$ is closed in B.*

Let $G \subseteq B$ a separable subset of B.

Then there are separable closed linear subspaces $G_1, G_2, \ldots$ of B that have the following properties:

(1) $G \subseteq G_n \subseteq G_{n+1}$ *for all* $n \in \mathbb{N}$
(2) $G_n \cap (X + Y)$ *is contained in the closure of the linear subspace* $(G_{n+1} \cap X) + (G_{n+1} \cap Y)$ *of* $G_{n+1} \cap (X + Y)$.
(3) $\|(\mathrm{id}_n \otimes \pi_{V \cap G_{n+1}})(b)\| \leq \|(\mathrm{id}_n \otimes \pi_V)(b)\|$ *for all* $b \in M_n(G_n)$, *where* V *stands for each of the four closed subspaces* X, Y, $Z := X + Y$ *and* $X \cap Y$ *of* B, *and* $\mathrm{id}_n \otimes \pi_V$ *denotes the quotient map* $M_n(B) \mapsto M_n(B)/M_n(V)$.

If B is a C-algebra, then separable C*-subalgebras G_n of B with properties* (1)–(3) *can be found for* $n = 1, 2, \ldots$.

Proof of Sublemma B.14.2. The Property (3) splits into the 4 cases where $V := X$, $V := Y$, $V := X + Y$ or $V := X \cap Y$. Each of (1), (2) and of the 4 cases of (3) can be considered separately for any given separable subspace $G_n \subseteq B$ (in place of any given separable $G \subseteq B$), i.e., we get six separable subspaces $G_{n+1,1}, G_{n+1,2}, G_{n+1,3}, \ldots, G_{n+1,6}$ of B that are as desired in steps (1),(2) and (3) independently. Then any separable subspace $G_{n+1} \subseteq B$ that contains the six subspaces $G_{n+1,k}$ $(k = 1, \ldots, 6)$ satisfies the conditions (1)–(3) with respect to the given G_n.

If, moreover, B is a C^*-algebra, then this shows that we can take as G_{n+1} any separable C^*-subalgebra of B that by the $G_{n+1,k}$ $(k = 1, \ldots, 6)$.

Therefore it suffices to find independently for given separable $G \subseteq B$ (e.g. for $G := G_n$ with before constructed $G_n \subseteq B$) and for each property (k), $k = 1, 2, 3$, and each part of (3) a "solution" $G_{n+1} \supseteq G_n$ with the in (1)–(3) listed properties.

Ad(1): It is an "input" condition: Given any separable subset G, e.g. $G := G_n \supseteq B$, then any separable subspace $G_{n+1,1}$ of B with $G \subseteq G_{n+1,1}$ satisfies (1).

Ad(2): Let G any closed separable linear subspace of B, (e.g. $G := G_n$ if G_n is constructed before). Then $G \cap (X + Y)$ is separable and closed. Take a dense sequence $z_1, z_2, \ldots \in G \cap (X + Y)$, and find $x_n \in X$ and $y_n \in Y$ with $z_n = x_n + y_n$. Let F any closed separable subspace of B that contains the closed linear span of the elements of G and of $\{x_1, y_1, x_2, y_2, \ldots\}$. Then $G \cap (X + Y)$ is contained in the *closure* of the linear subspace $(F \cap X) + (F \cap Y)$ of $F \cap (X + Y)$. And we can take $G_{n+1,2} := F$.

Ad(3): Recall that $\|(\mathrm{id}_n \otimes \pi_V)(b)\| = \mathrm{dist}(b, M_n(V))$ for all $b \in M_n(B)$.

Given any G (e.g. $G := G_n$, a before selected G_n) and let V one of the 4 listed spaces (resp. operator spaces) $X, Y, X + Y, X \cap Y$ in B. Take a sequence of matrices $g_1, g_2, \ldots$ that is dense in the unit ball of $M_n(G)$. For each $g_k \in M_n(G)$ we find $h_k \in M_n(V)$ such that

$$\|g_k - h_k\| \le (1 + 2^{-k}) \cdot \mathrm{dist}(g_k, M_n(V))\,.$$

We can take as $G_{n+1,k}$ $(k \in \{1, 2, 3, 4\}$ here depending on the considered $V)$ any separable closed linear subspace of B that contains all entries of the matrices $h_1, h_2, \ldots$, because it is not difficult to see that it has then the property that $\mathrm{dist}(g, M_n(G_{n+1,k} \cap V)) = \mathrm{dist}(g, M_n(V))$ for all $g \in M_n(G)$ ([3]).

If this is done for all $V \in \{X, Y, X + Y, X \cap Y\}$ then any separable closed linear subspace G_{n+1} of B that contains $G_{n+1,1} \cup \ldots \cup G_{n+1,4}$ has the property that, for all $g \in M(G)$ holds $\mathrm{dist}(g, M_n(G_{n+1}) \cap M_n(V)) = \mathrm{dist}(g, M_n(V))$ for the considered spaces $V \subseteq B$, □

Proof of Lemma B.14.1. If B is a Banach space B, and $X \subseteq B$ and $Y \subseteq B$ are closed linear subspaces, then we could consider B as a closed subspace of the C^*-algebra $\ell_\infty(M)$ for a set M of suitable cardinality. Thus it suffices to consider in the following always operator spaces, i.e., closed linear subspaces of a given closed linear subspace $B \subseteq \mathcal{L}(\mathcal{H})$.

Let G, $G_1, G_2, \ldots$ as in Sublemma B.14.2, define $G_\infty := \bigcup_n G_n$ and $D := \overline{G_\infty}$. Notice that Part (3) of Sublemma B.14.2 is equivalent to $\mathrm{dist}(b, M_n(V \cap G_{n+1})) = \mathrm{dist}(b, M_n(V))$ for all $b \in M_n(G_n)$. It implies $\mathrm{dist}(b, M_n(V \cap D)) = \mathrm{dist}(b, M_n(V))$

[3] Use here that for each contraction $g \in M_n(G)$ and $\varepsilon > 0$ there is an infinite subset R of $\mathbb{N}$ such that $\|g - g_k\| < \varepsilon$ for each $k \in R$.

for $b \in M_n(G_\infty)$ and each $n \in \mathbb{N}$. This carries over to all $b \in M_n(D)$ and $V \cap D$ in place of $V \cap G_\infty$, because $M_n(D)$ is the norm-closure of $M_n(G_\infty)$. It implies that for every $n \in \mathbb{N}$ and $V \subseteq B$ ($V \in \{X + Y, X, Y, X \cap Y\}$) holds that the natural injective linear map $\mathrm{id}_n \otimes \pi_V$ from $M_n(D)/M_n(D \cap V)$ into $B/M_n(V)$ of norm ≤ 1 is a complete isometry, as one can see from the formula

$$\mathrm{dist}(b, M_n(D \cap V)) \leq \mathrm{dist}(b, M_n(V)) \quad \text{for all } b \in M_n(D) .$$

It turns out that D is a closed linear subspace of B that satisfies all conditions (i), (ii) and (iii*) in Lemma B.14.1:

Clearly condition (i) follow from $G \subseteq G_1$.

If, in addition, B is a C^*-algebra, then the G_n in Conditions (1)–(3) of Sublemma B.14.2 can be chosen as C^*-subalgebras of B. I.e. we can then suppose that all G_n ($n = 1, 2, \ldots$) are C^*-algebras, that $G_\infty := \bigcup_n G_n$ is a *-subalgebra of B, and that $D := \overline{G_\infty}$ is a separable C^*-subalgebra of B.

The condition (iii) follows from the Property (3) of Sublemma B.14.2 for the operator system D. The isomorphisms $M_k \cong pM_np$ for all projections $p \in M_n$ with rank $= k < n$, shows that the operator space $D := \overline{\bigcup_n G_n}$ satisfies

$$\mathrm{dist}(d, M_n(V \cap D)) = \mathrm{dist}(d, M_n(V)) \quad \text{for all } d \in M_n(D),$$

for each $V \in \{X + Y,\, X,\, Y,\, X \cap Y\}$ and every $n \in \mathbb{N}$, because this is true for all $d \in G_k$ with $k > n$, by Part (3) of Sublemma B.14.2.

Clearly the sum $(D\cap X)+(D\cap Y)$ is contained in $D\cap(X+Y)$, because $D\cap X$ and $D \cap Y$ are closed subspaces of the closed subspace $D \cap (X + Y)$ of B.

We show that the linear space $(D \cap X) + (D \cap Y)$ is *dense* in $D \cap (X + Y)$:

Property (2) of Sublemma B.14.2 with $V := X + Y$ and the there constructed $G_n \subseteq G_{n+1} \subseteq \cdots$ satisfy

$$G_n \cap (X + Y) \subseteq \overline{(G_{n+1} \cap X) + (G_{n+1} \cap Y)} \subseteq \overline{(D \cap X) + (D \cap Y)} .$$

It implies that

$$(\bigcup_n G_n) \cap (X + Y) \subseteq \overline{(D \cap X) + (D \cap Y)} \subseteq D \cap (X + Y) .$$

Thus, $(D \cap X) + (D \cap Y)$ is dense in $D \cap (X + Y)$ if $(\bigcup_n G_n) \cap (X + Y)$ is dense in $D \cap (X + Y)$.

To show the latter, let $V := X + Y$ and $y \in D \cap V$, Then $y \in D$, $\pi_V(y) = 0$ and, by density of $\bigcup_n G_n$ in D, there exist a sequence $n_k \in \mathbb{N}$ with $n_k < n_{k+1}$ and elements $d_k \in G_{n_k}$ such that $y = \lim_k d_k$ and $\lim_k \pi_V(d_k) = 0$.

Recall that any closed subspace V of B holds $(\mathrm{id}_n \otimes \pi_V)(p_{11} \otimes b) = p_{11} \otimes \pi_V(b)$ for $b \in B$ for the quotient map $\pi_V \colon B \to B/V$ from B, i.e.,

$$\mathrm{dist}(b, V) = \|\pi_V(b)\| = \|(\mathrm{id}_n \otimes \pi_V)(p_{11} \otimes b)\| .$$

Thus, if we take $n := n_k$ in Part (3) of Sublemma B.14.2, then we obtain that $\|\pi_{G_{1+n_k} \cap V}(d_k)\| \leq \|\pi_V(d_k)\|$ for $d_k \in G_{n_k}$. It follows that there exists $e_k \in$

$G_{1+n_k} \cap V$ with $\|e_k - d_k\| \leq \|\pi_V(d_k)\|$. Hence $\lim_k \|e_k - d_k\| = 0$ and $\lim_k \|e_k - y\| = 0$, i.e., $y \in \overline{\bigcup_n (G_n \cap V)}$.

It says that $\bigcup_n (G_n \cap V)$ is dense in $D \cap V$ and implies that the subspace $(D \cap X) + (D \cap Y)$ is *dense* in $D \cap (X + Y) = D \cap V$.

Next we show that the dense linear subspace $(D \cap X) + (D \cap Y)$ of $D \cap (X+Y)$ is closed in $D \cap (X+Y)$. This shows then the predicted equality $(D \cap X) + (D \cap Y) = D \cap (X + Y)$ in Part(ii), and finishes the proof.

From now on let $V := X \cap Y \subseteq B$.

By Part (3) of Sublemma B.14.2 we have that $\mathrm{dist}(g, G_{n+1} \cap V) \leq \mathrm{dist}(g, V)$ for $g \in G_n$. Thus, $\mathrm{dist}(g, D \cap V) = \mathrm{dist}(g, V)$ for all $g \in G_\infty$. Since G_∞ is dense in D it follows that the restriction to D of the quotient map $\pi_V : b \in B \to b + V \in B/V$ defines an linear *isometry* η from the quotient space $D/(D \cap V)$ into B/V with kernel $D \cap V = D \cap X \cap Y$. In particular, $\eta | (D \cap X)/(D \cap V)$ and $\eta | (D \cap Y)/(D \cap V)$ are isometries into the subspaces X/V respectively Y/V of $(X + Y)/V$. We denote this restrictions of η by η_1 and η_2.

Recall that the space $D \cap V$ is a closed subspace of each of the closed subspaces $D \cap X$, $D \cap Y$ and $\overline{(D \cap X) + (D \cap Y)} = D \cap (X + Y)$. Thus, if the linear space $\eta(D \cap X) + \eta(D \cap Y)$ is closed in $(X + Y)/V$ then $(D \cap X) + (D \cap Y)$ is closed in $D \cap (X + Y)$, because

$$(D \cap X) + (D \cap Y) = \eta^{-1}(\eta(D \cap X) + \eta(D \cap Y)) \,.$$

This implies finally the predicted equation $(D \cap X) + (D \cap Y) = D \cap (X + Y)$.

The natural linear map T from the Banach space $X/V \oplus_\infty Y/V$ with norms $\|(x + V, y + V)\| := \max\big(\|\pi_V(x)\|, \|\pi_V(y)\| \big)$ onto $(X + Y)/V$ that is given by

$$T(x + V, y + V) := (x + y) + V$$

is surjective and has norm ≤ 2. The T is also injective because $x + y = v \in V$ implies that $x = v - y \in X \cap Y = V$, thus $x, y \in V$. The Open Mapping Theorem shows that the inverse $T^{-1} : (X+Y)/V \to X/V \oplus_\infty Y/V$ of the linear isomorphism T is bounded. In particular, T maps each closed subspace of $X/V \oplus_1 Y/V$ onto a closed subset of $(X + Y)/V$.

The map $\eta_1 \oplus \eta_2$ from $(D \cap X)/(D \cap V) \oplus_\infty (D \cap Y)/(D \cap V)$ into $X/V \oplus_\infty Y/V$ is an isometry. Thus, its image is a closed subspace of $X/V \oplus_1 Y/V$. It follows that T maps this image onto a closed subspace of $(X + Y)/V$. Calculation shows that $T \circ (\eta_1 \oplus \eta_2)$ maps $(D \cap X)/(D \cap V) \oplus_\infty (D \cap Y)/(D \cap V)$ onto $\eta(D \cap X) + \eta(D \cap Y)$. Thus, $\eta(D \cap X) + \eta(D \cap Y)$ is closed in $(X + Y)/V$. □

15. Passage to separable subalgebras (sep 2)

We define for $a, b \in A$ and $\varepsilon > 0$ minimal numbers $n := n(b, a, \varepsilon)$ with the property that there exist $c_1, \ldots, c_n, d_1, \ldots, d_n \in A$ with $\delta := \|b - \sum_k d_k^* a c_k\| < \varepsilon$.

The latter inequality implies by Lemma 2.1.9 that there exists a rational number ρ and $\ell \in \mathbb{N}$ with $\delta < \rho < \varepsilon$ such that there exist $c_1, \ldots, c_n \in A$ with $(b-\rho)_+ = \sum_k c_k^* a c_k$ if $a, b \in A_+$.

`New more precise text:`

We define numbers $n(b, a, \varepsilon; B)$ and $\gamma(b, a, \varepsilon; B) \geq n(b, a, \varepsilon; B)$ (the latter only in case $a, b \in B_+$ and $\|a\| = \|b\| = 1$) for C^*-subalgebras B of A and non-zero $a, b \in B$ with b in the closed ideal $J(a)$ of B generated by a, by letting $n := n(b, a, \varepsilon; B)$ the minimal number $n \in \mathbb{N}$ such that there exist $c_1, \ldots, c_n, d_1, \ldots d_n \in B$ with $\|b - \sum_{j=1}^n d_j^* a c_j\| < \varepsilon$. We can here take $d_j = c_j$ if $a, b \in B_+$, cf. Remark B.15.1. Moreover $n(b, a, \varepsilon) = n((b^*b)^{1/2}, (a^*a)^{1/2}, \varepsilon)$.

The number $\nu := \nu(b, a; \varepsilon)$ for $a, b \in B_+$ is the smallest number $\nu \in \mathbb{N}$ with the property that there exists *contractions* $c_1, \ldots, c_\nu \in B$ such that $\|b - \sum_{j=1}^n d_j^* a c_j\| < \varepsilon$.

`What about definition of above defined` γ`?`

Equivalently: There exists $X, Y \in M_n(B)$ with $\|b \otimes p_{11} - Y^*(a \otimes 1_n)X\| < \varepsilon$. This is because we can replace here $X, Y \in M_n(B)$ by the columns $[c_1, \ldots, c_n]^\top := X \cdot (1 \otimes p_{11})$ and $[d_1, \ldots, d_n]^\top := Y \cdot (1 \otimes p_{11})$ and vice versa. Here 1 denotes the unit element of the multiplier algebra of $\mathcal{M}(A)$.

Remark B.15.1. If $a, b \in B_+$ and there exists by $c_1, \ldots, c_n, d_1, \ldots, d_n \in A$ with $\|b - \sum_j d_j^* a c_j\| < \varepsilon$ then there exists $f \in A$ such that $e_j := (c_j + d_j)f$ satisfies $\|b - \sum_j e_j^* a e_j\| < \varepsilon$.

Indeed, if $a, b \in B_+$ then we can use that for the positive elements $g := b \otimes p_{11}$ and $h := a \otimes 1_n$ holds also $\|2g - (Y^*hX + X^*hY)\| < 2\varepsilon$. It implies that there exists $\delta \in (0, \varepsilon)$ such that $0 \leq 2g \leq (Y^*hX + X^*hY) + 2\delta(1 \otimes 1_n)$.

Clearly, by $X^*hY = 0$, $(Y^*hX + X^*hY) + (X^*hX + Y^*hY) = (X+Y)^*h(X+Y)$, which gives that $0 \leq g \leq T^*hT + \delta \cdot (1 \otimes n)$ for $T := \sqrt{2}(X+Y) \in M_n(A)$. By Lemma 2.1.9, there exists a contraction $d \in M_n(A)_+$ with $d^*(T^*hT)d = (g - (\varepsilon+\delta)/2)_+$. In particular, $\|g - Z^*hZ\| < \varepsilon$ for $Z := Td$.

Thus, with $[e_1, \ldots, e_n]^\top := Z(1 \otimes p_{11})$ we get $\|b - \sum_{j=1}^n e_j^* a e_j\| < \varepsilon$.

`Important are Parts (iii) and (iv)`

Proposition B.15.2. *For every C^*-algebra A and every separable subset $X \subset A$ of A there exists a separable C^*-subalgebra B of A with $X \subset B$ such that B has the following additional properties:*

(i) *The natural C^*-morphism $C \otimes^{\max} B \to C \otimes^{\max} A$ is injective for all separable C^*-algebras C (i.e., B is "relative weakly injective" in A),*
(Are properties (i) and (iii) equivalent ?)

(ii) *The natural maps $(C \otimes^{\min} B)/(Y \otimes^{\min} B) \mapsto (C \otimes^{\min} A)/(Y \otimes^{\min} A)$ are isometric for all separable C^*-algebras C and closed subspaces Y of C.*
??? Or better ?:
Require metric version of the "intersection property":

$(Y \otimes^{\min} A) \cap (C \otimes^{\min} B) = Y \otimes^{\min} B$.

Let $Z_1 \subseteq Z_2$ and $Z_3 \subseteq Z_2$ operator spaces (closed linear subspaces of $\mathcal{L}(\ell_2)$).

What has to be required on this spaces?

that the natural map from $Z_1/(Z_1 \cap Z_3)$ to Z_2/Z_3 is completely isometric ???

(iii) *For each $k \in \mathbb{N}$, $a, b \in M_k(B)_+$ and $\delta > 0$ holds that for every $c_1, \ldots, c_n \in M_k(A)$ there exists $d_1, \ldots, d_n \in M_k(B)$ with $\|d_j\| \leq \|c_j\|$ for $j = 1, \ldots, n$ and*

$$\|b - \sum_k d_k^* a d_k\| \leq \delta + \|b - \sum_k c_k^* a c_k\| .$$

(iv) *For every $a, b \in B$ and $\varepsilon > 0$, $n(b, a, \varepsilon; B) = n(b, a, \varepsilon; A)$ and $\gamma(b, a, \varepsilon; B) = \gamma(b, a, \varepsilon; A)$ if $a, b \in B_+$ and $\|a\| = \|b\| = 1$.*

(Where $n(\ldots)$ and $\gamma(\ldots)$ are defined ?)

(v) *$(B \cap I_1) + (B \cap I_2) = B \cap (I_1 + I_2)$ for any closed ideals I_1 and I_2 of A.*

??? ($\supseteq$ is in question!!! and by out-devision of $I_1 \cap I_2$ we can suppose that $l_1 \cdot I_2 = \{0\}$. But the question is if one finds separable B_m that satisfies at least one of the properties and this B_m are contained in the B_n with $n > m$ ... then the inductive limits gives this "all properties" B ...)

In particular, every closed ideal J of B is the intersection $J = B \cap I$ of a closed ideal I of A with B.

PROOF. `To be filled in ??`

??? Reduce (v) to σ-unital A with approximate unit in B and $A = I_1 + I_2$ generated as ideals by $B \cap (I_1 + I_2)$. ???

$B \subseteq A \subseteq A^{**}$ leads to $B^{**} \subseteq A^{**}$ in the sense that B^{**} is naturally isomorphic to the $\sigma(A^{**}, A^*)$-closure of $B \subseteq A^{**}$ in A^{**}.

It seems that B is "relative weakly injective" in A, if and only if there exists a c.p. contraction P from A into B^{**}

(A positive contraction would be enough, because its restriction can be normalised to a completely positive contraction S from A^{**} into $B^{**} \subseteq A^{**}$ with the property that $S(b) = b$ for all $b \in B \subseteq A^{**}$.

Since one can do this with $B \otimes M_n \subseteq A \otimes M_n$, one can obtain by cluster-point arguments that there is a completely positive contraction T from A into $B^{**} \subseteq A^{**}$ with the property that $T(b) = b$ for all $b \in B$.

□

16. Reductions to separable cases (sep 3)

An important technical property in the study of residually nuclear maps between non-simple C^*-algebras is the notion of local reflexivity for closed subspaces $B \subseteq \mathcal{L}(\mathcal{H})$ introduced by Effros and Haagerup in [**238**]:

DEFINITION B.16.1. A closed subspace $B \subseteq \mathcal{L}(\mathcal{H})$ (i.e., an operator space with its system of matrix norms) is **locally reflexive** if, for every finite-dimensional subspaces $X \subseteq B^{**}$, $F \subseteq B^*$, and $\varepsilon > 0$ there is a linear map $T\colon X \to B$ that satisfies the following properties (i) and (ii):

(i) $|f(T(x)) - x(f)\| \leq \varepsilon \|x\| \cdot \|f\|$ for all $x \in X$, $f \in F$, and
(ii) T is completely contractive, i.e., $\|T \otimes \mathrm{id}_n\| \leq 1$ for all $n \in \mathbb{N}$ for the maps $T \otimes \mathrm{id}_n\colon X \otimes M_n \to B \otimes M_n$ with norms on $X \otimes M_n$ induced from $B^{**} \otimes M_n \subseteq \mathcal{L}(\mathcal{H} \otimes \mathbb{C}^n)^{**}$.

REMARK B.16.2. One can find for each $n \in \mathbb{N}$ a linear map $T\colon X \to B$ that satisfies property (i) and $\|T \otimes \mathrm{id}_n\| \leq 1$ by the local reflexivity of the *Banach* spaces $B \otimes M_n$, but in general such T does not exist that it satisfies also $\|T \otimes \mathrm{id}_{n+k}\| \leq 1$ for $k \in \mathbb{N}$.

Does it say that there could exist $X_k \subseteq B^{**}$ and $Y_k \subseteq B^*$ of finite dimension such that,
for all $T_k \in L(X_k, B)$ with (i) holds that
$\lim_{k \to \infty} \|T_k \otimes \mathrm{id}_k\| = \infty$?

All exact C^*-algebras (or, more generally, 1-exact operator spaces) are locally reflexive. It is not known if locally reflexive C^*-algebras are exact in general.

Local reflexivity passes to C^*-quotients and C^*-subalgebras (in particular, $\prod_n M_n$ is *not* locally reflexive, because it contains $C^*(F_\infty)$ as a C^*-subalgebra).

The class of locally reflexive C^*-algebras A is invariant under tensor products with $\mathbb{K}$ and M_n.

But it is so far unknown if tensor products of locally reflexive A with M_{2^∞} (and – therefore – also min-tensor products with arbitrary exact C^*-algebras) again become locally reflexive. It is also not known if the class of locally reflexive C^*-algebras are invariant under inductive limits (at least for suitably “controlled” nets of C^*-morphisms?).

Local reflexivity is *not* preserved under passage to stable coronas, asymptotic coronas, multiplier algebras, and ultra-powers of A if A is not sub-homogenous (i.e., if A has only irreducible representations of dimension $\leq n$ for some $n \in \mathbb{N}$).

Indeed, it is not difficult to see that stable coronas, asymptotic coronas, multiplier algebras, and ultra-powers of A are sub-Stonean C^*-algebras. Recall that sub-Stonean C^*-algebras C have the property that for orthogonal positive contractions $a, b \in C_+$ there are orthogonal positive contractions $c, d \in C_+$ with $ca = a$ and $db = b$.

Sub-Stonean C^*-algebras C have the property that $B_1(\ell_\infty) = V(B_1(C))$ for every c.p. contraction $V\colon C \to \ell_\infty$ with $V(B_1(C)) \cap c_0$ dense in $B_1(c_0)$ (where $B_1(X)$ means the closed unit ball of a Banach space X).

If a C^*-algebra C with the latter property contains a C^*-subalgebra D, that has $\bigoplus_n M_n$ as a quotient, then C contains a C^*-subalgebra E, such that E has a quotient that is isomorphic to $\prod_n M_n = \ell_\infty(\mathbb{C}, M_2, M_3, \ldots)$.

The following more general property of a C^*-algebra C, stated as follows, is equivalent to the property that C has no non-zero closed ideal of type-I:

For every non-zero positive $e \in C_+$ in the C^*-algebra C, the σ-unital hereditary C^*-subalgebra $\overline{eCe}$ contains a C^*-subalgebra $D \subseteq \overline{eCe}$ such that $\prod_n M_n = c_0(\mathbb{C}, M_2, M_3, \ldots)$ is a quotient of the C^*-algebra D.

A non-zero C^*-algebra C is sub-homogenous, i.e., there exists $n_C \in \mathbb{N}$ such that all irreducible representations of C have dimension $\leq n_C$, if and only if, there does not exist a C^*-subalgebra $D \subseteq C$ with the property that $\prod_n M_n$ is a quotient C^*-algebra of D. (For a proof of this criteria it suffices to consider only the type-I algebras by Glimm's sub-quotient theorem, saying that each separable non-type-I C^*-algebra C contains a hereditary C^*-subalgebra D such that $C = D \cdot C + C \cdot D + \mathcal{N}(D, C)$ and $\mathcal{N}(D, C)/D \cong M_{2^\infty}$).

The *full* group C^*-algebras $C^*(G)$ of a lattices G in non-compact semi-simple Lie groups are not exact (and even not locally reflexive) because they all contain a copy of $C^*(F_2)$ and every separable unital C^*-algebra is a quotient of its subalgebra $C^*(F_\infty)$.

The reduced group C^*-algebras $C^*_{red}(G)$ are all exact for G in this class of discrete groups.

REMARK B.16.3. Suppose that $A \subseteq M$ is a C^*-subalgebra of a W*-algebra M. Then centre of the *-ultra-strong closure of A in M contains a family of mutually orthogonal projections $\{p_\kappa\}$ such that $Q := 1 - \sum_\kappa p_\kappa$ satisfies $QA = AQ = \{0\}$, and that each p_κ can be decomposed in M into a sum of a family mutually orthogonal countably decomposable projections in M of cardinality $\leq$ density of A.

(It suffices to consider the case where $M = A^{**}$.)

What was the original remark ??? Good for? ??

QUESTIONS B.16.4. Given a semi-finite properly infinite W*-algebra M and a separable C^*-subalgebra $A \subseteq M$.

Does there exist a family of mutually orthogonal countably decomposable projections $p_\gamma \in A' \cap M$ with $\sum p_\gamma = 1$ such that following properties (i)–(iii) are satisfied?

(i) p_γ is properly infinite,
(ii) for every weakly l.s.c. trace $\tau \colon N_+ \to [0, \infty]$ (on the positive part of $N := \{p_\gamma\, ;\ \gamma \in \Gamma\}' \cap M$) there is a weakly l.s.c. trace $\tau' \colon M_+ \to [0, \infty]$ with $\tau | A_+ = \tau' | A_+$,
(iii) for every projection p in the centre of N there is a projection q in the centre of M with $\|ap\| = \|aq\|$ for all $a \in A$.

Does there exist a separable unital C^*-subalgebra $A \subseteq C \subseteq M$ (with M a W*-algebra) such that following properties (i)–(iv,v????) are satisfied

(i) $\mathcal{O}_2$ is unitally contained in C, $\delta_\infty(C) \subseteq C$ and $\delta_\infty \oplus \mathrm{id}$ unitarily equivalent to δ_∞ by unitaries in C (for the weakly continuous $\delta_\infty \colon M \to M$).
(ii) Every closed ideal I of C is the intersection of a closed ideal of M with C.
(iii) For every projection p in the centre of M there is q in the centre of C with $\|ap\| = \|aq\|$ for all $a \in A$.
(iv) $C \cap K$ is an essential ideal of C.
(v) $C \cap K$ is stable (????????).

```
    local lifting, local lifting property,
locally liftable exact sequences
    weakly injective algebras,
relatively weakly injective subalg.,
approximately injective algebras
```

Recall that $A \otimes B$ denotes the *minimal* C^*-algebra tensor product of A and B.

LEMMA B.16.5. *Let A and B C^*-algebras, where A is separable and B is σ-unital.*

(i) *If X is a separable Banach space, $\mathcal{C} \subseteq \mathcal{L}(X, B)$ a point-norm closed set of contractions, J a σ-unital closed ideal of B. If for all $S, T \in \mathcal{C}$ and for every contraction $a \in J_+$, the element*

$$aS(\cdot)a + (1 - a^2)^{1/2}T(\cdot)(1 - a^2)^{1/2}$$

is again in $\mathcal{C}$, then $\pi_J \circ \mathcal{C}$ is point norm closed in $\mathcal{L}(X, B/J)$.
(ii) *A c.p. map $V \colon A \to B/J$ is locally c.p. liftable (or c.b. liftable ???) if*

$$J \otimes \mathcal{L}(\ell_2) \to B \otimes \mathcal{L}(\ell_2) \to (B/J) \otimes \mathcal{L}(\ell_2)$$

is exact. If, moreover ?????. See Effros –Haagerup.
(iii) *B is locally reflexive, if and only if,*

$$J_\tau \otimes \mathcal{L}(\ell_2) \to B_\tau \otimes \mathcal{L}(\ell_2) \to B^{**} \otimes \mathcal{L}(\ell_2)$$

is exact, if and only if, the natural C^*-morphism form $B^{**} \otimes^{\max} \mathcal{L}(\ell_2)$ into $(B \otimes \mathcal{L}(\ell_2))^{**}$ factorizes over $B^{**} \otimes^{\min} \mathcal{L}(\ell_2)$.
(iv) *More ??????????????*

PROOF. (i): We use metrics on $\mathcal{L}(X, B)$ and $\mathcal{L}(X, B/J)$ that define the point-norm topologies: Let $x_1, x_2, \ldots \in X$ a sequence that dense in the unit-ball of X. Then let $\rho_0(T, S) := \sum_n 2^{-n}\|T(x_n) - S(x_n)\|$ and similarly defined ρ_1 on $\mathcal{L}(X, B/J)$. Obviously $\rho_1(\pi_J \circ T, \pi_J \circ S) \le \rho_0(T, S)$ and $\rho_0(T, S) \le \|T - S\|$.

Moreover, if $E := \{e_\tau\} \subset J_+$ is a with respect to the separable C^*-subalgebra $C^*(T(X) \cup S(X)) \subseteq B$ quasi-central approximate unit, then $\rho_1(\pi_J \circ T, \pi_J \circ S)$ is equal to

$$\inf\{\, \rho_0\big((1-e_\tau)^{1/2}T(\cdot)(1-e_\tau)^{1/2}, (1-e_\tau)^{1/2}S(\cdot)(1-e_\tau)^{1/2}\big)\ ;\ e_\tau \in F\,\}\,.$$

Let $\mathcal{C} \ni T_n \colon X \to B$ such that $\pi_J \circ T_n$ converges in point-wise to some map $S \colon X \to B/J$.

Can select $n_k \in \mathbb{N}$ that $\rho_1(\pi_J \circ T_{n_k}, \pi_J \circ T_{n_k}) < 4^{-k}$. Then we define a new sequence $R_k \in \mathcal{L}(X, B)$ with the property that $\rho_0(R_k, R_{k+1}) < 2^{-k}$ with help step by step modification by replacing the $T_{n_{k+1}}$ by

$$R_{k+1} := (1-f_k)^{1/2} T_{n_{k+1}}(\cdot)(1-f_k)^{1/2} + f_k^{1/2} R_k(\cdot) f_k^{1/2}$$

with suitably chosen $f_k \in F \subseteq J_+$. It follows that the $R_k \in \mathcal{C}$ converge in point-norm on X to a map $R \in \mathcal{C}$ with $\pi_J(R) = S$.

To be filled in ??

□

17. Singly generated separable C^*-algebras (sep. 4)

Lemma B.17.1. *Let E denote a unital C^*-algebra with properly infinite unit and $s_1, s_2 \in E$ isometries with orthogonal ranges: $s_j^* s_k = \delta_{j,k} 1$, and let $e \in E_+$ denote a positive contraction.*

Then the singly generated C^*-subalgebra $C^*(X) = C^*(X^*, X)$ of E generated by the element

$$X := X(s_1, s_2, e) := s_1 \cdot \big(1 + s_1(2+e)^{-1}s_2^* + s_2(2+e)^{-1}s_1^*\big)$$

is identical with the C^*-subalgebra $C^*(s_1, s_2, e) \subseteq E$ generated by the elements $\{s_1, s_2, e\} \subseteq E$.

Proof. Obviously $X(s_1, s_2, e) \in C^*(s_1, s_2, e) \subseteq E$ by definition of X and $C^*(s_1, s_2, e) = C^*(s_1, s_2, a)$ for $a := (2+e)^{-1}$ by $e = a^{-1} - 2$.

Recall that $s_1, s_2 \in A$, $s_j^* s_k = 1_A$ and that $a := (2+e)^{-1} \in A_+$ is invertible with estimates $1/3 \leq a \leq 1/2$.

We define $Y := s_1(1 + s_1 a s_2^* + s_2 a s_1^*)$. Consider $f := s_1 a s_2^* + s_2 a s_1^*$. Then $f^* = f$, $f s_1 = s_2 a$ and $f^2 = s_1 a^2 s_1^* + s_2 a^2 s_2^*$. Thus $\|f\| \leq 1/2$, and it follows that $1/2 \leq h := 1 + f \leq 3/2$.

This element h allows to rewrite the above defined Y as $X = s_1 h$.

We show that the C^*-subalgebra $C^*(X) = C^*(X^*, X)$ of A generated by X contains s_1, s_2 and a, i.e., that $C^*(X) = C^*(s_1, s_2, a)$. Then $1 \in C^*(X)$ and $e = a^{-1} - 2 \in C^*(X)$, i.e., $C^*(X) = C^*(s_1, s_2, e)$.

The above discussion allows to see the following formulas: $X^*X = h^2 \geq 1/4$, $s_1 = X(X^*X)^{-1/2} = Xh^{-1} \in C^*(X)$, $1 = s_1^* s_1$, $f = h - 1 = (X^*X)^{1/2} - 1$ and $f s_1 = s_2 a$. Thus, $s_1, f, 1 \in C^*(X)$ and $a^2 = a s_2^* s_2 a = s_1^* f^2 s_1$. Since, by assumptions, $a \geq 1/3$ we get that $a, a^{-1}, e = a^{-1} - 2 \in C^*(X)$, and finally that $s_2 = f s_1 a^{-1} \in C^*(X)$. □

Compare next Proposition with [**770**, thm.2.3] and the Remark B.17.3 concerning other attempts to prove Proposition B.17.2.

PROPOSITION B.17.2. *If E is a separable C^*-algebra with a properly infinite unit element, then there exists a unital C^*-morphism $\psi\colon \mathcal{O}_\infty \to E$ and E is singly generated as C^*-algebra.*

PROOF. Let $s_1, s_2 \in E$ isometries with $s_1^* s_2 = 0$. Then let $t_k := s_1^k s_2$ for $k = 1, 2, \ldots$. The elements $t_k \in E$ satisfy that $t_j^* t_k = \delta_{j,k} 1_E$ for $j, k \in \mathbb{N}$, i.e., the $t_1, t_2, t_3, \ldots$ define a unital C^*-morphism from $\mathcal{O}_\infty$ into E.

By separability of E, there exists a norm-dense sequence $a_1, a_2, \ldots$ in the positive contractions in E. The positive contraction

$$e := \sum_{k=1}^{\infty} s_k (2^k + a_k)^{-1} s_k^* \in E_+$$

has the property that the C^*-subalgebra $C^*(t_1, t_2, e)$ of E generated by $\{t_1, t_2, e\}$ is identical with E, because $s_k, 1_E \in C^*(t_1, t_2)$ for all $k \in \mathbb{N}$ and $(2^k + a_k)^{-1} = s_k^* e s_k$ gives that $a_k = (s_k^* e s_k)^{-1} - 2^k 1_E$ is in $C^*(t_1, t_2, e)$.

Thus, E is singly generated by the element $X(t_1, t_2, e) \in E$ defined in Lemma B.17.1. □

REMARK B.17.3. The authors H. Thiel and W. Winter of [**770**, thm.2.3] quote Nagisa [**567**] who had referenced the result [**770**, thm.2.3] (and thus Proposition B.17.2) to the author (E.K.) of this book. Probably M. Nagisa was informed that the author wrote in some evening discussion (or in a break between talks) sometimes in the 1990th in MF Oberwolfach a formula on the blackboard in the discussion room that did show that every properly infinite unital ([4]) separable C^*-algebra is singly generated. It could be that this proof was different from the here given proof of Proposition B.17.2, but it was definitely different from all of the (incomplete) proof of [**770**, thm.2.3]. Thus, unfortunatly we couldn't use it as citation here, had to give our own proof. H. Thiel and W. Winter quote for the proof of [**770**, thm.2.3] an argument in the proof of [**580**, thm. 9]. But this quoted argument does not carry over to an element $Y := \sum_{k\geq 1}(s_k a_k s_k^* + 1/2^k s_k)$ with spectrum of $a_k = a_k^*$ in $[4^{-n}/2, 4^{-n}]$ as considered in their proof, because they claim – and need/use it (!) in their proof –

`Check next red text carefully again!!!`

`Perhaps, the constructions give two self-adjoint elements that generates all?`

... that the spectrum of Y is contained in $\{0\} \cup \bigcup_{k=1}^{\infty} [4^{-n}/2, 4^{-n}]$. But this is not the case in general, e.g. consider the there given formula in case where $A := \mathcal{O}_\infty$

[4]It is the case if and only if the algebra contains a copy of $\mathcal{O}_\infty$ unitally!

with generating isometries $s_1, s_2, \ldots$ satisfying $s_j^* s_k = \delta_{j,k}$ the spectrum of the element $\sum_k 4^{-k} s_k s_k^* + 2^{-k} s_k$ is exactly equal to $\{0\} \cup \bigcup_{k\geq 1}(4^{-k} + 2^{-k} D)$, where D is the unit-disc, in particular the spectrum is not contained in $\{0\} \cup \bigcup_{k\geq 1}[4^{-k}/2, 4^{-k}]$. Unfortunately this gap in the arguments for the proof of [**770**, thm.2.3] given by H. Thiel and W. Winter harms then any further argument of their proof.

Further details concerning sums of invertible positive elements and non-unitary isometries $s_1, s_2, \ldots \in E$ with $s_j^* s_k = \delta_{j,k}$:
Let us consider elements $X \in E$ defined by

$$X := \sum_{k\geq 1} (s_k a_k s_k^* + \gamma_k s_k)\,,$$

where the a_k are positive with $\mathrm{Spec}(a_k) \subseteq [\alpha_k, \beta_k]$ for "suitable" $0 < \beta_{k+1} < \alpha_k < \beta_k$. One can show that the spectrum of such element X is contained $\{0\} \cup \bigcup_{k\geq 1}([\alpha_k, \beta_k] + \gamma_k D)$ where $D := \{z \in \mathbb{C};\ |z| \leq 1\}$ is the unit disc.

Below we give a more precise formula for $\mathrm{Spec}(X)$ that allows to deduce that our, in Remark B.17.3 mentioned, special example $Y := \sum_{n=1}^{\infty} 4^{-n} s_n s_n + 2^{-n} s_n$ in $\mathcal{O}_\infty$ it is precisely equal to $\{0\} \cup \bigcup_n (4^{-n} + 2^{-n} D)$.

Let $P_n := \sum_{k=1}^{n} s_k s_k^*$ and consider stepwise the "triangular" decompositions of X as

$$X = P_n X P_n + (1 - P_n) X (1 - P_n) + P_n X (1 - P_n)\,.$$

It allows to identify X with an upper triangular matrix in $M_2(E)$ with entries $X_{11} = P_n X P_n$, $X_{12} = P_n X(1 - P_n)$ and $X_{22} = (1 - P_n) X (1 - P_n)$. This is possible, because all X of the above defined type satisfy $(1 - P_n) X P_n = 0$ for this projections P_n. It implies that

$$\{0\} \cup \mathrm{Spec}(X) = \{0\} \cup \mathrm{Spec}(P_n X P_n) \cup \mathrm{Spec}((1 - P_n) X (1 - P_n))\,.$$

If we proceed with $n \in \mathbb{N}$ by induction then we can see that this leads to

$$\mathrm{Spec}(X) \cup \{0\} = \{0\} \cup \bigcup_{k=1}^{\infty} \mathrm{Spec}(a_k + \gamma_k s_k)\,.$$

Here we have used that $(s_k a_k s_k^* + \gamma_k s_k) s_k s_k^* = s_k (a_k + \gamma_k s_k) s_k^*$. Using that $\mathrm{Spec}(S) = D$ for every non-unitary isometry $S \in E$, this leads to the estimate $\mathrm{Spec}(a_k + \gamma_k s_k) \subseteq \{0\} \cup (\mathrm{Spec}(a_k) + \gamma_k D)$.

In the special case where X is build with scalars $a_k = \beta_k \cdot 1_E$, and $\lim_k \beta_k = 0$ and $\lim_k \gamma_k = 0$ it gives the precise equation

$$\mathrm{Spec}(X) \;=\; \{0\} \cup \bigcup_k (\beta_k + \gamma_k D)\,.$$

This applies in particular to the above defined special element $Y \in \mathcal{O}_\infty$.

An other special case is the case where $\lambda := \sum_k \gamma_k^2 < \infty$ and $\lim_k \beta_k = 0$ we get that $S := \lambda^{-1/2} \sum \gamma_k s_k$ is an isometry in E and with $a := \sum_k s_k a_k s_k$ the C^*-algebra $C^*(a, S)$ contains automatically all s_k and a_k, i.e., is identical with $C^*(a_1, a_2, \ldots; s_1, s_2, \ldots)$.

Our conclusion is that the basic question for the study of above discussed phenomena should be:
Under which circumstances holds that $a, S \in C^*(a+S) \subset \mathcal{L}(\ell_2)$ for a given positive invertible operator $a \in \mathcal{L}(\ell_2)$ and a non-unitary isometry $S \in \mathcal{L}(\ell_2)$?

Here $\ell_2 := \ell_2(\mathbb{N})$ and the isometry S should have an infinite dimensional co-kernel $(1 - SS^*)\ell_2$, e.g. up to unitary equivalence $S \in \mathcal{L}(\ell_2)$ can be defined with an ONB by $Se_n := e_{2n}$.

More calculations. To be checked again.
No final decision obtained if the weakly separated case works:

Even if one selects the positive numbers more carefully, namely such that

$$([\alpha_k, \beta_k] + \gamma_k D) \cap ([\alpha_\ell, \beta_\ell] + \gamma_\ell D) = \emptyset ,$$

for $k \neq \ell$, then we still have to struggle to obtain at least two of the isometries to get the rest of all. This "weak" disjointness holds, e.g. in the case where we take $\alpha_k := 2^{-2k}$, $\beta_k := 2\alpha_k$ and $\gamma_k := (\alpha_k - \beta_{k+1})/4 = \alpha_k/8$, because then

$$\alpha_{k+1} = \alpha_k/4 < \beta_{k+1} = \alpha_k/2 < \alpha_k < 2\alpha_k = \beta_k$$

and

$$\beta_{k+1} + \gamma_{k+1} < \alpha_k - \gamma_k \ .$$

It follows from $\alpha_{k+1} = \alpha_k/4$ $\beta_{k+1} = \alpha_k/2$ and $\gamma_k = \alpha_{k+1}/2 = \alpha_k/8$.

This particular choice causes at least that there exist unitaries $u_1, u_2, \ldots \in C^*(X)$ that have the very weak property that at least $s_k u_k \in C^*(X)$, because the above defined very particular α_k, β_k and γ_k satisfy the additional conditions $\gamma_k < \alpha_k^2/(2\beta_k)$. (obtained form $\beta_k = 2\alpha_k$ and $\gamma_k = \alpha_k/8$).

It is not unlikely that there is some possible repair of the arguments in the proof of [**770**, thm.2.3] if one takes the γ_k very small in relation to to the lower bounds $\alpha_k > 0$ of invertible elements ... but we doubt this.

But then one can only find (not necessarily selfadjoint) idempotents $P_k \in C^*(X)$ with $P_k X = s_k a_k s_k^* + \gamma_k s_k$.

An other calculation gives $s_k a_k s_k^* + \gamma_k s_k = Y + Z$ with $Y := s_k(a_k + \gamma_k s_k)s_k^*$ and $Z := \gamma_k s_k(1 - s_k s_k^*)$ satisfy $ZY = 0$, $Z^2 = 0$, $(1 - s_k s_k^*)Z = 0$ and $(1 - s_k s_k^*)Y = 0$. In particular,

$$\{0\} \cup \mathrm{Spec}(Y + Z) = \{0\} \cup \mathrm{Spec}(Y) = \mathrm{Spec}(a_k + \gamma_k s_k)$$

for the invertible positive contraction a_k .

18. On asymptotically estimating functions

Let $A := \mathcal{L}(\ell_2)$, and let $F\colon (a, b) \in A \times A \to A$ and $G\colon (a, b) \in A \times A \to A$ with the properties that $G(a, b) = 0$ implies that $F(a, b) = 0$ and that there exists a bund $\gamma \in (0,\infty)$ such that $\max\{\,\|F(a,b)\|,\ \|G(a,b)\|\,\} \le \gamma$ for all contractions $a,b \in A$. We require moreover that for $(a_1,a_2,\ldots),(b_1,b_2,\ldots) \in \ell_\infty(A)$ holds

$$F(\,\pi_{c_0(A)}(a_1,a_2,\ldots),\pi_{c_0(A)}(b_1,b_2,\ldots)\,) \;=\; \pi_{c_0(A)}(F(a_1,b_1),F(a_2,b_2),\ldots)$$

– by suitable "local" re-imbedding of parts of $\ell_\infty(A)/c_0(A)$ into $\mathcal{L}(\ell_2)$ –, and

$$G(\,\pi_{c_0(A)}(a_1,a_2,\ldots),\pi_{c_0(A)}(b_1,b_2,\ldots)\,) \;=\; \pi_{c_0(A)}G(a_n,b_n)\|\,.$$

Likewise, for F is would be enough to have

$$\|F(\,\pi_{c_0(A)}(a_1,a_2,\ldots),\pi_{c_0(A)}(b_1,b_2,\ldots)\,)\| \ge \liminf_n \|F(a_n,b_n)\|\,,$$

and for G that

$$\|G(\,\pi_{c_0(A)}(a_1,a_2,\ldots),\pi_{c_0(A)}(b_1,b_2,\ldots)\,)\| \;\le\; \limsup_n \|G(a_n,b_n)\|\,.$$

Then there is a general method for such F and G that decides if there exists an increasing continuous function $\varphi \in \mathrm{C}_0(0,1]_+$ with $\|F(a,b)\| \le \varphi(\|G(a,b)\|)$ for all contractions $a,b \in A$:

Fix $t \in (0,1]$ and take the supremum $S(t)$ over the norms $\|F(a,b)\|$ for all contractions a,b with $\|G(a,b)\| \le t$ and call it ??? ...

It is certainly $\le \gamma$ and $t \mapsto S(t)$ is increasing.

There exist increasing continuous functions $\varphi(t)$ on $(0,1]$ with $S(t) \le \varphi(t)$ and $\lim_{t\to 0}\varphi(t) = \lim_{t\to 0} S(t)$.

If $0 < \mu := \lim_{t\to 0} S(t)$, then there exist sequences of contractions $a_1,a_2,\ldots$ and $b_1,b_2,\ldots$ with $\|G(a_n,b_n)\| < 2^{-n}$ and $\|F(a_n,b_n)\| \ge \mu - 2^{-n}$.

19. An elementary matrix norm bound

A simple explanation for the estimate in Remark 2.1.10 goes as follows:

We can write each matrix $a = [a_{jk}] \in M_n(A)$ as a sum of n sub-matrices $\mathrm{RL}(\ell)$ or as sum of n sub-matrices $\mathrm{LR}(\ell)$ that have the property that $\mathrm{RL}(\ell)^*\mathrm{RL}(\ell)$ and $\mathrm{LR}(\ell)^*\mathrm{LR}(\ell)$ are diagonal matrices. Thus the sub-matrices have norms $\|\mathrm{RL}(\ell)\|$ and $\|\mathrm{LR}(\ell)\|$ that is $\le$ the maximum of the norms of there entries a_{jk}. Then use that

$$a = \sum_{\ell=1}^{n} \mathrm{RL}(\ell) = \sum_{\ell=1}^{n} \mathrm{LR}(\ell)\,.$$

Such sub-matrices can be selected as follows:
$\mathrm{RL}(\ell)$ for $\ell \in \{1,\ldots,n\}$ the sub-matrix given with entries a_{jk} at the places (j,k) with $j+k \;=\; \ell \bmod (n)$ i.e., with the elements

$$\{\,a_{1,\ell-1},a_{2,\ell-2},\ldots,a_{\ell-2,2},a_{\ell-1,1}\,;\;\; a_{\ell,n},a_{\ell+1,n-1},\ldots,a_{n-1,\ell+1},a_{n,\ell}$$

on its given places and zero's otherwise. It is on 45^o degree from right to left downward directed lines.

Similarly let LR(ℓ) for $\ell \in \{1, \ldots, n\}$ denote the sub-matrix with entries on the left to right downward directed lines, parallel to the main diagonal LR(n) = diag($a_{11}, a_{22}, \ldots, a_{nn}$):
The sub-matrix LR(ℓ) is non-zero only on places (j, k) with $j - k = \ell \bmod (n)$:

$$\{\, a_{1,\ell}, a_{2,\ell+1}, \ldots , a_{\ell-1,n-1}, a_{\ell,n} \,;\; a_{\ell+1,1}, a_{\ell+2,2}, a_{\ell+3,3}, \ldots , a_{n-1,\ell-1}, a_{n,\ell}$$

All sub-matrices RL(ℓ) and LR(ℓ) have the property that the products

??????

Only the case of the right-to-left downward diagonal $a_{1,n}, a_{2,n-1}, \ldots, a_{n,1}$ (with $j+k = 1 \bmod (n)$) splits not into two – in orthogonal boxes contained – sub-matrices.

The same happens with the lines that are parallel to the main diagonal $a_{1,1}, a_{2,2}, \ldots, a_{n,n}$.

20. On flip-invariant subalgebras of $A \otimes A$

Let A a C^*-algebra and let $\gamma \colon A \otimes A \to A \otimes A$ the unique *-automorphism given by $\gamma(a \otimes b) = b \otimes a$ for $a, b \in A$. We call it the **flip** automorphism on $A \otimes A$.

It would be helpful to know more on the fix-point algebras of the flips on $\mathcal{O}_2 \otimes \mathcal{O}_2$, $\mathcal{O}_\infty \otimes \mathcal{O}_\infty$ and $\mathcal{P}_\infty \otimes \mathcal{P}_\infty \cong (1 - s_1 s_1^*)\mathcal{O}_\infty(1 - s_1 s_1^*) = {\mathcal{O}_\infty}^{st}$.

Also on $\mathcal{Z} \otimes \mathcal{Z}$?

More generally what about the fix-point algebra of the flip on $\mathcal{O}_n \otimes \mathcal{O}_n$, $M_{n^\infty} \otimes M_{n^\infty}$? Are they simple?

The flip algebra $(A \otimes A)^\gamma$ is nuclear if (and only if ??) A is nuclear.

Is $(A \otimes A)^\gamma$ also simple ??? (seems to be if we can say something on the case of tensorial $\mathcal{Z}$ absorption, but the flip algebras in $M_n \otimes M_n$ or $\mathbb{K} \otimes \mathbb{K}$ are not simple.)

if A is simple and unital without quotient of finite dimension? The fix-point algebras of the flips on $M_{n^\infty} \otimes M_{n^\infty}$ are simple (except possible the case $\mathcal{P}_\infty \otimes \mathcal{P}_\infty$), and they have all a central sequence of copies of $\mathcal{E}_2$ (the latter with exception of $M_{n^\infty} \otimes M_{n^\infty}$ or of the Jiang-Su algebra).

It makes them pi-sun C^*-algebras if the fix-point algebras of the flip on $M_{n^\infty} \otimes M_{n^\infty}$ is simple ????

and `Why this?`

The inductive limit for the latter is give by unital $M_{f(k)} \oplus M_{g(k)} \to M_{f(k+1)} \oplus M_{g(k+1)}$. This happens with some "over-crossing" and $M_{f(k)} \oplus M_{g(k)}$ is unitally contained in $M_{n^k} \otimes M_{n^k}$, in particular $n^{2k} = f(k) + g(k)$). $f(k) := n^k(n^k + 1)/2$, $g(k) := n^k(n^k - 1)/2$.

Iteration rules are given by $f(k+1) := \beta_n(f(k), g(k)) := f(k)n(n+1)/2 + g(k)n(n-1)/2$,

$g(k+1) := \gamma_n(f(k), g(k)) := f(k)n(n-1)/2 + g(k)n(n+1)/2$.

It comes from the rule for eigenvalues of the flip-unitary for $M_n \otimes M_n$ on $\ell_2(n) \otimes \ell_2(n)$:
Plus: $n + (n^2 - n)/2 = n(n+1)/2$ and Minus: $(n^2 - n)/2 = n(n-1)/2$.

Check of $f(k) + g(k) = n^{2k}$ is OK:

$$g(k+1) = n^k(n^k+1)n(n-1)/4 + n_k(n^k-1)n(n+1)/4 = n^{k+1}(n^{k+1}-1)/2,$$

and

$$f(k+1) := f(k)n(n+1)/2 + g(k)n(n-1)/2 = n^{k+1}(n^{k+1}+1)/2.$$

Is there a variant of next prop.
for $A = B \otimes \mathcal{Z}$?

Proposition B.20.1. *Let $A := B \otimes \mathcal{O}_\infty$ and let $\gamma \colon A \otimes A \to A \otimes A$ the flip isomorphism $\gamma(a_1 \otimes a_2) := a_2 \otimes a_1$.*

Then the fix-point algebra $(A \otimes A)^\gamma$ has only ideals I that are intersections of ideals J of $A \otimes A$ with $(A \otimes A)^\gamma$:

$$I = (A \otimes A)^\gamma \cap J.$$

The flip-algebra $(A \otimes A)^\gamma$ contains in its multiplier algebra a central sequence of unital copies of $\mathcal{O}_\infty$.

In particular, $(A \otimes A)^\gamma$ is simple and purely infinite if B is simple and exact.

Proof. It is easy to see (why $\subseteq$??) that for each closed ideal I of $A \otimes A$ the set $I + \gamma(I)$ is a γ-invariant closed ideal of $A \otimes A$ with

$$(A \otimes A)^\gamma \cap (I + \gamma(I)) = (A \otimes A)^\gamma \cap I.$$

We show that if $0 \leq b \in (A \otimes A)^\gamma$ and $c \in (A \otimes A)_+$ is contained in the ideal I of $A \otimes A$ generated by b then the element $c + \gamma(c)$ is in the closed ideal J of $(A \otimes A)^\gamma$ generated by b:

Let $0 \leq b \in (A \otimes A)^\gamma$ with $\|b\| = 1$, $c \in (A \otimes A)_+$ in the ideal of $A \otimes A$ generated by b and $\varepsilon \in (0, 1/4)$. Then there exists $g_1, \ldots, g_n \in A \otimes A$ with $\|c - \sum_{k=1}^n g_k^* b g_k\| < \varepsilon$. Define $\eta := \varepsilon/(n^2+1)(1+C^2)$, where $\delta := \max\{\|g_1\|, \ldots, \|g_n\|\}$.

Since b can be approximated by elements in the algebraic tensor product $A \odot A$ there exist isometries $s_1, \ldots, s_n, s_{n+1}, \ldots, s_{2n} \in \mathcal{M}(A)$ with mutually orthogonal ranges and the property that $\|(s_k \otimes s_{n+k})b - b(s_k \otimes s_{n+k})\| < \eta$ for above defined η and $k \in \{1, \ldots, n\}$.

The norms of $(s_k \otimes s_{n+k})^* b (s_k \otimes s_{n+k}) - b$ and of $(s_j \otimes s_{n+j})^* b (s_k \otimes s_{n+k})$ for $j \neq k$ are less than η.

Now let $h := \sum_k (s_k \otimes s_{n+k}) g_k$. The norm of $\delta^{-2}\big(h^*bh - \sum_{k=1}^n g_k^* b g_k\big)$ can be estimated by

$$\sum_k \|(s_k \otimes s_{n+k})^* b (s_k \otimes s_{n+k}) - b\| + \sum_{j \neq k} \|(s_j \otimes s_{n+j})^* b (s_k \otimes s_{n+k})\| \leq n^2 \eta .$$

Recall that $\gamma(h) = \sum_k (s_{n+k} \otimes s_k) \gamma(g_k)$.

It follows that $\gamma(h)^* h = 0$, $\|\gamma(h)^* b \gamma(h) - \gamma(c)\| < \varepsilon$ and

$$\|\gamma(h)^* b h\| \leq \delta^2 \big(\sum_{k,\ell=1}^{n} \|(s_{n+j} \otimes s_j)^* b (s_k \otimes s_{n+k})\| \big) \leq \delta^2 n^2 \eta .$$

It gives that

$$\| (c + \gamma(c)) - (h + \gamma(h))^* b (h + \gamma(h)) \| \leq 2(\varepsilon + \delta^2 n^2 \eta) < 4\varepsilon .$$

Notice that $c \leq c + \gamma(c)$ and that $c + \gamma(c)$ and $h + \gamma(h)$ are in $(A \otimes A)^\gamma$.

Thus, each ideal of the fix-point algebra $(A \otimes A)^\gamma$ of the flip automorphism on $A \otimes A$ is the intersection $J \cap (A \otimes A)^\gamma$ of an ideal J of $A \otimes A$ with $(A \otimes A)^\gamma$.

Let $(s_n), (t_n) \subset \mathcal{M}(A)$ sequences of isometries with $\lim_{n\to\infty}\big(\|s_n a - a s_n\| + \|t_n a - a t_n\|\big) = 0$ for each $a \in A$, and $s_n^* t_n = 0$, then $s_n \otimes s_n, t_n \otimes t_n \in \big(\mathcal{M}(A) \otimes \mathcal{M}(A)\big)^\gamma \subseteq \mathcal{M}\big((A \otimes A)^\gamma\big)$, the isometries $(s_n \otimes s_n)_n$ and $(t_n \otimes t_n)_n$ are central sequences for all elements of $A \otimes A$. □

Question B.20.2. What happens if $A \cong B \otimes \mathcal{E}(M_{2^\infty}, M_{3^\infty})$?

What happens in case that A is approximately divisible?

Corollary B.20.3. *If A is a pi-sun C*-algebra then its flip-algebra $(A \otimes A)^\gamma$ is again a pi-sun algebra.*

Proof. It is clear that $(A \otimes A)^\gamma$ is separable, unital and nuclear because $V(a) := (1/2)(a + \gamma(a))$ is a unital conditional expectation from the separable, unital and nuclear algebra $A \otimes A$ onto $(A \otimes A)^\gamma$. By Corollary F(ii), $A \cong A \otimes \mathcal{O}_\infty$ for all pi-sun algebras A. Thus Proposition B.20.1 applies to A and gives that $(A \otimes A)^\gamma$ is simple and contains a central sequence of copies of $\mathcal{O}_\infty$. (Recall here that $\mathcal{O}_\infty \cong \mathcal{O}_\infty \otimes \mathcal{O}_\infty \otimes \cdots$ and that $C^*(s_n^k t_n, k = 1, 2, \ldots)$ is isomorphic to $\mathcal{O}_\infty$ for each pair of isometries s_n, t_n with $s_n^* t_n = 0$.) □

21. On ideal structure of crossed products

Remark B.21.1. Let X a *non-compact* locally compact Hausdorff space. Then X is a *completely regular* space, i.e., for each closed subset $F \subseteq X$ and $x \in X \setminus F$ there exists $g \in \mathrm{C}_0(X)_+$ with $g(x) = 1$, $\|g\| = 1$ and $g(F) = \{0\}$. We denote by $\beta(X)$ the Stone-Cech compactification of X (maximal compact Hausdorff space with X as a dense subspace). Recall that it can be defined equivalently by the property that each continuous map $\phi\colon X \to Z$ from X into a compact (Hausdorff) space Z uniquely extends to a continuous map $\beta(\phi)\colon \beta(X) \to Z$. An other description of $\beta(X)$ is the the set of characters of $\mathrm{C_b}(X)$ with $\sigma(\mathrm{C_b}(X)^*, \mathrm{C_b}(X))$-topology, i.e., as Gelfand character space of $\mathrm{C_b}(X)$. Thus, there is a natural isomorphism $\mathrm{C_b}(X) \cong \mathrm{C}(\beta(X))$ by Gelfand-Naimark. and each continuous map from X into a compact metric space M – e.g. a closed disk – extends to a continuous map from $\beta(X)$ into M.

Let A a C^*-algebra and let $Y \subset \gamma(X)$ a non-empty compact subset of the corona space $\gamma(X) := \beta(X) \setminus X$ of X.

If we use the natural isomorphism $\mathrm{C}(\beta(X)) \cong \mathrm{C_b}(X)$ then $\mathrm{C_b}(X, A)$ becomes the $\mathrm{C}(\beta(X))$-algebra of continuous sections in a suitable continuous field of C^*-algebras $\{A_y\, ;\, y \in \beta(X)\}$ over $\beta(X)$. This is because the norm function map $f \in \mathrm{C_b}(X, A) \mapsto N(f) \in \mathrm{C_b}(X)$ defined by $N(f)(x) := \|f(x)\|$. It satisfies with $N(f)h = N(hf)$ for $h \in \mathrm{C_0}(X)$. This defines $\mathrm{C_b}(X, A)$ as continuous field over $\beta(X)$:

(1.) $\mathrm{C_b}(X, A)$ is a $\mathrm{C_b}(X)$-algebra:

If $g\colon X \to A$ in $\mathrm{C_b}(X, A)$ and $f \in \mathrm{C_b}(X)$, then $(f \cdot g) \in \mathrm{C_b}(X, A)$ for $(f \cdot g)(x) = f(x)g(x)$.

(2.) There is a natural norm function $N\colon g \in \mathrm{C_b}(X, A) \to N(g) \in \mathrm{C_b}(X)_+$ that satisfies $N(f \cdot g) = |f| \cdot N(g)$, $N(g_1 + g_2) \leq N(g_1) + N(g_2)$ and $N(g^* g) = N(g)^2$.

The property (1.) and (2.) together impliy that $\mathrm{C_b}(X, A)$ the algebra of continuous sections for the continuous field $(\, A_\omega\, ;\, \omega \in \beta(X)\,)$. Here A_ω is the quotient defined the C^*-seminorm $N(\cdot)(\omega)$ and is isomorphic to $\mathrm{C_b}(X, A)/(J_\omega \cdot \mathrm{C_b}(X, A))$ with J_ω equal to the kernel of the evaluation character $f \mapsto f(\omega)$ on $\mathrm{C_b}(X)$ for $\omega \in \beta(X)$. For our applications it is an important point that $\mathrm{C_b}(X, A)$ is also a lower s.c. field of C^*-algebras. and not only an upper s.c. field of C^*-algebras over the compact space $\beta(X)$.

If Y is a closed subspace of $\beta(X)$, then we can form the "restriction" C^*-algebra $\mathrm{C_b}(X, A)|Y := \mathrm{C_b}(X, A)/J_Y$, where J_Y is the ideal of bounded A-valued continuous functions $f \in \mathrm{C_b}(X, A)$ with the property that the function $g(x) := \|f(x)\|$ in $\mathrm{C_b}(X) = \mathrm{C}(\beta(X))$ satisfies $g|Y = 0$, i.e., J_Y is the closed ideal of $\mathrm{C_b}(X, A)$ generated $\mathrm{C_0}(\beta(X) \setminus Y) \cdot \mathrm{C_b}(X, A)$.

One can here also think of $\mathrm{C_b}(X, A)$ as an ideal of $\mathrm{C_b}(X, \widetilde{A}\,)$ where $\widetilde{A}$ denotes A if A is unital and $A + \mathbb{C}1 \subseteq \mathcal{M}(A)$ otherwise

We write always A_ω for $\mathrm{C_b}(X, A)|Y$ if $Y = \{\omega\}$ for a point $\omega \in \beta(X) \setminus X$ and, sometimes, also A^Y for $\mathrm{C_b}(X, A)|Y$.

(There are good reasons for the requirement $Y \cap X = \emptyset$ on Y.)

Well-known *examples* are $A_\infty := \mathrm{C_b}(X, A)|Y$ for $X = \mathbb{N}$, $Y := \beta(\mathbb{N}) \setminus \mathbb{N}$, $A_\omega := \mathrm{C_b}(X, A)|Y$ for $X = \mathbb{N}$, $Y := \{\omega\}$ where $\omega \in \beta(\mathbb{N}) \setminus \mathbb{N}$ is a point (corresponding to a free ultra-filter on $\mathbb{N}$) or $\mathrm{Q}(X, A) := \mathrm{C_b}(X, A)|Y$ for $Y := \gamma(X) = \beta(X) \setminus X$.

Let $f_a(x) := a$ for $x \in X$ and $a \in A$. The map $A \ni a \mapsto f_a(x) \in \mathrm{C_b}(X, A)$ defines a natural *-monomorphism from A into $\mathrm{C_b}(X, A)$ with $J_Y \cap A = \{0\}$ for all non-empty $Y \subset \beta(X) \setminus X$.

Therefore, there are natural *-monomorphisms $A \hookrightarrow \mathrm{C_b}(X, A)|Y$. We identify A with the image of A under this embedding. The hereditary C^*-subalgebras $A\,\mathrm{C_b}(X, A)A$ (respectively $A(\mathrm{C_b}(X, A)|Y)A$) of $\mathrm{C_b}(X, A)$ (respectively of $\mathrm{C_b}(X, A)|Y$) will be denoted by E_A or $E(X, A)$ (respectively $E_A|Y$ or $E(X, A)|Y$).

It turns out that σ-unital A (or $E(X, A)|Y$) is *essential* in $\mathrm{C_b}(X, A)|Y$ for at least one $Y \neq \emptyset$, if and only if, A is unital.

In particular, A is a *degenerate* C^*-subalgebra of $\mathrm{C_b}(X, A)|Y$ if A is non-unital but σ-unital (and X is non-compact).

It follows that there are natural unital *-monomorphisms $\varphi_1 \colon \mathcal{M}(A) \subset \mathrm{C_b}(X, \mathcal{M}(A))|Y \to ????$ and $\varphi_2 \colon \mathcal{M}(A) \to \mathcal{M}(E_A|Y)$. The morphism φ_2 is strictly continuous, because $\varphi_2|A$ is essential in E_A (by definition of $E_A|Y$).

The natural morphism $\varphi \colon \mathcal{M}(A) \subset \mathrm{C_b}(X, \mathcal{M}(A))|Y$ is unital and injective and satisfies $\varphi(a) \in A \subset \mathrm{C_b}(X, A)|Y$.

The algebra $\mathrm{C_b}(X, A)|Y$ is an ideal of the unital algebra $\mathrm{C_b}(X, \mathcal{M}(A))|Y$, therefore, there is a natural unital *-morphism $\psi \colon \mathrm{C_b}(X, \mathcal{M}(A))|Y \to \mathcal{M}(\mathrm{C_b}(X, A)|Y)$, with kernel $\pi(I)$, where π denotes the natural epimorphism from $\mathrm{C_b}(X, \mathcal{M}(A))$ onto $\mathrm{C_b}(X, \mathcal{M}(A))|Y$ and I is the ideal of $g \in \mathrm{C_b}(X, \mathcal{M}(A))$ with $gf \in J_Y$ for all $f \in \mathrm{C_b}(X, A)$.

It holds $\varphi(\mathcal{M}(A)) \cap \ker(\psi) = \{0\}$, because $(\varphi(b)f)(x) = af(x)$ for $b \in \mathcal{M}(A)$, $x \in X$, and $bf|Y = 0$ for all $b \in \mathrm{C_b}(X, A)$ implies $bA = \{0\}$. Thus, $\psi \circ \varphi \colon \mathcal{M}(A) \to \mathcal{M}(\mathrm{C_b}(X, A)|Y)$ is a unital *-monomorphism with $\psi \circ \varphi(a) = a \in A \subset \mathrm{C_b}(X, A)|Y$. Thus, $\psi \circ \varphi(\mathcal{M}(A)) \subset \mathcal{N}(\mathrm{C_b}(X, A)|Y, E_A)$ and the induced unital *-morphism from $\mathcal{M}(A)$ into $\mathcal{M}(E_A)$ is the unique strictly continuous extension of the non-degenerate *-monomorphism $A \to E_A$.

If $T \in \mathcal{L}(A, B)$ is a bounded linear map, then $T^X(f)(x) := T(f(x))$ defines a bounded linear map $T^X \colon \mathrm{C_b}(X, A) \to \mathrm{C_b}(X, B)$ with $T^X(J_Y) \subset T^X(J_Y)$ for $Y \subset \beta(X)$, i.e., $T^X(f)|Y = 0$ if $f|Y = 0$. It allows to define the linear quotient map $T^Y \colon \mathrm{C_b}(X, A)|Y \to \mathrm{C_b}(X, B)|Y$, i.e., T^Y satisfies $T^Y(f|Y) = T^X(f)|Y$ and $T^Y(a) = T(a)$ for all $a \in A$.
The map $\mathcal{L}(A, B) \ni T \to T^Y \in \mathcal{L}(\mathrm{C_b}(X, A)|Y, \mathrm{C_b}(X, B)|Y)$ is linear and isometric. If $\alpha \colon A \to B$ is a *-morphism (respectively *-monomorphism, *-isomorphism, completely positive) then $\alpha^Y \colon \mathrm{C_b}(X, A)|Y \to \mathrm{C_b}(X, B)|Y$ is a *-morphism (respectively *-monomorphism, *-isomorphism, completely positive) with $\alpha^Y(a) = \alpha(a) \in B$ for all $a \in A$. If $T(a) = cad$ for $c, d \in \mathcal{M}(A)$, then $T^Y \colon \mathrm{C_b}(X, A)|Y \to \mathrm{C_b}(X, A)|Y$ satisfies $T^Y(f|Y) = \psi \circ \varphi(c) \cdot (f|Y) \cdot \psi \circ \varphi(d)$ for $f \in \mathrm{C_b}(X, A)$, and $T^Y(f|Y) = c \cdot (f|Y)d$ if $f|Y \in E_A = A(\mathrm{C_b}(X, A)|Y)A$.

In particular, if $\alpha \in \mathrm{Aut}(A)$ and $M := (\mathrm{C_b}(X, A)|Y)^{**}$ p the support projection of E_A in M, then $\alpha^Y \in \mathrm{Aut}(\mathrm{C_b}(X, A)|Y)$, $\alpha^Y(A) = A$, $\alpha^Y(E_A) = E_A$, $(\alpha^Y)^{**}(A' \cap M) = A' \cap M$ and $(\alpha^Y)^{**}(p) = p$.

Moreover, if $\alpha = \mathrm{Ad}(u)$ (i.e., $\alpha(a) = uau^*$ for $a \in A$, where $u \in \mathcal{M}(A)$ is unitary), then $\alpha^Y = \mathrm{Ad}(U)$ for $U = V|Y$, where $V(x) := u$ for $x \in X$.

??????????????????????

LEMMA B.21.2. *Let $u \in \mathcal{M}(A)$ unitary, and $B := \mathrm{C_b}(X, A)|Y$ where $Y \neq \emptyset$ is a closed subset of $\beta(X) \setminus X$ (e.g. if $X = \mathbb{N}$ then $B := A_\infty$, $B := A_\omega$ are of this kind).*

*The *-isomorphism $\mu := \mathrm{Ad}(u)^Y \in \mathrm{Aut}(B)$ (cf. Remark B.21.1) is induced on B by $\gamma_u(f)(t) := \mathrm{Ad}(u)(f(t)) := uf(t)u^*$ for $t \in \mathbb{R}_+$ and $f \in \mathrm{C_b}(\mathbb{R}_+, A)$, and is given by the inner automorphism $\mathrm{Ad}(U)\colon B \ni b \mapsto UbU^* \in B$, for the unitary $U := \psi \circ \varphi(u)$ in $\psi(\varphi(\mathcal{M}(A))) \subset \psi(\mathrm{C_b}(X, \mathcal{M}(A)) \subset \mathcal{M}(B)$.*

In particular, $\mathrm{Ad}(U)(a) = \mathrm{Ad}(u)(a)$ for all $a \in A$.

*The second conjugate $\mathrm{Ad}(U)^{**}\colon B^{**} \to B^{**}$ is given by $\mathrm{Ad}(U)^{**}(b) = \eta(U)b\eta(U)^*$, where $\eta\colon \mathcal{M}(B) \to B^{**}$ means the natural strictly–*ultra-strongly continuous unital monomorphism.*

The $\sigma(B^{**}, B^*)$-closure of A in B^{**} is naturally W-isomorphic to A^{**} via a natural isomorphism $\eta_1\colon A^{**} \to B^{**}$. Let $q = \eta_1(1) \in B^{**}$ denote the unit of $\eta_1(A^{**}) \subset B^{**}$, and identify $\mathcal{M}(A)$ naturally with its image in A^{**}.*

Then

(i) *$\eta_1(a) = q \cdot \eta \circ \psi \circ \varphi(a)$ for all $a \in \mathcal{M}(A)$.*
(ii) *$A' \cap B^{**} = \eta_1(A^{**})' \cap B^{**}$ and $\mathrm{Ad}(U)^{**}(A' \cap B^{**}) = A' \cap B^{**}$.*
(iii) *$\mathrm{Ad}(U)^{**}(q) = q \in A' \cap B^{**}$ and $q\mathrm{Ad}(U)^{**}(b) = qb$ for all $b \in A' \cap B^{**}$, In particular $ab = a\mathrm{Ad}(U)^{**}(b)$ for all $a \in A$ and $b \in A' \cap B^{**}$.*

PROOF. **??**

$pB^{**}p$ is the second conjugate of ABA,

????? □

LEMMA B.21.3. *Suppose that $A \subset B := \mathrm{C_b}(X, A)|Y$ is as in Remark B.21.1, $\alpha \in \mathrm{Aut}(A)$, and $q \in B^{**}$ denotes the support projection of the hereditary C*-subalgebra $ABA = E_A|Y$ of B. Let $\beta := \alpha^Y : B \to B$ denote the natural extension of α to B (cf. Remark B.21.1).*

Then $\beta(q) = q$, q is in the centre of $A' \cap B^{**}$, and $\beta(A' \cap B^{**}) = A' \cap B^{**}$.

If there are $\kappa \in (0, 1)$ and a unitary $u \in \mathcal{M}(A)$ with $\|\alpha - \mathrm{Ad}(u)\| \leq 2\kappa$, then $\|\beta(p) - p\| \leq \kappa$ for all projections $p \in (A' \cap B^{**})q$.

In particular, if p is a projection in $A' \cap B^{**}$, then $a\beta^{**}(p)p = 0$ for all $a \in A$ implies that $qp = 0 = q\beta^{**}(p)$.

PROOF. The linear map $\beta - \mathrm{Ad}(U)$ is equal to the natural extension $(\alpha - \mathrm{Ad}(u))_Y$ of $\alpha - \mathrm{Ad}(u) \in \mathcal{L}(A, A)$ to a bounded linear operator of $\mathrm{C_b}(\mathbb{R}_+, B)|Y$, where $U \in \mathcal{M}(B)$ is defined as in Lemma B.21.2. It follows $\|\beta - \mathrm{Ad}(U)\| \leq 2\kappa$.

Since $\beta(a) = \alpha(a)$ for all $a \in A$, we get $\beta^{**}(A' \cap B^{**}) = A' \cap B^{**}$ and $\beta^{**}(q) = q$. The projection q is in the centre of B^{**}, because q is in the $\sigma(B^{**}, B^*)$-closure of A and commutes with A.

By Lemma B.21.2, $\mathrm{Ad}(U)^{**}(b) = b$ for all $b \in (A' \cap B^{**})q$. Thus, for projections $p \in (A' \cap B^{**})q$,

$$2\|p - \beta^{**}(p)\| = \|(q - 2p) - \beta^{**}(q - 2p)\| \le 2\kappa\,.$$

The equation $A\beta^{**}(p)p = \{0\}$ implies $\beta^{**}(qp)qp = 0$. But then $\|\beta^{**}(qp) - qp\| \le \kappa < 1$ implies that $0 = qp = q\beta^{**}(p) = \beta^{**}(qp)$. □

22. On semi-projective relations

Next Def. makes no sense !? In this formulation... only?

Definition B.22.1. An operator-polynomial relation $R\colon F^n \to B_\infty$ (on elements of a subset F of a C^*-algebra A) is *semi-projective* on F^n if there exists for each element $X \in F^n$ with $R(X) = 0$ a sequence $X_k \in F^n$ with $R(X_k) = 0$ and $\lim_k \|X_k - X\| = 0$.

23. Non-2-sub-additive quasi-traces exist.

We list some more details than given at the reference places:

Where is the "reference place"?

The unital type-I C^*-algebra A is a (very special) unital extension E:

$$0 \to c_0(\mathbb{K}) \to E \to_\psi \mathrm{C}([0,1]^2) \to 0\,.$$

It means that the closed ideal J generated by all commutators in the unital C^*-algebra E is isomorphic to $c_0(\mathbb{K}) \cong c_0 \otimes \mathbb{K}$. The commutative quotient E/J of E is isomorphic to $\mathrm{C}([0,1]^2)$ and, if $\psi\colon E \to \mathrm{C}([0,1]^2)$ is the defining map for the extension, then the (central) unital quasi-trace τ_E on E is given by $\tau_A \circ \pi_{c_0(\mathbb{K})}$, where τ_A is the Aarnes quasi-state on $\mathrm{C}([0,1]^2)$.

The following says: $C := \mathrm{C}([0,1]^n)$ is a "projective" C^*-algebra ? In the sense: If $\psi : C \to B/J$ is a unital *-monomorphism, then there exists a unital *-morphism $\phi : C \to B$ with $\phi = \pi_J \circ \psi$.

But what happens with the question concerning additivity, if μ is a quasi trace then for all strictly commuting elements a, b in the image holds additivity ... ???

THE NEW OBSERVATION IS:

Because $\mathrm{C}([0,1]^2)$ is projective inside the class of unital Abelian C^*-algebras one gets that an extension with $\ell_\infty(\mathbb{K})$ can be modified to an extension by $c_0(\mathbb{K})$ such that $\pi_{c_0(\mathbb{K})}(C^*(S,T)) \cap \ell_\infty(\mathbb{K}) = \{0\}$.

It gives an extension $0 \to c_0(\mathbb{K}) \to E \to \mathrm{C}([0,1]^2)$ that has the property that

(1) E is a type I C^*-algebra with Abelian quotient of Dimension $= 2$.

(2) This extension has the property that every local unital quasi-trace τ on $C([0,1]^2)$ is additive on $\tau|C^*(x,1)_+$ for all normal elements $x \in E$.

(3) The composition $\tau_E := \tau_A \circ \pi_{c_0(\mathbb{K})}$ is a is additive on each commutative C^*-subalgebra of E. But is not 2-sub-additive.

Why is it not 2-sub-additive ??

(4) There exist elements $x, y \in E_+$ with $\tau_E(x) = 0$, $\tau_E(y) = 0$ and $\tau_E(x+y) = 1$.

The restriction map

$$C_0(X) \ni f \mapsto f|Z \in C(Z) \cong C([0,1]^2)$$

defines an epimorphism from $A/J \cong C_0(X)$ onto $C([0,1]^2)$ and has the property that ?????????

It is not unlikely that one can manage that that $X = Z \cong [0,1]^2$ using the index-preserving compressions $(T^*)^n(\cdot)T^n$ on the Toeplitz algebra

$$0 \to \mathbb{K}(\ell_2) \to \mathcal{T} = C^*(T) \to \ Cf(S_1)\,.$$

Then one would get a honest extension $0 \to c_0(\mathbb{K}) \to A \to C([0,1]^2)$.

`But we need that` $\|[(T^*)^n a T^n, (T^*)^n b T^n]\|$ `becomes small if` $ab - ba \in \mathbb{K}(\ell_2)$
`for positive contraction` $a, b \in \mathcal{L}(\ell_2)$ `with` $ab - ba \in \mathbb{K}$.

We use the following Lemma:

Lemma B.23.1. *Let $a, b \in \mathcal{L}(\ell_2)$ positive contractions that satisfy $ab - ba \in \mathbb{K}$, $p \in \mathbb{K}$ a projection and $\varepsilon(0, 1/2]$. Then there exists a positive contraction $c \in \mathbb{K}$ such that $p \leq c$, $\|ca - ac\| < \varepsilon$, $\|cb - bc\| < \varepsilon$ and*

$$\|(1-c)a(1-c)^2b(1-c) - (1-c)a(1-c)^2b(1-c)\| < \varepsilon\,.$$

I.e. $(1-c)a(1-c)$ and $(1-c)b(1-c)$ commute up to ε and are compact perturbations of a and b.

Proof. It is essentially the existence of an approximate unit $\{e_n \in A_+\,;\ n = 1, 2, \ldots\}$ in σ-unital C^*-algebras A that satisfies $e_n e_{n+1} = e_n$, $\|e_n\| = 1$ and is quasi-central with respect to a separable C^*-subalgebra $B \subseteq \mathcal{M}(A)$, – in the sense that $\lim_n \|be_n - e_n b\| = 0$ for all $b \in B$.

The proof uses obvious modifications of the proof of [**616**, thm. 3.12.14], and has to observe that the arguments for [**616**, cor. 3.12.15,cor. 3.12.16] work also for σ-unital A and separable $B \subseteq \mathcal{M}(A)$. It shows that we can find a sequence (e_n) with this properties inside the (algebraic) convex hull of any given countable approximate unit $\{p_1, p_2, \ldots\}$ of σ-unital C^*-algebra A that have the additional property $p_n p_{n+1} = p_n$. (Such an approximate unit $\{p_n\,;\ n \in \mathbb{N}\}$ of A exists in every σ-unital C^*-algebra A.)

In our special case we apply this to $A := \mathbb{K}(\ell_2)$ and take the projections $p_n \in A$ of rank $n \in \mathbb{N}$ as approximate unit of A, that maps $\ell_2(\mathbb{N})$ to the linear span of the first n elements of the canonical basis of $\ell_2(\mathbb{N})$. Now let $B := C^*(\mathbb{K}(\ell_2), a, b) \subseteq \mathcal{L}(\ell_2) = \mathcal{M}(A)$. $\square$

REMARK B.23.2. Let $f_0 \in \mathrm{C}([0,1]) = C^*(f_0, 1)$ denote the identity map $f_0(t) := t$ for all $t \in [0,1]$ and let $1 \in \mathrm{C}([0,1])$ denote the function that is constant equal to 1.

The functions $g, h \in \mathrm{C}([0,1]^2) = \mathrm{C}([0,1]) \otimes \mathrm{C}([0,1])$ are the coordinate maps $g(x,y) = x$ and $h(x,y) = y$, corresponding to $f_0 \otimes 1$ and $1 \otimes f_0$ in the tensor product notation.

Notice that $\mathrm{C}([0,1]^2) = C^*(g, h, 1)$ and that this means in the tensor notation that $\mathrm{C}([0,1]) \otimes \mathrm{C}([0,1]) = C^*(f_0 \otimes 1, 1 \otimes f_0, 1 \otimes 1)$.

LEMMA B.23.3. *The algebra* $\mathrm{C}([0,1]^2)$ *is the universal C^*-algebra with respect to the above given relations and has following properties:*

If A is a unital C^*-algebra that is generated by commuting positive contactions $S, T \in A$ and 1_A, then there exists a unique C^*-algebra morphism $\varphi\colon \mathrm{C}([0,1]^2) \to A$ *with $\varphi(g) = S$, $\varphi(h) = T$ and $\varphi(1) = 1_A$.*

In particular, if $S, T \in A$ are commuting positive contractions in a unital C^*-algebra A and if $\psi\colon C^*(S, T, 1_A) \to \mathrm{C}([0,1]^2)$ is a unital C^*-morphism with $\psi(S) = f$ and $\psi(T) = g$ then ψ is an isomorphism form $C^*(S, T, 1_A)$ onto $\mathrm{C}([0,1]^2)$.

PROOF. The universality of $\mathrm{C}([0,1]^2)$ in the class of unital commutative C^*-algebras is easy to see, because $\mathrm{C}([0,1])$ is the universal unital C^*-algebra generated by a positive contraction, and $\mathrm{C}([0,1])$ is nuclear. This implies that any pair of element-wise commuting unital C^*-morphisms $\phi_1, \phi_2\colon \mathrm{C}([0,1]) \to A$ define a unital C^*-morphism $\varphi\colon \mathrm{C}([0,1]^2) \to A$ with $\varphi(g) = \phi_1(f_0)$ and $\varphi(h) = \phi_2(f_0)$.

Let $\psi\colon C^*(S, T, 1_A) \to \mathrm{C}([0,1]^2)$ a unital C^*-morphism with $\psi(S) = g$ and $\psi(T) = h$. Then the universal epimorphism φ from $\mathrm{C}([0,1]^2)$ onto $C^*(S, T, 1_A)$ satisfies $\psi \circ \varphi = \mathrm{id}$ of $\mathrm{C}([0,1]^2)$, because $\psi \circ \varphi$ is unital, $\psi \circ \varphi(g) = g$ and $\psi \circ \varphi(h) = h$. Therefore ψ must be surjective and φ injective. Thus ψ and φ are isomorphisms. $\square$

Let $\gamma_n\colon S^1 \to [0,1]^2$ a sequence of piecewise smooth continuous map that contains in its uniform closure the set of all continuous maps $\gamma\colon S^1 \to [0,1]^2$ that are piecewise smooth Jordan curves ([5]).

Denote by $\mathcal{T} \subset \mathcal{L}(\ell_2)$ the Toeplitz algebra. Notice that $\mathbb{K} \subset \mathcal{T}$ and that there is a natural isomorphism from $\mathrm{C}(S^1)$ onto $\mathcal{T}/\mathbb{K} \subset \mathcal{C}$, where $\mathcal{C} := \mathcal{L}(\ell_2)/\mathbb{K}$ denotes the *Calkin* algebra.

The maps γ_n define a sequence of unital C^*-morphisms $\varphi_n\colon \mathrm{C}([0,1]^2) \to \mathrm{C}(S^1) \subset \mathcal{C}$ and, therefore, a unital C^*-morphism $\Phi\colon \mathrm{C}([0,1]^2) \to \ell_\infty(\mathrm{C}(S_1)) \subset \ell_\infty(\mathcal{C})$.

[5] I.e. the closure of the set of maps γ_n – but considered as positive contractions in $\mathrm{C}(S^1) \oplus \mathrm{C}(S^1)$ – contains all those maps $\gamma\colon S^1 \to [0,1]^2$ that are piecewise smooth Jordan curves.

The C^*-morphism Φ is faithful on $\mathrm{C}([0,1]^2)$, and is a unital C^*-monomorphism, because for every point $x \in [0,1]^2$ there exists a piece-wise smooth Jordan curve $\gamma\colon S^1 \to [0,1]^2$ with $x \in \gamma(S^1)$.

The generators $\{1, \Phi(g), \Phi(h)\} \subset \ell_\infty(\mathrm{C}(S_1))$ of can be lifted to $1 \in \ell_\infty(\mathcal{T}) \subset \ell_\infty(\mathcal{L}(\ell_2))$ and to, not necessarily commuting, positive contractions $X, Y \in \ell_\infty(\mathcal{T})$. The positive contractions $X = (x_1, x_2, \ldots)$ and $Y = (y_1, y_2, \ldots)$ satisfy $XY - YX \in \ell_\infty(\mathbb{K})$. It follows that the n-th entries with $\pi_{\mathbb{K}}(x_n) = \varphi_n(g)$ and $\pi_{\mathbb{K}}(y_n) = \varphi_n(h)$ can be modified step by step by a compact perturbation with elements in $1 + \mathbb{K}$, as considered and shown in Lemma B.23.1. We get new positive contractions s_n and t_n with $x_n - s_n, y_n - t_n \in \mathbb{K}$ and $\|s_n t_n - t_n s_n\| < 2^{-n}$. The new positive contractions $S := (s_1, s_2, \ldots)$ and $T := (t_1, t_2, \ldots)$ in $\ell_\infty(\mathcal{T}) \subset \ell_\infty(\mathcal{L}(\ell_2))$ have the properties that $S - X, T - Y \in \ell_\infty(\mathbb{K})$,

$$ST - TS \in c_0(\mathbb{K}) \subset \ell_\infty(\mathbb{K}) \subset \ell_\infty(\mathcal{T}),$$

$S + \ell_\infty(\mathbb{K}) = \Phi(g)$ and $T + \ell_\infty(\mathbb{K}) = \Phi(h)$. The new positive contractions $S + c_0(\mathbb{K})$ and $T + c_0(\mathbb{K})$ are commuting positive contractions in $\ell_\infty(\mathcal{T})/c_0(\mathbb{K})$ and the commutative unital C^*-algebra $D \subset \ell_\infty(\mathcal{T})/c_0(\mathbb{K})$ generated by them (and 1) maps onto the C^*-algebra $\Phi(\mathrm{C}([0,1]^2)) \subseteq \ell_\infty(\mathrm{C}(S^1))$ in a way that $S + c_0(\mathbb{K})$ maps to $\Phi(g)$ and $T + c_0(\mathbb{K})$ maps to $\Phi(h)$. By the injectivity of Φ, it follows from Lemma B.23.3 that $\pi_{\ell_\infty(\mathbb{K})}$ maps the commutative C^*-algebra $\pi_{c_0(\mathbb{K})}(C^*(S,T,1))$ onto $\Phi(\mathrm{C}([0,1]^2))$ in a way that the canonical that the described generators are respected.

??????? Alternative description: ?????

Since $ST - TS \in c_0(\mathbb{K})$ it follows that $\pi_{c_0(\mathbb{K})}(S)$ and $\pi_{c_0(\mathbb{K})}(T)$ generate commutative C^*-subalgebra A of $\ell_\infty(\mathcal{T})/c_0(\mathbb{K})$ with the property that it is generated by two commuting positive contraction, that gives

?????

It follows, that $B := C^*(S,T,1) + c_0(\mathbb{K})$ is a C^*-algebra with the property $B/c_0(\mathbb{K}) \cong \mathrm{C}([0,1]^2)$, because $C^*(S,T,1) \cap \ell_\infty(\mathbb{K}) = C^*(S,T,1) \cap c_0(\mathbb{K})$.

`To be checked if we have moreover ???`

For all normal elements $b \in B$ (respectively $b \in C^*(S,T,1) + \ell_\infty(\mathbb{K})$) holds that the function $f := \pi_{c_0(\mathbb{K})}(b)$ (respectively the function $f := \pi_{\ell_\infty(\mathbb{K})}(b)$) in $\mathrm{C}([0,1]^2)$ has zero winding numbers, – with respect to alls closed curves $\gamma\colon S^1 \to [0,1]^2$ in $[0,1]^2$ and all points in $\mathbb{C} \setminus f(\gamma(S^1))$. (It is here not of interest if clockwise or anti-clockwise parametrized.)

The extensions have the property that

$$f \in \mathrm{C}([0,1]^2) \cong (C^*(S,T,1) + \ell_\infty(\mathbb{K}))/\ell_\infty(\mathbb{K}) \subseteq \ell_\infty(\mathrm{C}(S^1))$$

has only zero winding numbers,

???? if and only if, ???? "if" is O.K.
???? But what about the converse ?:
???? Suppose that f has only zero winding

???? numbers. Then f can be approximately
???? factorized over 1-dimensional spaces:
???? Means if X is compact and metric space:
???? If $f \in \mathrm{C}(X)$ and $\varepsilon > 0$,
???? there exists $g\colon X \to Y$
???? with Y 1-dimensional, and
???? $h\colon Y \to \mathbb{C}$ with ???? $\|h \circ g - f\| < \varepsilon$. ????

if there is a normal element in $x \in \ell_\infty(\mathbb{K}) + C^*(S, T, 1)$, i.e., x satisfies $x^*x = xx^*$, with $f = \pi_{\ell_\infty(\mathbb{K})}(x)$ ([6]).

The latter is the case, if and only if, there exists, – for a given $y \in C^*(S, T, 1) + c_0(\mathbb{K}) \subset \ell_\infty(\mathcal{T})$ with $\pi_{c_0(\mathbb{K})}(y) = f$ –, an element $z \in \ell_\infty(\mathbb{K})$ with the property that $z + y$ is normal: $(z + y)^*(z + y) = (z + y)(z + y)^*$. The element y satisfies $y^*y - yy^* \in c_0(\mathbb{K})$ by commutativity of $(C^*(S, T, 1) + c_0(\mathbb{K}))/c_0(\mathbb{K})$.

(If one could here manage that $y^*z, zy^* \in c_0(\mathbb{K})$, then one gets at least that $z^*z - zz^* \in c_0(\mathbb{K})$, but we don't know that.)

It leads to the following question about contractions with index zero in the Toeplitz algebra $\mathcal{T}$:

Question B.23.4. Do we need for the determination of the winding numbers only to look for invertible elements in $\mathrm{C}(S^1)$?

Let $f \in \mathrm{C}([0, 1])$. We need for the conclusion that the restriction $\tau_A | \mathrm{C}(f, 1)_+$ of the Aarnes quasi-state τ_A on $\mathrm{C}([0, 1])_+$ to the positive part of $\mathrm{C}(f, 1)_+$ is there additive, the following property of the given $f \in \mathrm{C}([0, 1])$:

For *each* continuous map $\gamma\colon S^1 \to [0, 1]^2$ and $z \notin f(\gamma(S_1))$ the winding number $w(f \circ \gamma, z)$ is equal to zero.

It can happen that $z \in f \circ \gamma_1(S_1)$ for some other Jordan curve $\gamma_1(S_1) \subseteq [0, 1]^2$ ... So z can be in the spectrum of some other factor $f \circ \gamma_1(S_1) \subseteq [0, 1]$.

But we have at least the positive direction: If there exists a normal element $g \in C^*(S, T, 1) + \ell_\infty(\mathbb{K})$ with $\pi_{\ell_\infty(\mathbb{K})}(g) = f$ then all winding numbers are zero.

Question: Suppose that one of it is not zero. Does there exist a non-additive quasi-state on $\mathrm{C}(f, 1)_+$?????

Does there exist for an increasing function $g \in \mathrm{C}_0((0, 1])$ with the following property?:

Let $X \in \mathcal{T}$ a contraction with index $\mathrm{index}(X) = 0$ and $\|X^*X - XX^*\| < \varepsilon$ then there exists $Y \in \mathcal{T}$ with $Y^*Y = YY^*$, $X - Y \in \mathbb{K}$ and $\|X - Y\| \leq g(\varepsilon)$.

Can take here contraction $X \in \mathcal{T}$ with polar decomposition $ZA = X$ for positive self-adjoint $A := (X^*X)^{1/2} \in \mathcal{T}_+$ and $Z \in \mathcal{L}(\mathcal{H})$ an isometry with index zero. It shows that one can replace Z by a unitary

[6] We can here suppose that $\|x\| = \|f\| = 1$, because we can f multiply with a positive scalar without changing the winding numbers of f and the normality of x, because all happens in the commutative C^*-algebra $C^*(x, x^*)$ and its quotients.

????. Get ???

Unfortunately, we do not know if this implies also the existence of a normal element $y \in C^*(S,T,1) + c_0(\mathbb{K})$.

Is this is equivalent (!) to the property that all the indices of the $f := \pi_{c_0(\mathbb{K})}(y)$ are zero?

It can be represented by a normal element in B [or only that there is an element x in $\ell_\infty(\mathbb{K})$ such that $f + x$ is normal].

[Need only that the indices vanish !!!! This should not change by compact perturbations ...]

(This is true if we consider the bigger $C^*(S,T) + \ell_\infty(\mathbb{K})$ instead.

Have then to show: If we have a normal representative in $C^*(S,T) + \ell_\infty(\mathbb{K})$ then we have a normal representative in B.)

??? Similar observations ?? show that the map $\mu := \tau_A \circ \varphi \colon B_+ \to [0,\infty)$ from the free product $B := \mathrm{C}[0,1] * \mathrm{C}[0,1]$ into $[0,\infty)$ is a unital quasi-trace that has additive restrictions $\mu|C_+$ for each commutative C^*-subalgebra C of B. It requires only the additivity on C_+ for all $C := C^*(a+ib)$ with commuting $a, b \in B_+$.

`Check next red and blue again! Look to the original notes and compare.`

The non-subadditive quasi-measure on μ_A on $[0,1]^2$ and the corresponding non-2-sub-additive quasi-state τ_A on $\mathrm{C}([0,1]^2)_+$, given by J. Aarnes in [**3**], has the property that there exists $g, h \in \mathrm{C}([0,1]^2)_+$ with $\tau_A(g) = 0$, $\tau_A(h) = 0$ and $\tau(g+h) > 2$. And it has the – for us important – property that the restriction $\tau_A|C^*(1,f)_+$ is additive, if and only if, the function $f\colon [0,1]^2 \to \mathbb{C}$ has zero "winding numbers" with respect to closed (Jordan) paths in $P \subset [0,1]^2$ and points in $\mathbb{C}\backslash f(P)$.

Now take the universal unital free product C^*-algebra $B := \mathrm{C}([0,1]) * \mathrm{C}([0,1])$ and the natural unital C^*-algebra epimorphism $\varphi\colon B \to \mathrm{C}([0,1]^2)$. One can show that all images $f = \varphi(b) \in \mathrm{C}([0,1]^2)$ of normal elements, i.e., $b \in B$ with $b^*b = bb^*$, have only zero winding numbers. (The proof uses the natural relation between winding numbers of parametrized closed curves and the index of operators in the Toeplitz algebra $0 \to \mathbb{K}(\ell_2) \to \mathcal{T} \to \mathrm{C}(S^1) \to 0$.) It implies that the restriction $\mu|B_+$ of $\mu := \tau_A \circ \varphi$ is a unital quasi-trace of $B = \mathrm{C}([0,1]) * \mathrm{C}([0,1])$. This μ can not be 2-sub-additive because otherwise τ_A must be 2-sub-additive on $\mathrm{C}([0,1]^2)_+$, by using here that the set of elements $x \in B$ with $\mu(x^*x) = 0$ must be a closed ideal of B if μ is 2-sub-additive.

One can explore the relation between winding numbers of elements of $\mathrm{C}([0,1]^2)$ and indices of the Toeplitz algebra $\mathcal{T}$ even more and take a sequence $\psi_n\colon S^1 \to [0,1]^2$ of pice-wise smooth closed curves $\psi_n\colon S^1 \to [0,1]^2 \cong [0,1] + i[0,1] \subseteq \mathbb{C}$ that are uniformly dense in the set of all closed curves $\psi\colon S^1 \to [0,1]^2$. It defines a sequence of unital C^*-epimorphisms $\varphi_n\colon \mathrm{C}([0,1]^2) \to \mathrm{C}(S^1) \cong \mathcal{T}/\mathbb{K}(\ell_2)$.

The latter sequence φ_n can be explored to show that there exist l.s.c. quasi-traces τ on certain type I C^*-algebras A:

It is an extension $0 \to J \to A \to_\phi \mathrm{C}([0,1]^2) \to 0$ with an ideal J that is an extension of $\mathrm{C}_0((0,1))$ (or of $\mathrm{C}_0(0,1]$?) by $c_0(\mathbb{K})$, that has the property that $\mu_A \circ \phi$ is not a 2-sub-additve, but is bounded and unital, is defined on all of A_+, and has additive restrictions to each commutative C^*-subalgebras of A. Moreover, there exists no "bound" $\gamma \in (0,\infty)$ with the property $\tau(a+b) \leq \gamma \cdot \max(\tau(a), \tau(b))$, because it can happen that $\tau(a+b) > 0$ – but $\mu(a) = 0 = \mu(b)$ for some non-commuting $a, b \in A_+$.

`HERE is an older summary:` J.F. Aarnes [**3**] described a ???????

There exists a unital extension $0 \to c_0(\mathbb{K}) \to A \to \mathrm{C}([0,1]^2) \to 0$ such that τ is given by $\tau = \tau_A \circ \phi$, where τ_A denotes the example of a globally non-additive unital quasi-state on $\mathrm{C}([0,1]^2)$ that is additive on each C^*-subalgebra $C^*(f,1)$ where $f\colon [0,1]^2 \to \mathbb{C}$ factorizes approximately over a tree (that is in this case of J.F. Aarnes described in [**3**]).

`It should be better to give a citation, not an explanation?!!`

Much more easy to handle, despite not of of type I, is the unital free product $B := \mathrm{C}[0,1] * \mathrm{C}[0,1]$ and the non-2-subadditive quasi-state $\tau_0 := \tau_A \circ \pi$, where here π denotes the natural C^*-epimorphism π from B onto $\mathrm{C}([0,1]) \otimes \mathrm{C}[0,1]) = \mathrm{C}([0,1]^2)$.

The key observation uses a suitable chosen unital *-monomorphism η from $\mathrm{C}([0,1]^2)$ into

$$\ell_\infty(\mathrm{C}(S^1)) \cong \ell_\infty(\mathcal{T})/\ell_\infty(\mathbb{K}),$$

where here $\mathcal{T} := C^*(T) \subset \mathcal{L}(\ell_2)$ means the Toeplitz algebra generated by the forward shift $Te_n = e_{n+1}$ on $\ell_2(\mathbb{N})$, and the defining countable family of maps from $\mathrm{C}([0,1]^2)$ to $\mathrm{C}(S^1)$ are given by a uniformly dense sequence in all pice-wise linear continuous maps (could also take smooth maps) from S^1 into $[0,1]^2 = [0,1] + i[0,1] \subseteq \mathbb{C}$. For each map $\gamma\colon S^1 \to [0,1]^2$ define a unital C^*-morphism $\widehat{\gamma}\colon f \mapsto f \circ \gamma$ All this C^*-morphisms lift to unital C^*-morphisms from B into $\mathcal{T}$, and define a unital C^*-morphism from B into $\ell_\infty(\mathcal{T})$.

Then the free product $B = \mathrm{C}[0,1] * \mathrm{C}[0,1]$ has an "universal lifting property" that implies that all unital C^*-morphisms $h\colon B \to \mathcal{C}$ into the Calkin algebra $\mathcal{C} := \mathcal{L}(\ell_2)/\mathbb{K}(\ell_2)$ lift to unital C^*-morphisms $H\colon B \to \mathcal{L}(\ell_2)$.

By using the BDF theory, this implies that each image of each normal element maps to an element with the property that all entries have zero indices ...

????

BDF = Brown Douglas Fillmore

supports an index argument for the characterization of normal operators (modulo compact perturbation) among the essentially normal operators:

An operator $S \in \mathcal{L}(\ell_2)$ is a compact perturbation of a normal operator, if and only if, all indices of $S - \lambda$ are equal to zero for all $\lambda \notin \mathrm{Spec}(\pi_{\mathbb{K}}(S))$, cf. [**207**, cor. IX.7.4].

This implies that all winding-numbers for $\pi(S) \in \mathrm{C}([0,1]^2)$ are zero.

The construction shows that a function $f \in \mathrm{C}([0,1]^2)$ is the image $\pi(g)$ of a normal element $g \in B$, if and only if, f can be uniformly approximated by functions $f_n \in \mathrm{C}([0,1]^2)$ that factorize over a finite tree T_n (which is then automatic homotopic to the root of T_n), i.e., $f_n = \varphi_n \circ \psi_n$ with $\psi_n \colon [0,1]^2 \to T_n$ and $\varphi_n \colon T_n \to [0,1]^2$, $\lim_n \|f_n - f\| = 0$.

An important property of such tree-factorable functions f_n is that they are homotopic inside there images $f_n([0,1]^2) \subset \mathbb{C}$ to a constant map (or at least "inside any neighbourhood of its image", by a simpler proof).

It is not difficult to check that the Aarnes quasi-state μ_0 on $\mathrm{C}([0,1] \times [0,1])$ becomes additive on the subalgebras $C^*(f) \subset \mathrm{C}([0,1]^2)$ generated by f with this special property (being a uniform limit of tree-factorable functions on $[0,1]^2$). Thus the restriction of $\tau_0 := \mu_0 \circ \pi$ every abelian C^*-subalgebra of $B := \mathrm{C}[0,1] * \mathrm{C}[0,1]$ is additive. But $\mu_0 \circ \pi$ can not be additive, because π is surjective and the Aarnes quasi-state μ_0 is not additive on $\mathrm{C}([0,1]^2)$.

An application of quasi-diagonal elements shows that this implies the existence of a unital type I C^*-algebra A that has a non-additive quasi-state is an extension $c_0(\mathbb{K}) \to A \to \mathrm{C}_0((0,1], \psi(B))$ by modification of a C^*-morphism ψ from the unitization of $\mathrm{C}_0((0,1], B)$ into $\ell_\infty(\mathcal{T}) \subseteq \ell_\infty(\mathcal{L}(\ell_2))$ constructed from the C^*-morphism that we have described above.

This equivalent properties of τ are long known for a sort of "normal" quasi-states on finite AW*-algebras M, and the proof of the equivalence of the three properties of τ goes over variants of suitable ultra-power constructions that give on suitable hereditary C^*-algebras $D \subseteq A$ with $\tau | D_+$ bounded a C^*-morphism $\varphi \colon D \to M$ where M is a hereditary C^*-subalgebra of an AW*-algebra such that all maximal abelian C^*-subalgebras of M are hereditary C^*-subalgebras of Abelian W*-algebras.

24. Central sequence algebras, the ε-test and its application.

The here given formulation and proof of the ε-test Lemma given in the Appendix of [**448**] corrects also a really obvious(!) typo in the there given formulation and proof of this Lemma.

To each free filter ω on the natural numbers $\mathbb{N}$ and to each C^*-algebra A one can associate the ultrapower A_ω and the central sequence C^*-algebra $A_\omega \cap A'$ as follows:

Let $c_\omega(A)$ denote the closed two-sided ideal of the C^*-algebra $\ell^\infty(A)$ of bounded sequences from A given by

$$c_\omega(A) = \left\{(a_n)_{n\geq 1} \in \ell^\infty(A) \mid \lim_{n\to\omega} \|a_n\| = 0\right\}.$$

We use the notation $\lim_{n\to\omega} \alpha_n$ (and sometimes just $\lim_\omega \alpha_n$) to denote the limit of a sequence $(\alpha_n)_{n\geq 1}$ along the filter ω. This limit exists for all free ultra-filters ω on $\mathbb{N}$.

The ultrapower A_ω is defined to be the quotient C^*-algebra $\ell^\infty(A)/c_\omega(A)$; and we denote by π_ω the quotient mapping $\ell^\infty(A) \to A_\omega$. Let $\iota\colon A \to \ell^\infty(A)$ denote the "diagonal" inclusion mapping $\iota(a) = (a, a, a, \dots) \in \ell^\infty(A)$, $a \in A$; and define $\iota_\omega := \pi_\omega \circ \iota\colon A \to A_\omega$. Both mappings ι and ι_ω are injective. We shall often suppress the mapping ι_ω and view A as a sub-C^*-algebra of A_ω. The relative commutant, $A_\omega \cap A'$, then consists of elements of the form $\pi_\omega(a_1, a_2, a_3, \dots)$, where $(a_n)_{n\geq 1}$ is a bounded asymptotically central sequence in A. The C^*-algebra $A_\omega \cap A'$ is called a *central sequence algebra*.

We shall most often insist that the free filter ω is an ultrafilter, and we avoid using $A^\infty := \ell^\infty(A)/c_0(A)$ and $A_\infty := A' \cap A^\infty$, which have similar properties and produce similar results (up to different selection procedures). One of the reasons is that we need an *epimorphism* from A_ω onto the W*-algebra $N^\omega := \ell_\infty(N)/c_{\tau,\omega}(N)$ (to be defined below), cf. Theorem B.24.3 below, where N is the weak closure of A in the GNS representation determined by a tracial state τ on A. The sequence algebra $N^\infty := \ell_\infty(N)/c_{\tau,0}(N)$ (with $c_{\tau,0}(N)$ the bounded sequences in N with $\lim_n \|a\|_{2,\tau} = 0$) is not a W*-algebra. Another reason for preferring free ultra-filters to general free filters is that, for $A \neq \mathbb{C}$, simplicity of A_ω is equivalent to pure infiniteness and simplicity of A. The algebras A_ω are the fibers of the continuous field A_∞ with base space $\beta(\mathbb{N}) \setminus \mathbb{N}$. The structure of this bundle appears to be complicated.

Recall from [**448**] that if B is a C^*-algebra and if A is a separable sub-C^*-algebra of B_ω, then we define the central sequence algebra

$$F(A, B) := (A' \cap B_\omega)/\mathrm{Ann}(A, B_\omega).$$

This C^*-algebra has interesting properties. For example, $F(A, B) := F(A \otimes \mathbb{K}, B \otimes \mathbb{K})$. We let $F(A) := F(A, A)$. The C^*-algebra $F(A)$ is unital if A is σ-unital. If A is unital, then $F(A) = A' \cap A_\omega$. We refer to [**448**] for a detailed account on the C^*-algebras $F(A, B)$ and $F(A)$. We shall often, in the unital case, denote the central sequence algebra $A_\omega \cap A'$ by $F(A)$.

We have the following useful selection principle for sequences in the filter ω with a countable number conditions from [**448**, Lemma A.1]. For completeness we add a proof ([7]).

[7] We correct here a misleading typo in the original proof given in [**448**]!.

LEMMA B.24.1 (The ε-test). *Let ω be a free ultrafilter. Let $X_1, X_2, \dots$ be any sequence of sets and suppose that, for each $k \in \mathbb{N}$, we are given a sequence $(f_n^{(k)})_{n\geq 1}$ of functions $f_n^{(k)}\colon X_n \to [0,\infty]$.*

For each $k \in \mathbb{N}$ define a new function $f_\omega^{(k)}\colon \prod_{n=1}^\infty X_n \to [0,\infty)$ by

$$f_\omega^{(k)}(s_1, s_2, \dots) := \lim_{n\to\omega} f_n^{(k)}(s_n), \qquad (s_n)_{n\geq 1} \in \prod_{n=1}^\infty X_n.$$

Suppose that, for each $m \in \mathbb{N}$ and each $\varepsilon > 0$, there exists $s = (s_1, s_2, \dots) \in \prod_{n=1}^\infty X_n$ such that $f_\omega^{(k)}(s) < \varepsilon$ for $k = 1, 2, \dots, m$. It follows that there is $t = (t_1, t_2, \dots) \in \prod_{n=1}^\infty X_n$ with $f_\omega^{(k)}(t) = 0$ for all $k \in \mathbb{N}$.

PROOF. For each $n \in \mathbb{N}$ define a decreasing sequence $(X_{n,m})_{m\geq 0}$ of subsets of X_n by $X_{n,0} = X_n$ and

$$X_{n,m} = \big\{ s \in X_n\,;\ \max\{f_n^{(1)}(s), \dots, f_n^{(m)}(s)\} \,<\, 1/m \big\},$$

for $m \geq 1$. We let $m(n) := \sup\{m \leq n\,;\ X_{n,m} \neq \emptyset\}$; and for each integer $k \geq 1$, let $Y_k := \{n \in \mathbb{N}\,;\ k \leq m(n)\}$. Fix some $k \geq 1$. By assumption there exists $s = (s_n) \in \prod_n X_n$ such that $f_\omega^{(j)}(s) < 1/k$ for $1 \leq j \leq k$. This entails that there exists a set $Z_k \in \omega$ such that $f_n^{(j)}(s_n) < 1/k$ for $1 \leq j \leq k$ and for all $n \in Z_k$. This again implies that $X_{n,k} \neq \emptyset$ for all $n \in Z_k$; which finally shows that $m(n) \geq \min\{k, n\}$ for all $n \in Z_k$. It follows that $Z_k \setminus \{1, 2, \dots, k-1\} \subseteq Y_k$, from which we conclude that $Y_k \in \omega$ (because ω is assumed to be free). Now,

$$\lim_{n\to\omega} \frac{1}{m(n)} \;=\; \liminf_{n\to\omega} \frac{1}{m(n)} \;\leq\; \inf_k \sup_{n\in Y_k} \frac{1}{m(n)} \;\leq\; \inf_k \frac{1}{k} = 0.$$

By definition of $m(n)$ we can find $t_n \in X_{n,m(n)} \subseteq X_n$ for each $n \in \mathbb{N}$. Put $t = (t_n)_{n\geq 1}$. Then $f_n^{(k)}(t_n) \leq 1/m(n)$ for all $k < m(n)$ by definition of $X_{n,m(n)}$, so

$$f_\omega^{(k)}(t) \;=\; \lim_{n\to\omega} f_n^{(k)}(t_n) \;\leq\; \lim_{n\to\omega} \frac{1}{m(n)} \;=\; 0,$$

for all $k \geq 1$ as desired. □

Let N be a W*-algebra with separable predual and let τ be a faithful normal tracial state on N. Consider the associated norm, $\|a\|_{2,\tau} = \tau(a^*a)^{1/2}$, $a \in N$, on N. Let N^ω denote the W*-algebra $\ell_\infty(N)/c_{\omega,\tau}(N)$, where $c_{\omega,\tau}(N)$ consists of the bounded sequences $(a_1, a_2, \cdots)$ with $\lim_\omega \|a_n\|_{2,\tau} = 0$. (As mentioned above, if ω is a free filter, which is not an ultrafilter, then N^ω is not a W*-algebra.)

REMARK B.24.2. Since the pre-dual N_* of the W*-algebra N is separable, the algebra $N' \cap N^\omega$ contains a copy of the hyper-finite II_1 factor $\mathcal{R}$ with separable predual, if and only if, for each $k \in \mathbb{N}$ there exists a sequence of unital *-homomorphisms $\psi_n\colon M_k \to N$ such that $\lim_{n\to\infty} \|[\psi_n(t), a]\|_{2,\tau} = 0$ for all $t \in M_k$ and $a \in N$, if and only if, there is a *-homomorphism $\varphi\colon M_2 \to N' \cap N^\omega$ such that $t \in N \mapsto t \cdot \varphi(1) \in N^\omega$ is faithful. (It suffices to consider elements t in the centre of N.)

This equivalence was shown by Dusa McDuff, [**550**], in the case where N is a *factor*. She gets moreover that $N \cong N\overline{\otimes}\mathcal{R}$, if and only if, N has a central sequence that is not hyper-central. Such a II_1 factor is called a *McDuff factor*.

The result below was proved by Y. Sato in [**707**, Lemma 2.1] in the case where A is nuclear. We give here an elementary proof of this useful result, that does not assume nuclearity of A. The result implies that the central sequence C^*-algebra $A_\omega \cap A'$ has a subquotient isomorphic to the hyperfinite II_1 factor $\mathcal{R}$ whenever A has a factorial trace so that the corresponding II_1 factor, arising from GNS representation with respect to that trace, is a McDuff factor. In Remark **??** in the next section we show how one can give an easier proof of the theorem below using that the kernel J_τ of the natural *-morphism $A_\omega \to N^\omega$ is a so-called σ-ideal. The proof given below does not (explicitly) use σ-ideals.

THEOREM B.24.3. *Let A be a separable unital C^*-algebra, τ be a faithful tracial state on A, let N be the weak closure of A under the GNS representation of A with respect to the state τ, and let ω be a free ultrafilter on $\mathbb{N}$. It follows that the natural morphisms*

$$A_\omega \to N^\omega\,, \qquad A' \cap A_\omega \to N' \cap N^\omega$$

are surjective.

PROOF. Let π_A and π_N denote the quotient mappings $\ell^\infty(A) \to A_\omega$ and $\ell^\infty(N) \to N^\omega$, respectively. Denote the canonical map $A_\omega \to N^\omega$ by Φ, and let $\widetilde{\Phi}\colon \ell^\infty(A) \to N_\omega$ denote the map $\Phi \circ \pi_A$.

We show that $\Phi\colon A_\omega \to N^\omega$ is surjective: If $x = \pi_N(x_1, x_2, \dots)$ is an element in N^ω, then, by Kaplansky density theorem, there exists $a_k \in A$ with $\|a_k\| \leq \|x_k\|$ and with $\|a_k - x_k\|_{2,\tau} \leq 1/k$. It follows that $(a_1, a_2, \dots) \in \ell^\infty(A)$ and that $\widetilde{\Phi}(a_1, a_2, \dots) = x$.

To prove that the natural map $A' \cap A_\omega \to N' \cap N^\omega$ is surjective, it suffices to show that if $b = (b_1, b_2, \dots) \in \ell^\infty(A)$ is such that $\widetilde{\Phi}(b) \in N^\omega \cap N'$, then there is an element $c \in \ell^\infty(A)$ such that $\pi_A(c) \in A_\omega \cap A'$ and $\widetilde{\Phi}(c) = \widetilde{\Phi}(b)$. Let such a $b \in \ell^\infty(A)$ be given, put $B = C^*(A, b) \subseteq \ell^\infty(A)$, and put $J = (\widetilde{\Phi})^{-1}(0) \cap B$. Notice that an element $x = (x_1, x_2, \dots) \in \ell^\infty(A)$ belongs to the kernel $(\widetilde{\Phi})^{-1}(0)$ of $\widetilde{\Phi}$ if and only if $\lim_{n\to\omega} \|x_n\|_{2,\tau} = 0$. Notice also that $ba - ab \in J$ for all $a \in A$.

Let $(d^{(k)})_{k\geq 1}$ be an increasing approximate unit for J consisting of positive contractions which is asymptotically central with respect to the separable C^*-algebra B. Then

$$\begin{aligned} 0 &= \lim_{k\to\infty} \|(1 - d^{(k)})\big(ba - ab\big)(1 - d^{(k)})\| \\ &= \lim_{k\to\infty} \|(1 - d^{(k)})b(1 - d^{(k)})a - a(1 - d^{(k)})b(1 - d^{(k)})\| \end{aligned}$$

for all $a \in A$.

We use the ε-test (Lemma B.24.1) to complete the proof:
Let $(a_k)_{k\geq 1}$ be a dense sequence in A. Let each X_n be the set of positive contractions

in A. Define $f_n^{(k)}: X_n \to [0,\infty)$ by

$$f_n^{(1)}(x) = \|x\|_{2,\tau}, \qquad f_n^{(k+1)}(x) = \|(1-x)b_n(1-x)a_k - a_k(1-x)b_n(1-x)\|, \ k \geq 1 .$$

Notice that $f_\omega^{(1)}(d^{(\ell)}) = \lim_{n\to\omega} \|d_n^{(\ell)}\|_{2,\tau} = 0$ for all ℓ because each $d^{(\ell)}$ belongs to J. Note also that

$$f_\omega^{(k)}(d^{(\ell)}) = \|(1-d^{(\ell)})b(1-d^{(\ell)})a_k - a_k(1-d^{(\ell)})b(1-d^{(\ell)})\|.$$

It is now easy to see that the ε-test in Lemma B.24.1 is satisfied, so there exists a sequence $d = (d_n)_{n\geq 1}$ of positive contractions in A such that $f_\omega^{(k)}(d) = 0$ for all k. As $f_\omega^{(1)}(d) = 0$ we conclude that $\widetilde{\Phi}(d) = 0$.

Put $c = (1-d)b(1-d)$. Then $\widetilde{\Phi}(c-b) = 0$, so $\widetilde{\Phi}(c) = \widetilde{\Phi}(b)$. Since $f_\omega^{(k)}(d) = 0$, we see that $ca_k - a_kc = 0$ for all $k \geq 2$. This shows that $\pi_A(c) \in A_\omega \cap A'$. □

Correction to:

'*The UCT, the Milnor Sequence, and a Canonical Decomposition of the Kasparov Groups*' Author: Schochet C.L.

Source: K-theory, Volume 14, Number 2, June 1998 , pp. 197-199(3)

Publisher: Springer

Abstract: In this note we correct a mistake in K-Theory 10 (1996), 49–72. In that paper we asserted that under bootstrap hypotheses the short exact sequence (injective at the beginning and surjective at the end):

$$\underset{\longleftarrow}{\lim}^1 \operatorname{Hom}_{\mathbb{Z}}(K_*(A_i), K_*(B)) \to \operatorname{Ext}^1_{\mathbb{Z}}(K_*(A), K_*(B)) \to \underset{\longleftarrow}{\lim} \operatorname{Ext}^1_{\mathbb{Z}}(K_*(A_i), K_*(B))$$

which arises in the computation of $KK_*(A,B)$ is a split sequence. This is not always the case. Thus $KK_*(A,B)$ decomposes into the three components

$$\operatorname{Hom}_{\mathbb{Z}}(K_*(A), K_*(B)), \qquad \underset{\longleftarrow}{\lim} \operatorname{Ext}^1_{\mathbb{Z}}(K_*(A_i), K_*(B))$$

and

$$\underset{\longleftarrow}{\lim}^1 \operatorname{Hom}_{\mathbb{Z}}(K_*(A_i), K_*(B)).$$

However, this is a decomposition in the sense of composition series, not as three direct summands. The same correction applies to the Milnor sequence. If there is no prime p for which both $K_*(A)$ and $K_*(B)$ have p-torsion then the decomposition is indeed as direct summands. The other results of the paper are unaffected.

APPENDIX C

Temporary (!!) monitor and To-Do List

1. Circulation of Changes

We still have no example of a nuclear separable C^*-algebra that is purely infinite but is not strongly purely infinite !!! (2014, first discussed ?).

On simple C*-algebras A this two properties are the same! (For obvious reason!)

Def. equivalent to "purely infinite" (p.i.):

The element $a \in A_+$ is "purely infinite" if $a \oplus a \precsim a$ (inside $M_2(A)$ and means there that $\mathrm{diag}(a, a) \precsim \mathrm{diag}(a, 0)$). Here one can take also non-positive $a \in A$ with $a \oplus a \precsim a$, because $a \approx a^* a \approx (a^* a)^* = a(a^*)$.

This is equivalent to the property of $a \in A$ that If $b \in A_+$ and $b \neq 0$ is in the closed ideal $I(a)$ of A generated by a, then $b \oplus a \precsim a$.

(This is equivalent to $a \oplus a \precsim a$ and is the original definition of a being "p.i." given by J. Cuntz ! Give here precise Citation of Definition in paper of Cuntz!!!)

The Definition C.1.1 is equivalent to $a \oplus a \precsim a$ for all $a \in A_+$.

In general $a \in A_+$ is called "infinite" if there exists non-zero $x \in A$ with $x \oplus a \precsim a$.

Lemma:
, Let A a C*-algebra and $X \subseteq A$ a countable subset of A. The there exists a *(*separable) C*-subalgebra B of A with the properties that $X \subseteq B$ and for all elements $c, d \in \mathbb{K}(\ell_2) \otimes B$ holds:

$c \precsim d$ in $\mathbb{K}(\ell_2) \otimes B$, if and only if, $c \precsim d$ in $\mathbb{K}(\ell_2) \otimes A$.

This separable C*-subalgebra B of A is mostly much bigger then the C*-subalgebra generated by the separable X, but B is still a separable C*-algebra.

Moreover one can manage (by suitable enlarging of B by its construction) that B is nuclear if A is nuclear.

(But notice here that exactness is anyway a hereditary property! And remind that exactness is the same as *Subnuclearity*.) Give here citation!

This implies not only that elements of B are infinite (resp. purely infinite) in B, if and only if, this elements are infinite (resp. purely infinite) in A (which is usually a weaker property). This property of B implies also that each closed ideal J of B is the intersection $I \cap B = J$

Definition C.1.1. A (non-zero) C*-algebra A is called *purely infinite*, if and only if,

(i) The C*-algebra A has no characters, and
(ii) for every element $a, b \in A_+ \setminus 0$ with b in the closed ideal $I(a)$ of A, generated by a, there is a sequence of elements $c_1, c_2, \ldots \in A$ with $\lim_n c_n^* a c_n = b$. (In the sense $\lim_n \|b - c_n^* a c_n\| = 0$.)

Observations concerning Definition C.1.1:

Part (ii) of the Definition C.1.1 of purely infinite (p.i.) C*-algebras A (also called "properly infinite" C*-algebras ?) is equivalent to:
For each $d_1, d_2 \in A$, $a \in A_+$ and $\varepsilon > 0$ there exists $d_3 \in A$ with

$$\|d_1^* a d_1 + d_2^* a d_2 - d_3^* a d_3\| < \varepsilon\,.$$

This equivalence can be shown by complete induction, because each element $b \in I(a)_+$ for the closed ideal $I(a)$ of A generated by a can be approximated arbitrary near by elements of the kind

$$e_1^* a e_1 + e_2^* a e_2 + \cdots + e_n^* a e_n \in I(a)_+\,.$$

We discuss here the "permanence properties" of this definition of purely infinite (= properly infinite ?) C*-algebras:

Proposition C.1.2. *The class of purely infinite C*-algebras A as defined in Definition C.1.1 has following permanence properties:*

(i) *Quotients, ideals, and hereditary C*-subalgebras,*
(ii) *Inductive limits of purely infinite C*-algebras,*
(This is still not proven !!! But every positive element $a \in A_+$ of an inductive limit is the limit of a sequence of properly infinite positive elements. It seems that the limit of p.i. elements is p.i., which gives the proof.)
(iii) *Every separable subset X of A is contained in a separable purely infinite C*-subalgebra B of A. Moreover one can find such B with the property that each ideal J of B is the intersection $IcapB = J$ of a closed ideal of B.*
(Then X contained in B, that can be much bigger than $C^*(X) \subseteq A$.
Can we manage to find such a C-subalgebra B that is in addition relatively weakly injective in A? Unfortunately: It is Not known!?)*

(But what about extensions?)

Observations:

Question: Can we prove that (all sorts of) purely infinite C*-algebras have the Cuntz property:

For all $a \in A_+$ holds $a \oplus a \precsim a$.

This property should work also for inductive limits.

If this is shown than one must show that Cuntz-pi of A implies that A is a p.i. C*-algebra.

(But this depends from the definition of "p.i." etc.)

(It is then to show that hereditary C*-subalgebras of D of A have no characters. But that is equivalent to the property that $\rho(A) \cap \mathbb{K}(H) = \{0\}$ for each irreducible representation $\rho : A \mapsto \mathcal{L}(H)$ of A holds that $\rho(A) \cap \mathbb{K}(H) = 0$.)

Remark C.1.3. Notice that, moreover, one can manage to find separable C*-subalgebras A_τ of A in part (iv) of Proposition C.1.2 that are in addition relatively weakly injective in A.

This follows from the general observation that each separable C*-subalgebra B of A is contained in a separable C*-subalgebra D of A that is relatively weakly injective in A, i.e. there exist a completely positive contraction $E\colon A \to D^{**}$ with $E(d) = d$ for all $d \in D$.

Where is this (= the latter) shown ?

Proof. Ad(i): Suppose that A is a p.i. C*-algebra, and $J \subset A$ a (non-zero) closed ideal. Then J and A/J can not have no characters.

(See considerations below.)

The part (ii) of Definition C.1.1 is moreover shown for all hereditary C*-subalgebras.

Ad(ii): The case of inductive limits:

Since, by part (i), the properties of purely infinite C*-algebras pass to (non-zero) quotients we can suppose that A is the inductive limit of C*-subalgebras $A_\tau \subseteq A$ of A and the A_τ are purely infinite.

If A is a C*-algebra with a character ξ then every (e.g. separable) C*-subalgebra B of A is in the kernel of ξ or the restriction $\xi|B$ to B is a character. Thus, if A is an inductive limit of C*-algebras A_τ without characters, then A has no character.

Suppose that A is an *inductive limit* of an upward directed net of C*-subalgebras $A_\tau \subseteq A$ and each A_τ is purely infinite. Then for each $a, b \in A_+$ with the property that b is contained in the closed ideal J of A generated by a, and each chosen $\delta \in (0,1)$ (small enough) there exists $n \in \mathbb{N}$ and $d_1, \ldots, d_n \in A$ with $\|b - \sum_k d_k^* a d_k\| < \delta$.

The problem is about the estimates ...

can be simplified if we use that we must show only that there exists for each $d_1, d_2 \in A$ and $\varepsilon > 0$ an element $d_3 \in A$ with the property that

$$\|d_3^* a d_3 - d_1^* a d_1 - d_2^* a d_2\| < \varepsilon\,.$$

Let $\gamma > 0$ (sufficiently small) and find $b, e_1, e_2, e_3 \in A_\tau$, with norms of $a - b$, $d_j - e_j$ $(j = 1, 2)$ with norms below γ, and

$$\|e_3^* b e_3 - e_1^* b e_1 - e_2^* b e_2\| < \gamma\,.$$

then ?????????

??? This gives ???:

For each $b \in A_+$ and each positive element c of the closed ideal J generated by b there exists a sequence of elements $x_n \in A$ such that $\|c - x_n^* b x_n\|$ converges to zero.

Have the same problem: norm- estimate $\|e_3^* b e_3 - e_3^* a e_3\|$ and a way to come from a to b ...

$d_j - e_j$ for $j = 1, 2$, $a - b$ have to be estimated:

Now we take $\gamma > 0$ small enough such that

$e - b$, $a - f$, $g_k - d_k$

$\|e - b\|$, $\|a - f\|$, $\|g_k - d_k\| < \gamma$ can be chosen arbitrary small?

Find $A_\tau \subseteq A$, such that it contains ????

Find $h \in A_\tau$ with $\|h^* f h - \sum_k g_k^* f g_k\|$ (arbitrary small !) say $< \mu$ for some before given $\mu > 0$.

The problem is: $\|h\|$ and $\|h^* f h - h^* a h\| <$???.

???? we can find $A_\tau \subseteq A$ and $e, f, ? \in A_\tau$????

Has to be studied more careful !!! It seems that the cut-down possibility $(a-\varepsilon)_+$ plays a role ...

(1) If $J \subseteq A$ is a nonzero closed ideal of A with $J \neq A$ then J and A/J have no characters:

Obviously all (closed) ideals J of A and quotients A/J have no characters if A has no characters, because each character ξ of A/J defines the (non-zero) character $a \mapsto \chi(a) := \xi(\pi_J(a))$ on A. But this can not exist by property (i) of A.

And if η is a character of J with kernel K. Then K is a closed ideal of A and $J/K \subseteq A/K$ is a closed ideal of A/K that is one-dimensional. Thus, $J/K = \mathbb{C} \cdot p$ for some projection $p \in A/K$. Since J/K is a closed ideal of A/K this implies that $x \mapsto xp \in \mathbb{C} \cdot p$ for $x \in A/K$ defines a character on A/K. Above we have seen that the quotients A/K can not have a character. Thus, J can not have a character.

So far we have seen that closed ideals and quotients of A can not have a character.

(The question about characters of hereditary C*-subalgebras of A will be considered further below in ????? ....)

Here is the general observation concerning this direction:

Lemma:
Let $D \subseteq A$ a hereditary C*-subalgebra of A (i.e. $D = DAD = \overline{DAD}$) and $I \subseteq D$ a closed ideal of D. Then the closed ideal $J \subseteq A$ of A generated by the hereditary C*-subalgebra I of A has the property that $J \cap D = I$.

Remark:
The same happens with von-Neumann algebras M: Let $P^*P = P \in M$ a projection and Q a projection in the centrum $c(PMP)$ of PMP. Then let R in the centre $c(M)$ of M the smallest projection with the property $RQ = Q$, which means equivalently that $RM = RMR$ is the weak closure (i.e. the $\sigma(M, M_*)$-closure) of the linear span of MQM.

Then R is the smallest projection in the centrum $c(M)$ of M with the property that $RQ = Q$, and it turns out that R, P and Q satisfy that $RP = Q$.

(3) Now let $D \subseteq A$ a (non-zero) hereditary C*-sub-algebra of A. Suppose that D has a character, say η. Let $I \subseteq D$ denote the kernel-ideal of η. Then the closed ideal J of A generated by I has the property that $J \cap D = I$ (It is an exercise Lemma! Cited above.) and that – therefore – $\mathbb{C} \cong D/I \subseteq A/J$ is a one-dimensional hereditary C*-subalgebra of A/J that is naturally isomorphic to $\mathbb{C}$

and is needed for what ???

Thus, A/F contains an isomorphic image of some algebra of compact compact operators ... on a Hilbert space (of dimension ≥ 1). But this was excluded by the requirements that no hereditary C*-sub-algebra of A has a character.

(0) The elements c_n in Part (ii) can be taken in $\overline{aAb}$ because the Part (ii) of this definition can be expressed equivalently:

If nonzero $b \in A_+$ is contained in the closed ideal of A generated by $a \in A_+$ then, for every $0 < \varepsilon < \|b\|$, there exists $\delta > 0$ and $d \in A$ with $d^*(a-\delta)_+d = (b-\varepsilon)_+$.

In particular, the Part(ii) passes automatically to all (non-zero) hereditary C*-subalgebras $D \subseteq A$ of A, i.e., if A is p.i., then D satisfies Part (ii) of Definition C.1.1.

Let $J \subseteq A$ a closed ideal and $x, y \in (A/J)_+$ such that y is in the closed ideal of $x \in (A/J)_+$, and $\varepsilon \in (0, \|y\|)$.

Then there exist elements $a \in A_+$ and $d_1, \ldots d_n \in A$ with $\pi_J(a) = x$ and $\|\pi_J(b) - y\| < \delta$ for $b := d_1^*ad_1 + \cdots + d_1^*ad_1$ and $\delta := \varepsilon/3$. By Part (ii) of Definition C.1.1 there exists $c \in A$ with $\|c * ac - b\| < \delta$. Thus, $\|\pi_J(c)^*x\pi_J(c) - y\| < \varepsilon$.

The Parts (i) is also satisfied for D: Suppose that D has a character ϕ, then there exists a contraction $e \in D_+$ with $\phi(e) = 1$. It extends to a pure state ρ on A. (Because in general states of D extend to states on A. Then the extreme points of this extensions turn out to be pure state on A.)

And then ???

$x, y \in (A/J)_+$ □

(XXXX????)

It is not clear if strong pure infiniteness and the pure infiniteness are really different !!!

Here is a definition that is equivalent to "strongly purely infinite" (s.p.i.):

If $S = [a_{j,k}] \in M_2(A)_+$ then there exists a sequence of diagonal matrices $T_n = s_n \oplus t_n \in M_2(A)$ such that $T_n^* S T_n$ converges to the diagonal matrix $a_{1,1} \oplus a_{2,2}$. (Gives $s_n^* a_{1,1} s_n \approx a_{1,1}$, $t_n^* a_{2,2} t_n \approx a_{2,2}$, $s_n^* a_{1,2} t_n \approx 0$, and $t_n^* a_{2,1} s_n \approx 0$.)

Gives with $a_{j,k} := a$ for all cases $j, k \in \{1, 2\}$ that a is properly infinite in A, because $s_n^* a s_n \approx a$, $t_n^* a t_n \approx a$ $s_n^* a t_n \approx 0$. It is equivalent $a \oplus a \precsim a$, by considering the case $a_{1,1} := a$, $a_{i,j} = 0$ for $(i, j) \neq 0$.

Need to show my and others notations and definitions!

Definition of: "approximately divisible" ?? where ??? Def. of: "???" etc.

2. Proposed changes (1)

Change it now, because it can produce misunderstandings !

1.) General notations for matrices (to be decided and then changed where different notation was used):

`Adjust in all chapters the use of`

$$M_{m,n}(A) \cong A \otimes M_{m,n}(\mathbb{C}) \cong M_{m,n}(\mathbb{C}) \otimes A$$

`by this rules:`

The columns with n-entries should be in $(1, n)$ -matrices ... $\in M_{n,1}(A)$ ... not in $M_{1,n}(A)$!!!

Lin. Alg. book of Boseck S.76: Matrix of type (m, n) has m rows and n columns. Set of this matrices denoted by $\mathcal{A}_{m,n}$. $\mathcal{A}_{m,r} \cdot \mathcal{A}_{r,n} \subset \mathcal{A}_{m,n}$.

M. Koecher: $K^{(m,n)}$ set of matrices with m rows and n columns. $K^{(m,r)} \cdot K^{(r,n)} \subset K^{(m,n)}$.

H. Anton: $m \times n$-matrix has m rows and n columns. $m \times r$-matrix multiplied with $r \times n$-matrix is $m \times n$-matrix. Transposed matrix of A denoted by A^T.

H.-J. Kowalsky: (m,n) -matrix has m rows and n columns.

G. Strang: $m \times n$-matrix has m rows and n columns:

All have first rows: $a_{1,1}, a_{1,2}, a_{1,3}, \ldots$ next row: $a_{2,1}, a_{2,2}, a_{2,3}, \ldots$

TO DO LIST: from Nov. 2014!!! Not done July/Aug 2021!!!

Adjust in all chapters of the book the use of $\sim$ and $\approx$!!!
And the same with $[a]_\sim$, $\langle a\rangle_\sim$, $[a]_\approx$, $\langle a\rangle_\approx$.
Also adjust all the matrix calculations to the above
cited terminology. ??

Chp 1. Careful check of Introduction.

Ad Chp.2:

Ad 2.1. Shorten: bundle version of $\mathrm{C}(X, A)$ with simple A.

Ad 2.2. Other parts only as overview article.

Ad Chp. 3. Check what is really needed later.

It would be good if we could show that:

Question:

Let A denote a separable exact unital C^*-algebra and consider a unital nuclear c.p. contraction $V\colon A \to \mathcal{M}(\mathcal{O}_2 \otimes \mathbb{K})$ with $V(a^*a) - V(a)^*V(a) \in \mathcal{O}_2 \otimes \mathbb{K}$.

Find a c.p. extension $W\colon A \otimes \mathcal{O}_2 \to \mathcal{M}(\mathcal{O}_2 \otimes \mathbb{K})$ with $W(a \otimes 1) - V(a) \in \mathcal{O}_2 \otimes \mathbb{K}$ for $a \in A$ and $W(x^*x) - W(x)^*W(x) \in \mathcal{O}_2 \otimes \mathbb{K}$ for $x \in A \otimes \mathcal{O}_2$.

Perhaps, we can replace $\mathcal{O}_2$ by the infinite tensor product $\mathcal{O}_2 \otimes \mathcal{O}_2 \otimes \cdots$ and try to adjust V with help of suitable elements of $1 + \mathcal{O}_2 \otimes \mathbb{K}$ ... ???

In particular it should be interesting for **nuclear** A. (It is true if A is in the UCT-class. Perhaps here is a critical point if canceling the important UCT-assumption.)

($<--$ Why it is true in UCT-class ?)

For exact A the question is less interesting because we can replace A by $A \otimes \mathcal{O}_2$ at beginning of the embedding-proof for exact A in $\mathcal{O}_2$.

Since $\mathcal{O}_2 \cong \mathcal{O}_2 \otimes \mathcal{O}_2 \otimes \cdots$, it is likely that $\mathcal{O}_2$ has the property that any separable C^*-subalgebra of $\mathrm{Q}^{\mathrm{s}}(\mathcal{O}_2)$ commutes with a unital copy of $\mathcal{O}_2$ in $\mathrm{Q}^{\mathrm{s}}(\mathcal{O}_2)$.

($\mathrm{Q}^{\mathrm{s}}(\mathcal{O}_2)$ means here the "stable" corona $\mathcal{M}(\mathcal{O}_2 \otimes \mathbb{K})/\mathcal{O}_2 \otimes \mathbb{K}$ of $\mathcal{O}_2$?)

It could replace homotopy invariance considerations, because otherwise one gets only unital embedding of $A \otimes \mathcal{O}_2$ that are "extremal" in $\mathcal{O}_2$ for nuclear A but are not extremal for A itself. (What means here "extremal"?)

It seems to be necessary to study following questions:

Question: If A is a separable unital nuclear C^*-algebra and $\varphi\colon A \to \mathrm{Q}^{\mathrm{s}}(\mathcal{O}_2)$ a unital *-monomorphism where

$$\mathrm{Q}^{\mathrm{s}}(\mathcal{O}_2) := \mathrm{Q}(\mathcal{O}_2 \otimes \mathbb{K}) := \mathcal{M}(\mathcal{O}_2 \otimes \mathbb{K})/(\mathcal{O}_2 \otimes \mathbb{K})$$

It is likely that φ extends to $\psi\colon A \otimes \mathcal{O}_2 \to \mathrm{Q}^{\mathrm{s}}(\mathcal{O}_2)$ with $\psi(a \otimes 1) = \varphi(a)$.

"Likely" only ???

Look what happens with the unital c.p. maps V from M_n to $\mathrm{Q}^{\mathrm{s}}(\mathcal{O}_2)$. Try to find an "arbitrary" small perturbation W of V that commutes with a unital copy of $\mathcal{O}_2$ in $\mathrm{Q}^{\mathrm{s}}(\mathcal{O}_2)$.

Alternatively we could proof that:

Nuclear *-monomorphisms ϕ of exact unital separable A into s.p.i. "corona" spaces C extends to $A \otimes \mathcal{O}_\infty$, i.e., that $\phi(A)' \cap C$ has a properly infinite unit.

(Where this is proved? Could prove?)

(What about c.p. maps from M_n to C? By doubling the rows that define this maps ?)

Should be a consequence of a conclusion of a generalized Weyl–von-Neumann theorem that could prove that ϕ dominates $\phi \oplus \phi$. If C is s.p.i., e.g. in the case where C is the corona $C = \mathrm{Q}^{\mathrm{s}}(B)$ of a σ-unital strongly p.i. C^*-algebra B.

It gives that ϕ extends at least to $\psi\colon A \otimes \mathcal{O}_\infty \to C$ with $\psi(a \otimes 1) = \phi(a)$. Remind here the definition of the Cuntz algebra:

$$\mathcal{O}_\infty := C^*(s_1, s_2, \ldots ; s_j^* s_k = \delta_{jk} 1)\,.$$

Then $\psi(1 \otimes p)$ for $p = 1 - s_1 s_1^*$ is the unit of a copy of $\mathcal{O}_2$ in $p\mathcal{O}_\infty p$, and $q := \psi(1 \otimes p)$ is a full properly infinite element of C with $0 = [q] \in \mathrm{K}_0(C)$. (The embedding γ of $\mathcal{O}_2$ in $p\mathcal{O}_\infty p$ will be denoted by $\gamma\colon b \in \mathcal{O}_2 \mapsto \gamma(b) \in p\mathcal{O}_\infty p$ and satisfies $\gamma(1) = p$.)

If, in addition, the algebra C has a properly infinite unit 1 with $0 = [1] \in \mathrm{K}_0(C)$ (– as it is the case e.g. for all stable coronas $C := \mathrm{Q}^{\mathrm{s}}(B)$ or for quotients C of $\mathrm{Q}^{\mathrm{s}}(B)_\infty$ –) then there is an isometry $T \in C$ with $TT^* = q$. (In fact, the requirement that $\psi(1 \otimes p)$ is full and properly infinite implies that 1 is properly infinite in C.)

We can define a new unital $\psi_0\colon A \otimes \mathcal{O}_2 \to C$ by $\psi_0(a \otimes b) := T^*\psi(a \otimes \gamma(b))T$.

Then $a \mapsto \phi_0(a) := \psi_0(a \otimes 1)$ is a nuclear unital *-monomorphism that commutes with a copy of $\mathcal{O}_2$ unitally contained in $\phi_0(A)' \cap C$.

We can define ϕ back from this map by

$$\phi(a) = \psi(a\otimes 1) = \psi(1\otimes s_2)^*\psi(a\otimes p)\psi(1\otimes s_2) = (\psi(1\otimes s_2)^*T)\psi_0(a\otimes 1)(T^*\psi(1\otimes s_2))\,.$$

Notice that $V := T^*\psi(1 \otimes s_2)$ is an isometry with $1 - VV^*$ full and properly infinite in $\mathcal{O}_2$.

The remaining problem is the following:

Suppose that the "liftable" copy (in sense of given split extension) $\lambda\colon A \otimes \mathcal{O}_2 \to$???? ???

Now suppose that there exists a ("liftable") nuclear unital *-monomorphism $\lambda\colon A\otimes\mathcal{O}_2 \to C$ with the property that there exists sequences of isometries $t_1, t_2, \ldots$ and $r_1, r_2, \ldots$ such that, for all $a \in A$, $\lambda(a\otimes 1) = \lim_n t_n^* \phi_0(a) t_n$ and $\phi_0(a) = \lim_n r_n^* \lambda(a\otimes 1) r_n$.

Apply a "fitting together" procedure to get with properties of the "corona algebra" that there are isometries t and r with $r^*\lambda(a\otimes 1)r = \phi_0(a)$ and $s^*\phi_0(a)s = \lambda(a\otimes 1)$ for $a \in A$. Since both commute with (different) unital copies of $\mathcal{O}_2$ in its commutants it follows from Corollary 4.3.7 that ϕ_0 and $\lambda((\cdot)\otimes 1)$ are unitary equivalent in C. (If C is a stable corona, then this equivalence is given by a product of exponentials.)

In particular: check the material of concurring sections.

Use the beamer presentations (Muenster !!! details???), compare with its contents.

Add needed case:

$A \subseteq \mathcal{M}(D)$, $D \subseteq \mathcal{M}(B)$ non-degenerate (necessary ??? only for $\mathcal{M}(D) \subseteq \mathcal{M}(B)$, could be e.g. enough that DBD is a corner of B), D s.p.i.)

Then residually nuclear $V\colon A \to B$
– with respect to the action

$$J \in \mathcal{I}(B) \mapsto A \cap \mathcal{M}(D, D \cap \mathcal{M}(B, J))$$

–, is 1-step approximately inner in $\mathcal{M}(B)$.

(Or is section 2.2 ?? of Chp.???? 2? the right place for the proof of this?).

We could use the minimality of the m.o.c.c. of residually nuclear c.p. maps among the cones with same invariant ideals:

It is enough to consider separable A, because non-separable A is the inductive limit of a net of separable C^*-sub-algebras $A_\tau \subseteq A$ with the following additional properties:

For each countable subset $X \subseteq A$ there is an separable A_τ with $X \subseteq A_\tau$.

Each closed ideal of A_τ is the intersection of a closed ideal of A with A_τ, and A_τ is residually relatively weakly injective in A in the sense that $(A_\tau/(A_\tau \cap J)) \otimes^{\max} F$ is naturally a C^*-subalgebra of $(A/J) \otimes^{\max} F$ for each C^*-algebra F.

(It seems to turn out that it suffices to consider here only separable C^*-algebras F ?)

If A s.p.i. then A_τ can be chosen such that A_τ is in addition s.p.i.

It implies that the restriction $V|A_\tau$ of V to A_τ of each residually nuclear map $V\colon A \to B$ with respect to some l.s.c. action Ψ of $\operatorname{Prim} B$ on A is also residually nuclear with respect to the induced action of $\operatorname{Prim} B$ on A_τ, i.e., for $I := \Psi(J)$ and $I_\tau := I \cap A_\tau := \Psi_\tau(J)$ holds: $V(I_\tau) \subseteq J$ and $[V|A_\tau]\colon A_\tau/I_\tau \to B/J$ is nuclear, because $[V|A_\tau]$ is equivalent to the restriction of $[V]\colon A/I \to B/J$ to $\pi_I(A_\tau) \subseteq A/I$ by the isomorphism $[\pi_I]\colon A_\tau/I_\tau \to \pi_I(A_\tau)$.

If B_τ is a separable C^*-subalgebra of B such that $V(A_\tau) \subseteq B_\tau$, "symbolic" invariance $H_\Psi(A_\tau)B_\tau \otimes \mathbb{K} \subseteq B_\tau \otimes \mathbb{K}$, each closed ideal of B_τ is the intersection of a closed ideal of B with B_τ and B_τ is residually weakly injective in B, then $V|A_\tau\colon A_\tau \to B_\tau$ is still residually nuclear with respect to the "induced" action $\Phi\colon \mathcal{I}(B_\tau) \to \mathcal{I}(A)$ given by $\Phi(J) := \Psi(BJB) \cap A_\tau$.

Here we simplify notation:

BJB denotes the closed linear span of the set of products b_1cb_2 with $c \in J$ and $b_1, b_2 \in B$. Indeed, $J = B_\tau \cap BJB$,

$$V(\Phi(J)) \subseteq V(A_\tau) \cap BJB \subseteq B_\tau \cap BJB = J$$

and $[V]\colon A_\tau/\Phi(J) \to B_\tau/J$ is nuclear, because $V(A_\tau) \subseteq B_\tau$, $[V]\colon A_\tau/\Phi(J) = A_\tau/(A_\tau \cap BJB) \to B/BJB$ is nuclear, and there is a natural isomorphism from B_τ/J onto $\pi(B_\tau) \subseteq B/BJB$ which is relatively weakly injective in B/BJB by assumption.

Another question is to find suitable separable C^*-sub-algebras B_τ of B such that for a given action $H(A_\tau)B_\tau \subseteq B_\tau$ and, for $J \in \mathcal{I}(B)$,

$$(H|A_\tau)^{-1}(\mathcal{M}(B_\tau, J \cap B_\tau)) = A_\tau \cap H^{-1}(\mathcal{M}(B, J))\,.$$

More generally: Let $E \subseteq \mathcal{M}(B)$ and $F \subseteq B$ separable C^*-subalgebras, $\mathcal{S}$ a countable family of closed ideals of B.

Find a separable C^*-subalgebra $C \subseteq B$ that contains F and satisfies $EC \subseteq C$, each closed ideal I of C is the intersection $I = C \cap J$ of a closed ideal J of B with C, and $E \cap \mathcal{M}(B, J) = H^{-1}(\mathcal{M}(C, C \cap J))$ for all closed ideals J of B (for the *-homomorphism $H\colon E \to \mathcal{M}(C)$ with $H(e)c = ec$ for $e \in E$ and $c \in C$).

What about the desire that C is relatively injective in B? Or is approximately injective in B?

Can we find such C with the additional property that there exists a normal conditional expection from B^{**} (or from D^{**} with $D := \overline{CBC}$) onto C^{**}? Perhaps, this seems to be equivalent to the injectivity of the natural morphism

$$C \otimes F \mapsto B \otimes F$$

for all (separable) C^*-algebras F.

Reduce to separable case? Here necessary?

The idea would be to compare the composition $\mathcal{C}_{\mathrm{nuc}}$ of the l.s.c. action Ψ_1 of $\operatorname{Prim} B$ on D composed with $\mathcal{C}_{\mathrm{nuc}}$ of the l.s.c. action Ψ_2 of $\operatorname{Prim} D$ on A with the $\mathcal{C}_{\mathrm{nuc}}$ of the l.s.c. action of $\operatorname{Prim} B$ on A:

If the composition $\Psi_2 \circ \Psi_1$ defines the same action as Ψ, and if the m.o.c. cone $\mathcal{C}_{\mathrm{nuc}}(\Psi_2; A, D)$ and $\mathcal{C}_{\mathrm{nuc}}(\Psi_1; D, B)$ separate Ψ_2 respectively Ψ_1, then the minimality of $\mathcal{C}_{\rm nuc}(\Psi; A, B)$ among the m.o.c.c. with same induced action delivers that

$$\mathcal{C}_{\rm nuc}(\Psi; A, B) \subseteq \mathcal{C}_{\rm nuc}(\Psi_2; A, D) \circ \mathcal{C}_{\rm nuc}(\Psi_1; D, B)\,.$$

Since – at the present state of text – we do not know that (for *separable* A, B and D) every l.s.c. action Ψ between there ideal lattices can be separated by the corresponding m.o.c.c. of Ψ-residually nuclear maps, we get some more work:

We have to show that we can the question reduce to the cases of (other) separable A, B and D with the additional property that B and D contain *regular* abelian C^*-subalgebras C.

WHERE is "regular C^*-subalgebra" defined?

Perhaps by the property that each pure state can be extended to a pure state in a unique manner?

We fix a residually nuclear c.p. map $V\colon A \to B$ with respect to an action Ψ of $\mathrm{Prim}(B)$ that has the following property:

The – lower semi-continuous – action $\Psi\colon \mathcal{I}(B) \to \mathcal{I}(A)$ is given by $\Psi(J) := H^{-1}(\mathcal{M}(B, J))$ where $H\colon A \to \mathcal{M}(B)$ is a *-homomorphism with the property that H – in the topology of point-wise strict convergence – 1-step innerly approximately factorizes through $H_1\colon A \to \mathcal{M}(D)$ and $H_2\colon D \to \mathcal{M}(B)$ in a sense that the maps $a \mapsto b^*H(a)b$ can be approximated in point-norm topology of maps of the form $a \mapsto c^*H_2(d^*H_1(a)d)c$ for suitable $c \in B$ and $d \in D$ depending on $b \in B$. Moreover we require that D is strongly p.i.

Since it suffices to show that for given $a_1, \ldots, a_n \in A_+$, and $\varepsilon > 0$ there is $b \in B$ with $\|V(a_j) - b^*H(a_j)b\| < \varepsilon$ for $j = 1, \ldots, n$, it suffices to consider suitable separable C^*-sub-algebras A_τ, B_τ and D_τ of A, B and D, such that $a_1, \ldots, a_n \in A_\tau$ and that the A_τ, B_τ, D_τ same property the restrictions of H, H_1 and H_2 have the same

This can be done by replacing first A by its "good" separable C^*-algebras A_τ that contains $a_1, \ldots, a_n$ – as described above. Since $V(a_j)$ is contained in the closed ideal generated by $b^*H(a_j)b$ $(b \in B)$ and is – at the same time – also in the closed ideal generated by $c^*H_2(d^*H_1(a_j)d)c$ $(c \in B,\ d \in D)$ we find a separable C^*-subalgebra $A_\tau \ni a_1, \ldots a_n$ of A, a separable C^*-subalgebra B_τ of B and a separable strongly p.i. subalgebra D_τ of D such that $H(A_\tau)B_\tau \subseteq B_\tau$, $H_2(D_\tau)B_\tau \subseteq B_\tau$, $H_1(A_\tau)D_\tau \subseteq D_\tau$ and that $a \mapsto b^*H(a)b$ can be approximated by the restrictions to A_τ.

Then we replace D and B by suitable σ-unital hereditary C^*-subalgebras D_τ and B_τ such that $H_1(A_\tau)D_\tau = D_\tau$ and $H_2(D_\tau)B_\tau = B_\tau$.

This is possible, because ?????

The following covers only the case where the action of prime(B) on A is also monotone upper s.c.

Can't see any reason for this!

The good approach to separable D_τ and B_τ is the study of the Dini-function:

X Dini-space, Y locally q-compact sober T_0 space, e.g. $X := \mathrm{Prim}(A)$, $Y := \mathrm{prime}(B)$. $\Psi\colon \mathbb{O}(Y) \to \mathbb{O}(X)$ l.s.c. and monotonous upper s.c. Then (equivalently) each Dini-function f on X defines a a Dini function on Y.

Since the set of Dini-functions on X (e.g. $X = \mathrm{Prim}(A)$) is uniformly separable, one has to find in a C^*-algebra corresponding to Y a sequence of elements that correspond to a dense sequence in the image of the Dini functions on X.

Then one enlarge it to a suitable B_τ with all the needed properties.

`Older approach:`

(1) Reduction to A separable, D and B σ-unital. Then all can be reduced to the case where D, B are also separable, by careful selection of the separable full C^*-sub-algebras of B and D that have the same "semi-metrics" $\rho(a,b;n) \in [0,\infty]$ than those coming from B respectively from D.

(Use here: If A separable, then $V(A) \subseteq B$ generates a separable C^*-subalgebra.)

(2) Then consider the maps that factorize over abelian C^*-subalgebras of $D_\omega \subseteq \mathcal{M}(B)_\omega \to \mathcal{M}(B_\omega)$.

(2') Or (perhaps better), consider equivariant c.p. maps $A \to D_\omega$ that factorize over abelian C^*-subalgebras of D_ω. Approximate them by 1-step inner c.p. maps.

(3) Then go from separable abelian C^*-subalgebras $C \subseteq D_\omega \to \mathcal{M}(B_\omega)$ equivariant to B_ω and approximate the residually nuclear c.p. maps by 1-step inner maps.

Use here the embedding $C \subseteq C \otimes \mathcal{O}_\infty \subseteq D_\omega$

(4) Show that the maps from (1)-(3) define the l.s.c. action of $\mathcal{I}(B_\omega) \to \mathcal{I}(A)$ of $\mathrm{prime}(B_\omega)$ on A.

(5) Show that the point norm closure of the set of maps $A \to B_\omega$ defined by (1)-(3) is an m.o.c. cone. (The convexity via Cuntz criterion has to be shown).

(6) All? ???

Passage to the non-degenerate case by compressions:

B and D first by the hereditary C^*-subalgebras $C := ADAB \cdot (B_\omega) \cdot BADA$ and $E := AD \cdot (ADA)_\omega \cdot DA$ (that is naturally contained in the multiplier algebra $\mathcal{M}(C)$ of C) of the ultra-powers of B and E, to obtain separable "regular" abelian C^*-subalgebras, that are suitable for the problem.

One of the points is to show that residual nuclear $V\colon A \to B$ is also residual nuclear as map from A into C – one with respect to the l.s.c. action Ψ_1 of $\mathcal{I}(B)$ on $\mathcal{I}(A)$, the other with respect to the l.s.c. action Ψ_2 of $\mathcal{I}(C)$ on $\mathcal{I}(A)$ –, which needs a check that $I := \Psi_2(J) = \Psi_1(J \cap B)$. Then $[V]_I\colon A/I \to B/(J \cap B) \subseteq C/J$ is again nuclear, and it follows that $V\colon A \to C$ is again residually nuclear.

Now fix a residually nuclear map from $V: A \to B$. We find separable C^*-algebras F of C and G of E such that $AG = G$, $GF = F$, G is strongly p.i., G and F contain regular Abelian C^*-subalgebras, each closed ideal of G is the intersection of a closed ideal of E with G, each closed ideal C

????????????????

Concerning work on Chp. 4. :

4a) Perhaps: Study of K_1-injectivity on extra place?

Give *short !!!* proof of Cuntz lemma on " full properly infinite projections " ?

4b) Clean presentation of the “basic proposition”? Now a Theorem ?

4c) Again case: $A \subseteq E$ (via H_0) J ideal of E, $V: A \to J$ 1-step inner (approximately ?).

Suppose $E \supset A$ separable, for all separable $X \subseteq E$ and $Y \subseteq J$, there exists a positive contraction $e \in E$ (?) with $ex = xe$ for all $x \in X$ and $ey = y = ye$ for all $y \in Y$.

How the Grothendieck group looks like?

When there is a “majorizing” element? At least of larger semigroup?

Consider an abelian semigroup S with following property:

There exists $x_1 \in S$ with:

For each $x \in S$ there exists $y \in S$ with $x + y = x_1$. Then there exists x_0 with $2x_1 + x_0 = x_1$. Thus $2x_0 + 2x_1 = x_0 + x_1$. Then $x + y + x_0 + x_1 = x_0 + 2x_1 = x_1$ shows that $S + x_1$ is a subgroup of the semigroup S, and is isomorphic to the Grothendieck group of S and its "zero" element is equal $x_0 + x_1$.

$(h_1: A \to J) \in S(A, E, H_0, J)$ (last good notation?) with property:

If $[h] \in S(A, H_0, E)$ with $h(A) \subseteq J$ we get/require that $[h] \in S(A, h_1, E)$.

Special case: $x = s^*t^*H_0ts$, $y =$???, $(1 - ss^*)t^*H_0(\cdot)t(1 - ss^*) \in S(A, H_0, E)$.

implies $h_1 \oplus h_1 \precsim h_1$?

Does it imply the existence and uniqueness of h_0 ??

Ad Chp. 5

Ad 5a) Partial results for $A \subseteq \mathcal{O}_2$ perhaps only to list?

Anyway now shifted to Appendix B ?

At least of consequences of the more general results (on WvN, Ext)?

5b) More systematic “stable” section. Select only the later needed, e.g. for asymptotic morphisms, Rørdam’s criteria ...

5c) $\mathrm{Ext}(\mathcal{C}\,;\ A, B)$ in case B s.p.i. “Kasparov for $\mathcal{C}$”.

5d) Homotopy invariance (even of $\mathrm{Ext}(A, \mathcal{O}_2) = \mathrm{Ext}_{nuc}(A, \mathcal{O}_2)$) follows first from Kasparov's homotopy invariance of KK -theory,

and from $\delta_2 \sim \mathrm{id}$ on $\mathcal{O}_2$:

Perhaps one shows (before) that the unital endomorphism δ_2 is *unitarily homotopic* to identity map of $\mathcal{O}_2$.

5e)

$\mathrm{Ext}(\mathcal{C}\,;\, A, B)$ in front of other Ext-notion?

5f) Characterization of "zero" element of $\mathrm{Ext}(\mathcal{C}\,;\, A, B)$:

B σ-unital and stable,

$H\colon\ A \otimes \mathcal{O}_2 \hookrightarrow \mathcal{M}(B)/B$,

A stable, A exact, inclusion H nuclear, in case of $\mathcal{C} = \mathrm{CP}_{\mathrm{nuc}}(\Psi;\, A, B)$.

But H must be fitting with the related "action" Ψ.

It must be underlined that "stability" of the corresponding extension algebra is only granted if the map H dominates zero.

(This is always reached if one tensors – again ? – with $\mathbb{K}$.)

One problem is: When $\mathrm{Q}^s(B)$ is strongly p.i? Same with $\mathcal{M}(B)$?

Positive if $B \cong B \otimes \mathcal{O}_\infty$ ($\cong B \otimes \mathcal{D}_\infty$). Then moreover every separable C^*-subalgebra of B "commutes approximately" with a unital copy of $\mathcal{O}_\infty$ in B_∞.

This should carry over to $\mathrm{Q}^{\mathrm{s}}(B)$. (Still a conjecture!)

Equivariant H:

$\pi_B(\mathcal{M}(B, J)) \cap H(A \otimes 1) = H((A \cap \mathcal{M}(B, J)) \otimes 1)$ for all closed ideals J of B.

It should follow that $a \mapsto H(a \otimes 1)$ is unitary equivalent to $\pi_B \circ H_0\colon A \to \mathrm{Q}^s(B)$.

Important:

Is it better to start with the classification of $A \otimes \mathcal{O}_2 \to \mathrm{Q}^s(B)$ nuclear?

It is not so useful in case of A nuclear and $B = \mathbb{K} \otimes \mathcal{O}_2$, because it would not allow to show that the lift is the range of a c.p. projections that is an ?? what ?? in the set of unital positive maps.

5g) Is it possible to prove the triviality of
$\mathrm{Ext}(\mathcal{C};\, A \otimes \mathcal{D}_2, B)$ and $\mathrm{Ext}(\mathcal{C};\, A, B \otimes \mathcal{D}_2)$ directly? Not using KK ? (Here $\mathcal{D}_2 = \mathcal{O}_2 \otimes \mathcal{O}_2 \otimes \cdots$ and the point is that we do not borrow the homotopy - invariance from KK.)

Partly from suitable material from Chapter 3?

A general Theorem about unitary equivalence in $\mathrm{Q}(B)$ (for B stable and σ-unital) of morphisms $h_1, h_2\colon A \otimes \mathcal{O}_2 \hookrightarrow \mathrm{Q}(B)$ would be useful.

Minimally necessary: $h_1(a \otimes 1)$ and $h_2(a \otimes 1)$ generate the same closed ideal of $\mathrm{Q}(B)$ for each $a \in A_+$.

There is (by some Corollary in 4) a unitary in $\mathrm{Q}(B)$ that makes them unitary equivalent. The $\mathrm{Q}(B)$ is K_1-bijective.

In case $B = \mathcal{O}_2 \otimes \mathbb{K}$ we can use that $B \cong B \otimes \mathcal{O}_2 \otimes \mathcal{O}_2 \otimes \cdots$. It gives that any separable C^*-subalgebra of $\mathrm{Q}(\mathcal{O}_2 \otimes \mathbb{K})$ commutes with a unital copy of $\mathcal{O}_2$. Since it commutes also with some countable approximations by c.p. maps of a C^*-morphism from a separable C^*-algebra A into $\mathrm{Q}(\mathcal{O}_2 \otimes \mathbb{K})$, and since $\mathrm{Q}(\mathcal{O}_2 \otimes \mathbb{K})$ has trivial K_*-groups

Similar problems appear in the study of Prim-space extensions. (By getting them manageable by tensor them $\otimes \mathcal{O}_2$.)

E.g. if $H_k(a) := h_k(a \otimes 1)$ have weakly nuclear c.p. lifts, A separable and exact,

$H_1(a)$ and $H_2(a)$ generate the same ideal of $\mathrm{Q}(B)$ for each $a \in A_+$.

If A is stable (respectively the corresponding general extension stable), then it should be possible to give the equivalence by a unitary in $\mathcal{U}_0(\mathrm{Q}(B))$.

The needed basic informations have to be developed (in parts) in Chapters 3 and 4.

Chp. 6:

Embedding Theorem needs the characterization of the "big zero-element" of $\mathrm{Ext}(\mathcal{C}\,;\ A, B)$.

A exact, stable and separable, B stable, σ-unital and strongly p.i.

$\mathcal{C} = \mathrm{CP}_{\mathrm{nuc}}(A,B) \cap \mathrm{CP}(\Psi; A, B)$ with $\Psi \colon \mathbb{O}(\mathrm{Prim}(B)) \to \mathbb{O}(\mathrm{Prim}(A))$ l.s.c. and *monotone* u.s.c. (that is weaker than u.s.c. ???)

Requires to use and study $\mathcal{C} \otimes \mathrm{id}_{\mathcal{O}_2}$ What is needed really and minimally?

Chp 7.

New chapter 7:

equal to old Chapter 10 (or 11?)

plus first parts of old Chapter 9.

What is the precise definition of "Cuntz semigroup"?

From `Black.Robert.Tik.Toms.Wint.2010` [**85**]:

sec:2.2. The Cuntz semigroup. Let A be a C*-algebra. Let us consider on $(A \otimes \mathbb{K})_+$ the relation $a \precsim b$ if $v_n b v_n^* \to a$ (i.e., the sequence $(v_n b v_n^*)_n$ converges to a for the considered $a, b \in (A \otimes \mathbb{K})_+$) for some sequence (v_n) in $A \otimes \mathbb{K}$. Let us write $a \sim b$ if $a \precsim b$ and $b \precsim a$. In this case we say that a is Cuntz equivalent to b. Let $\mathrm{Cu}(A)$ denote the set $(A \otimes \mathbb{K})_+ / \sim$ of Cuntz equivalence classes. We use $\langle a \rangle$ to denote the class of a in $\mathrm{Cu}(A)$. It is clear that

$$\langle a \rangle \leqslant \langle b \rangle \;\Leftrightarrow\; a \precsim b$$

defines an order on $\mathrm{Cu}(A)$. We also endow $\mathrm{Cu}(A)$ with an addition operation by setting

$$\langle a \rangle + \langle b \rangle := \langle a' + b' \rangle ,$$

where a' and b' are orthogonal and Cuntz equivalent to a and b respectively (the choice of a' and b' does not affect the Cuntz class of their sum). The semigroup $\mathrm{W}(A)$ is then the sub-semigroup of $\mathrm{Cu}(A)$ of Cuntz classes with a representative in $\bigcup_n M_n(A)_+$.

Alternatively, $\mathrm{Cu}(A)$ can be defined to consist of equivalence classes of countably generated Hilbert modules over A. The equivalence relation boils down to isomorphism in the case that A has stable rank one, but is rather more complicated in general. We do not require the precise definition of this relation in the sequel, and so omit it; the interested reader may consult [5] or [1] for details.

[1] P. Ara, F. Perera, and A. S. Toms. *K-theory for operator algebras. Classification of C*-algebras*, Commun. Contemp. Math. To appear.(2008?)

[5] Coward, K.T., Elliott, G.A., Ivanescu, C., [2008], *The Cuntz semigroup as an invariant for C*-algebras*, J. Reine Angew. Math. **623**, 161–193.

" We note, however, that the identification of these two approaches to $\mathrm{Cu}(A)$ is achieved by associating the element $\langle a \rangle$ to the class of the Hilbert module $a\ell_2(A)$. If X is a countably generated Hilbert module over A, then we use $[X]$ to denote its Cuntz equivalence class; with this notation the sub-semigroup $\mathrm{W}(A)$ is identified with those classes $[X]$ for which X is finitely generated. "

(E.K.: I can not see how this fits bijectively together with the $\precsim$ classes in $A \otimes \mathbb{K}$...)

2.4. Functionals and Cu.

Let S be a semigroup in the category Cu. A functional on S is a map $\lambda\colon S \to [0,\infty]$ that is additive, order preserving, preserves suprema of increasing sequences and satisfies $\lambda(0) = 0$. We use $F(S)$ to denote the functionals on S. We will make use of a lemma, established in [**268**].

3. THE RADIUS OF COMPARISON

3.1.Original definition.

The *radius of comparison* was originally introduced in [18 ??] as an invariant for unital C*-algebras. (18 is cited in [**268**])

Let A be a unital C*-algebra, and let $\mathrm{QT}_2^1(A)$ denote the set of normalized 2-quasi-traces on A. The radius of comparison of A, denoted by $\mathrm{rc}(A)$, is the infimum of the set of real numbers $r > 0$ with the property that $a, b \in \sqcup_{n=1}^{\infty} M_n(A)$ (or noted $a, b \in \bigsqcup_{n=1}^{\infty} M_n(A)$) satisfy $a \precsim b$ whenever

$$d_\tau(\langle a\rangle) + r \,<\, d_\tau(\langle b\rangle), \quad \tau \in \mathrm{QT}_2^1(A)\,. \tag{5.1}$$

By the results of Subsection 2.4 (??) (of which paper/book ??), this is equivalent to the demand that $x, y \in \mathrm{Cu}(A)$ satisfy $x \leqslant y$ whenever

$$\lambda(x) + r < \lambda(y)\,,$$

for all $\lambda \in F(\mathrm{Cu}(A))$ which are normalized in the sense that $\lambda(\langle 1_A\rangle) = 1$. The motivation for this definition comes from the stability properties of topological vector bundles.

4.4.?? When is $\mathrm{W}(A)$ hereditary?

Recall that $W(A)$ is the sub-semigroup of $\mathrm{Cu}(A)$ of elements $\langle a\rangle$ with $a \in M_n(A)_+$ for some n. In fact, $\mathrm{W}(A)$ is the original definition of the Cuntz semigroup. Here we consider the question of when this sub-semigroup is hereditary, i.e., has the property that if $x \leqslant y$ in $\mathrm{Cu}(A)$ and $y \in \mathrm{W}(A)$, then $x \in \mathrm{W}(A)$.

We prove that finite "radius of comparison" suffices. This result was previously unknown, even in the case of "strict comparison".

Theorem 4.4.1.???

Let A be a C*-algebra for which the projections in every quotient of $A \otimes \mathbb{K}$ are finite. Let $a \in A_+$ be strictly positive and suppose that $r_{A,a} < k \in N$. If $\langle b\rangle \in \mathrm{Cu}(A)$ is such that

$$\lambda(\langle b\rangle) \,\leqslant\, n\lambda(\langle a\rangle) \;\text{ for all }\; \lambda \in F(\mathrm{Cu}(A))\,,$$

for some $n \in \mathbb{N}$, then b is Murray–von-Neumann equivalent to an element of $M_{2(n+k)}(A)_+$.

Lemma 4.4.2.???

If b_1 and b_2 are Murray–von-Neumann equivalent to elements in $M_n(A)$ then $b_1 + b_2$ is Murray–von-Neumann equivalent to an element in $M_{2n}(A)$.

(Case $n = 1$ checked ???)

Question 4.4.3.???

Is there a C*-algebra for which $\mathrm{W}(A)$ is not a hereditary subset of $\mathrm{Cu}(A)$?

6. Collection of Definitions of pure infinite C*-algebras

In the separate paper is a shorter and more transparent (??) calculation of the inequalities below?

`Beginning here: Collections of Defs for p.i.`

This is NOW (2022 !!!) only for my private use!!! (improving of estimates started July 2021)

It could be useful for the study of extensions of p.i. algebras ???

The below considered estimates are used to prove and improve the following estimate:

Let $a, b \in A_+$ positive contractions, then, using polar decomposition of $a-b$ in positive and negative parts $(a-b)_+$ and $(a-b)_- = (b-a)_+$ of

$$a - b = (a-b)_+ - (a-b)_- \,.$$

It gives that $a - (a-b)_+ = b - (b-a)_+$, by using that $(a-b)_- = (b-a)_+$. This symmetry allows to estimates the norms of $a - (a-b)_+$ and $b - (b-a)_+$ by using the norms of $(a+b) - |a-b|$ and $b - (a-b)_- = b - (b-a)_+$. Since $|a-b| = (a-b)_+ + (a-b)_-$ it follows that

$$a + b - ((a-b)_+ + (a-b)_-) = (a - (a-b)_+) + (b - (a-b)_-)$$

Since the two terms at the right side are equal and

$$|a-b| = \sqrt{(a-b)^2} = (a-b)_+ + (a-b)_- \,,$$

we get here immediately that

$$2(a - (a-b)_+) = (a+b) - |a-b| = 2(b - (b-a)_+)\,.$$

If we use that $|a-b| = \sqrt{(a-b)^2}$ and $a+b$ are (positive) roots of the positive operators $X := (a-b)^2$ and $Y := (a+b)^2$. For all positive operators $X, Y \in A_+$ holds

$$2\|a - (a-b)_+\| = \|Y^{1/2} - X^{1/2}\| \leq (\|Y - X\|)^{1/2}\,.$$

We get in our special case that $Y - X = 2(ab + ba)$,

$$\|Y^{1/2} - X^{1/2}\| \leq \|Y - X\|^{1/2} \leq 2\|ab\|^{1/2},$$

and finally that

$$\|b - (b-a)_+\| = \|a - (a-b)_+\| = (1/2)\|(a+b) - |a-b|\| \leq \|ab\|^{1/2}$$

PROOF of $\|Y^{1/2} - X^{1/2}\| \leq \|Y - X\|^{1/2}$? (Refer to Pedersen book, concerning citation on operator monotone functions. But there exits other papers on this – cite them also!).

$Y \leq X + \gamma \cdot 1$ with $\gamma := \|Y - X\|$ implies

$$Y^{1/2} \leq (X + \gamma)^{1/2} \leq X^{1/2} + \gamma^{1/2}$$

The estimate $(\beta + \gamma)^{1/2} \leq \beta^{1/2} + \gamma^{1/2}$ for $\beta, \gamma \in (0, \infty)$ is easy to see by taking on both sides quadrants. Thus $\|Y^{1/2} - X^{1/2}\| \leq \|Y - X\|^{1/2}$, and in our special case where X and $\gamma \cdot 1$ we get ??????)

In this special case we get $Y - X = 2(ab + ba)$, and $\|Y - X\| \leq 4\|ab\|$, hence

$$\|(a - (a - b)_+)\| = \|(b - (b - a)_+)\| \leq \|ab\|^{1/2} .$$

See below, but with other notations, because of desired generality.

We use here the "operator monotony": It is e.g. given in the book *C*-algebras and their automorphism groups* of G.K. Pedersen:

Prop. (1.3.8): Let $X, Y \in \mathcal{L}(H)$ positive operators. If $0 < \|Y - X\| \leq 1$, then

The operator function $t \mapsto t^{\beta}$ is operator monotone on $\mathbb{R}_+$ for $\beta \in (0, 1)$.

We use this in case $\beta = 1/2$ for the proof of following Result:

Lemma: For all positive operators $X, Y \in \mathcal{L}(H)_+$ holds the inequality of norms:

$$\|Y^{1/2} - X^{1/2}\| \;\leq\; \|Y - X\|^{1/2} .$$

And, therefore,

$$\|Y - X\| \;\leq\; \|Y^2 - X^2\|^{1/2}$$

Proof: Notice that this follows by the symmetries in X and Y, – as e.g. $\|Y - X\| = \|X - Y\|$ that we consider here as the $\|Y - X\| \cdot ??? \cdot \mathrm{id}_H$ –, from the general observation that the operator monotony (which says that $0 \leq a \leq b$ implies $0 \leq a^{1/2} \leq b^{1/2}$) implies that

$$Y^{1/2} \leq X^{1/2} + \|Y - X\|^{1/2} ,$$

because $Y \leq (X + \|Y - X\| \cdot \mathrm{id}_H)$ and, always, $(X + \|Y - X\|)^{1/2} \leq X^{1/2} + \|Y - X\|^{1/2}$, because $C * (X, \|Y - X\| \cdot \mathrm{id}_H)$ is commutative.

By symmetry between X and Y it follows that

$$X^{1/2} \leq Y^{1/2} + \|Y - X\|^{1/2}$$

using $\|Y - X\| = \|X - Y\|$. Thus,

$$\|X^{1/2} - Y^{1/2}\| \leq \|Y - X\|^{1/2} .$$

So, it is enough to apply the operator monotony with $\beta = 1/2$ to the obvious inequality $Y \leq X + \|Y - X\|$. We get that $Y^{1/2} \leq (X + \|Y - X\|)^{1/2}$ by operator monotony. And,- similarly -, $X^{1/2} \leq (Y + \|Y - X\|)^{1/2}$.

The operator X and the scalar $\|Y - X\|$ (– here considered as the operator $\|Y - X\| \cdot \mathrm{id}_H \in \mathcal{L}(H)_+$ –) are in a commutative C*-subalgebra of $\mathcal{L}(H)$. There, in the commutative C*-algebra $C^*(X, \|Y - X\| \cdot \mathrm{id}_H) \subseteq \mathcal{L}(H)$, all monotone increasing continuous functions apply to the positive elements in commutative C*-algebras as order-monotone function ... like: $0 \leq Z^* = Z \mapsto Z := X + \|Y - X\|$. Thus, $(X + \|Y - X\|)^{1/2} \leq X^{1/2} + \|Y - X\|^{1/2}$,

By taking squares one can see that this is in the commutative C*-subalgebra $C^*(X, \|Y - X\| \cdot 1)$ equivalent to the obvious inequality

$$X + \|Y - X\| \leq X + \|Y - X\| + 2(\|Y - X\| \cdot X)^{1/2}.$$

?????????

This works because for all nonnegative numbers(!) u and v holds that

$$(u + v)^{1/2} \leq u^{1/2} + v^{1/2},$$

because we have then that $u + v \leq u + v + 2(uv)^{1/2}$.

This carries over to all positive and elements $u, v \in A_+$ ... ???

Here is something missing:

It follows for positive contractions A, B that

$$\|(A + B) - \sqrt{(A - B)^2}\| \leq 2\|AB\|^{1/2}$$

for positive contractions A, B. ??

(Above it is better explained!)

Want to know:

$$\|A - (A - B)_+\| \leq 2\|AB\|^{1/2}$$

It comes from $C := A + B$ and $D := |A - B|$ and

$$C^2 - D^2 = (A^2 + AB + BA + B^2) - (A^2 - AB - BA + B^2) = 2(AB + BA)\,.$$

Thus, $\|C^2 - D^2\| \leq 4\|AB\|$ and

$$\|C - D\| \leq (\|C^2 - D^2\|)^{1/2} \leq 2\|AB\|^{1/2}\,.$$

Above calculations have the following desired application:

Let $0 \leq A, B \leq 1$ in a C*-algebra then

$$2(A - (A - B)_+) = (A + B) - \sqrt{(A - B)^2} = (A + B) - |A - B|$$

It follows that

$$\|A + B - |A - B|\| \leq 2\|AB\|^{1/2}$$

and $\|A - (A - B)_+\| \leq \|AB\|^{1/2}$.

Notice here also that: $AB = 0$ if and only if $A - (A - B)_+ = 0$.

The above shown later used application is:

$$\|B - (A - B)_-\| = \|A - (A - B)_+\| \leq \|AB\|^{1/2}\,.$$

!!! Other topic now below !!!:

7. On passage to suitable separable (!) C*-subalgebras

Let $X \subseteq A$ a countable (or norm-separable) subset of a C*-algebra A, then there exists a separable C*-subalgebra B of A that contains X, and such that $X \subseteq B \subseteq A$ have following properties:

1.) $b_1 \precsim_{M_n(B)} b_2$, if and only if, $b_1 \precsim_{M_n(A)} b_2$ for all $b_1, b_2 \in M_n(B)$ and $n \in \mathbb{N}$.

2.) $B \subseteq A$ is exact, if A is exact.

((2.) Means "Exactness is hereditary". Where is it proved ? Give reference and/or outline of proof.)

Let (more general) B a C*-subalgebra of an "exact" C*-algebra A. $A \otimes^{min} C$ is defined by the minimal C*-norm on the algebraic tensor product $A \otimes C$.

The algebras $B \otimes^{min} J --> B \otimes^{min} C --> B \otimes^{min} C/J$ are natural subalgebras of the algebras

$$A \otimes^{min} J --> A \otimes^{min} C --> A \otimes^{min} C/J$$

Notice here that $A \otimes^{min} C --> A \otimes^{min} C/J$ and $B \otimes^{min} C --> B \otimes^{min} C/J$ are always surjective, and are well-defined from the algebraic tensor products $A \otimes C --> A \otimes C/J$ by completion with the minimal C*-norms.

We see elow that $B \otimes^{min} J$ is the kernel of $B \otimes^{min} C --> B \otimes^{min} C/J$ if $A \otimes^{min} J$ is the kernel of $A \otimes^{min} C --> A \otimes^{min} C/J$.

If the kernel of $B \otimes^{min} C --> B \otimes^{min} C/J$ would be different from $B \otimes^{min} J$ then it must be bigger than $B \otimes^{min} J$. But if A is exact, then this kernel is always contained in $(A \otimes^{min} J) \cap (B \otimes^{min} C)$.

If we take approximate units $e_\sigma \in B_+$ and $f_\tau \in J_+$ of B and of J, then

$$Y_{\sigma,\tau} := (e_\sigma \otimes f_\tau) X (e_\sigma \otimes f_\tau)$$

converges to X for each element of $X \in (A \otimes^{min} J) \cap (B \otimes^{min} C)$. But, each $Y_{\sigma,\tau}$ is contained in $B \otimes^{min} J$. Thus,

$$(A \otimes^{min} J) \cap (B \otimes^{min} C) = B \otimes^{min} J$$

and it shows that $B \subseteq A$ is exact, if A is exact.

Notice here that there is a natural isomorphism $A \otimes^{min} C/J \cong (A \otimes^{min} C)/(A \otimes^{min} J)$ for exact C*-algebras A.

The question is equivalent to:

Is the kernel $(A \otimes^{min} J) \cap B \otimes^{min} C \subset A \otimes^{min} C$ of $B \otimes^{min} C --> (A \otimes^{min} C)/(A \otimes^{min} J)$ bigger than $B \otimes^{min} J$?

In general this kernels are contained in

$$F(B, C; J) := \{x \in B \otimes^{min} C; \varphi \otimes \mathrm{id}(x) \in J\}?$$

And we can ask the stronger question: Is $F(B, C; J) = (A \otimes^{min} J) \cap B \otimes^{min} C$ under which circumstances?

If one can it reduce (!) to the separable case for A the one can use that $B \subseteq A \subseteq \mathcal{O}_2$ proves exactness of B.

This would then require to show that exactness is preserved under inductive limits ... in addition.

(give Ref's !!!)

3.) If A is nuclear, then B can be chosen nuclear, by an iteration argument for B becoming a suitable inductive limit $X \subseteq B_1 \subseteq B_2 \subseteq \cdots$ and let B the closure of $\bigcup_n B_n$.

(One can moreover manage that B is approximately injective, weakly injective etc. if A has such properties, also (??) slice-map properties (??) could be earned from A ...??? Check this carefully !!!). (Below is an other reduction attempt ...)

Now let A be a *separable* C*-algebra and let J a closed ideal of A, and $a_0 \in J$ a strictly positive contraction for J, i.e. with

$$J = \overline{A a_0 A} = \overline{a_0 A a_0} = \overline{a_0 J a_0}\,.$$

Assume (from now on) that a_0 is properly infinite, i.e., $a_0 \oplus a_0 \precsim_J a_0$ in J (and then also $a_0 \oplus a_0 \precsim_A a_0$ and vice versa). Notice that $a_0 \oplus a_0 \precsim_B a_0$ also for every C*-subalgebra B of A with $J \subseteq B$.

Suppose that A/J contains an infinite element $x \in (A/J)_+$, i.e., there exists nonzero $y \in (A/J)_+$ with $x \oplus y \precsim_{A/J} x$. Then the closed ideal I of A/J generated by all the elements $y \in (A/J)_+$ with $x \oplus y \precsim x$ contains (by separability of A/J) a strictly positive contraction $z \in I_+$. (And z is non-zero because because I_+ is non-zero.)

This implies that $z(A/J)z$ and $(A/J)z(A/J)$ are both dense in I.

It turns out that $x \oplus z \precsim_{A/J} x$ and – since I is an ideal where z is a strictly positive contraction – that also $z \oplus z \precsim_{A/J} z$, i.e., that z is properly infinite in A/J.

We can lift z to a positive contraction $a_1 \in A_+$ with $\pi_J(a_1) = z$.

Then can consider the positive element $e := a_0 + (1 - a_0)^{1/2} a_1 (1 - a_0)^{1/2}$ with $\pi_J(e) = a_1$ and $e \geq a_0$.

Thus, $J \subseteq \overline{eAe}$ and $\pi_J(\overline{eAe}) = I$.

Is e infinite? Even this is not clear!

Is $a_0 \oplus e \precsim e$ and is $a_1 \oplus e \precsim e$?

Can we also take $a_0 + a_1^{1/2}(1 - a_0)a_1^{1/2}$???

Here some minimal conditions that let hope that A is p.i. (=: all nonzero elements are "infinite"):

(0) This part (0) is true for all C*-algebras:

The J. Cuntz relation $a \precsim_A b$ is compatible with with the corresponding relation in hereditary C*-subalgebras:

If $D \subseteq A$ is a hereditary C*-subalgebra of A and $a, b \in D$ satisfy $a \precsim_A b$ in A, then also $a \precsim_D b$ in D.

If $c_n b d_n$ converges to a in A where $c_n, d_n \in A$, then one finds $e_n c_n f_n, g_n d_n h_n \in \overline{rAr} \subseteq D$, for $r := a^*a + aa^* + b^*b + bb^*$, such that $(e_n c_n f_n) b (g_n d_n h_n)$ converges to $a \in \overline{rAr}$.

It is possible to find for every separable subspace $X \subseteq A$ (or every countable subset $Y \subseteq A$ of A) a separable C*-subalgebra $C \subseteq A$ that contains X (respectively contains Y) such that for $a, b \in \mathbb{K} \otimes C$ holds $a \precsim b$ in $\mathbb{K} \otimes C$, if and only if, $a \precsim b$ in $\mathbb{K} \otimes C$. Remind here $a \precsim_D b$ for positive elements $a, b \in D$ in a C*-algebra D means that there exists a sequence (d_n) in D with $a = \lim_{1 \to \infty} \precsim d_n^* b d_n$.

(In addition one can C select as a nuclear C*-subalgebra of A if A is nuclear, this is automatic for exactness, but it is an *open question* if $C \supseteq X$ can be always chosen that there exists in addition a conditional expectation from A^{**} onto C^{**}.)

(0) Original definition of pure infiniteness of a C*-algebra A is that $a \oplus a \precsim_A a$ for all $a \in A_+$. (It says that there exists sequences (c_n) and (d_n) in A such that $c_n^* a c_n$ and $d_n^* a d_n$ converge both to a, but $c_n^* a d_n$ converges to 0.)

(1) Minimal requirements (!) to the idea of "p.i." C*-algebras are:

(1a) For every hereditary C*-subalgebra D of A and every pure state ρ on D there exists elements $d, e \in D_+$ with $\rho(e) > 0$ and $e \oplus d \precsim d$.

(Then A contains a closed ideal J with $e \in J$, and $f \oplus d \precsim d$ for all $f \in J$.)

Notice here that the question if every non-zero positive contraction $b \in A_+$ is properly infinite (p.i.) is equivalent to the following question:

If $D := \overline{bAb}$ is the hereditary C*-subalgebra of A that contains b as strictly positive element of D, then for each element c of the closed ideal J of A generated by D there exists sequences (e_n) and (f_n) in A with $c = \lim e_n b f_n$.

Here one can pass to suitable separable C*-subalgebras $B \subseteq A$ of A, or of D, with the property that for $b, c \in B$ holds $b \precsim_B c$, if and only if, $b \precsim_A c$. This implies also that each (closed) ideal of B is the intersection of B with a closed ideal of A.

The same can be done with $A \otimes \mathbb{K}(\ell_2)$ and its C*-subalgebra $B \otimes \mathbb{K}(\ell_2)$.

To exclude also the cases $\mathbb{C} \cong D$ or $\mathbb{K} \cong D$ for hereditary C*-subalgebras of A/J one has to suppose that ??????

But we must to say much more! For example:
If E is a hereditary C*-subalgebra ... ????

Then B satisfies again (1a) and the question if every positive contraction of b of B ?????

(1c) Possibly (formally) "stronger" as (1a) is the following:

For every closed ideal $J \neq A$ (that can be $J = \{0\}$) and (non-zero) hereditary C*-subalgebra D of A/J, the algebra D contains an "infinite" element $0 \neq d \in D_+$ (i.e. that d is non-zero).

It is defined by the property that there exists non-zero $e \in D_+$ with $e \oplus d \precsim_D d$, i.e. it means that there exists a sequences of elements $f_n, g_n \in D$ with $\lim_n f_n * df_n = d$, $\lim_n g_n * df_n = 0$ and $\lim_n g_n * dg_n = e$.

??? Thus, ???? $e \oplus$??? is in the ideal of A/J one-step map by d ?????

Since ????

(Or is here also $e \in A/J$ allowed?

Yes is allowed, because the elements $e \in A/J$ with $e \oplus d \precsim_{A/J} d$ build a closed ideal K of A/J. The intersection $K \cap D$ of K with D is identical with .... ?????)

In particular, then each (!) nonzero hereditary C*-sub-algebra D of A has no character.

Equivalently expressed: A has no irreducible representation that contains in its image non-zero compact operators on a Hilbert space. Or: A does not contain two ideals $I \subseteq J \subseteq A$ such that J/I is isomorphic to the algebra of compact operators $\mathcal{K}(\mathbb{H})$ on an infinite dimensional or (non-zero) finite dimensional Hilbert space $\mathbb{H}$.

We call $a \in A_+$ *infinite* if there exists some non-zero element $b \in A_+$ such that $a \oplus b \precsim a$. Here we use the Cuntz-majorization $x \precsim y$ in $A \otimes \mathbb{K}$, and $a \oplus b$ means the the 2×2 matrix in $M_2(A)$ with diagonal entries a and b.

Let the following be a "suitable"(?) definition of a "locally purely infinite" C*-algebra A:

For every closed ideal J of A and (nonzero) hereditary C*-sub-algebra D of A/J there exists an infinite element in D (which is then infinite A/J), but for hereditary C*-sub-algebras D of A/J this is the same as being infinite in D).

Questions:

(Q1) Is this class of C*-algebras invariant under passage to hereditary sub-algebras and quotients?

(Q2) Is every separable subset X of A contained in a (suitable) separable C*-sub-algebra B of A that is again a "locally purely infinite C*-algebra"?

The reduction to the separable case is very important. One should take those separable C*-sub-algebras $B \subseteq A$ with the property that elements in $B \otimes \mathbb{K}$ have the same $\precsim --$ relations in $B \otimes \mathbb{K}$ as in $A \otimes \mathbb{K}$.

But the important point is: If $b \in B$ is infinite in A then b should be infinite in B. ... And this for all hereditary sub-algebras ...

It seems "easy" to show that inductive limits of locally purely infinite C*-algebras are again locally purely infinite.

The point is: How looks like a hereditary subalgebra of a quotient of this inductive limit?

Is it itself an inductive limit? (Of useful things).

On reduction to the separable case:

Let $X \subseteq A$ a separable subset of A.

Then there exists a separable C*-sub-algebra B of A that contains X and has the property that for all $a, b \in B$ holds: $a \precsim_B b$, if and only if, $a \precsim_A b$. It implies also that each closed ideal of B is is an intersection of a closed ideal of A with B.

(But in general B does not separate the ideals of A.)

8. MORE on infinite elements

Let A a C*-algebra ...

Let A a separable C*-algebra and D a hereditary C*-sub-algebra. Let $h \in D$, denote by $I(h)$ the closed ideal of elements $a \in A$ with $a \oplus h \precsim_A h$, then the intersection $I(h) \cap D$ has the property that $b \in (I(h) \cap D)$, if and only if, $b \oplus h \precsim_D h$.

(Check this again! Seems to work.)

Moreover $I(h)$ is generated by $I(h) \cap D$.

If $I(h)$ or $I(h) \cap D$ contain a strictly positive contraction $c \in A_+$ (i.e. cAc dense in $I(h)$, or cAc is dense in $I(h) \cap D$) then c is properly infinite and $I(h) = I(c)$ respectively $I(h) \cap D = I(c) \cap D$.

Such element $c \in A_+$ exists if A or D is separable.

It should be equivalent to require that for each ????

A question of Bruce Blackadar:

Is it possibly true that the classifiable simple C*-algebras are precisely the (simple) inductive limits of sequences of *semiprojective* (separable) nuclear C*-algebras?

E.K.: What is the Definition of *semiprojective* C*-algebras?

Kind of approximate lifting property? ????

9. On ideals generated by n-homogenous elements

Let A a C*-algebra and H_n the (smallest) hereditary C*-subalgebra of A that is generated (or only "defined") by the n-homogenous elements in A_+.

Definition: An element $a \in A_+$ is n-homogenous, if and only if, there exists a C*-algebra morphism

$$\varphi \colon C_0((0,1], M_n) = C_0((0,1]) \otimes M_n \mapsto A$$

with the property that $a = \gamma \cdot \varphi(f_0 \otimes 1_n)$ for some $\gamma \in (0, \infty)$ and $f_0(t) := t$, for $t \in (0,1]$.

H_n is the smallest hereditary C*-subalgebra of A that is generated by the convex combinations of the n-homogenous elements in A_+. Since the set of n-homogenous is invariant under automorphisms of A, – especially by inner automophisms –, it follows that H_n is a closed ideal of A.

This ideal H_n has the property that A/H_n has only irreducible representations on Hilbert spaces of dimensions $\leq (n-1)$.

(as ideal and not necessarily fixing ???)

GO ON NOW !!!!!!

10. On order in A_+ for C*-algebras A:

It is very likely that the result in the following proposition is well-known, but we could not find a reference for it in text-books.

Proposition:
If two elements $a, b \in A_+$ satisfy $a \leq b$, then for each $\gamma > 1$ there exists an operator $d \in C*(a,b) \subseteq A$ with $d^*bd = a^\gamma$.

What happens ????

What we really later need is that:

If two elements $a, b \in A_+$ satisfy $a \leq b$ then there exists for each $\varepsilon \in (0, \|a\|)$ an element $dinA$ with the property $d^*bd = (a-\varepsilon)_+$.

Similar problem: If $\|a-b\| < \gamma < \min(\|a\|, \|b\|)$ Does there exists $d \in A$ with $(a-\gamma)_+ = d^*bd$?

Proof: ...

It suffices to consider the case $a \neq 0$ (by rescaling later a, b and d with non-negative real numbers). Moreover, it suffices to consider only the case where $A := C*(a,b)$.

We consider the multiplier algebra $\mathcal{M}(A)$ and write γ (and δ) in place of $\gamma \cdot 1_{\mathcal{M}(A)}$ (and in place of $\delta \cdot 1_{\mathcal{M}(A)}$), and consider mainly $\delta = 2^{-n}$ for $n := 1, 2, \ldots$.

Let $e_n := (b+2^{-n})^{-1/2}a^{1/2}$ and $d_n := e_n \cdot a^\lambda$ with $\lambda = (\gamma-1)/2$, i.e., $\gamma = 1+2\lambda$.

We (want to ???) show that the d_n converge to an element of $d \in C*(a,b)$ with $d^*bd = a^\gamma$ and $\|b\| \leq 1$.

??? is really

Use that $\|e_n\|^2 = \|e_n e_n^*\| = \|e_n^* e_n\|$

and then that $\|d_n\| \leq \|a\|^\lambda \cdot \|e_n\|$ and estimate by

$$e_n e_n^* = (b+2^{-n})^{-1/2}a(b+2^{-n})^{-1/2} \leq (b+2^{-n})^{-1/2}b(b+2^{-n})^{-1/2} = (b+2^{-n})^{-1}b\,.$$

In particular $\|e_n\| \leq 1$ for all $n = 1, 2, \ldots$.

Recall that $e_n = (b+2^{-n})^{-1/2}a^{1/2}$.

The definition of e_n shows that $e_n^*(b+2^{-n})e_n = a$. It is equivalent to $e_n^* b e_n = a - 2^{-n}e_n^* e_n$, If the (e_n) converges in A to an element $e \in C*(a,b) \subseteq A$ then $e^*be = a$ and $\|e\| \leq 1$.

The problem is that this e_n do not converge in A (itself)?

$d_n := e_n \cdot a^\lambda$ with $\lambda = (\gamma-1)/2$, i.e., $\gamma = 1+2\lambda$.

All is now proven up to the estimate of $\|d_n - d_m\|$:

$\|d_n - d_m\| \leq \|a\|^\lambda \|e_n - e_m\|$ If $\|a\|^{\leq}1$ then we get same estimates ... ???

Recall that $e_n := (b+2^{-n})^{-1/2}a^{1/2}$ and $d_n := e_n \cdot a^\lambda$,

$X_n := (b+2^{-n})^{-1/2}b^{1/2}$ converges in the point norm ???

Let $f_{n,m} := (b+2^{-n})^{-1/2} - (b+2^{-m})^{-1/2}$. Since $0 \leq x \leq y$ implies

Then $f_{n,m}^* = f_{n,m}$ and $(d_n - d_m)\cdot(d_n - d_m)^* = f_{n,m} a f_{n,m}$. Now $a \leq b$ implies that

$$f_{n,m} a f_{n,m} \leq f_{n,m} b f_{n,m} = [b^{1/2}(b+2^{-n})^{-1/2} - b^{1/2}(b+2^{-m})^{-1/2})]^2 .$$

??? It follows that (d_n) is a Cauchy sequence in A if ??? (??)

Then $\|d_n - d_m\|^2 = \|(d_n - d_m)(d_n - d_m)^*\|$, and $a \leq b$ implies that ?????

$$(d_n - d_m)(d_n - d_m)^* \leq ((b+2^{-n})^{-1/2} - (b+2^{-m})^{-1/2})b((b+2^{-n})^{-1/2} - (b+2^{-m})^{-1/2})$$

11. On dense (algebraic) ideals of C*-algebras:

Let A a C*-algebra and let $J \subseteq A$ an *algebraic* ideal of A that is dense in A, i.e., for every $a \in A$ there exists a sequence (c_n) in J with $\|a - c_n\| < 1/n$. Here we do not require that J is invariant under the involution $c \mapsto c^*$, i.e. we do not here require that $c \in J$ implies that $c^* \in J$.

Precisely expressed: J is a norm-dense linear subspace of A with the properties $b \cdot a, a \cdot b \in J$ for all $b \in J$ and $a \in A$.

One can see from this defining properties that $J_* := \{c^*; c \in J\} \subseteq A$ is again a dense algebraic ideal in A, because the involution $x \to x^*$ is isometric in A and the inclusions $a^* \cdot J \subseteq J$ and $J \cdot a^* \subseteq J$ for $a \in A$ imply that $J_* \cdot a \subseteq J_*$ and $a \cdot J_* \subseteq J_*$ for all $a \in A$.

It follows that the sets of products $J_* \cdot J$ and $J \cdot J_*$ are contained in $J_* \cap J$ and are both dense sets in A, that are invariant under multiplication by elements from A.

Thus, the intersection $J_* \cap J \subseteq J$ is again a dense ideal of A because $(J_* \cdot J) \cup (J \cdot J_*) \subseteq J_* \cap J$.

If J is a dense algebraic ideal of A, then J has following properties:

(1) for every $a \in A_+$ and $0 < \varepsilon < 1$ there exists $b \in J_+ := A_+ \cap J$ with $\|a - b\| < \varepsilon$.

Proof of property (1): It is enough to consider the case where $a \in A_+$ has norm $\|a\| = 1$. Then $\|a^{1/2}\| = \|a\|^{1/2} = 1$. Let $\beta := (1+\varepsilon)^{1/2} - 1$, i.e., $(1+\beta)^2 = 1+\varepsilon$ and $\varepsilon = \beta^2 + 2\beta$.

Since J is dense in A, there exists $c \in J$ with $\|a^{1/2} - c\| < \beta$. Then $c^*c \in A_+ \cap J$ and it follows that $\|a - c^*c\| < \beta(2+\beta) = \varepsilon$ by using the following general estimate in C*-algebras A:

If $x, y \in A$ and $\|x - y\| < \beta$, then

$$\|x^*x - y^*y\| < \beta \cdot (\|x\| + \|y\|) \leq \beta \cdot (\beta + 2\|x\|)$$

because $\|y\| \leq \|x\| + \|y - x\|$. Then take here $x := a^{1/2}$ and $y := c$.
